But this was not a power sufficiently strong to secure paganism against that villifick, that decline and dissolation, which finally attends all the productions of this world. This religion, which had subfitted for near five thousand years, and almost from the origin of the human race, gradually declined in proportion as the lights of Christianity and philosophy illuminated the minds of mankind. For though the pagan religion, and the fables on which it was founded, were pleasing and favourable to the polite arts, they were not however calculated to satisfy the minds of philosophers, nor to promote the real good of mankind, by securing their temporal and eternal happiness. It is even surprising that so great a genius as the emperor Julian should attempt to revive the embers of paganism, which infenibly declin'd, and had received a mortal blow at the beginning of the fourth century by the emperor Constantin the great. Julian employed all the resources of his imagination, of his eloquence, of his power, and even of his own fatal example, to revive it; but in vain. The fatal period of paganism was arrived, and nothing could save it from destruction. The furious Theodosius, to whom bigotted priests and historians have alligned the name of Great, totally overthrew it toward the clofe of the fame century, destroyed those temples and altars which yet subfitted, dispersed its colleges, and exterminated its priests. From that dire epoch, nothing of paganism has remained, except some ruins dispersed in the remote parts of the earth, and among people wretched and almost unknown; where this religion, once so flourishing and universal, is now degenerated into grofs and dignitifal idolatry.

MYURUS, in medicine, an epithet for a sort of sinking pulle, when the second stroke is less than the first, the third than the second, and so on.
NABOB, a viceroy or governor of one of the provinces of the Mogul's empire, in India.

NABONASSAR, or Eul. of Nabonassar. See Astronomy, p. 473.

NADIR, in astronomy, that point of the heavens which is diametrically opposite to the zenith, or point directly over our heads. See Astronomy, p. 435.

NÆVI, in surgery, marks or excrescences made on the skin of an infant before its birth, vulgarly supposed to be occasioned by the imagination of the mother.

NAHUM, or the prophecy of Nahum, a canonical book of the Old Testament.

Nahum, the seventh of the twelve lesser prophets, was a native of Elkoshai, a little village of Galilee. The subject of his prophecy is the destruction of Nineveh, which he describes in the most lively and pathetic manner; his style is bold and figurative, and cannot be exceeded by the most perfect masters of oratory. This prophecy was verified at the siege of that city by Allyagos, in the year of the world 3373, 622 years before Christ.

NAIADS, in mythology, the nymphs of the fountains. See Mythology.

NAIANT, in heraldry, a term used in blazoning fishes, when borne in an horizontal posture, as if swimming.

NAJAS, in botany, a genus of the monoeica monandria class. The calyx of the male is cylindrical and bicolored; the corolla consists of four segments; and there are no filaments. The female has neither calix nor corolla, but one pistil and an ovated capsule. There is only one species, viz. the marina, found in the European seas.

NAI, angulus, in anatomy. See Anatomy, p. 266.

NALEs, in building, &c. small spikes of iron, brass, &c. which being drove into wood, serve to bind several pieces together, or to hold something upon them.

NAIL, also a measure of length, containing the sixteenth part of a yard.

NAIRN, a borough and port town of Scotland, eighteen miles east of the town of Inverness.

NAISSANT, in heraldry, is applied to any animal issuing out of the midst of some ordinary, and shewing only his head, shoulders, forefeet and legs, with the tip of his tail; the rest of his body being hid in the shield, or some charge upon it; in which it differs from insinuant, which denotes a living creature arizing out of the bottom of any ordinary or charge.

NAKED SEEDS, in botany, are those that are not enclosed in any pod or cafe.

NAMA, in botany, a genus of the pentandria digynia class. The calyx consists of five leaves, and the corol-
NARWAL, in ichthyology, *Monodon*.

NARDUS, in botany, a genus of the triandria monogynia class. It has no calix, and the corolla consists of six leaves, and the nectarium of one entire funnel-shaped leaf; and the stamina are situated within the nectarium. There are 13 species, only two of which are natives of Britain, viz. the poeticus, common pale daffodil, or primrose peerless; and the pseudo-narcissus or wild English daffodil.

NARCISSUS, the daffodil, in botany, a genus of the triandria monogynia class. The corolla consists of six leaves, and the nectarium of one entire funnel-shaped leaf; and the stamina are situated within the nectarium. There are 13 species, only two of which are natives of Britain, viz. the poeticus, common pale daffodil, or primrose peerless; and the pseudo-narcissus or wild English daffodil.

NARCISSUS, in botany, a genus of the triandria monogynia class. It has no calix, and the corolla consists of two valves. There are five species, only one of which, *Ch. filicae*, or malt-grass, is a native of Britain.

NARRATION, in oratory and history, a recital or rehearseful of a fact as it happened, or when it is supposed to have happened. See Description.

NARWAL, in ichthyology. See Monodon.
it up from the surface of the ground, and call it soap-
earth. The earliest account we have of it is in the
Scriptures, where we find that the salt called nitre in
three times would ferment with vinegar, and had an
alterative quality, so that it was used in baths and in
washing things. Solomon compares the singing of

N A T U R A L  H I S T O R Y.

Natural History, is that science which not only
gives complete descriptions of natural productions
in general, but also teaches the method of arranging them
into Classes, Orders, Genera, and Species. This defi-

The First Class, MAMMALIA, is subdivided into 7
Orders; the characters of which are taken from the
number, structure, and situation of the Teeth.

Order I. The Primates, have 4 incisors, or
fore-teeth, in each jaw, and one dog-tooth. N. B.
By one dog-tooth, Linnæus means one on each
side of the fore-teeth in both jaws.—This order
includes 4 genera, viz. Homo, Simia, Lemur,
Vespertilio. See these articles.

Order II. The Bruta, have no fore teeth in ei-
ther jaw.—This order includes 6 genera, viz.
Elephas, Trichechus, Bradypus, Myrmecophaga,
Manis, Dasylys. See these articles.

Order III. The Feræ, have, for the most part,
6 conical fore-teeth in each jaw.—This order in-
cludes 10 genera, viz. Phoca, Canis, Felis, Vi-
verra, Mustela, Ursus, Didelphis, Talpa, Sorex,
Erinaceus. See these articles.

Order IV. The Glires, have 2 fore-teeth in
each jaw, and no dog-teeth.—This order in-
cludes 6 genera, viz. Hystric, Lepus, Caflor, Mus,
Sciurus, Nodilia. See these articles.

Order V. The Pecora, have no fore teeth in
the upper jaw, but 6 or 8 in the under-jaw.—
This order includes 6 genera, viz. Camelus,
Mufchus, Cervus, Capra, Ovis, Bos. See these
articles.

Order VI. The Bellüe, have 6 teeth in each jaw.—
This order includes 4 genera, viz. Equus, Hippopotamus, Sus, Rhinoceros. See
these articles.

Order VII. The Cats, or wh;le kind, have no
uniform character in their teeth, being very dif-

tant from one another; but are sufficiently
resembled by the other orders of Mammals,
like those of the orders, almost entirely taken from the Teeth,
The Second Clasp, AVES, is subdivided into six Orders, the characters of which are taken chiefly from the structure of the Bill.

Order I. The Accipitres, have a hooked bill, the superior mandible, near the base, being extended on each side beyond the inferior; and in some, the superior mandible is armed with teeth. This order includes 4 species, viz. Vultur, Falco, Strix, Lanius. See these articles.

Order II. The Picæ, have a convex, compressed bill, resembling a knife. This order contains 22 genera, viz. Buphaga, Certhia, Corvus, Culcua, &c. See these articles.

Order III. The Anseres, have an obtuse bill, gibbous at the base, broadest at the point, covered with a smooth skin, and furnished with teeth: The tongue is fleshy; and the toes are palmarated, or webbed. This order includes 12 genera, viz. Anca, Anas, Columbus, Diomedia, &c. See these articles.

Order IV. The Grallæ, have a long, obtuse, and somewhat cylindrical bill: The tongue is undivided, and fleshy; and the thighs are naked. This order contains 18 genera, viz. Ardea, Fulica, Tringa, Charadrius, &c. See these articles.

Order V. The Gallinæ, have a convex bill; the superior mandible is vaulted over the inferior, and the margin of the superior mandible folds over the inferior one: The nostrils are half covered with a convex cartilaginous membrane: The restractes, or principal quill-feathers of the tail, are always more than twelve in number; and the feet are divided, but connected at the innermost joint. This order contains 7 genera, viz. Didus, Phasianus, Meleagris, Pavo, &c. See these articles.

Order VI. The Passeres, have a conical sharp-pointed bill; and the nostrils are oval, wide, and naked. This order contains 15 genera, viz. Caprimulgus, Alauda, Columba, &c. See these articles.

The generic characters of this class are taken from peculiarities in the bill, the nostrils, the tongue, the feet, the feathers, the face, the figure of the body, &c. The characters which serve to distinguish the species are very various: For example, the colour of particular feathers or parts of feathers; crests of feathers on the head, disposed in different manners; the colour of the cere or wax; the colour of the feet; the shape and length of the tail; the number, situation, &c. of the toes; the colour and figure of the bill; &c.

The Third Clasp, AMPHIBIA, is divided into four Orders.

Order I. The Reptiles, have legs, and breathe by the mouth. This order contains 4 genera, viz. Testudo, Draco, Lacerta, Rana. See these articles.

Order II. The Serpentes, have no legs, and breathe by the mouth. This order contains 6 genera, viz. Crotalus, Boa, Coluber, Anguis, Anymphia, Cecilia. See these articles.

Order III. The Nantes, are furnished with lungs, and at the same time breathe by lateral gills, and the rays of their fins are cartilaginous. This order contains 14 genera, viz. Accipenfer, Balistes, &c. See these articles.

Order IV. The Meantes, have both lungs and gills; and the feet are furnished with toes and claws. This order contains but one genus, viz. the Siren. See Siren.

The generic characters of this class are taken from the general figure of the body; from their having tails or no tails; being covered with a bill; having teeth or no teeth in the mouth; being furnished with wings; having covered or naked bodies; from the number, situation, and figure of the futa and scales; from the number and situation of the spiracula; from the situation of the mouth, &c.

The specific characters are so various, that it would be superfluous to enumerate them.

The Fourth Clasp, PISCES, is subdivided into four Orders, the characters of which are taken from the situation of the belly-fins.

Order I. The Apodes, have no belly-fins. This order contains 8 genera, viz. Ammodytes, Anarrhicas, Muræna, &c. See these articles.

Order II. The Jugulares, have the belly-fins placed before the pectoral fins. This order includes 5 genera, viz. Callionymus, Blennius, Gadus, &c. See these articles.

Order III. The Thoracici, have the belly-fins placed under the pectoral fins. This order comprehends 15 genera, viz. Gabius, Labrus, Sardus, &c. See these articles.

Order IV. The Abdominales, have the belly-fins placed behind the pectoral fins. This order contains 17 genera, viz. Fistularia, Efox, Clupea, Cyprinus, &c. See these articles.

The generic characters of this class are taken from peculiarities in the head, the mouth, the teeth, the nostrils, the rays in the membrane of the gills, the eyes, the general figure of the body, the figure of the tail, the situation of the spiracula, &c.

The specific characters are taken from peculiarities in all the parts above enumerated, and many others.
The Fifth Class, INSECTA, is subdivided into 7 Orders. the characters of which are taken from the wings.

Order I. The Coleoptera, have four wings, the two superior ones being semicrustaceous, and furnished with a straight future.—This order comprehends 40 genera, viz. Attelabus, Scorabaeus, Cocinella, Melo, &c. See these articles.

Order II. The Hemiptera, have four wings, the two superior ones being semicrustaceous, and incumbent, i.e., the inner edges lie above one another.—This order includes 12 genera, viz. Blatta, Gryllus, Cicada, &c. See these articles.

Order III. The Lepidoptera, have four wings, all of them imbricated with scales.—This order contains 3 genera, viz. Papilio, Sphinx, Phalæna. See these articles.

Order IV. The Neuroptera, have four wings interwoven with veins, like a piece of network, and no sting in the anus.—This order includes 7 genera, viz. Libella, Ephemera, Hesperobus, &c. See these articles.

Order V. The Hymenoptera, have the same characters with the former, only the anus is armed with a sting. But this mark is peculiar to the females and neuters; for the males have no sting.—This order comprehends 10 genera, viz. Apis, Formica, Vespa, &c. See these articles.

Order VI. The Diptera have two wings, and two ciliated halteres or balances behind each wing.—This order contains 10 genera, viz. Combilus, Asilus, Tipula, &c. See these articles.

Order VII. The Apteræ, have no wings. This order contains 14 species, viz. Acarus, Araneæ, Pediculus, &c. See these articles.

The Sixth Class, VERMES, is divided into five Orders.

Order I. The Intestina, are the most simple animals, being perfectly naked, and without limbs of any kind.—This order contains 7 genera, viz. Lumbicus, Spiniæcus, Palsioa, Gordius, Acanth, Hirudo, Mycine. See these articles.

Order II. The Mollusca, are likewise simple naked animals, without any shell; but they are brachiated, or furnished with a kind of limb.—This order comprehends 18 genera, viz. Alcida, Limaré, Doris, Tethys, Aphrodita, Sepia, &c. See these articles.

Order III. The Testacea, have the same characters with those of Order II, but are covered with a shell.—This order includes 39 genera, viz. Anomia, Cardium, Argonauta, Bulla, Buccinum, &c.

Order IV. The Lithophyta, are compound animals, fixed upon a calcareous base constructed by the creatures themselves.—This order includes the corals, of which there are 4 genera, viz. Tubipora, Madrepora, &c. See these articles.

Order V. The Zoophyta, are compound animals, furnished with a kind of flowers, and having a vegetating root and stem.—This order contains 3 genera, viz. Spongæa, Gorgonæa, Tubularia, Hydra, &c. See these articles.

This short explanation will enable any person who understands the Latin language to peruse the Systema Naturæ of Linnaeus without the assistance of a master; which was the principal object of this article.

NATURAL PHILOSOPHY, that which considers the powers and properties of natural bodies, and their mutual actions on one another. See MECHANICS, OPTICS, ASTRONOMY, HYDROSTATICS, PNEUMATICS.

NATURALIZATION, See LAW, Tit. x. 6.

NATURALS, among physicians, whatever naturally belongs to an animal, in opposition to non-naturals. See NON-NATURALS.

NATURE, according to Mr. Boyle, has eight different significations; it being used, 1. For the Author of nature, whom the schoolmen call Natura Naturans, being the same with God. 2. By the nature of a thing, we sometimes mean its essence; that is, the attributes which make it what it is, whether the thing be corporeal or not; as when we attempt to define the nature of a fluid, of a triangle, &c. 3. Sometimes we confound that which a man has by nature, with what accrues to him by birth; as when we say, that such a man is noble by nature. 4. Sometimes we take nature for an internal principle of motion; as when we say, that a stone by nature falls to the earth. 5. Sometimes we understand, by nature, the established course of things. 6. Sometimes we take nature for an aggregate of pow-

powers belonging to a body, especially a living one; in which sense physicians say, that nature is strong, weak, or spent; or that, in such or such diseases, nature left to herself will perform the cure. 7. Sometimes we use the term nature for the universe, or whole system of the corporeal works of God; as when it is said of a phoenix, or chimera, that there is no such thing in nature. 8. Sometimes too, and that most commonly, we express by the word nature a kind of semi-deity, or other strange kind of being.

If, says the same philosopher, I were to propose a notion of nature, less ambiguous than those already mentioned, and with regard to which many axioms relating to that word may be conveniently understood, I should first distinguish between the universal and the particular nature of things. Universal nature I would define to be the aggregate of the bodies that make up the world, in its present state, considered as a principle; by virtue whereof they act and suffer, according to the laws of motion prescribed by the Author of all things. And this makes way for the other subordinate notion; since the particular nature of an individual consists in the general nature applied to a distinct portion of the universal...
NAVARRE, a province of Spain, bounded by French
province of Navarre on the north-east, by Arragon on the south-
east, by Old Castile on the south-west, and by Guip-
coa on the west; it is a mountainous country.
French Navarre, separated from Spanish Navarre
on the south-west by the Pyrenees; it is only thirty
miles long, and fifteen broad; being one of the most
barren provinces in France.
NAVE, in architecture, the body of a church where the
people are disposed, reaching from the ballater, or
rail of the choir, to the chrefh door.
NAVEL, in anatomy, the centre of the lower part of
the abdomen; being that part where the umbilical ve-
fels paffed out of the fetus to the placenta of the mo-
th. See Midwifery.
NAVEL-WORT, in botany. See Cotyledon.
NAVEREINI, a town of Gascony, in France, sixteen
miles south-east of Bayonne.
NAVEW, in botany. See Brassica, of which it is a
species.
NAVICULARE OS, in anatomy. See Anat. p. 186.
NAVIDAD, a port-town of Mexico, in the province of
Mecheconian: W. long. 110°, and N. lat. 19°.

NAVIGATION.

NAVI G ATI ON, is the art of conducing or carrying a
ship from one port to another. In order to un-
derstand this science, particularly the theoretical parts of it, it
is necessary that the student be acquainted with the general
principles of Geometry, Astronomy, and Trigono-
metry. See these articles.

Sect. I. Of the Log-line and Compass.
1. The method commonly made use of for measuring
a ship's way at sea, or how far the runs in a given space
of time, is by the log-line, and half-minute glafs.
2. The log is a flat piece of wood, in shape like a foun-
der, having a piece of lead faftened to its bottom, which
makes it fland or swim upright in the water: to this log
is tied or faftened a long line, which is called the log-line;
and this is commonly divided into certain spaces, each of
which is, or ought to be, a proportional part of a
nautical mile (60 of which make a degree of a great circle
on the earth) as half a minute (the time allowed for the
experiment) is of an hour.
3. These spaces are called knots, because at the end of
each of them there is a piece of twine with knots in it,
inreved between the strands of the line, which fhews how
many of these spaces or knots are run out during the
half minute. They commonly begin to be counted at the
distance of about 10 fathom or 60 feet from the log; that
fi the log, when it is hove over board, may be out of the
edge of the ship's wake before they begin to count; and
for the more ready discovery of this point of commence-
ment, there is commonly flaffened at it a piece of red rag.
4. The log being thus prepared, and hove over board
from the poop, and the line veered out (by the help of a
reel, that turns easily, and about which it is wound) as
faft as the log will carry it away, or rather as the ship fails
from it, will fhew, according to the time of veering, how
far the ship has run in a given time, and consequently her
rate of failing.
5. A degree of a meridian, according to the exacft
measures, contains about 69.545 English miles; and each
mile by the statute being 5280 feet, therefore a degree
of a meridian will be about 367200 feet; whence the $\frac{2}{6}$
of that, viz. a minute, or nautical mile, muft contain
6120 standard feet; consequently, since $\frac{1}{4}$ minute is the
$\frac{1}{7}$ part of an hour, and each knot being the fame part
of a nautical mile, it follows, that each knot will contain
the $\frac{1}{7}$ of 6120 feet, viz. 51 feet.
6. Hence it is evident, that whatever number of knots
the ship runs in half a minute, the fame number of miles
the will run in one hour, fuppofing her to run with the
fame degree of velocity during that time; and therefore
it is the general way to heave the log every hour to know
her rate of failing: but if the foce or direction of the
wind vary, and not continue the fame during the whole
hour; or if there has been more fail fet, or any fail handed,
that fo the ship has run swifter or slower in any part of
the hour than she did at the time of heaving the log;
then there muft be an allowance made accordingly for it,
and this muft be according to the differece of the artift.
7. Sometimes when the ship is before the wind, and
there is a great sea fettin after her, it will bring home
the log, and consequently the ship will fail fatter than is
given by the log. In this cafe it is ufual, if there be a very
great sea, to allow one mile in ten, and lefs in proportion,
if the fea be not fo great. But for the generality, the
ship's way is really greater than that given by the log;
and therefore, in order to have the reckoning rather before
than behind the ship, (which is the fame way,) it will be
proper to make the space on the log-line between knot
and knot to confilt of 50 feet instead of 51.
8. If the space between knot and knot on the log-line
should happen to be too great in proportion to the half-
minute glafs, viz. greater than 50 feet, then the distance
given by the log will be too short; and if that space be
too small, then the distance run (given by the log) will be
too great; therefore to find the true distance run in ei-
ther cafe, having measured the distance between knot and
knot, we have the following proportion, viz.
As the true distance, 50 feet, is to the measured distance;
fo are the miles of distance given by the log, to the true
distance in miles that the ship has run.

Example
EXAMPLE I. Suppose a ship runs at the rate of 65 knots in half a minute; but measuring the space between knot and knot, I find it to be 56 feet: Required the true distance in miles.

Making it, As 50 feet is to 56 feet, so is 6.25 knots to 7 knots; I find that the true rate of failing is 5.72 miles in the hour.

EXAMPLE II. Suppose a ship runs at the rate of 64 knots in half a minute; but measuring the space between knot and knot, I find it to be only 44 feet: Required the true rate of failing.

Making it, As 50 feet is to 44 feet, so is 6.5 knots to 5.72 knots; I find that the true rate or failing is 5.72 miles in the hour.

As the number of seconds the glafs runs, is to half a minute, or 30 seconds; so is the distance given by the log, to the true distance.

EXAMPLE I. Suppose a ship runs at the rate of 74 knots in the time the glafs runs; but measuring the glafs, I find it runs 34 seconds: Required the true rate of failing.

Making it, As 34 seconds is to 30 seconds, so is 7.5 to 6.6; I find that the ship fails at the rate of 6.6 miles an hour.

EXAMPLE II. Suppose a ship runs at the rate of 64 knots; but measuring the glafs, I find it runs only 25 seconds: Required the true rate of failing.

Making it, As 25 seconds is to 30 seconds, so is 6.5 knots to 7.8 knots; I find that the true rate of failing is 7.8 miles an hour.

In order to know how many seconds the glafs runs, you may try it by a watch or clock, that vibrates seconds; but if neither of these be at hand, then take a line, and to the end fastening a plummet, hang the other upon a nail or peg, so as the distance from the peg to the centre of the plummet be 395 inches: Then this put into motion will vibrate seconds; i.e. every time it passes the perpendicular, you are to count one second; consequently, by observing the number of vibrations that it makes during the time the glafs is running, we know how many seconds the glafs runs.

If there be an error both in the log line and half-minute glafs, viz. if the difference between knot and knot and the log-line be either greater or less than 50 feet, and the glafs runs either more or less than 30 seconds; then the finding out the ship's true distance will be somewhat more complicate, and admit of three cases, viz.

CASE I. If the glafs runs more than 30 seconds, and the distance between knot and knot be less than 50 feet, then the distance given by the log-line, viz. by allowing 1 mile for each knot the ship fails while the glafs is running, will always be greater than the true distance, since either of these errors give the distance too great. Consequently, to find the true rate of failing in this case, we must first find (by Art. 8.) the distance, on the supposition that the log-line is only wrong, and then with this (by Art. 9.) we shall find the true distance.

EXAMPLE. Suppose a ship is found to run at the rate of 6 knots; but examining the glafs, I find it runs 35 seconds; and measuring the log-line, I find the distance between knot and knot to be but 46 feet: Required the true distance run.

First, (by Art. 8.) We have the following proportion, viz. As 50 feet : 46 feet :: 6 knots : 5.52 knots. Then (by Art. 9.) As 35 seconds : 30 seconds :: 5.52 knots : 4.73 knots. Consequently the true rate of failing is 4.73 miles an hour.

CASE II. If the glafs be less than 30 seconds, and the distance between knot and knot be more than 50 feet; then the distance given by the log will always be less than the true distance, since either of these errors lessen the true distance.

EXAMPLE. Suppose a ship is found to run at the rate of 7 knots; but examining the glafs, I find it runs only 25 seconds; and measuring the space between knot an knot on the log line, I find it is 54 feet: Required the true rate of failing.

First, (by Art. 9.) As 25 seconds : 30 seconds :: 7 knots : 8.4 knots. Then (by Art. 8.) As 50 feet : 54 feet :: 8.4 knots : 9.072 knots. Consequently the true rate of failing is 9.072 miles an hour.

CASE III. If the glafs runs more than 30 seconds, and the space between knot and knot be greater than 50 feet; or if the glafs runs less than 30 seconds, and the space between knot and knot be less than 50 feet: then, since in either of these two cases the effects of the errors are contrary, it is plain the distance will sometimes be too great, and sometimes too little, according as the greater quantity of the error lies; as will be evident from the following examples.

EXAMPLE I. Suppose a ship is found to run at the rate of 64 knots per glafs; but examining the glafs, it is found to run 36 seconds; and by measuring the space between knot and knot, it is found to be 58 feet: Required the true rate of failing.

First, (by Art. 8.) As 50 feet : 58 feet :: 9.5 knots : 11.02 knots. Then (by Art. 9.) As 36 seconds : 30 seconds :: 9.072 knots : 8.7 knots. Consequently the ship's true rate of failing is 8.7 miles an hour.

EXAMPLE II. Suppose a ship runs at the rate of 6 knots per glafs; but examining the glafs, it is found to run only 20 seconds; and by measuring the log-line, the distance between knot and knot is found to be but 36 feet: Required the true rate of failing.

First, (by Art. 8.) As 50 feet : 38 feet :: 6 knots : 4.56 knots. Then (by Art. 9.) As 20 seconds : 30 seconds :: 4.56 knots : 6.84 knots. Consequently the true rate of failing is 6.83 miles an hour.

But if in this case it happen, that the time the glafs takes to run be to the distance between knot and knot, as 30, the seconds in half a minute, is to 50, the true distance
distance between knot and knot; then it is plain, that
whatever number of seconds the glass consists of, and
whatever number of feet is contained between knot and
knot; yet the distance given by the log line, will be the
ture distance in miles.

12. Though the method of measuring the ship's way
by the log-line, described in the foregoing articles, be
that which is now commonly made use of; yet it is sub
ject to several errors, and these very considerable. For
first, the half-minute or quarter-minute glasses (by which,
and the log, the ship's way is determined) are seldom or
never true, because dry and wet weather have a great
influence on them; so that at one time they may run
more, and at another time fewer than 30 seconds, and
it is evident that a small error in the glass will cause a
sensible one in the ship's way. Again, the chief property
of the log is to have it swim upright, or perpendicular to
the horizon; but this is too often wanting in logs, because
few mariners examine whether it is so or not; and generally
take it upon trust, being satisfied if it weigh a little
more at the stern than the head: and from this there
flows an error in the reckoning; for if the log does not
swim upright, it will not hold water, nor remain steady
in the place where it is heaved, since the least check in
the hand in veering the line will make it come up fe-
veral feet: this repeated will make the errors become
fathom's, and perhaps knots, which, how insensible fo-
ever they appear, are miles and parts of miles, and amount
to a good deal in a long voyage. Another inconvenience
attending the log-line is its stretching and shrinking; for
when a new line is first used, let it be ever so well ftreteh-
ed upon the deck, and measured as true as possible, yet
after wetting it shrinks considerably; and consequently to
be the better assured of the ship's way by the log-line, we
ought to measure and alter the knots on it every time be-
fore we use it; but this is seldom done often than once
a week, and sometimes not above once or twice in a
whole voyage; also when the line is measured to its
greatest degree of shrinking, it is generally left there;
and when, by much use, it comes to stretch again, it is
f seldom or never mended, though it will stretch beyond
what it first shrunk. These, and many other errors,
too well known, attending that method of measuring the
ship's way by the log-line, plainly answers for a great
many errors committted in reckonings. So it is to be
wished, that either this method were improved or amend
ed, or that some other method left subject to error were
found out.

13. The meridian and prime vertical of any place cuts
the horizon in 4 points, at 90 degrees distance from one
another, viz. North, South, East, and West; that part
of the meridian which extends itself from the place to
the north point of the horizon is called the north line;
that which tends to the south point of the horizon, is
called the south line; and that part of the prime vertical
which extends towards the right hand of the observer,
when his face is turned to the north, is called the eafi
line; and lastly, that part of the prime vertical which
tends towards the left hand, is called the west line; the
four points in which these lines meet the horizon, are
called the cardinal points.
there form certain angles with one another; and since, if we move never so little towards the east or west, from one place to another, we thereby change our meridian, in every place the east and west line being perpendicular to the meridian; it follows, that the east and west line in the first place will not coincide with the east and west line in the second, but be inclined to it at a certain angle: and consequently all the other rhomb lines at each place will be inclined to each other, they always forming the same angles with the meridian. Hence it follows, that all rhombs, except the four cardinals, must be curves or helicoidal lines, always tending towards the pole, and approaching it by infinite gyrations or turnings, but never falling into it. Thus let $P$ (No. 2.) be the pole, $EQ$ an arch of the equator, $PE$, $PA$, &c. meridians, and $EFGHKL$ any rhomb: then because the angles $PEF$, $PFG$, &c. are by the nature of the rhomb line equal, it is evident that it will form a curve line on the surface of the globe, always approaching the pole $P$, but never falling into it; for if it were possible for it to fall into the pole, then it would follow, that the same line could cut an infinite number of other lines at equal angles, in the same point; which is absurd.

19. Because there are $32$ rhumbs (or points in the compass) equally distant from one another, therefore the angle contained between any two of them adjacent will be $11^\circ 15'$, viz. $\frac{1}{12}$ part of $360^\circ$; and so the angle contained between the meridian and the $NNE$, will be $22^\circ 30'$, and between the meridian and the $W$ will be $22^\circ 30'$; and so of the rest, as in the following table.

A Table of the Angles which every $\frac{1}{2}$ Point of the Compass makes with the Meridian.

Sect. 2. Of Plain Sailing.

1. This method of failing supposes the earth to be a plane, and the meridians parallel to one another; and likewise the parallels of latitude at equal distance from one another, as they really are upon the globe. Though this method be in itself evidently false; yet in a short run, and especially near the equator, an account of the ship's way may be kept by it tolerably well.

2. The angle formed by the meridian and rhumb that a ship fails upon, is called the ship's course. Thus if a ship fails on the NNE rhomb, then her course will be $22^\circ 30'$, and so of others.

3. The distance between two places lying on the same parallel counted in miles of the equator, or the distance of one place from the meridian of another counted above on the parallel passing over that place, is called meridional distance; which, in plain failing, goes under the name of departure.

4. Let $A$ (No. 3.) denote a certain point on the earth's surface, $AC$ its meridian, and $AD$ the parallel of latitude passing through it; and suppose a ship to fail from $A$ on the NNE rhomb till she arrive at $B$; and through $B$ draw the meridian $BD$, (which, according to the principles of plain failing, must be parallel to $CA$) and the parallel of latitude $BC$; then the length of $AB$, viz. how far the ship has failed upon the NNE rhomb, is called her distance; $AC$ or $BD$ will be her difference of latitude, or nothing; $CB$ will be her departure, or easting; and the angle $CAB$ will be the course. Hence it is plain, that the distance failed will always be greater than either the difference of latitude or departure; if being the hypotenuse of a right-angled triangle, whereof the other two are the legs; except the ship fails either on a meridian, or a parallel of latitude; for if the ship fails on a meridian, then it is plain, that her distance will be just equal to her difference of latitude, and she will have no departure; but if she fail on a parallel, then her distance will be the same with her departure, and she will have no difference of latitude. It is evident also from the figure, that if the course be less than $4$ points, or $45$ degrees, its complement, viz. the other oblique angle, will be greater.
greater than 45 degrees, and so the difference of latitude will be greater than the departure; but if the course be greater than 4 points, then the difference of latitude will be less than the departure; and lastly, if the course be just 4 points, the difference of latitude will be equal to the departure.

5. Since the distance, difference of latitude, and departure, form a right-angled triangle, in which the oblique angle opposite to the departure is the course, and the other its complement; therefore, having any two of these given, we can (by plain trigonometry) find the rest; and hence arise the cases of plain-sailing, which are as follow.

CASE I. Course and distance given, to find difference of latitude and departure.

Example. Suppose a ship fails from the latitude of 30° 25' north, NNE, 32 miles, (No. 4.) Required the difference of latitude and departure, and the latitude come to. Then (by right angle trigonometry,) we have the following analogy, for finding the departure and sum of the distance AC, viz.

As radius — — — — 10.00000

To the distance AC — 32 — — — 1.50515

So is the side of the course A 22° 30' — — — 9.58284

to the departure BC — — — 12.25 — 1.08799

So the ship has made 12.25 miles of departure easterly, or has got so far to the eastward of her meridian. Then, for the difference of latitude or northing the ship has made, we have (by rectangular trigonometry) the following analogy, viz.

As radius — — — — 10.00000

To the distance AC — 32 — — — 1.50515

So is the side of the course A 22° 30' — — — 9.58284

To the difference of lat. AB 29.57 — 1.47077

So the ship has northing 1.47077

And since her former latitude was north, and her difference of latitude northerly; therefore, To the latitude failed from — — — 30°, 25' N

Add the difference of latitude — — — — 0°, 29.57

And the sum is the latitude come to 30°, 54.57 N

By this case are calculated the tables of difference of latitude, and departure, to every degree, point, and quarter-point of the compasses.

CASE II. Course and difference of latitude given, to find distance and departure.

Example. Suppose a ship, in the latitude of 45° 25' north, NNE, 32 miles, (No. 4.) Required the course and departure. Hence arise the cases of plain-sailing, which are as follow. And (by rectangular trigonometry) we have the following analogy, for finding the departure BD, viz.

As radius — — — — 10.00000

To the difference of latitude AB 90 — 1.95424

So the ship has got 73.84 miles to the eastward of her former meridian.

Again, for the distance AD, we have (by rectangular trigonometry) the following proportion, viz.

As radius — — — — 10.00000

To the distance AD — — — — 116.4 2.00600

So is the side of the course F 56° 50' — 9.91985

And the remainder — — — — 0°, 40'

equal to 70 miles, is the difference of latitude.

By rectangular trigonometry we have the following proportion for finding the angle of the course F, viz.

As the distance failed DF 126 — 2.10037

is to radius — — — — 10.00000

so is the diff. of latitude FD 70 — 1.84510

And since her former latitude was north, and her difference of latitude northerly; therefore, From the latitude failed from — — — 56° 50'

Subtract the observed latitude — — — 55° 10'

and the remainder — — — — 0°, 40'

equal to 70 miles, is the difference of latitude.

By rectangular trigonometry we have the following proportion for finding the angle of the course F, viz.

As the distance failed DF 126 — 2.10037

is to radius — — — — 10.00000

So is the side of the course F 56° 50' — 9.91985

And the remainder — — — — 0°, 40'

equal to 70 miles, is the difference of latitude.

By rectangular trigonometry we have the following proportion for finding the angle of the course F, viz.

As the distance failed DF 126 — 2.10037

is to radius — — — — 10.00000

So is the side of the course F 56° 50' — 9.91985

And the remainder — — — — 0°, 40'

equal to 70 miles, is the difference of latitude.

By rectangular trigonometry we have the following proportion for finding the angle of the course F, viz.

As the distance failed DF 126 — 2.10037

is to radius — — — — 10.00000

So is the side of the course F 56° 50' — 9.91985

And the remainder — — — — 0°, 40'

equal to 70 miles, is the difference of latitude.

By rectangular trigonometry we have the following proportion for finding the angle of the course F, viz.

As the distance failed DF 126 — 2.10037

is to radius — — — — 10.00000

So is the side of the course F 56° 50' — 9.91985

And the remainder — — — — 0°, 40'

equal to 70 miles, is the difference of latitude.
to the tangent of course G — 29°, 19' — 9.74928
which, because the ship is failing between southeasterly and easterly, will be south 29° 19' east, or SSE 1/2 east nearly.

Then for the distance, we shall have (by rectangular trigonometry) the following analogy, viz.

As radius — — — — — 10.00000
is to the diff. of latitude GK — 114 — 2.05690
so is the secant of the course — 29°, 19' — 10.0592

to the distance GL — — — 130.8 — 2.11642

consequently the ship has failed on a SSE 1/2 east course 130.8 miles.

Case V. Distance and departure given, to find course and difference of latitude.

Example. Suppose a ship at sea fails from the latitude of 34° 24' north, between north and west 124 miles, and is found to have made of setting 86 miles. Required the course steered, and the difference of latitude or northings made good.

In this case (by rectangular trigonometry) we have the following proportion for finding the course ADB, (No. 8.) viz.

As the distance AD — 124 — 2.09342
is to radius — — — — — 10.00000
so is the departure AB — 86 — 1.93450

to the fine of the course D — 43°, 54' — 9.84108
so the ship's course is north 33° 54' west, or NW 1/2 west nearly.

Then for the difference of latitude, we have (by rectangular trigonometry) the following analogy, viz.

As radius — — — — — 10.00000
is to the diff. of latitude BD — 89.35 — 1.95108
so is the secant of the course 43°, 54' — 9.85766

to the distance AD — 124 — 2.09342

which is equal to 1 degree and 29 minutes nearly. Hence, to find the latitude the ship is in, since both latitudes are north, and the ship failing from the equator; therefore,

To the distance failed from — — — — 124 — 2.09342
add the difference of latitude — — — — — 1°, 29'

the sum is — — — — — 35°, 53'

the latitude the ship is in is north.

Case VI. Course and departure given, to find distance and difference of latitude.

Example. Suppose a ship at sea, in the latitude of 43° 40' north, who's departure from the ship is 54 miles. Required the distance and difference of latitude made good on that course.

In this case, by Rectangular Trigonometry, and by Case 2. we have the following proportion for finding the distance, (No. 9.) viz.

As the fine of the course G — 33°, 45' — 9.74474
is to the departure HM — 96 — 1.98227
so is radius — — — — — 10.00000

to the distance GM — 172.8 — 2.22375

Then, for the difference of latitude, we have (by rectangular trigonometry) the following analogy, viz.

As the tangent of course G — 33°, 45' — 9.82489
is to the departure HM — 96 — 1.98227
so is radius — — — — — 10.00000

to the difference of latitude GH — 143.7 — 2.15738

equal to 2°, 24' nearly. Consequently, since the latitude the ship failed from was south, and the failing still towards the south,

To the latitude failed from — — — — — 24°, 30'
add the difference of latitude — — — — — 2°, 24'

and the sum is — — — — — 26°, 54'
is the latitude she is come to south.

6. When a ship steers several courses in 24 hours, then the reducing all these into one, and thereby finding the course and distance made good upon the whole, is commonly called the resolving of a traverse.

7. At sea they commonly begin each day's reckoning from the noon of that day, and from that time they let down all the different courses and distances steamed by the ship till noon next day upon the log-board; then from these several courses and distances had from the compass and log-line, they compute the difference of latitude and departure for each course (by Case 1. of Plain Sailing); and these, together with the courses and distances, are let down in a table called the traverse table; which consists of five columns: in the first of which are placed the courses and distances; in the two next the differences of latitude belonging to these courses, according as they are north or south; and in the two last are placed the courses belonging to these courses, according as they are east or west. Then they sum up all the northings, and all the southings; and taking the difference of these, they know the difference of latitude made good by the ship in the last 24 hours, which will be north or south, according as the sum of the northings or southings is greatest: The same way, by taking the sum of all the eastings, and likewise of all the westings, and substracting the lesser of these from the greater, the difference will be the departure made good by the ship last 24 hours, which will be east or west according as the sum of the eastings is greater or less than the sum of the westings; and from the difference of latitude and distance made good by the ship last 24 hours, found as above, they find the true course and distance made good upon the whole (by Case 4. of Plain Sailing), as also the course and distance to the intended port.

Example. Suppose a ship at sea, in the latitude of 48° 24' north at noon any day, is bound to a port in the latitude of 43° 40' north, whose departure from the ship is 144 miles east; consequently the direct course and distance of the ship is SSE 1/2 east 315 miles; but by reason of the shifting of the winds she is obliged to steer the following courses till noon next day, viz. SE 36 miles, SSE 64 miles, NNE 48 miles, SSW 1/2 west 54 miles, and SEAS 1/2 east 74 miles. Required the course and distance made good the last 24 hours, and the bearing and distance of the ship from the intended port.

The solution of this traverse depends entirely on the 1st and 4th cases of Plain Sailing; and first we must (by Case 1.) find the difference of latitude and departure for each course. Thus,

1 Course SEAS distance 36 miles.

For departure.

As radius — — — — — 10.00000
is to the distance — — — — — 56 — 1.74819

**Diff. of Lat.** 187.91 46.97 **Pep.** 24 hours; consequently, to find the true course and distance made good by the ship in that time, it will be, (by Case 4 of Plain Sailing.)

As the difference of latitude — 187.91 2.27393

is to radius — — 10.00000

so is the departure — 46.97 1.67182
to the tangent of the course 14°, 03' 9.39789

which is S E 1/2 east nearly. Then for the distance, it will be,

As radius — — 10.00000

is to the difference of latitude 187.91 2.27393

so is the secant of the course 14°, 03' 10.00450
to the tangent of the course 14°, 03' 9.39789

there remains — — 45°, 16' N
take the latitude the ship is bound for lies in the latitude of 43° 40' north, and consequently south of the ship; therefore,

From the latitude the ship is in — — 45°, 16' N
take the latitude the ship is bound for — — 43°, 40' N

and there remains — — 1°, 36' or 96 miles, the difference of latitude or southing the ship has to make. Again, the whole easting the ship had to make being 144 miles, and the having already made 46.97 or 47 miles of easting; therefore the departure or easting the ship has to make will be 97 miles; consequently, to find the direct course and distance between the ship and the intended port, it will be (by Case 4 of Plain Sailing)

As the difference of latitude — 96° 1.68227

is to radius — — 10.00000

so is the departure — 97° 1.98677
to the tangent of the course 45°, 19' 10.00450

And

As radius — — 10.00000

is to the difference of latitude 96° 1.68227

so is the secant of the course 45°, 19' 10.15293
to the difference — — 136.5 2.13620

whence the true bearing and distance of the intended port is SE, 136.5 miles.
**NAVIGATION.**

**SECTION 3. OF PARALLEL SAILING.**

1. Since the parallels of latitude do always decrease the nearer they approach the pole, it is plain a degree on any of them must be less than a degree upon the equator. Now in order to know the length of a degree on any of them, let PB (No. 10.) represent half the earth's axis, PA a quadrant of a meridian, and consequently A a point on the equator, C a point on the meridian, and CD a perpendicular from that point upon the axis, which plainly will be the sine of CP the distance of that point from the pole, or the co-sine of CA its distance from the equator; and CD will be to AB, as the sine of CP, or co-sine of CA, is to the radius. Again, if the quadrant PAB is turned round upon the axis PB, it is plain the point A will describe the circumference of the equator whose radius is AB, and any other point C upon the meridian will describe the circumference of a parallel whose radius is CD.

**Cor. I.** Hence (because the circumference of circles are as their radii) it follows, that the circumference of any parallel is to the circumference of the equator, as the co-sine of its latitude is to radius.

**Cor. II.** And since the wholes are as their similar parts, it will be, As the length of a degree on any parallel is to the length of a degree upon the equator, so is the co-sine of the latitude of that parallel to radius.

**Cor. III.** Hence, as radius is to the co-sine of any latitude, so are the minutes of difference of longitude between two meridians, or their distance in miles upon the equator, to the distance of these two meridians on the parallel in miles.

**Cor. IV.** And as the co-sine of any parallel is to radius, so is the length of any arch on that parallel (intercepted between two meridians in miles) to the length of a similar arch upon the equator, or minutes of difference of longitude.

**Cor. V.** Also, as the co-sine of any one parallel is to the co-sine of any other parallel, so is the length of any arch on the first, in miles, to the length of the same arch on the other in miles.

2. From what has been said, arises the solution of the several cases of parallel sailing, which are as follow.

**Case I.** Given the difference of longitude between two places; both lying on the same parallel; to find the distance between those places.

**Example I.** Suppose a ship in the latitude of $54^\circ 20'$ north, fails directly west on that parallel till she has suffered her longitude $12^\circ 45'$; required the distance sailed on that parallel.

The difference of longitude reduced into minutes, or nautical miles, is $765'$, which is the distance between the meridian she sailed from, and the meridian come to upon the equator; then to find the distance between these meridians on the parallel of $54^\circ 20'$, or the distance sailed, it will be, by Cor. 3. of the last article,

As radius — — — — 10,00000

is to the co-sine of the lat. — $54^\circ 20'$ — 9,76572
so are the minutes of diff. long. — 765 — 2.88306
to the distance on the parallel — 446.1 — 2.64938

**Example II.** A degree on the equator being 60 minutes or nautical miles; required the length of a degree on the parallel of $51^\circ 32'$.

By Cor. 3. of the last article, it will be

As radius — — — — 10,00000

is to the co-sine of the latitude $51^\circ 32'$ — 9,79393
so are the minutes in 1 degree on the equa. $60 1.77815$
to — — — — 27.32 1.57198
the miles answering to a degree on the parallel of $51^\circ 32'$.

By this problem the following table is constructed, shewing the geographic miles answering to a degree on any parallel of latitude; in which you may observe, that the columns marked at the top with D.L. contain the degrees of latitude belonging to each parallel; and the adjacent columns marked at the top, Miles, contain the geographic miles answering to a degree upon those parallels.

A Table shewing how many Miles answer to a Degree of Longitude, at every Degree of Latitude.

Though this table does only shew the miles answering to a degree of any parallel, whose latitude consists of a whole number of degrees; yet it may be made to serve for any parallel whose latitude is some number of degrees and minutes, by making the following proportion, viz.

As 1 degree, or 60 minutes, is to the difference between the miles answering to a degree in the next greater and next less tabular latitude than that proposed; so is the excess of the proposed latitude above the next tabular latitude, to a proportional part; which, subtracted from the miles answering to a degree of longitude in the next less tabular latitude, will give the miles answering to a degree in the proposed latitude.

Example. Required to find the miles answering to a degree on the parallel of 56° 44'.

First, The next less parallel of latitude in the table than the proposed is that of 56°, a degree of which (by the table) is equal to 33.85 miles; and the next greater parallel of latitude in the table, than that proposed, is that of 57°, a degree of which is (by the table) equal to 32.68 miles; the difference of these is 87, and the difference between these parallels is 1 degree or 60 minutes; also the distance between the parallel of 56° 44', is 44 minutes: then by the preceding proportion it will be, As 60 is to 87, so is 44 to 638, the difference between a degree on the parallel of 56° and a degree on the parallel of 56° 44'; which therefore taken from 33.55, the miles answering to a degree on the parallel of 56°, leaves 32.912, the miles answering to a degree on the parallel of 56° 44', as was required.

Case II. The distance failed in any parallel of latitude, or the distance between any two places on that parallel, being given, to find the difference of longitude.

Example. Suppose a ship in the latitude of 55° 30' north fails directly east 685.6 miles; required how much she has deviated her longitude.

By Cor. 4. Art. 1. of this section, it will be

As the cos of the lat. 55° 30' — 9.73202
so is the distance failed 685.6 — 2.93607
to min. of diff. long. 1213 — 3.08405
which reduced into degrees, by dividing by 60, makes 20° 15', the difference of longitude the ship has made.

This may also be solved by help of the foregoing table, viz. by finding from it the miles answering to a degree on the proposed parallel, and dividing with this the given number of miles, the quotient will be the degrees and minutes of difference of longitude required.

Thus in the last example; I find, from the foregoing table, that a degree on the parallel of 55° 36' is equal to 33.89 miles; by this I divide the proposed number of miles 685.6, and the quotient is 20.13 degrees, i.e. 20° 15', the difference of longitude required.

Case III. The difference of longitude between two places on the same parallel, and the distance between them, being given; to find the latitude of that parallel.

Example. Suppose a ship fails on a certain parallel directly west 624 miles, and then has differed her longitude 18° 46' or 1126 miles: Required the latitude of the parallel she failed upon.

By Cor. 3. Art. 1. of this section, it will be,

As the min. of diff. long. 1126 — 3.05154
so is the distance failed 624 — 2.79518
so is radius — — 10.00000
to the cos of the lat. 56° 21' — 9.74304
consequently the latitude of the ship or parallel she failed upon was 56° 21'.

From what has been said, may be solved the following problems.

Prob. I. Suppose two ships in the latitude of 46° 30' north, distant 654 miles, fail both directly north 256 miles, and consequently are come to the latitude of 50° 46' north: Required their distance on that parallel.

By Cor. 6. Art. 1. of this section, it will be,

As the cos of — 46° 30' — 9.83781
so is the distance failed — 654 — 2.81558
to — — 601 — 2.77680
the distance between the ships when on the parallel of 50° 46'.

Prob. II. Suppose two ships in the latitude of 45° 48' north, distant 846 miles, fail directly north till the distance between them is 624 miles: Required the latitude come to, and the distance failed.

By Cor. 5. Art. 1. of this section, it will be,

As their first distance — 846 — 2.94279
so is their second distance — 624 — 2.79518
so is the co-s of — 45° 48' — 9.84334
to the co-s of — 59° 04' — 9.71115
the latitude of the parallel the ships are come to.

Consequently to find their distance failed,

From the latitude come to — 59° 04'
subtract the latitude failed from, — 45° 48'
and there remains — — 13° 16'
equal to 796 miles, the difference of latitude or distance failed.

Sec. 4. Of Middle-latitude Sailing.

When two places lie both on the same parallel, we shew in the last section, how, from the difference of longitude given, to find the miles of easting or westing between them, & e contra. But when two places lie not on the same parallel, then their difference of longitude cannot be reduced to miles of easting or westing on the parallel of either place: for if counted on the parallel of that place that has the greatest latitude, it would be too small; and if on the parallel of that place having the least latitude, it would be too great. Hence the common way of reducing the difference of longitude between two places, lying on different parallels, to miles of easting or westing, & e contra, is by counting it on the middle parallel between the places, which is found by adding the latitudes of the two places together, and taking half the sum, which will be the latitude of the middle parallel required. And hence arises the solution of the following cases.

Case I. The latitudes of two places, and their difference of longitude, given; to find the direct course and distance.

Example,
EXAMPLE. Required the direct course and distance between the Lizard in the latitude of 50° 06' north, and longitude of 5° 14' west, and St Vincent in the latitude of 17° 10' N. and longitude of 24° 20' W.

First, To the latitude of the Lizard — 50°, 06' N.
add the latitude of St Vincent — 17°, 10
Then the sum is — 67°, 10 N.
Half the sum or latitude of the middle parallel is — 33°, 35' N.
Also the difference of latitude is equal to 1146 miles of southing. Again,
From the longitude of St Vincent — 24°, 20' W.
take the longitude of the Lizard — 05°, 14'
there remains — 16°, 06
equal to 1146 min. of diff. of long. west.

Then for the miles of southing, or departure, it will be, by Cafe 1. of Parallel Sailing,
As radius — 10.00000
is to the co-fine of the middle parallel — 33°, 35' — 9.92069
fo is the departure — 1146 — 3.05918
to the miles of wefting — 954.7 — 2.97987
And for the course it will be, by Cafe 4. of Plain Sailing,
As the diff. of lat. — 1970 — 3.29447
is to radius — 10.00000
so is the course — 954.7 — 2.97987
to the diff. of latitude — 1146 — 2.15229
which, because it is between south and west, it will be SSW 1/4 west nearly.

For the distance, it will be, by the same course,
As radius — 10.00000
is to the diff. of lat. — 1970 — 3.29447
so is the secant of the course — 25°, 51' — 9.68540

whence the direct course and distance from the Lizard to St Vincent is SSW 1/4 W. 2189 miles.

Case II. One latitude, course, and distance failed being given, to find the other latitude and difference of longitude.

EXAMPLE. Suppose a ship in the latitude of 50° 00' north, sails south 50° 06' west, 150 miles: Required the latitude the ship has come to, and how much she has differed her longitude.

First, For the difference of latitude, it will be, by Cafe 1. of Plain Sailing,
As radius — 10.00000
is to the distance — 150 — 2.17609
so is the line of the course — 50°, 06' — 9.88489
to the departure — 115.1 — 2.06098
As for the difference of longitude, it will be, by Case 2. of Plain Sailing,
As the course of the middle parallel 49° 1/2 — 9.81519
is to radius — 10.00000
fo is the departure — 115.1 — 2.06098
to the min. diff. of longitude — 176.1 — 2.24579
equal to 2° 56', which is the difference of longitude the ship has made westerly.

Case III. Course and difference of latitude given; to find the distance failed, and difference of longitude.

EXAMPLE. Suppose a ship in the latitude of 53° 34' north, fails SE5S, till by observation she is found to be in the latitude of 51° 12', and consequently has differed her latitude 2° 22' or 142 miles: Required the distance failed, and the difference of longitude.

First, For the departure, it will be (by Cafe 2. of Plain Sailing),
As radius — 10.00000
is to the diff. of latitude — 142 — 2.15229
so is the tang. of course — 33° 45' — 9.82489
to the departure — 94.8 — 1.97718
And for the distance it will be, by the same course,
As radius — 10.00000
is to the diff. of latitude — 142 — 2.15229
so is the secant of the course — 25° 06' — 10.08015
to the distance — 170.8 — 2.23244

Then, since the latitude failed from was 53° 34' north, and the latitude come to 51° 12' north; therefore the middle parallel will be 52° 23'; and consequently, for the difference of longitude, it will be (by Cafe 2. of Parallel Sailing)
As the course of the middle parallel — 52° 23' — 9.78560
is to the departure — 194.8 — 1.97718
so is radius — 10.00000
to min. of diff. of longitude — 145.5 — 2.19158
equal to 2° 35', the difference of longitude easterly.

Case IV. Difference of latitude and distance failed, given; to find the course and difference of longitude.

EXAMPLE. Suppose a ship in the latitude of 43° 26' north, fails between south and east, 246 miles, and then is found by observation to be in the the latitude of 41° 06' north: Required the direct course and difference of longitude.

First, For the course, it will be, by Cafe 3. of Plain Sailing.
As the distance — 246 — 2.39094
is to radius — 10.00000
so is the diff. of latitude — 140 — 2.14613
to the co-fine of the course — 55° 19' — 9.75519
which, because the ship fails between south and east, will be south 55° 19' east, or SE5E nearly.

Then for departure, it will be, by the same course,
As radius — 10.00000
is to the distance — 246 — 2.39094
1. To find the difference of longitude, it will be, by Case 6. of Plain Sailing,
   As the fine of the course -- 33°, 45' -- 9.74474
   is to the departure -- 123 -- 2.08991
   so is radius -- -- -- 10.00000
   to the distance -- 221.4 -- 2.24317

2. And for the difference of latitude it will be, by the same Case,
   As the tang. of course -- 33°, 45' -- 9.82489
   is to the departure -- 123 -- 2.08991
   so is radius -- -- -- 10.00000
   to the diff. of latitude -- 184 -- 2.26502
   which is equal to 3° 04', the difference of longitude westerly.

3. Case VI. Difference of latitude and departure given, to find course, distance, and difference of longitude.

4. Example. Suppose a ship in the latitude of 50° 46', north, fails between south and east 146 miles, and is then found by observation to be in the latitude of 43° 24' north; required the course, distance, and difference of longitude.

5. First, By Case 4. of Plain Sailing, it will be for the course,
   As the diff. of latitude -- 103 -- 2.28536
   is to departure -- 146 -- 2.16137
   so is radius -- -- -- 10.00000
   to the tang. of course -- 36°, 55' -- 9.87581
   which, because the ship is failing between south and east, will be south 36° 55' east, or SEE ½ east nearly.
   For the distance, it will be, by the same Case,
   As radius -- -- -- 10.00000
   to the diff. of latitude -- 103 -- 2.28536
   so is the secant of the course -- 36°, 55' -- 10.09718
   to the distance -- 241.4 -- 2.38774
   Then for the difference of longitude, it will be, by Case 2. of Parallel Sailing,
is to radius

so is the departure 126 to the tang. of the course 30°, 29' 9.76996

which, because it is between south and west, will be south 30° 20' west, or SSW 3/4 west nearly.

And for the distance, it will be, by the fame Case,

As radius is to the diff. of lat. 214. 2.33°4 2.32041

so is the secant of the course 30°, 29' 10.06461 to the distance 248.4 2.39502

2. From what has been faid, it will be easy to solve a traverse, by the rules of Middle Latitude Sailing.

Example. Suppose a ship in the latitude of 43° 25' north, fails upon the following courses, viz. SW/S 63 miles, SSW 1/4 west 45 miles, SE/E 54 miles, and SW/W 74 miles: Required the latitude the ship has come to, and how far she has differed her longitude.

First, By Case 2. of this Sect. find the difference of latitude and difference of longitude belonging to each course and distance, and they will stand as in the following table.

<table>
<thead>
<tr>
<th>Course</th>
<th>Distance</th>
<th>Diff. of Lat.</th>
<th>Diff. of Longit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW/S</td>
<td>63</td>

</tr>
</tbody>
</table>

Hence it is plain the ship has differed her latitude 186.2 minutes, or 3° 6' and so has come to the latitude of 40° 16' north, and has made of difference of longitude 143.8 minutes, or 2° 23' 48'' westerly.

The method of failing, though it be not strictly true, yet it comes very near the truth, as will be evident, by comparing an example wrought by this method with the same wrought by the method delivered in the next Section, which is strictly true; and it serves, without any considerable error, in runnings of 450 miles between the equator and parallel of 30 degrees, of 300 miles between that and the parallel of 60 degrees, and of 150 miles as far as there is any occasion, and consequently must be sufficiently exact for 24 hours run.

Sect. 5. Of Mercator's Sailing.

1. Though the meridians do all meet at the pole, and the parallels to the equator do continually decrease, and that in proportion to the co-fines of their latitudes; yet in old sea charts the meridians were drawn parallel to one another, and consequently the parallels of latitude made equal to the equator, and to a degree of longitude on any parallel as large as a degree on the equator; also in these charts the degrees of latitude were still represented (as they are in themselves) equal to each other, and to the degrees of the equator. By these means the degrees of longitude being increased beyond their just proportion, and the more so the nearer they approach the pole, the degrees of latitude at the same time remaining the same, it is evident places must be very erroneously marked down upon these charts with respect to their latitude and longitude, and consequently their bearing from one another very false.

2. To remedy this inconvenience, so as still to keep the meridians parallel, it is plain we must protrast, or lengthen, the degrees of latitude in the same proportion as those of longitude are, that so the proportion in sailing and wefting may be the same with that of southing and northering, and consequently the bearings of places from one another be the same upon the chart as upon the globe itself.

Let ABD (No. 11.) be a quadrant of a meridian, A the pole, D a point on the equator, AC half the axis, B any point upon the meridian, from which draw BF perpendicular to AC, and CG perpendicular to CD; then BF will be the line, and CG the co-fine of BD the latitude of the point B; draw D the tangent and CE the secant of the arch CD. It has been demonstrated in Sect. 3. that any arch of a parallel is to the like arch of the equator as the co-fine of the latitude of that parallel is to radius. Thus any arch as a minute on the parallel described by the point B, will be to a minute on the equator as BF is to CD; but since the triangles CGB and CDE are similar, therefore CG will be to CD as CG is to CE, i.e. the co-fine of any parallel is to radius as radius is to the secant of the latitude of that parallel.

But it has been just now shown, that the co-fine of any parallel is to radius, as the length of any arch as a minute on that parallel is to the length of the like arch on the equator; therefore the length of any arch as a minute on any parallel, is to the length of the like arch on the equator, as radius is to the secant of the latitude of that parallel; and so the length of any arch, as a minute on the equator, is longer than the like arch of any parallel in the same proportion, as the secant of the latitude of that parallel is to radius. But since in this projection the meridians are parallel, and consequently each parallel of latitude equal to the equator, it is plain the length of any arch as a minute on any parallel, is increased beyond its just proportion, at such rate as the secant of the latitude of that parallel is greater than radius; and therefore to keep up the proportion of northing and southing to that of easting and wefting, upon this chart, as it is upon the globe itself, the length of a minute upon the meridian at any parallel must also be increased beyond its just proportion at the same rate, i.e. as the secant of the latitude of that parallel is greater than radius. Thus to find the length of a minute upon the meridian at the latitude of 75 degrees, since a minute of a meridian is every where equal on the globe, and also equal to a minute upon the equator, let it be represented by unity: then making it as radius is to the secant of 75 degrees, so is unity to a fourth number, which is 3.864 nearly; and consequently, by whatever line you represent one minute on the equator of this chart, the length of one minute on the enlarged meridian
meridian at the latitude of 75 degrees, or the distance between the parallel of 75° 00' and the parallel of 75° 01', will be equal to 3 of these lines, and 1 of one of them. By making the same proportion, it will be found, that the length of a minute on the meridian of this chart at the parallel of 60°, or the distance between the parallel of 60° 00' and that of 60° 01', is equal to two of these lines. After the same manner, the length of a minute on the enlarged meridian may be found at any latitude; and consequently beginning at the equator, and computing the length of every intermediate minute between that and any parallel, the sum of all these shall be the length of a meridian intercepted between the equator and that parallel; and the distance of each degree and minute of latitude from the equator upon the meridian of this chart, computed in minutes of the equator, forms what is commonly called a table of meridional parts.

If the arch BD (No. 11) represent the latitude of any point B, then (CD being radius) CE will be the secant of that latitude: but it has been shown above, that radius is to the secant of any latitude, as the length of a minute upon the equator is to the length of a minute on the meridian of this chart at that latitude; therefore CD is to CE, as the length of a minute upon the equator is to the length of a minute upon the meridian, at the latitude of the point B. Consequently, if the radius CD be taken equal to the length of a minute upon the equator, CE, or the secant of the latitude, will be equal to the length of a minute upon the meridian at that latitude. Therefore, in general, if the length of a minute upon the equator be made radius, the length of a minute upon the enlarged meridian will be everywhere equal to the secant of the arch contained between it and the equator.

Con. 1. Hence it follows, since the length of every intermediate minute between the equator and any parallel, is equal to the secant of the latitude (the radius being equal to a minute upon the equator) the sum of all these lengths, or the distance of that parallel on the enlarged meridian from the equator, will be equal to the sum of all the secants, to every minute contained between that and any parallel; and the sum of all these divided into 10 equal parts will give the degree of each degree of latitude. Consequently, if the radius CD of the arch be taken equal to the length of a minute upon the equator, CE, or the secant of the latitude, will be equal to the length of a minute upon the meridian at that latitude. Therefore, in general, if the length of a minute upon the equator be made radius, the length of a minute upon the enlarged meridian will be everywhere equal to the secant of the arch contained between it and the equator.

Con. 2. Consequently, the distance between any two parallels on the same side of the equator, is equal to the difference of the sums of all the secants contained between the equator and each parallel, and the distance between any two parallels on contrary sides of the equator, is equal to the sum of the sums of all the secants contained between the equator and each parallel.

5. By the tables of meridional parts, which may be seen in Paton, and other writers on this subject, may be constructed the nautical chart, commonly called Mercator's chart. Thus, for example, let it be required to make a chart that shall commence at the equator, and reach to the parallel of 60 degrees, and shall contain 80 degrees of longitude.

Draw the line EQ representing the equator, (see No. 12) then take, from any convenient line of equal parts, 4800 (the number of minutes contained in 80 degrees,) which set off from E to Q, and this will determine the breadth of the chart.

Divide the line EQ into eight equal parts, in the points 10, 20, 30, &c. each containing 10 degrees, and each of these divided into 10 equal parts will give the degree of each degree upon the equator: then through the points E, 10, 20, &c. drawing lines perpendicular to EQ, these shall be meridians.

From the scale of equal parts take 4572.4 (the meridional parts answering to 60 degrees,) and let that off from E to A and from Q to B, and join AB: then this line will represent the parallel of 60, and will determine the length of the chart.

Again, from the scale of equal parts take 603.1 (the meridional parts answering to 10 degrees,) and let that off from E to 10 on the line EA; and through the point 10 draw 10, 10, parallel to EQ; and this will be the parallel of 10 degrees. The same way, setting off from E on the line EA, the meridional parts answering to each degree, &c. of latitude; and through the several points drawing lines parallel to EQ, we shall have the several parallels of latitude.

If the chart does not commence from the equator, but is only to serve for a certain distance on the meridian between two given parallels on the same side of the equator; then the meridians are to be drawn as in the last example: and for the parallels of latitude you are to proceed thus, viz. from the meridional parts answering to each point of latitude in your chart, subtract the meridional parts answering to the least latitude, and set off the differences severally, from the parallel of least latitude, upon the two extreme meridians; and the lines joining these points of the meridians shall represent the several parallels upon your chart.

Thus let it be required to draw a chart that shall serve from the latitude of 20 degrees north to 60 degrees north, and that shall contain 80 degrees of longitude.

Having drawn the line DC to represent the parallel of 20 degrees (see No. 12) and the meridians to it, as in the foregoing example; set off 663.3 (the difference between the meridional parts answering to 20 degrees, and those of 20 degrees) from D to 30, and from C to 30: then join the points 30 and 30 with a right line, and that shall be the parallel of 30. Also set off 1397.6 (the difference between the meridional parts answering to 40 degrees, and those of 20 degrees) from D to 40, and from C to 40, and joining the points 40 and 40 with a right line, that shall be the parallel of 40. And proceeding after the same way, we may draw as many of the intermediate parallels as we have occasion for.

But if the two parallels of latitude that bound the chart, are on the contrary sides of the equator; then draw a line representing the equator and meridians to it, as in the first example; and from the equator set off on each side of it the several parallels contained between it and the given parallels as above, and your chart is finished.

If Mercator's chart, constructed as above, hath its equator extended on each side of the point E 180 degrees, and if the several places on the surface of the earth be there laid down according to their latitudes and longitudes, we shall have what is commonly called Mercator's map of the earth. This map is not to be considered as a similar and just representation of the earth's surface; for in it the
figures of countries are distorted, especially near the poles: but since the degrees of latitude are everywhere increased in the same proportion as those of longitude are, the bearings between the places will be the same in this chart as on the globe; and the proportions between the latitudes, longitudes, and nautical distances, will also be the same on this chart, as on the globe itself; by which means the several cases of navigation are solved after a most easy manner, and adapted to the meanest capacities.

N.B. Here you must take notice, that in all charts, the upper part is the north side, and the lower part or bottom is the south side; also that part of it towards the right hand is the east, and that towards the left hand the west side of the chart.

6. Since, according to this projection, the meridians are parallel right lines; it is plain, that the rhombs which form always equal angles with the meridians, will be straight lines; which property renders this projection of the earth's surface much more easy and proper for use than any other.

7. This method of projecting the earth's surface upon a plane, was first invented by Mr Edward Wright, but first published by Mercator; and hence the failing by the chart, was called Mercator's failing.

8. In No. 13, let A and E represent two places upon Mercator's chart, AC the meridian of A, and CE the parallel of latitude passing through E; draw AE, and set off upon AC the length AB equal to the number of minutes contained in the difference of latitude between the two places, and taken from the same scale of equal parts the chart was made by, or from the equator, or any graduated parallel of the chart, and through B draw BD parallel to CE meeting AE in D. Then AC will be the enlarged difference of latitude, AB the proper difference of latitude, CE the difference of longitude, BD the departure, AE the enlarged distance, and AD the proper distance, between the two places A and E; also the angle BAD will be the course, and AE the rhomb line between them.

9. Now since in the triangle ACE, BD is parallel to one of its sides CE; it is plain the triangles ACE, ABD, will be similar, and consequently the sides proportional. Hence arise the solutions of the several cases in this failing, which are as follow.

Case I. The latitudes of two places given, to find the meridional or enlarged difference of latitude between them.

Of this case there are three varieties, viz. either one of the places lies on the equator, or both on the same side of it; or lastly, on different sides.

1. If one of the proposed places lies on the equator, then the meridional difference of latitude is found by subtracting the meridional parts answering to the least latitude from those answering to the greatest, and the difference is that required.

Example. Required the meridional difference of latitude between the Lizard in the latitude of 50° 00' north, and Antigua in the latitude of 17° 30' north.

From the meridional parts of — 50°, 00' 3474.5 subtract the meridional parts of 17°, 30' 1066.7

| Difference of latitude | 2407.8 |

2. If the two proposed places be on the same side of the equator, then the meridional difference of latitude is found by adding together the meridional parts answering to each latitude, and the sum is that required.

Example. Required the meridional difference of latitude between Antigua in the latitude of 17° 30' north, and Lima in Peru in the latitude of 12° 30' South.

To the merid. parts answering to 17°, 30' 1066.7 add these answering to — 12°, 30' 756.1

| Sum | 1822.8 |

3. If the places lie on different sides of the equator, then the meridional difference of latitude is found by adding together the meridional parts answering to each latitude, and the sum is that required.

Example. Required the meridional difference of latitude between the Lizard in the latitude of 50° 00' north, and Port-Royal in Jamaica in the latitude of 17° 40'; differing in longitude 70° 46', Port-Royal lying to far to the westward of the Lizard.

Preparation.

From the latitude of the Lizard — 50°, 00' subtract the latitude of Port-Royal — 17°, 40'

| Difference of latitude | 32°, 20' |

and there remains

| Difference of latitude | 32°, 20' |

and there remains

| Difference of latitude | 2397.3 |

Geometrically. Draw the line AC (No 14.) representing the meridian of the Lizard at A, and set off from A, upon that line, AE equal to 1940 (from any scale of equal parts) the proper difference of latitude, also AC equal to 2397 3 (from the same scale) the meridional or enlarged difference of latitude. Upon the point C raise CB perpendicular to AC, and make CB equal to 4246 the minutes of difference of longitude.

Join AB, and through E draw ED parallel to BC: so the case is constructed; and AD applied to the same scale of equal parts the other legs were taken from will give the direct distance, and the angle DAE measured by the line of chords will give the course.

By Calculation.

For the angle of the course EAD, it will be, (by Rectangular Trigonometry.)

\[ AC : CB :: R : T, BAC, \text{ i.e.} \]

As the meridional diff. of lat. 2397.3 — 3 37970 is
is to the difference of long. — 42°6.0 — 3.62798
so is radius — — — — 10.00000

to the tang. of the direct course 60° 33' — 10.24828
which, because Port Royal is southward of the Lizard,
and the difference of longitude westerly, will be south
60° 33' west, or SWW 1/2 west nearly.

Then for the distance AD, it will be, (by rectangular
trigonometry)
R : AE : : Sec. A : AD, i. e.
As the radius — — — — 10.00000
is to the proper diff. of lat. — 1940 — 3.28780
so is the secant of the course — 60° 33' — 10.30833
to the difference — 3945.6 — 3.59613
consequently the direct course and distance between the
Lizard and Port-Royal in Jamaica, is south 60° 33',
3945.6 miles.

Case III. Course and distance failed given, to find dif-
ference of latitude and difference of longitude.

Example. Suppose a ship from the Lizard in the lati-

tude of 50° 00' north, fails south 35° 40' west 156 miles.
Required the latitude come to, and how much she has al-
tered her longitude.

GEOMETRICALLY. 1. Draw the line BK (No. 15.)
representing the meridian of the Lizard at B; from B
draw the line BM, making with BK an angle equal to
35° 40', and upon this line set off BM equal to 156 the
given distance, and from M let fall the perpendicular MK
upon BK.

Then for BK the proper difference of latitude, it will be,
(by rectangular trigonometry),
R : MB : : S, BMK : BK,
i. e. As radius — — — — 10.00000
is to the distance — 156 — 2.19212
so is the cosine of the course 35° 40' — 9.00978
to the proper difference of lat. 127 — 2.10290
equal to 2° 07'; and since the ship is failing from a north
latitude towards the south, therefore the latitude come to
will be 47° 53' north. Hence the meridional difference
of latitude will be 193.4.

2. Produce BK to D, till BD be equal to 193 4
through D draw DL parallel to MK, meeting DM pro-
duced in L; then DL will be the difference of longitude:
to find which by calculation, it will be, (by rectangular
trigonometry),
R : BD : T, LBD : DL,
i. e. As radius — — — — 10.00000
is to the meridional diff. of lat. 193.4 — 2.28646
so is the tangent of the course 35° 40' — 9.85594
to minutes of diff. of long. — 138.8 — 2.14240
equal to 2° 18' 38'' the difference of longitude the ship
has made westerly.

Case IV. Given course and both latitudes, viz. the
latitude failed from, and the latitude come to; to find
the difference failed, and the difference of longitude.

Example. Suppose a ship in the latitude of 54° 20'
north, fails south 35° 45' east, until by observation she is
found to be in the latitude of 51° 45' north; required
the difference failed, and the difference of longitude.

GEOMETRICALLY. Draw AB (No. 16.) to repre-
sent the meridian of the ship in the first latitude, and set
off from A to B 155 the minutes of the proper difference of
latitude, also AG equal to 257.9 the minutes of the enlarged
difference of latitude. Through B and G, draw the lines
BC and GK perpendicular to AG; also draw AK making
with AG an angle of 30° 45', which will meet the two
former lines in the points C and K; so the case is con-
structed, and AC and GK may be found from the line of
equal parts: To find which,

By Calculation:
First, For the difference of longitude, it will be, (by
rectangular trigonometry),
R : AG : : T, GAK : GK,
i. e. As radius — — — — 10.00000
is to the enlarged diff. of lat. — 257.9 — 2.41143
so is the tangent of the course — 33°, 45' — 9.82489
to min. of diff. of longitude — 172 3 — 2.23034
equal to 2° 52' 18'', the difference of longitude the ship
has made easterly.

This might also have been found, by first finding the
departure BC (by Case 2. of Plain Sailing,) and then it
would be
AB : BC : : AG : GK, the difference of longitude
required.

Then for the direct distance AC, it will be, (by rect-
angular trigonometry),
R : AB : : Sec. A : AC,
i. e. As radius — — — — 10.00000
is to the proper diff. of lat. — 155 — 2.19033
so is the secant of the course — 33°, 45' — 10.08015
to the direct distance — 186.4 — 2.27048
consequently the ship has failed south 33° 45' east
186.4 miles, and has differed her longitude 2° 52' 18''
easterly.

Case V. Both latitudes, and distance failed, given;
to find the direct course, and difference of longitude.

Example. Suppose a ship from the latitude of 45°
26' north, fails between north and east 195 miles, and
then by observation she is found to be in the latitude of
48° 06' north; required the direct course and difference
of longitude.

GEOMETRICALLY. Draw AB (No. 17.) equal to
160 the proper difference of latitude, and from the point
B raise the perpendicular BD; then take 195 in your
compasses, and letting one foot of them in A, with the o-
ther cross the line BD in D. Produce AB, till AC be equ-

tal to 233.6 the enlarged difference of latitude. Thro' C
draw CK parallel to BD, meeting AD produced in K:
so the case is constructed; and the angle A may be me-
sured by the line of chords, and CK by the line of equal
parts: To find which,

By Calculation:
First, For the angle of the course BAD it will be, (by
rectangular trigonometry)
AB : R : : AD : Sec. A. i. e.
As the proper diff. of lat. — 160 — 2.26412
is to radius — — — — 10.00000
so is the distance — 195 — 2.29003
to the secant of the course — 34°, 52' — 10.08351
which, because the ship is failing between north and
east, will be north 34° 52' east, or NEE in 19° 47' easterly.

Then for the difference of longitude, it will be, (by
rectangular trigonometry),
5 C
NAVIGATION.

GEOMETRICALLY. 1. Having drawn the meridian AB, (No. 19.) make the angle BAD equal to 42° 33'. Draw FD parallel to AB at the distance of 116. which will meet AD in D. Let fall upon AB the perpendicular DB. Then AB will be the proper difference of latitude, and AD the direct distance: To find which by calculation, first, for the distance AD it will be, (by rectangular trigonometry)

\[
\frac{S}{A} : \frac{BD}{R} = \frac{AD}{R}
\]

i. e. As radius \[10.00000\]
is to the proper diff. of latitude \[212.2 \ 2.10165\]
fo is the tang. of the course \[42°, 33' \ 9.82010\]
to the direct distance \[116 \ 2.06446\]

Then for the proper difference of latitude, it will be, by rectangular trigonometry

\[
\frac{T}{A} : \frac{BD}{R} = \frac{AD}{R}
\]

i. e. As the tang. of the course \[42°, 33' \ 9.66281\]
is to the departure \[116 \ 2.06446\]
fo is radius \[10.00000\]
to the proper difference of latitude \[126.4 \ 2.10165\] equal to 2° 6'. Consequently the ship has come to the latitude of 52° 20' north, and so the meridional difference of latitude will be 212.2.

2. Produce AB to E, till AE be equal to 212.2; and through E draw EC parallel to BD, meeting AD produced in C; then EC will be the difference of longitude; to find which by calculation, it will be, (by rectangular trigonometry)

\[
\frac{R}{AE} = \frac{T}{A}
\]

i. e. As radius \[10.00000\]
is to the merid. diff. of latitude \[212.2 \ 2.32675\]
fo is the tang. of the course \[42°, 33' \ 9.66281\]
to the min. of diff. of longitude \[194.8 \ 2.28556\] equal to 3° 14' 48'' the difference of longitude easterly.

This might have been found otherwise thus: because the triangles ACE, ADB, are similar; therefore it will be,

\[
\frac{AB}{BD} = \frac{AE}{EC}
\]

i. e. As the proper diff. of latitude \[126.4 \ 2.10165\] is to the departure \[116 \ 2.06446\]
fo is the enlarged diff. of latitude \[212.2 \ 2.32675\] to min. diff. of longitude \[194.8 \ 2.28556\]

CASE VIII. Both latitudes and departure given, to find course, distance, and difference of longitude.

Example. Suppose a ship from the latitude of 46° 20' N. fails between south and west, till she has made of departure 126.4 miles; and is then found by observation to be in the latitude of 43° 25' north. Required the course and distance failed, and difference of longitude.

Geometrically. Draw AK (No. 20.) to represent the meridian of the ship in her first latitude; set off upon it AC, equal to 165, the proper difference of latitude. Draw BC perpendicular to AC, equal to 126.4 the departure, and join AB. Set off from A, AK equal to 233.3, the enlarged difference of latitude; and through K draw KD parallel to BC, meeting AB produced in D; fo the case is constructed, and DK will be the difference of longitude, AB the distance, and the angle A the course; to find which.

By Calculation:

First, For DC the difference of longitude, it will be,

\[
AC = \frac{R}{AE}
\]

de 

Example. Suppose a ship fails from the latitude of 54° 36' north, south 42° 33' east, until she has made of departure 116 miles. Required the latitude she is in, her direct distance failed, and how much she has altered her longitude.
NAVIGATION.

AC : CB : AK : KD.
i.e. As the proper diff. of latitude 165 2.21748
is to the departure — — 126.4 2.10175
so is the enlarged diff. of latitude — 233.3 2.36791
to min. of diff. longitude — 178.7 2.25218
equal to $3^\circ 56' 42''$, the difference of longitude westerly.

Then for the course it will be, (by rectangular trigonometry,)

$AC : BC : R : T$.

i.e. As the proper diff. of latitude 165 2.21748
is to the departure — — 126.4 2.10175
so is radius — — 10.00000
to the tangent of the course $37^\circ, 27'$ 9.88427
which, because the ship sails between south and west,
will be south $37^\circ 27'$ west, or SWS $6^\circ 30'$ westerly.

Lastly, For the distance AB; it will be, (by rectangular trigonometry,)

i.e. As the sine of the course $37^\circ, 27'$ 9.78399
is to the departure — — 126.4 2.10175
so is radius — — 10.00000
to the direct distance — 207.9 2.31780

Case IX. One latitude, distance failed, and departure given; to find the other latitude, difference of longitude, and course.

Example. Suppose a ship in the latitude of $40^\circ 00'$, north, fails between south and east 138 miles, and has then made of departure $112.6$. Required the latitude come to, the direct course, and difference of longitude.

Geometrically. First, Draw $BD$ (No. 21.) for the meridian of the ship at $B$; and parallel to it draw $FE$, at the distance of $112.6$, the departure. Take $138$, the distance, in your compasses, and fixing one point of them in $B$, with the other cross the line $FE$ in the point $E$; then join $B$ and $E$, and from $E$ let fall upon $BD$ the perpendicular $ED$; so $BD$ will be the proper difference of latitude, and the angle $B$ will be the course; to find which, by calculation,

First, for the course it will be, (by rectangular trigonometry,)

i.e. As the proper diff. of latitude 79.8 1.90180
is to the departure — — 112.6 2.05154
so is the enlarged diff. of latitude — 117.7 2.07073
to the diff of longitude — 166.1 2.22044
equal to $2^\circ 46' 06''$, the difference of longitude easterly.

9. From what has been said, it will be easy to solve a traverse according to the rules of Mercator's failing.

Example. Suppose a ship at the Lizard in the latitude $50^\circ 00'$, north, is bound to the Madera in the latitude of $32^\circ$, $20'$ north, the difference of longitude between them being $11^\circ 40'$, the west end of the Madera lying so much to the westward of the Lizard, and consequently the direct course and distance (by Case 2. of this Sect.) is south $26^\circ 15'$ west 1181.9 miles; but by reason of the winds she is forced to sail on the following courses (allowance being made for lee-way and variation, &c.) viz. SSW 44 miles, SWS $\frac{1}{2}$ west 36 miles, SWS 56 miles, and S&E 28 miles. Required the latitude the ship is in, her bearing and distance from the Lizard, and her direct course and distance from the Madera, at the end of these courses.

The geometrical construction of this traverse is performed by laying down the two ports according to construction of Case 2. of this Sect. and the several courses and distances according to Case 3. by which we have the following solution by calculation.

1. Course SSW, distance 44 miles.

For difference of latitude:

As radius — — 10.00000
is to the distance — 44 1.64345
so is the sine of the course $22^\circ, 30'$ 9.96562

to the difference of latitude — 40.5 1.60907
and since the course is sountherly, therefore the latitude come to will be $49^\circ 20'$ north, and consequently the meridional difference of latitude will be $61.8$. Then

For difference of longitude,

As radius — — 10.00000
is to the enlarged diff. of lat. $61.8$ 1.79099
so is the tangent of the course $22^\circ, 30'$ 9.01722
to min of diff of longitude $25.6$ 1.40821

2. Course SWS, distance 36 miles.

For difference of latitude:

As radius — — 10.00000
is to the distance — 36 1.55630
so is the sine of the course $16^\circ, 52'$ 9.98990

to the difference of latitude $34.46$ 1.53726
and since the course is southerly, therefore the latitude comes to will be $48^\circ 45'$. Hence the meridional difference of latitude will be $53.4$. Then

For difference of longitude:

As radius — — 10.00000
is to the enlarged diff. of lat. $53.4$ 1.72754
so is the tangent of the course $16^\circ, 52'$ 9.48171
to the difference of longitude $16.19$ 1.20925

3. Course SW&S, distance 56 miles.

For difference of latitude:

As radius — — 10.00000
is to the distance — 56 1.74819
so is the sine of the course $33^\circ, 45'$ 9.91985

2dly, Produce $B$ to $A$, till $BA$ be equal to $117.7$; and through $A$ draw $AC$ parallel to $DE$, meeting $BE$ produced in $C$; then $AC$ will be the difference of longitude; to find which by calculation, it will be,
NAVIGATION

to the difference of latitude — 46° 56' 1.66846
consequently the latitude come to is 47° 59', and therefore the enlarged difference of latitude will be 69.2.

Then,

For difference of longitude:

As radius — 10.00000
is to the enlarged diff. of lat. 69.2 1.84011
so is the tang. of the course 33° 45' 9.83469
to the difference of longitude 46.24 1.66500

4. Course S8E, distance 28 miles.
For difference of latitude:

As radius — 10.00000
is to the distance 28 1.44716
so is the co-sine of the course 11° 15' 9.99157
to the difference of latitude 8.59 0.93414
consequently the latitude come to will be 47°, 15'; and hence the meridional difference of latitude will be 43.2.

Then,

For difference of longitude:

As radius — 10.00000
is to the enlarged diff. of lat. 43.2 1.62548
so is the tang. of the course 11° 15' 9.99866
to the diff. of longitude 8.59 0.93414

Now these several courses and distances, together with the difference of latitude and longitude belonging to each of them, being set down in their proper columns in the Traverse Table, will stand as follow.

<table>
<thead>
<tr>
<th>Courses</th>
<th>Distances</th>
<th>Diff. of Lat.</th>
<th>Diff. of Long.</th>

</tbody>
</table>

Hence it is plain that the ship has made of southing 149.13 minutes, and consequently has come to the latitude of 47° 31' north, and so the meridional difference of latitude between that and her first latitude will be 226.1; and since she has made of difference of longitude 79.44 minutes westerly; therefore for the direct course and distance between the lizard and the ship it will be, (by Cache 2. of this Section.)

For the direct course:

As the merid. diff. of latitude 226.1 — 2.35430
is to radius — 10.00000
so is the difference of longitude 79.44 1.90004
to the tang. of the course — 9.54579
which because the difference of latitude is southerly, and the difference of longitude westerly, will be southerly 9.54579, or S8E 8° 7' westerly. Then,

For the direct distance:

As radius — 10.00000
is to the proper diff. of lat. 149.13 2.17349
so is the secant of the course 19° 22' 10.02530
to the direct distance — 158 2.19879
From the latitude the ship is in — 47°, 31' N
subtract the lat. of the Madera — 32°, 20' N

and there remains — 15°, 11'
equal to 911 minutes, the proper difference of latitude between the ship and the Madera.

Again, from the merid. parts answering to the latitude the ship is in

Take the meridional parts answering to the latitude of the Madera

and there remains 1196.4
the enlarged difference of latitude between the ship and the Madera.

Also, from the diff. of long. between the Lizard and the Madera

Take the difference of long. between the Lizard and the ship

and there remains 10°, 20.44 W
equal to 620.36 min. of difference of longitude between the ship and the Madera westerly.

Then for the direct course and distance between the ship and the Madera, it will be,

For the direct course:

As the merid. diff. of latitude 1196.4 — 3.07788
is to radius — 10.00000
so is the difference of longitude 620.36 2.79278
to the tang. of the course — 27°, 25' 9.71493
For the direct distance:

As radius — 10.00000
is to the proper diff. of latitude 911 2.95952
so is the secant of the course 27°, 25' 10.05174
to the direct distance — 1027 3.0126

10. It is very common, in working a day's reckoning at sea, to find the difference of latitude and departure to each course and distance; and adding all the departures together, and all the differences of latitudes for the whole departure, and difference of latitude made good that day, from thence (by Case 8. of this Section) to find the difference of longitude, &c. made good that day. Now that this method is false, will evidently appear, if we consider that the fame departure reckoned on two different parallels will give unequal differences of longitude; and consequently, when several departures are compounded together and reckoned on the fame parallel, the difference of longitude resulting from that cannot be the same with the sum of the differences of longitude resulting from the several departures on different parallels; and therefore we have chosen, in the [example of a traverse, to find the difference of longitude answering to each particular course and distance, the sum of which must be the true difference of longitude made good by the ship on thefe several courses and distances.

11. We shewed, at Art. 5. of this Section, how to construct a Mercator's chart; and now we shall proceed to its several uses, contained in the following problems.

Prob. 1. Let it be required to lay down a place upon
N A V I G A T I O N.

The chart, its latitude, and the difference of longitude between it and some known place upon the chart being given.

Example. Let the known place be the Lizard lying on the parallel of 50° 00' north, its meridian. Set off AE from E upon the equator EQ, towards Q, which will reach from E to F. Through F draw the meridian FG, and this will be the meridian of St Katharines; then set off from Q to H upon the graduated meridian QB, 28 degrees; and through H draw the parallel of latitude HM, which will meet the former meridian in K, the place upon the chart required.

Prob. II. Given two places upon the chart, to find their difference of latitude and difference of longitude.

Through the two places draw parallels of latitude; then the distance between these parallels numbered in degrees and minutes upon the graduated meridian will be the difference of latitude required; and through the two places drawing meridians, the distance between these, counted in degrees and minutes on the equator or any graduated parallel, will be the difference of longitude required.

Prob. III. To find the bearing of one place from another upon the chart.

Example. Required the bearing of St Katharines at K, (see No. 12.) from the Lizard at L.

Draw the meridian of the Lizard AE, and join K and L with the right line KL; then by the line of chords measuring the angle KLE, and with that entering the tables; we shall have the thing required.

This may also be done, by having compasses drawn on the chart (suppose at two of its corners); then lay the edge of a ruler over the two places, and let fall a perpendicular, or take the nearest distance from the centre of the compass next the first place, to the ruler's edge; then with this distance in your compasses, slide them along by the ruler's edge, keeping one foot of them close to the ruler, and the other as near as you can judge perpendicular to it, which will describe the rhomb required.

Prob. IV. To find the distance between two given places upon the chart.

This problem admits of four cases, according to the situation of the two places with respect to one another.

Case I. When the given places lie both upon the equator.

In this case their distance is found by converting the degrees of difference of longitude intercepted between them into minutes.

Case II. When the two places lie both on the same meridian.

Draw the parallels of those places; and the degrees upon the graduated meridian, intercepted between those parallels, reduced to minutes, give the distance required.

Case III. When the two places lie on the same parallel.

Example. Required to find the distance between the points K and N, (see No. 12.) both lying on the parallel of 28° 00' north. Take from your scale the chord of 60°, or radius in your compasses, and with that extent on KN as a base make the isosceles triangle KPN; then take from the line of lines the co-line of the latitude, or fine of 72° and set that off from P to S and T. Join S and T with the right line ST, and that applied to the graduated equator will give the degrees and minutes upon it equal to the distance; which, converted into minutes, will be the distance required.

The reason of this is evident from the section of Parallel Sailing; for it has been there demonstrated, that radius is to the co-line of any parallel, as the length of any arch on the equator, to the length of the same arch on that parallel. Now in this chart KN is the distance of the meridians of the two places K and N upon the equator; and since, in the triangle PNK, ST is the parallel to KN, therefore PN:PT::NK:TS. Consequently TS will be the distance of the two places K and N upon the parallel of 28°.

If the parallel the two places lie on be not far from the equator, and they not far asunder; then their distance may be found thus. Take the distance between them in your compasses, and apply that to the graduated meridian, so as the one foot may be as many minutes above, as the other is below the given parallel; and the degrees and minutes intercepted, reduced to minutes, will give the distance.

Or it may also be found thus. Take the length of a degree on the meridian at the given parallel, and turn that over on the parallel from the one place to the other, as oft as you can; then as oft as that extent is contained between the places, so many times 60 miles will be contained in the distance between them.

Case IV. When the places differ 60 miles.

Example. Suppose it were required to find the distance between the two places a and e upon the chart.

By

Prob. II. Find the difference of latitude between them; and take that in your compasses from the graduated equator, which set off on the meridian of a, from a to b; then through b draw be parallel to de; and taking ac in your compasses, apply it to the graduated equator, and it will shew the degrees and minutes contained in the distance required, which multiplied by 60 will give the miles of distance.

The reason of this is evident from Art. 8. of this Sect. for it is plain ad is the enlarged difference of latitude, and ab the proper; consequently ac the enlarged distance, and ac the proper.

Prob. V. To lay down a place upon the chart, its latitude and bearing from some known place upon the chart being known, or (which is the same) having the course and difference of latitude that a ship has made, to lay down the running of the ship, and find her place upon the chart.

Example. A ship from the Lizard in the latitude of 50° 00' north, sails SSW till she has differed her latitude 36° 40'. Required her place upon the chart.

Count from the Lizard at L. on the graduated meridian downwards (because the course is southerly) 36° 40' to H; through
through which draw a parallel of latitude, which will be the parallel the ship is in; then from L draw a SSW line Lf, cutting the former parallel in f, and this will be the ship's place upon the chart.

**Prob. VI.** One latitude, course, and distance, failed, given; to lay down the running of the ship, and find her place upon the chart.

*Example.* Suppose a ship at a in the latitude of 20° 00' north, sails north 37° 20', east 191 miles: Required the ship's place upon the chart.

Having drawn the meridian and parallel of the place a, set off upon it the rhomb line ae, making with ab an angle of 37° 20'; and upon it set off 191 from a to e; through c draw the parallel eb; and taking ab in your compasses, apply it to the graduated equator, and observe the number of degrees it contains; then count the same number of degrees on the graduated meridian from C to b, and through b draw the parallel he, which will cut ac produced in the point e, the ship's place required.

**Prob. VII.** Both latitudes and distance failed, given; to find the ship's place upon the chart.

*Example.* Suppose a ship fails from a, in the latitude of 20° 00' north, between north and east 191 miles, and is then in the latitude of 45° 00' north: Required the ship's place upon the chart.

Draw de the parallel of 45°, and set off upon the meridian of a upwards, ab equal to the proper difference of latitude taken from the equator or graduated parallel. Through b draw bc parallel to de; then with 191 in your compasses, fixing one foot of them in a, with the other crofs b c in c. Join a and c with the right line ac, which produced will meet de in e, the ship's place required.

**Prob. VIII.** One latitude, course and difference of longitude, given; to find the ship's place upon the chart.

*Example.* Suppose a ship from the Lizard in the latitude of 50° 00' north, sails SW&W, till her difference of longitude is 42° 36': Required the ship's place upon the chart.

Having drawn AE the meridian of the Lizard at L, count from E to F upon the equator 42° 36'; and through F draw the meridian EG; then from L draw the SW&W line LK, and where this meets FG, as at K, will be the ship's place required.

**Prob. IX.** One latitude, course, and departure, given; to find the ship's place upon the chart.

*Example.* Suppose a ship at a in the latitude of 20° 00' north, fails north 37° 20' east, till she has made of departure 116 miles: Required the ship's place upon the chart.

Having drawn the meridian of a, at the distance of 116, draw parallel to it the meridian k l. Draw the rhomb line ae, which will meet k l in some point c; then through c draw the parallel eb, and a b will be the proper difference of latitude, and b c the departure. Take a b in your compasses, and apply it to the equator or graduated parallel; then observe the number of degrees it contains, and count so many on the graduated meridian from C upwards to b. Through b draw the parallel he, which will meet ac produced in some point as e, which is the ship's place upon the chart.

**Prob. X.** One latitude, distance, and departure, given; to find the ship's place upon the chart.

*Example.* Suppose a ship at a in the latitude of 20° 00' north, sails 116 miles between north and east, and then is found to have made of departure 116 miles: Required the ship's place upon the chart.

Having drawn the meridian and parallel of the place a, set off upon the parallel a m equal to 116, and through m draw the meridian k l. Take the given distance 116 in your compasses; letting one foot of them in a, with the other crofs k l in e. Join a e, and through e draw the parallel eb; so eb will be the departure, and ab the proper difference of latitude; then proceeding with this, as in the foregoing problem, you will find the ship's place to be e.

**Prob. XI.** The latitude failed, difference of latitude, and departure, given; to find the ship's place upon the chart.

*Example.* Suppose a ship from a in the latitude of 20° 00' north, sails between north and east, till she be in the latitude of 45° 00' north, and is then found to have made of departure 116 miles: Required the ship's place upon the chart.

Having drawn the meridian of a, set off upon it, from a to b, 25 degrees, (taken from the equator or graduated parallel,) the proper difference of latitude; then thro' b draw the parallel b c, and make b c equal to 116 the departure, and join a c. Count from the parallel of a on the graduated meridian upwards to b 25 degrees, and through b draw the parallel e b, which will meet ac produced in some point e, and this will be the place of the ship required.

12. In the section of Plain Sailing it is plain that the terms meridional distance, departure, and difference of longitude, were synonymous, constantly signifying the same thing: which evidently followed from the supposition of the earth's surface being projected on a plane, in which the meridians were made parallel, and the degrees of latitude equal to one another and to those of the equator. But since it has been demonstrated (in this section) that if, in the projection of the earth's surface upon a plane, the meridians be made parallel, the degrees of latitude must be unequal, still increasing the nearer they come to the pole. It follows that these terms must denote lines really different from one another.

**Sect. 6. Of Oblique Sailing,**

The questions that may be propofed on this head being innumerable, we shall only give a few of the most useful.

**Prob. I.** Coafting along the shore, I saw a cape bear from me NNE; then I fowed away NW&W 20 miles, and I observed the fame cape to bear from me NE&NE. Required the distance of the ship from the cape at each fation.

**Geometrically.** Draw the circle NWSE (No. 22.) to repreffent the compafs, NS the meridian, and WE the eaf't and weft line, and let C be the place of the ship in her first fation; then from C let off upon the NW&W line, CA 20 miles, and A be the place of the ship in her second fation.
NAVIGATION

From C draw the NNE line CB, and from A draw AB parallel to the NEW line CD, which will meet CB in the place of the cape, and CB will be the distance of it from the ship in its first station, and AB the distance in the second: to find which,

By Calculation:

In the triangle ABC are given AC, equal to 20 miles; the angle ACB, equal to 73° 45', the distance between the NNE and NW line; also the angle ABC, equal to 39° 22', the distance between the NNE and SSW line; and consequently the angle A, equal to 69° 30'.

Hence for CB, the distance of the cape from the ship in her first station, it will be (by oblique trigonometry)

\[ S \text{. ABC : AC :: S. BAC : CB} \]

\[ i. e. \text{ As the sine of } 
\frac{1}{2} \text{ the sum of sides AC and CB } 37^\circ 22' \quad 9.91417 \]

\[ \text{the distance from the ship at the first station.} \]

Then for AB, it will be, by oblique trigonometry,

\[ S \text{. ABC : AC :: S. BAC : AB} \]

\[ i. e. \text{ As the sine of } 
\frac{1}{2} \text{ the difference of sides 12.71 } 1.10415 \]

\[ \text{the distance of the cape from the ship at her second station.} \]

By Calculation:

In the triangle ABC are given AC, equal to 20 miles; the angle ACB, equal to 73° 45', the distance between the NNE and NW line; also the angle ABC, equal to 39° 22', the distance between the NNE and SSW line; and consequently the angle A, equal to 69° 30'.

Hence for CB, the distance of the cape from the ship at her first station.

\[ S \text{. ABC : AC :: S. BAC : CB} \]

\[ i. e. \text{ As the sine of } 
\frac{1}{2} \text{ the sum of sides AC and CB } 37^\circ 22' \quad 9.91417 \]

\[ \text{the distance from the ship at the first station.} \]

Then for AB, it will be, by oblique trigonometry,

\[ S \text{. ABC : AC :: S. BAC : AB} \]

\[ i. e. \text{ As the sine of } 
\frac{1}{2} \text{ the difference of sides 12.71 } 1.10415 \]

\[ \text{the distance of the cape from the ship at her second station.} \]

Prob. III. Coasting along the shore, I saw two headlands; the first bore from me NW from the second NNE; then standing away E by N 15° northerly 20 miles; I found the first bore from me WN, and the second N 22° westerly. Required the bearing and distance of these two headlands.

Geometrically. Having drawn the compasses NWSE (No. 24.) let C represent the first place of the ship; from which draw the NW line CB, and the NNE line CD, also the ENE line CA, which make equal to 20. From A draw AB parallel to the WNW line, and AD parallel to the NW line meeting the two first lines in the points B and D; then B will be the first and D the second headlands. Join the points B and D, and BD will be the distance between them, and the angle CDB the bearing from the NNE line: to find which

By Calculation:

1. In the triangle ABC are given the angle BCA, equal to 106° 04', the distance between the WNW line, and the ENE line; the angle ABC, equal to 30° 30', the distance between the WSW line, and the NNE line; the angle BAC, equal to 59° 22', the distance between the WSW line, and the SW line; also the side CA equal to 20 miles; whence for CB, it will be (by oblique trigonometry)

\[ \frac{1}{2} \text{ the sum of sides } AC \quad 9.80228 \]

\[ \text{the distance between the first headland and the ship in her first station.} \]

2. In the triangle ACD, are given the angle ACD, equal to 47° 49', the distance between the ENE line, and the NEE line; the angle CAD, equal to 92° 49', the distance between the WSW line, and the NWW line, the angle CDA equal to 39° 22', the distance between the S line, and the S line; also the side CA equal to 20 miles.

Hence for CD, it will be (by oblique trigonometry)

\[ \frac{1}{2} \text{ the difference of sides } 9.80228 \]

\[ \text{the distance between the second headland and the ship in her first station.} \]

3. In the triangle BCD, are given BC 18.79, CD 9.99960, and the angle BCD, equal to 59° 22', the distance between the NEE line, and the NNE line.

Hence for the angle CDB, it will be (by oblique trigonometry)

\[ \frac{1}{2} \text{ the difference of sides } 1.49835 \]

\[ \text{the distance between the second headland and the ship in her first station.} \]
To is the fine of BCD — 56° 15' — 9.91985

to BD — 26° 21' — 1.41843

distance between the two headlands.

This, and the first problem, are of great use in drawing the plot of any harbour, or laying down any sea coast.

Suppose a ship that makes her way good within 6 ¼ points of the wind, at north, is bound to a port bearing east 86 miles distance from her: Required the course and distance upon each tack, to gain the intended port.

**Geometrically.** Having drawn the compass NE SW, (No. 25.) let C represent the ship's place, and set off upon the east line CA 86 miles, so A will be the intended port. Draw CD and CB on each side of the north line at 6 ¼ points distance from it, and through A draw AB parallel to CD meeting CB in B; then the ENE ¼ E line CB, will be the course of the ship upon the starboard tack, and CB its distance on that tack; also the ESE ¼ E line AB, will be the course on the larboard tack, and BA the distance on that tack: to find which

**By Calculation:**

In the triangle ABC are given, the angle ACB, equal to 160°, 53', the distance between the east and ENE ¼ E line; the angle CBA, equal to 146° 14', the distance between the ENE ¼ E and the WNW ¼ W lines; the angle BAC equal to 16° 53', the distance between the east and ESE ¼ E lines; also AC 86 miles.

Hence since the angle at A and C are equal, the legs CB and BA will likewise be equal; to find either of which (suppose CB) it will be (by oblique angled trigonometry.)

As the fine of B — 146°, 14' — 9.74493

is to AC — 86 — 1.93450

so is the fine of A — 16°, 53' — 9.46393

to CB — 44°, 94' — 1.65260

distance the ship must sail on each tack.

There is a great variety of useful questions of this nature that may be proposed; but the nature of them being better understood by practice at sea, we shall leave them, and go on to Current Sailing.

**Sect. 7. Concerning Currents, and how to make proper allowances.**

**1. Currents** are certain settings of the stream by which all bodies (as ships, &c.) moving therein, are compelled to alter their course or velocity, or both; and submit to the motion impressed upon them by the current.

**Case I.** If the current sets just with the course of the ship, (i.e.) moves on the same rhomb with it; then the motion of the ship is increased, by as much as is the drift or velocity of the current.

**Example.** Suppose a ship fails SE 8 at the rate of 6 miles an hour, in a current that sets NNE 6 miles an hour: Required the ship's true rate of failing.

Here it is evident that the ship's true rate of failing will be 8 miles an hour.

**Case II.** If the current sets directly against the ship's course, then the motion of the ship is lessened by as much as is the velocity of the current.

**By Calculation:**

As the apparent distance AD — 96 — 1.98227

is to the current's motion DC — 45 — 1.65321

so is radius — — 10.0000

to the tangent of the true course DAC — — 25°, 07' — 9.67094

consequently the ship's true course is S 25°, 07' E, or SSE 2° 39', easterly.

Then for the true distance AC, it will be, (by rectangular trigonometry.)

As the fine of the course A — 25°, 07' — 9.62784

is to the departure DC — 45 — 1.65321

so is radius — — 10.0000

to the true distance AC — — 106 — 2.02357

**Example.** Suppose a ship fails SE 120 miles in 20 hours, in a current that sets WNW at the rate of 2 miles an hour: Required the ship's true course and distance failed in that time.
NAVIGATION.

Geometrically. Having drawn the compas NESW (No. 27.) let C represent the place the ship failed from; draw the SE line CA, which make equal to 120°; then will A be the place the ship capest at.

From A draw AB parallel to the WNE line CD, equal to 40°, the motion of the current in 20 hours, and join CB; then B will be the ship's true place at the end of 20 hours, CB her true distance, and the angle SCB her true course. To find which

By Calculation;

In the triangle ABC, are given CA 120, AB 40, and the angle CAB equal to $43° 45'$, the distance between the ENE and SE lines, to find the angles B and C, and the side CB.

First, For the angles C and B, it will be, (by oblique trigonometry)

As the sum of the sides CA and AB 160 — 2.20412 is to their difference 80 — 1.90309
so is the tang. of half the sum $73°, 07'$ 10.51783
to the tang. of half their differ. $59°, 45'$ 10.21680
consequently the angle ABC will be $131°, 52'$, and the angle ACB $14°, 23'$. Hence the true course is S $30°, 27'$ E, or SSE $2°, 07'$ westerly.

Then for the true distance CB, it will be, (by oblique trigonometry)

As the line of $B$ $131°, 52'$ — 9.87199
is to AC $120°$ — 2.07918
so is the line of A $55°, 45'$ — 9.74474
to the true distance CB $89°, 53'$ — 1.95194

Example III. Suppose a ship coming out from sea in the night, has sight of Scilly light, bearing NESW $12°$ 4 leagues, it being then flood tide setting ENE 2 miles an hour, and the ship running after the rate of 5 miles an hour. Required upon what course and how far the ship has sailed, it will he

DAC equal to 67° 30' Whence for AC, the distance run

As radius 10.00000
is to the differ. of latitude AD 8 — 0.90309
so is the current's drift LC 2 — 0.69897
to the angle LDC, the course the ship must steer is S 88° 03' E.

Then for the distance AB, it will be (by oblique trigonometry)

As the line of B $155°, 33'$ — 9.61689
is to AL 57.45 — 1.76080
so is the line of L $17°, 32'$ — 9.47894
to AB 41.06 — 1.62283
consequently, since the ship is sailing at the rate of 5 miles an hour, it follows, that in sailing 8th 24th of $88°, 03'$ E, she will arrive at the Lizard.

Example IV. A ship from a certain headland in the latitude of $34°$ 00' north, fails SEWS 12 miles in three hours, in a current that sets between north and east; and then the same headland is found to bear WNW, and the ship to be in the latitude of $33°, 52'$ north. Required the setting and drift of the current.

Geometrically. Having drawn the compas NESW (No. 29.) let A represent the place of the ship, and draw the SWS line AB equal to 12 miles, also the ESS line AC.

Set off from A upon the meridian AD, equal to 8 miles, the difference of latitude, and through D draw DC parallel to the east and west line WE, meeting AC in C. Join C and B with the right line BC; then C will be the ship's place, the angle ABC the setting of the current from the SWS line, and the line BC will be the drift of the current in 3 hours. To find which

By Calculation:

In the triangle ADC right angled at D, are given the difference of latitude AD equal to 8 miles, the angle DAC equal to $67°, 30'$ Whence for AC, the distance the ship has failed, it will be

As radius $10.00000$
is to the differ. of latitude AD 8 — 0.90309
so is the current's drift D

DAC $67°, 30'$ 10.41716
to the distance run AC 20.9 — 1.32025
Again, in the triangle ABC, are given AB equal to $5°$ E
N A V I G A T I O N.

12 miles, AC equal to 20.9, and the angle BAC equal to 33° 45', the distance between the SE&S and ESE lines. Whence for the angle at B, it will be,

As the sum of the sides AC and AB 32.9 1.51720
is to their difference — 8.9 — 0.94930
so is the tang. of half the sum of the angles C and B 73° 07' — 10.51806
tang. of ½ their diff. 41°, 43' ¼ — 9.95095
consequently the angle B is 114° 51', and to the setting of the current will be N 81° 06' E or ESE 2° 21' E.

Then for BC the current's drift in 3 hours, it will be,

0° 21' E — 4.266 miles an hour.

The fine of B — 114°, 51' — 9.92700
is to radius 10.00000
the current's drift in 3 hours, and consequently the current is to compass EBN 2° 21' E 4.266 miles an hour.

Sect. 8. Concerning the Variation of the Compass, and how to find it from the true and observed Amplitudes or azimuths of the sun.

1. The variation of the compass is how far the north or south point of the needle stands from the true north or south point of the horizon towards the east or west; or it is an arch of the horizon intercepted between the meridian of the place of observation and the magnetic meridian.

2. It is absolutely necessary to know the variation of the compass at sea, in order to correct the ship's course; for since the ship's course is directed by the compass, it is evident that if the compass be wrong the true course will differ from the observed, and consequently the whole reckoning differ from the truth.

3. The sun's true amplitude is an arch of the horizon comprehended between the true east or west point thereof, and the centre of the sun at rising or setting; or it is the number of degrees, &c. that the centre of the sun is distant from the true east or west point of the horizon, towards the south or north.

4. The sun's magnetic amplitude is the number of degrees that the centre of the sun is from the east or west point of the compass, towards the south or north point of the same at rising or setting.

5. Having the declination of the sun, together with the latitude of the place of observation, we may from thence find the sun's true amplitude, by the following astronomical proposition, viz.

As the co-flne of the latitude is to the radius.
so is the fine of the sun's declination to the fine of the sun's true amplitude which will be north or south according as the sun's declination is north or south.

Example. Required the sun's true amplitude in the latitude of 41° 50' north, the 23d day of April 1731.

First, I find (from the tables of the sun's declination) that the sun's declination the 23d of April is 15° 54' north; then for the true amplitude, it will be, by the former analogy.

As the co-flne of the lat. 41° 50' — 9.87221
is to radius 10.00000
so is the fine of the decl. 15° 54' — 9.43769
to the fine of the amplitude. 21°, 35' — 9.56548
which is north, because the declination is north at that time; and consequently, in the latitude of 41° 50' north, the sun rises on the 23d of April 21° 35' from the east part of the horizon towards the north, and sets so much from the west the same way.

6. The sun's true azimuth is the arch of the horizon intercepted between the meridian and the vertical circle passing through the centre of the sun at the time of observation.

7. The sun's magnetic azimuth is the arch of the horizon intercepted between the magnetic meridian and the vertical, passing through the sun.

8. Having the latitude of the place of observation, together with the sun's declination and altitude at the time of observation, we may find his true azimuth after the following method, viz.

Make it,

As the tangent of half the complement of the latitude is to the tangent of half the sum of the distance of the sun from the pole and complement of the altitude.

So is the tangent of half the difference between the distance of the sun from the pole and complement of the altitude.

To the tangent of a fourth arch which fourth arch added to half the complement of the latitude will give a fifth arch, and this fifth arch lessened by the complement of the latitude will give a sixth arch.

Then make it,

As the radius is to the tangent of the altitude.
so is the tangent of the sixth arch to the co-flne of the sun's azimuth.

which is to be counted from the south or north, to the east or west, according as the sun is situated with respect to the place of observation.

If the latitude of the place and declination of the sun be both north or both south, then the declination taken from 90° will give the sun's distance from the pole; but if the latitude and declination be on contrary sides of the equator, then the declination added to 90° will give the sun's distance from the nearest pole to the place of observation.

Example. In the latitude of 51° 32' north, the sun having 19° 39' north declination, his altitude was found by observation to be 38° 18'. Required the azimuth.

By the first of the foregoing analogies, it will be

As the tangent of ½ the complement of the altitude 61° 01' 10.25655
is to the tangent of ½ the sum of the distance of the sun from the pole and complement of the altitude

so is the tangent of half their difference 9° 19° 7.21499

to the tang. of a 4th arch 40° 20° 9.92885
which fourth arch 40° 20° added to 19° 14° half the complement of the latitude, give a fifth arch 59° 34'; and this fifth arch lessened by 38° 28°, the complement of the latitude, gives the sixth arch 21° 06'; then for the
the azimuth, it will be, by the second of the preceding analogies,

As radius ——— 10,00000

is the tangent of the altitude 38°, 18' 9.89949

so is the tangent of the sixth arch 21°, 06' 9.58644

to the co-sine of the azimuth 72°, 15' 9.48393

which, because the latitude is north and the sun fouth of
the place of observation, must be counted from the south
towards the east or west; and consequently, if the alti-
tude of the sun was taken in the morning, the azimuth
will be S 72° 15' E, or ESE 4° 45' E; but if the alti-
tude was taken in the afternoon, the azimuth will be
S 72° 15' W, or WSW 4° 45' westerly.

9. Having found the sun's true azimuth or azimuth
by the preceding analogies, and his magnetic azimuth
or azimuth by observation, it is evident, if they agree,
there is no variation; but if they disagree, then if the
true and observed azimuths at the rising or setting of
the sun be both of the same name, i.e. either both
north, or both south, their difference is the variation;
but if they be of different names, i.e. one north and
the other south, their sum is the variation. Again, if
the true and observed azimuth be both of the same name,
i.e. either both east or both west, their difference is the
variation: but if they be of different names, their sum is
the variation. And to know whether the variation is
easterly, observe this general rule, viz.

Let the observer's face be turned to the sun: then if
the true azimuth or azimuth be to the right hand of
the observed, the variation is easterly; but if it be to the
left, westerly.

To explain which, let NESW (No. 30.) represent a
compass, and suppose the sun is really ESE at the time
of observation, but the observer sees him off the east
point of the compass, and so the true azimuth or azi-
muth of the sun is to the right of the magnetic or ob-
erved; here it is evident that the ESE point of the
compass ought to lie where the east point is, and so the
north where the NW is; consequently the north point
of the compass is a point too far east, i.e. the variation
in this case is easterly. The same will hold when the azi-
muth or azimuth is taken on the west side of the mer-
idian.

Again, let the true azimuth or azimuth be to the
left hand of the observed. Thus, suppose the sun is really
EWN at the time of observation, but the observer sees
him off the west point of the compass, and so the true
azimuth or azimuth to the left of the observed: Here
it is evident that the EWN point of the compass ought
not to stand where the east point is, and so the north
where the N6E point is; consequently the north point
of the compass lies a point too far west, i.e. the varia-
tion is westerly. The same will hold when the azi-
muth is observed on the west side of the meridian.

Example I. Suppose the sun's true azimuth at ri-

ing was found to be E 14° 20' N, but by the compass it

is found to be E 26° 12': Required the variation, and

which way it is.

Since they are both the same way, therefore

From the magnetic azimuth ——— E 26°, 12' N.

take the true azimuth ——— E 14°, 20' N.

and there remains the variation ——— 11°, 52 E.

which is easterly, because in this case the true azimuth
is the right of the observed.

Example II. Suppose the sun's true azimuth at set-
ing is W 34° 26' S, and his magnetic azimuth W 23°
13' S: Required the variation, and which way it is.

Since they lie both the same way, therefore

From the sun's true azimuth ——— W 34°, 26' S.

take his magnetic azimuth ——— W 23°, 13' S.

there remains the variation ——— 11°, 13 W.

which is westerly, because the true azimuth is, in this
case, to the left hand of the observed.

Example III. Suppose the sun's true azimuth at rising
is found to be 13° 7° 4' N, and his magnetic E 12° 32' S:

Required the variation, and which way it lies.

Since the true and observed azimuths lie different
ways, therefore

To the true azimuth ——— E 13°, 24' N.

add the magnetic azimuth ——— E 12°, 32' S.

the sun is the variation ——— 25°, 56 W.

which is westerly, because the true azimuth is, in this
case, to the left of the observed.

Example IV. Suppose the sun's true azimuth at set-
ing is found to be W 8° 24' N, but his magnetic azi-
muth is W 10° 13' S: Required the variation.

To the true azimuth ——— W 8°, 24' N.

add the magnetic ——— W 10°, 13' S.

the sun is the variation ——— 18°, 37 E.

which is easterly, because the true azimuth is to the
right of the observed.

Example V. Suppose the sun's true azimuth at the
time of observation, is found to be N 86° 40' E, but by
the compass it is N 73° 24' E: Required the variation,
and which way it lies.

From the true azimuth, ——— N 86°, 40' E.

take the magnetic, ——— N 73°, 24' E.

there remains the variation, ——— 13°, 16 E.

which is westerly, because the true azimuth is to the
right of the observed.

Example VI. Suppose the sun's true azimuth is S
3° 24' E and the magnetic S 4° 36' W: Required
the variation, and which way it lies.

To the true azimuth ——— S 3°, 24' E.

add the magnetic azimuth ——— S 4°, 36' W.

the sun is the variation ——— 8°, 00 W.

which is westerly, because the true azimuth is to the
left of the observed.

10. The variation of the compass was first observed
at London, in the year 1580, to be 11° 15' easterly, and
in the year 1622 it was 6° 05' E; also in the year
1634, it was 4° 05' E, still decreasing, and the needle
approaching the true meridian, till it coincided with it,
and then there was no variation; after which, the varia-
tion.
tion began to be westerly; and in the year 1672, it was 2° 30' W; also in the year 1683, it was 4° 30' W; and since that time the variation still continues at London to increase westerly; but how far it will go that way, time and observations will probably be the only means to discover.

Again, at Paris, in the year 1640, the variation was 3° 00' E; and in the year 1666, there was no variation; but in the year 1681, it was 2° 30' W, and still continues to go westerly.

In short, from observations made in different parts of the world, it appears, that in different places the variation differs both as to its quantity and denomination, it being east in one place, and west in another; the true cause and theory of which, for want of a sufficient number of observations, has not as yet been fully explained.

Sec. 9. The Method of keeping a Journal at sea; and how to correct it, by making proper allowances for the leeway, variation, &c.

1. Lee-way is the angle that the rhomb line, upon which the ship endeavours to fail, makes with the rhomb she really fails upon. This is occasioned by the force of the wind or surge of the sea, when she lies to the windward, or is close hauled, which causes her to fall off and glide sideways from the point of the compass the capes at. Thus let NESW (No. 31.) represent the compass; and suppose a ship at C capes at, or endeavours to fail upon, the rhomb Ca; but by the force of the wind, and surge of the sea, she is obliged to fall off, and make her way upon the rhomb Cb; the angle aCb is the leeway; and if that angle be equal to one point, the ship is said to make one point leeway; and if equal to two points, the ship is said to make two points leeway, &c.

2. The quantity of this angle is very uncertain, because some ships, with the same quantity of fail, and with the same gale, will make more leeway than others; it depending much upon the mould and trim of the ship, and the quantity of water that she draws. The common allowances that are generally made for the leeway, are as follow.

4. If one top fail must be handed, then the ship is supposed to make between two and three points leeway.

5. When both top-fails must be handed, then the allowance is about four points for leeway.

6. If it blow so hard, as to occasion the fore-course to be handed, the allowance is between 5½ and 6 points.

7. When both main and fore-courses must be handed, then 6 or 6½ points are commonly allowed for leeway.

8. When the mizen is handed, and the ship is trying a hull, she is then commonly allowed about 7 points for leeway.

3. Though these rules are such as are generally made

4. Having the course steered, and the leeway, given; we may from thence find the true course by the following method, viz. Let your face be turned directly to the windward; and if the ship have her larboard tacks on board, count the leeway from the course steered towards the right hand; but if the starboard tacks be on board, then count it from the course steered towards the left hand. Thus, suppose the wind is at NNW, and the ship lies up within 6 points of the wind, with her larboard tacks on board, making one point leeway; here it is plain, that the course steered is ENE, and the true course EWN; also suppose the wind is at NNW, and the ship lies up within 6½ points of the wind, with her starboard tack on board, making 1½ point leeway; it is evident that the true course, in this case, is WSW.

5. We have shewed, in the last section, how to find the variation of the compass; and from what has been said there, we have this general rule for finding the ship's true course, having the course steered and the variation given, viz. Let your face be turned towards the point of the compass upon which the ship is steered; and if the variation be westerly, count the quantity of it from the course steered towards the right hand; but if easterly, towards the left hand; and the course thus found is the true course steered. Thus, suppose the course steered is NNE, and the variation one point easterly; then the true course steered will be NNW: Also suppose the course steered is NESE, and the variation one point westerly; then in this case, the true course will be NE; and so of others.

Hence, by knowing the leeway variation, and course steered, we may from thence find the ship's true course; but if there be a current under foot, then that must be tried, and proper allowances made for it, as has been shown in the section concerning Currents, from thence to find the true course.

6. After making all the proper allowances for finding the ship's true course, and making as just an estimate of the distance as we can; yet by reason of the many accidents that attend a ship in a day's running, such as different rates of falling between the times or hearing the log,
the want of due care at the helm by not keeping her steady, but suffering her to yaw and fall off; sudden storms, when no account can be kept, &c.; the latitude by account frequently differs from the latitude by observation; and when that happens, it is evident there must be some error in the reckoning; to discover which, and where it lies, and also how to correct the reckoning, you may observe the following rules.

If the ship fail near the meridian, or within 2 or 3 points thereof; then if the latitude by account disagrees with the latitude by observation, it is most likely that the error lies in the distance run; for it is plain that in this case it will require a very sensible error in the course to make any considerable error in the difference of latitude, which cannot well happen if due care be taken at the helm, and proper allowances be made for the lee-way, variation, and currents. Consequently if the course be pretty near the truth, and the error in the distance run regularly through the whole, we may, from the latitude obtained by observation, correct the distance and departure by account, by the following analogies, viz. As the difference of latitude by account is to the true difference of latitude, so is the departure by account to the true departure, and so is the direct distance by account to the true direct distance.

The reason of this is plain: for let AB (No. 33) denote the meridian of the ship at A, and suppose the ship fails upon the rhomb AE near the meridian, till by account she is found in C, and consequently her difference of latitude by account is AB; but by observation she is found in the parallel ED, and so her true difference of latitude is AD, her true distance AE, and her true departure DE; then since the triangles ABC ADE are similar, it will be AB : AD :: BC : DE, and AB : AD :: AC : AE.

Example. Suppose a ship from the latitude of 43° 50' north, after having failed upon several courses near the parallel of east and west, for the space of 24 hours, is found by dead reckoning to be in the latitude of 42° 45' north, and to have made 160 miles of westing; but by a good observation the ship is found to be in the latitude of 42° 35' north: Required the true course, and direct distance failed.

With the true difference of latitude 75 miles, and departure 160 miles, we shall find (by Case 4. of Plain Sailing) the true course to be S 64° 55' W, and the direct distance 176.7 miles.

3dly, If the courses are for the most part near the middle of the quadrant, and the direct course within 2 and 6 points of the meridian; then the error may be either in the course, or in the distance, or in both, which will cause an error both in the difference of latitude and departure; to correct which, having found the true difference of latitude by observation, with this, and the direct distance by dead reckoning, find a new departure (by Case 3. of Plain Sailing:) then half the sum of this departure, and that by dead reckoning, will nearly be equal to the true departure; and consequently with this, and the true difference of latitude, we may (by Case 4. of Plain Sailing) find the true course and distance.

Example. Suppose a ship from the latitude of 44° 38' north, falls between fourth and east upon several courses, near the middle of the quadrant, for the space of 24 hours, and is then found by dead reckoning to be in the latitude of 42° 15' north, and to have made of westing 136 miles; but by observation she is found to be in the latitude of 42° 09' north: Required her true course and distance.

With the true difference of latitude 154 miles, and the direct distance by dead reckoning 197.4, you will find (by Case 3. of Plain Sailing) the new departure to be 123.4, and half the sum of this and the departure by dead reckoning will be 123.7 the true departure; then with this, and the true difference of latitude, you will find (by Case 4. of Plain Sailing) the true course to be S 39° 04' E, and the direct distance 198.2 miles.

7. In keeping a ship's reckoning at sea, the common method is to take from the log-book the several courses and distances steered by the ship left 24 hours, and to transfer these together with the most remarkable occurrences into the log-book, into which also are inserted the courses corrected, and the difference of latitude and difference of longitude made good upon each; then the whole day's work being finished in the log-book, if the latitude by account agree with the latitude by observation, the ship's place will be truly determined; but if not, then the reckoning must be corrected according to the preceding rules, and placed in the journal.

The form of the Log-book and Journal, together with an example of 2 days work, you have here subjoined.

Note. To express the days of the week, they commonly use the characters by which the sun and planets are expressed, viz. O denotes Sunday, & Monday, & Tuesday, & Wednesday, & Thursday, & Friday, and & denotes Saturday.

Hence the ship, by account, has come to the latitude of 47° 46' north, and has differed her longitude 2° 5' westerly; so this day I have made my way good S 31° 31' W, distance 157.4 miles.

At noon the Lizard bore from me N 31° 31' E, distance 157.4 miles; and having observed the latitude, I found it agreed with the latitude by account.

A Journal from the Lizard towards Jamaica in the ship Neptune, J. M. commander.
NAUMACHIA, in antiquity, a show or spectacle among the ancient Romans, representing a sea-fight.

NAUMBURG, a city of Germany, the capital of the county of Sax Naumburg, in Upper Saxony, situated in E. long. 12°, N. lat. 51° 15'.

NAUSEA, in medicine, a reaching, or propensity and endeavour to vomit, arising from a loathing of food, excited by some viscid humour that irritates the stomach.

NAUTICAL PLANISPHERE, a description of the terrestrial globe upon a plane for the use of mariners, more usually called chart.

NAUTILUS, in zoology, a genus belonging to the order of vermes testacea. The shell consists of one spiral valve, divided into several apartments by partitions. There are 17 species, principally distinguished by peculiarities in their shells.

NAVY, the fleet or shipping of a prince or state. The management of the British navy-royal, under the lord high admiral of Great Britain, is entrusted to principal officers and commissioners of the navy, who hold their places by patent. The principal officers of the navy are four, viz. the treasurer, whose business it is to receive money out of the exchequer, and to pay all the charges of the navy, by warrant from the principal officers: comptroller, who attends and comp-}

The commission of the navy are five: the first executes that part of the comptroller's duty which relates to the comptrolling the victuallers accounts; the second, another part of the said comptroller's duty, relating to the account of the store-keepers of the yard; the third has the direction of the navy at the port of Portsmouth; the fourth has the same at Chatham; and the fifth, at Plymouth.

There are also other commissioners at large, the number more or less according to the exigencies of public affairs; and since the increase of the royal navy, these have several clerks under them, with salaries allowed by the king.

The victualling of the royal navy hath formerly been undertaken by contract; but is now managed by commissioners, who hold their office on Tower-hill, London.

The navy-office is where the whole business concerning the navy is managed by the principal officers and commissioners.

The royal navy of Great Britain is now in a very flourishing state; having been diligently kept up in late reigns, as the natural strength of the kingdom. When it is complete, it is divided into three squadrons, distinguished by the different colours of the flags carried by the respective admirals belonging to the same.

NAXIA, one of the islands of the Archipelago, about an hundred miles in circumference, situated in E. long. 26°, and N. lat. 36° 30'.

NAZARENES, in church history, a name originally given to all Christians in general, on account that Jesus Christ was of the city of Nazareth; but afterwards restrained to a sect of heretics, whose religion consisted of a strange jumble of Judaism and Christianity; observing at the same time the Mosaic law and the several rites of the Christian religion.

NAZARITES, among the Jews, persons who either of themselves, or by their parents, were dedicated to the observance of nazarite ship. They were of two sorts: namely, such as were bound to this observance for only a short time, as a week or month; or those who were bound to it all their lives. All that we find peculiar in the latter's way of life, is, that they were to abstain from wine and all intoxicating liquors, and never to shave or cut off the hairs of their heads. The first sort of Nazarites were moreover to avoid all defilement; and if they chanced to contract any pollution before the term was expired, they were obliged to begin afresh. Women as well as men might bind themselves to this vow.

NEALED, among seamen, is used when the sounding is deep water close to the shore; as also when the shore is sandy, clayey, oozy, or foul and rocky ground.

NEAPED. When a ship wants water so that she cannot get out of the harbour, off the ground, or out of the dock, the seamen say the ship is neaped, or be-neaped.

NEATH, a town of Glamorganshire, in south Wales, situated on the river Neath, near the Bristol channel, twenty-eight miles north west of Landaff.

NEBULY, or Nebulee, in heraldry, is when a coat is charged with several little figures, in form of words, running within one another, or when the outline of a bordure, ordinary, &c. is indented or waved, as represented in Plate CXXXIV. fig. 3.

NECESSARY, in a philosophical sense, that which cannot but be, or cannot be otherwise.

NECESSITY, whatever is done by a necessary cause, or a power that is irresistible, in which sense it stands opposed to freedom. See METAPHYSICS.

NECK, in anatomy, is that slender part situated between the head and trunk of the body. See ANATOMY.

NECKAR, a river of Germany, which rises in the south part of the circle of Swabia, and falls into the Rhine at Manheim.

NECROMANCY, a species of divination, performed by raising the dead, and extorting answers from them. See DIVINATION.

NECTAR, among ancient poets, the drink of the fabulous deities of the heathens, in contradistinction from their solid food, which was called ambrosia.

NECTARINE. See PERSIC.

NECTARINE. See PERSIC.

NECTARIUM, among botanists. See BOTANY, p. 627.

NECYDALIS, in zoology, a genus of insects belonging to the order of coleoptera. The feelers are fetaeous; the elytra are shorter and narrower than the wings; and the
the tail is simple. There are eleven species, chiefly distinguided by the size and figure of the elytra.

NEEDHAM, a market-town of Suffolk, situated on the river Orwell, eight miles north-west of Ipswich.

NEEDLE, a very common little instrument or utensil, made of steel, pointed at one end, and pierced at the other, used in sewing embroidery, tapestry, &c.

Needles make a very considerable article in commerce, though there is scarce any commodity cheaper, the consumption of them being almost incredible. The sizes are from no. 1, the largest, to no. 25 the smallest. In the manufacture of needles, German and Hungarian steel are of most repute.

In the making of them, the first thing is to pass the steel through a coal fire, and under a hammer, to bring it out of its square figure into a cylindrical one. This done, it is drawn through a large hole of a wire-drawing iron, and returned into the fire, and drawn through a second hole of the iron, smaller than the first, and thus successively from hole to hole, till it has acquired the degree of fineness required for that species of needles, observing every time it is to be drawn, that it be greased over with lard, to render it more manageable. The steel thus reduced to a fine wire, is cut in pieces of the length of the needles intended. These pieces are flatted at one end on the anvil, in order to form the head and eye; they are then put into the fire, to soften them farther; and thence taken out and pierced at each extreme of the flat part on the anvil, by force of a punchon of well tempered steel, and laid on a leaden block to bring out, with another punchon, the little piece of steel remaining in the eye. The corners are then filed off the square of the heads, and a little cavity filed on each side of the flat of the head; this done, the point is formed with a file, and the whole filed over; they are then laid to heat red hot on a long flat narrow iron, crooked at one end, in a charcoal fire, and when taken out thence are thrown into a bason of cold water to harden. On this operation a good deal depends; too much heat burns them, and too little leaves them soft; great care here too must be taken of the degree of heat. They are then straightened one after another with the hammer, the coldness of the water used in hardening them having twitted the greatest part of them.

The next proceeds is the polishing them. To do this, they take twelve or fifteen thousand needles, and range them in little heaps against each other on a piece of new buckram sprinkled with emery-dust. The needles thus disposed, emery dust is thrown over them, which is again sprinkled with oil of olives; at last the whole is made up into a roll, well bound at both ends. This roll is then laid on a polishing table, and over it a thick plank laden with flones, which two men work backwards and forwards a day and a half or two days successively, by which means the roll thus continually agitated by the weight and motion of the plank turns itself to certain points in or under the horizon. See Navigation.

Needle fish. See Syngnathus.

Needles, two capes, or head-lands, at the west end of the isle of Wight, which is very difficult to pass on account of the sands and rocks.

NEFASTI dies, in Roman antiquity, an appellation given to such days wherein it was not allowed to administer justice, usually marked in the calendar by N. or N. P. i.e. nefastus prima, when only nefastus for the first part of it.

NEGAPATAN, a port-town of the hither India, situated on the coast of Coromandel: E. long. 79°, N. lat. 11° 15'.

NEGATION, in logic, an act of the mind affirming one thing to be different from another; as, that the soul is not matter.

Negative, in general, something that implies a negation: thus we say, negative quantities, negative signs, negative powers, &c. See Metaphysics and Logic.

NEGOMBO, a port-town on the west coast of the isle of Ceylon, in the Indian ocean, subject to the Dutch: E. long. 78°, N. lat. 7° 41'.

NEGRAIS, a port-town of Pegu, in the further India, situated on the west side of the bay of Bengal: E. lon. 92° 30', N. lat. 17°.

NEGRI Point, the most westerly promontory of the island of Jamaica.

NEGROES, properly the inhabitants of Nigritia in Africa, also called blacks and moors; but this name is now given to all the blacks.

The origin of the negroes, and the cause of this remarkable difference from the rest of the human species, has much perplexed the naturalists. Mr. Boyle has observed, that it cannot be produced by the heat of the climate: for though the heat of the sun may darken the colour of the skin, yet experience does not shew that it is sufficient to produce a new blackness, like that of the negroes.

In Africa itself, many nations of Ethiopia are not black, nor were there any blacks originally in the West Indies. In many parts of Asia, under the same parallel with the African region, inhabited by blacks,
the people are but tawny. He adds, that there are negroes in Africa, beyond the southern tropics; and a river sometimes parts nations, one of which is black and the other only tawny. Dr Barriere alludes that the gall of negroes is black, and being mixed with their blood is deposited between their skin and scar-flesh. However, Dr Mitchel of Virginia, in the philosophical transactions, 0° 47′, has endeavoured by many learned arguments to prove, that the influence of the sun in hot countries, and the manner of life of their inhabitants, are the remote causes of the colour of negroes, Indians, &c. and indeed it would be a strong confirmation of his doctrine, if we would see any people, originally white, become black and woolly by transplantation, or vice versa.

Negroes are brought from Guinea, and other coasts of Africa, and sent into the colonies in America, to cultivate tobacco, sugar, indigo, &c. and in Mexico and Peru, to dig in the mines; and this commerce, which is scarce defensible on the foot either of religion or humanity, is now carried on by all the nations that have settlements in the West Indies. These negroes make the best slaves who are brought from Angola, Senegal, Cape Verd, the river Gambia, the kingdoms of Jolofes, Daniel, Galland, &c.

There are various ways of procuring them: some, to avoid famine, fell themselves, their wives and children, to their princes, or other great men; others are made prisoners of war; and great numbers are seized in excursions made for that very purpose by the petty princes upon one another's territories, in which it is usual to sweep away all without distinction of age or sex.

Negroes-island, one of the Philippine islands, in the Indian ocean, subject to Spain; so called, because most of the inhabitants are blacks: E. long. 120°, N. lat. 10′.

Negroland, or Negritia, a country of Africa, which lies between 18° west and 15° east longitude, and between 10° and 20° of north latitude, the great river Niger running through it. It is bounded by Zaara, or the desert, on the north, by unknown countries on the east, by Guinea on the south, and by the Atlantic ocean on the west.

Negropont, or Ecripos, the capital of the island of Negropont, anciently called Euboza, situated in the Archipelago, on the west side of the island; where the strait is so narrow, that it is joined to the continent by a bridge: E. lon. 24° 30′, N. lat. 38° 30′.

Nehemiah, a canonical book of the Old Testament so called from the name of its author. Nehemiah was born in Babylon, during the captivity, and succeeded Ezra in the government of Judah and Jerusalem. He was a Jew, and was promoted to the office of cup-bearer to Artaxerxes Longimanus, king of Persia; when the opportunity he had of being daily in the king's presence, together with the favour of Esther the queen, procured him the favour of being authorized to repair and fortify the city of Jerusalem, in the same manner as it was before its destruction by the Babylonians. On his going to Jerusalem, he assisted the rebuilding of the walls in fifty-two days, and dedicated the gates of the city with great solemnity. He then reformed some abuses which had crept among his countrymen, particularly the extortion of the usurers, by which the poor were so oppressed as to be forced to sell their lands and children for support: after which he returned to Persia, and came back again with a new commission, by virtue of which he regulated every thing relating both to the state and religion of the Jews. The history of these transactions is the subject of this book.

Nellenburg, a city of Swabia, in Germany, capital of a county of the same name, situated fifteen miles north of Conflance.

Nemæa, a town in the Morea, thirty miles south of Corinth, where the ancient Nemæan games were celebrated.

Nemæan Games, were so called from Nemæa, a village between the cities of Cleone and Philus, where they were celebrated every third year. The exercices were chariot races, and all the parts of the pentathlon. These games were instituted in memory of Opheletes, or Archemorus, the son of Euphextes and Creusa, and nursed by Hyperipyle; who, leaving him in a meadow, while she went to shew the besiegers of Thebes a fountain, at her return found him dead, and a serpent twisted about his neck; whence the fountain, before called Lantè, was named Archemorus; and the captains, to comfort Hypeipyle, instituted these games. Others ascribe their institution to Hercules, after his victory over the Nemæan lion.

Nemours, a town in the Isle of France, forty-two miles south of Paris: E. long 2° 45′, N. lat. 48° 17′.

Neomedia, or Noumenia, a festival of the ancient Greeks, at the beginning of every lunar month, which was, as the name imports, observed upon the day of the new moon, in honour of all the gods, but especially Apollo, who was called Neoménios; because the sun is the fountain of light, and whatever distinction of times and feasons may be taken from other planets, yet they are all owing to him as the original of those borrowed rays by which they shine.

Nephytes, new plants, a name given by the ancient Christians to those heathens who had newly embraced the faith; such persons being considered as regenerated, or born anew by baptism. The term neephytes has been also used for new priests, or those just admitted into orders, and sometimes for the novices in monasteries. It is still applied to the converts made by the missionaries among the infidels.

Neottia, in botany. See Ophrys.

Nepa, in zoology, a genus of insects belonging to the order of hemiptera. The rostrum is inflected; the antennae are shorter than the thorax; and the hind-feet are hairy, and fitted for swimming. There are seven species.

Nepenthès, in botany, a plant of the gynandra tetrandra clas. The calyx consists of four segments; it has no corolla; and the capsule has four cells. *There is but one species, a native of Ceylon.

15 Perambulator
by J. Neper, baron of Merchiston, in Scotland, where-
by the multiplication and division of large numbers are
much facilitated.

As to the construction of Neper's rods: suppose the
tomnial table of multiplication to be made upon a
plate of metal, ivory, or paste-board, and then con-
cieve the several columns (standing downwards from
the digits on the head) to be cut asunder; and these
are what we call Neper's rods for multiplication. But
then there must be a good number of each; for as
many times as any figure is in the multiplicand, so
many rods of that species (i.e., with that figure on the
top of it) must we have; though six rods of each spe-
cies will be sufficient for any example in common af-
fairs: there must also be as many rods of o's.

But before we explain the way of using these rods,
there is another thing to be known, viz. that the fi-

tures on every rod are written in an order different
from that in the table. Thus, the little square space
or division in which the several products of every co-
cumn are written, is divided into two parts by a line
across from the upper angle on the right to the lower
on the left; and if the product is a digit, it is set in
the lower division; if it has two places, the first is
set in the lower, and the second in the upper division;
but the spaces on the top are not divided; also there
is a rod of digits, not divided, which is called the in-
dex rod, and of this we need but one single rod. See
the figure of all the different rods, and the index, fi-
parate from one another, in Plate CXXXIV. fig. 1.

Multiplication by Neper's rods. First lay down the in-
dex rod; then on the right of it set a rod whose top is
the figure in the highest place of the multiplicand;
next to this again, set the rod whose top is the next
figure of the multiplicand; and so on in order, to the
first figure. Then is your multiplicand tabulated for
all the nine digits; for in the fame line of squares
standing against every figure of the index rod, you
have the product of that figure, and therefore you
have no more to do but to transfer the products and
sum them. But in taking out these products from the
rods, the order in which the figures stand obliges you
to a very easy and small addition; thus, begin to take
out the figure in the lower part, or unit's place, of
the square of the first rod on the right; add the fi-
ture in the upper part of this rod to that in the lower
part of the next, and so on, which may be done as
faf as you can look on them. To make this practice
as clear as possible, take the following example.

Example: To multiply 4768 by 185. Having set
the rods together for the number 4768 (ibid n° 2.)
against 5 in the index, I find this number, by adding
according to the rule,

\[23840\]
\[38144\]
\[14304\]

Total product \[1835680\]

To make the use of the rods yet more regular and
easy, they are kept in a flat square box, whose breadth
is that of ten rods, and the length that of one rod, as
thick as to hold six (or as many as you please) the
capacity of the box being divided into ten cells for
the different species of rods. When the rods are put
up in the box (each species in its own cell distinguish
by the first figure of the rod set before it on the face
of the box near the top) as much of every rod (ends
without the box as shews the first figure of that rod;
also upon one of the flat sides without and near the
edge) upon the left hand, the index rod is fixed; and
along the foot there is a small ledge, so that the rods
when applied are laid upon this side, and supported
by the ledge, which makes the practice very easy; but
in case the multiplicand should have more than nine-
places, that upper face of the box may be made broader.
Some make the rods with four different faces,
and figures on each for different purposes.

Division by Neper's rods. First tabulate your divi
er; then you have it multiplied by all the digits, out
of which you may chuse such convenient divisors as
will be next less to the figures in the dividend, and
write the index anfwerinc in the quotient, and so continually
till the work is done. Thus 2179788, divided by
6123, gives in the quotient 356.

Having tabulated the divisor 6123, you see that
6123 cannot be had in 2179; therefore take five pla-
ce, and on the rods find a number that is equal or
next less to 21797, which is 18369; that is, 3 times the
divisor; wherefore set 3 in the quotient, and sub-
tract 18369 from the figures above, and there will
remain 3428; to which add 8, the next figure of the
dividend, and seek again on the rods for it, or the
next less, which you will find to be five times; there-
fore set 5 in the quotient, and subtract 30615 from
34288, and there will remain 3673; to which add 8,
the half figure in the dividend, and finding it to be just
6 times the divisor, set six in the quotient.

\[
\begin{array}{c}
6123 \\
2179788 \\
\text{(356)} \\
18369\
\end{array}
\]

\end{array}
\]

NEPETA, in botany, a genus of the didynamta gymno-
sperma class. The intermediate lacinium of the inferior
lip is crenated; the margin of the faus is reflected; and
the laminas are near each other. There are 14 species,
one only of which, viz. the cataria, nap, or cat-mint,
is a native of Britain.

NEPHEW, a term relative to uncle and aunt, signifying
a brother or sister's son; who, according to the civil
law, is in the third degree of consanguinity; but according
to the canon, in the second.

NEPHRITIC, something that relates to the kidneys.

NEPHRIC WOOD, a wood of a very dense and compact
texture, and of a fine grain, brought us from New Spain,
in small blocks, in its natural state, and covered with
its bark.

This wood is a very good diuretic, and is said to be
of great use with the Indians in all diseases of the kidneys and bladder, and in suppurations of urine, from whatever cause. It is also recommended in fevers and obstructions of the viscera. The way of taking it, among the Indians, is only an infusion in cold water.

**Nephritics**, in pharmacy, medicines proper for diseases of the kidneys, especially the stone.

Such particularly are the roots of althaea, dog's grafts, asparagus, fago, pellitory of the wall, malows, pin-pinilla, red chick peas, peach kernels, turpentine, the nephritic stone, the nephritic wood, &c. and diabetic.

**Nephritis**, in medicine, an inflammation of the kidneys.

**Nereis**, in zoology, a genus belonging to the order of Nephritics.

**Nereids**, in the pagan theology, sea-nymphs, daughters of Nereus and Doris.

The nereids were esteemed very handsome; so much that Calliope, the wife of Cepheus king of Ethiopia, having triumphed over all the beauties of the age, and daring to vie with the nereids, they were so enraged that they sent a prodigious sea-monster into the country; and to appease them, she was commanded by the oracle to expose her daughter Andromeda, bound to a rock, to be devoured by the monster.

In ancient monuments the nereids are represented riding upon sea horses, sometimes with an entire human form, and at other times with the tail of a fish.

**Nereis**, in zoology, a genus belonging to the order of vermese mollusca. The body is oblong, linear, and fitted for creeping; it is furnished with lateral pincelled tentacula. There are eleven species.

**Nerica**, a province of Sweden, bounded by Wefima on the north, by Sunderland on the south, and by Gotland on the south and west.

**Nerium**, in botany, a genus of the pentandria monogynia class. The seeds are furnished with plumes; and the tube of the corolla terminates in a lacerated corona. There are four species, none of them natives of Britain.

**Nest.** See Nidus.

**Nestorians**, a Christian sect, the followers of Ne-florus, bishop and patriarch of Constantinople; who, about the year 529, taught that there were two persons in Jesus Christ, the divine and the human, which are united, not hypothetically or substantially, but in a mystical manner; whence he concluded, that Mary was the mother of Christ and not the mother of God. For this opinion, Nestorius was condemned and deposed by the council of Ephesus; and the decree of this council was confirmed by the emperor Theodosius, who banished the bishop to a monastery.

**Netherlands**, anciently called Belisia, but since denominated Low-Countries or Netherlands from their low situation, are situated between 0° and 7° of east longitude; and between 50° and 53° 30' of north latitude; and are bounded by the German sea on the north, Germany on the east, by Lorrain and France on the south, and by another part of France and the British seas on the west; extending near three hundred miles in length from north to south, and two hundred miles in breadth from east to west. The confit of seventeen provinces; ten of which are called the Austrian and French Netherlands, and the other seven the United Provinces.

**Nettings**, in a ship, a sort of grates made of small ropes tied together with rope-yarn or twine, and fixed on the quarters and in the tops; they are sometimes stretched upon the ledges from the wade trees to the roof trees, from the top of the forecastle to the poop; and sometimes are laid in the wale of a ship, to serve instead of gratings.

**Netzuno**, a port town of Italy, in the Campagna di Roma, situated on the Mediterranean, thirty miles south-east of Rome.

**Nevens**, a city of France, capital of the Nivernois:

**Neufchatel**, the capital of the counties of Neufchatel and Vallengin, in Switzerland.

**Neuilly**, a town of Normandy in France, twenty-three miles north-east of Rouen.

**Nevin, or Newin**, a market town of North Wales, eighteen miles south west of Caernarvon.

**Nevis**, one of the Caribbee-islans, divided from the east end of St. Christophers by a narrow channel.

**Neurada**, in botany, a genus of the decandra decagynia class. The calix consists of five segments, and the corolla of five leaves; the capsule has ten cells, and ten sharp-pointed seeds. There is but one species, a native of Egypt.

**Neuratics**, in pharmacy, medicines good in disorders of the nerves.

**Neustat**, a city of Germany, thirty miles south of Vienna.

**Neustat** is also a town of Lower Saxony, sixteen miles north-west of the city of Hanover.

**Neuter, or Neuter gender**, in grammar, one of the three genders of nouns, so called as being neither masculine nor feminine. See Grammar.

**Neutrals salts**, among chemists, a sort of salts neither acid nor alkaline, but partaking of the nature of both. See Chemistry.

**Neutrality**, the state of a person or thing that is neuter, or that takes part with neither side.

**Newark**, a borough town of Nottinghamshire, fifteen miles north-east of Nottingham. In sends two members to parliament.

**Newborough**, a market town of Anglesey, fifteen miles north-west of Beaumaris.

**Newburg, a city of Bavaria, in Germany, twenty-eight miles north-east of Augsburg.**

**Newburg** is also the name of two other towns of Germany.
many; one in Swabia, twenty five miles west of Stuttgart; and the other likewise in Swabia, twelve miles north of Bassil.

NEWBURY, a market town of Berkshire, fifteen miles west of Reading.

NEWCASTLE, the county-town of Northumberland, situated upon the river Tyne: W. long. 1° 10', N. lat. 55’. It sends two members to parliament.

NEWCASTLE, a borough-town of Staffordshire, ten miles north of Stafford. It sends two members to parliament.

NEWCASTLE, a market town of Caernarvonshire, in South Wales, fifteen miles north of Caernarthen.

NEWEL, in architecture, is the upright post which a pair of winding stairs turn about; this is properly a cylinder of stone, which bears on the ground, and is formed by the end of the steps of the winding stairs.

NEWFIDLERS SEA, a lake thirty five miles long, on the north-west part of Upper Hungary.

NEW FOREST, a part of Hampshire, opposite to the Isle of Wight, appropriated by act of parliament for the growth of oaks to build the royal navy. See Forest.

NEWFOUNDLAND, a triangular island, three hundred and fifty miles in length from north to south, and two hundred miles in breadth at the base from east to west; situated in North America, between 55° and 61° of west longitude, and between 47° and 52° of north latitude; bounded by the narrow straits of Belleisle on the north, by the Atlantic ocean on the east and south, and by the bay of St. Lawrence on the west. It is subject to England; but the fishing banks on this coast are frequented by most European nations.

NEWHAUSEL, a city of Upper Hungary, situated on the river Neytra: E. long. 18° 12’, N. lat. 48° 24’.

NEWMARK, a city of Transylvania, subject to the house of Austria: E. long. 23° 25’, N. lat. 47° 35’.

NEWMARK is also a town of Germany in the palatinate of Bavaria, thirty miles north-west of Ratibon.

NEWMARKET, a market town, situated both in Cambridgeshire and Suffolk, twelve miles east of Cambridge.

NEWNHAM, a market town, ten miles south-west of Gloucester.

NEWPORT, a port town of Flanders, nine miles south-west of Oostend.

NEWPORT is also a borough town of the Isle of Wight, which sends two members to parliament.

NEWPORT is also a borough of Cornwall, ten miles west of Launceston, which sends two members to parliament.

NEWPORT is also the name of several market towns; one fifteen miles east of Shrewsbury, another eighteen miles south-west of Monmouth, and a third sixteen miles north-east of St Davids.

NEWPORT-PAGNEL, a market-town, sixteen miles north of Allibury.

NEWSTAT, the name of several towns; one eight miles north of Landau; another fifteen miles south-west of Ratibon; a third in Silesia, fifteen miles south of Breslau; a fourth in Hungary, sixty-five miles east of Tockay; and a fifth in Moravia, ten miles north of Olmutz.

NEWT, or EFT, in zoology. See Lacerta.

NEWTON, a borough town, thirty five miles south of Lancaster.

It sends two members to parliament.

NEWTON is also a borough town in the Isle of Wight, twelve miles south of Southampton; it sends two members to parliament.

NEWTONIAN PHILOSOPHY, the doctrine of the universe, and particularly of the heavenly bodies, their laws, affections, &c. as delivered by Sir Isaac Newton. See Astronomy, Mechanics, Optics, &c.

NEYLAND, a market-town of Suffolk, fourteen miles south-west of Ipswich.

NIAGARA, a prodigious cataract in Canada, in North America, between the lakes Erie and Ontario, where the water falls from high rocks 156 feet perpendicular. The mist which this fall occasions may be seen at fifteen miles distance rising as high as the clouds, and forming a beautiful rainbow.

NIBANO, a town of Italy, in the duchy of Parma, thirty five miles west of Parma.

NICARAGUA, a province of Mexico, bounded by the province of Honduras on the north, by the North sea on the east; by the province of Costa Rica on the south-east, and by the South sea on the south-west; being 400 miles long, and 120 broad. Nicargua lake runs through the middle of the province.

NICARIA, one of the islands of the Archipelago, in Asiatic Turkey: E. long. 25° 5’, N. lat. 37°.

NICASTRO, a town of Naples, in the territory of Casabia; E. long. 16° 40’, N. lat. 39° 15’.

NICE, the capital of the county of the same name, situated on the Mediterranean, at the mouth of the river Var: E. long. 7° 15’, N. lat. 43° 40’.

NICE is also a town of Asiatic Turkey, fifty miles south-east of Constantino-pole.

NICHE, in architecture, a hollow sunk into a wall, for the commodious and agreeable placing a statue.

NICOBAR ISLANDS, a cluster of islands situated in the Indian ocean, at the entrance of the gulf of Bengal, between 9° and 10° N. lat.

NICOLAITANS, in church-history, Christian heretics who assumed this name from Nicolas of Antioch; who, being a Gentile by birth, first embraced Judaism, and then Christianity; when his zeal and devotion recommended him to the church of Jerusalem, by whom he was chosen one of the first deacons. Many of the primitive writers believe that Nicolas was rather the occasion than the author of the infamous practices of those who assumed his name, who were expressly condemned by the spirit of God himself, Rev. ii. 6. And indeed their opinions and actions were highly extravagant and criminal. They allowed a community of wives; made no difference between ordinary meats and those offered to idols. According to Eusebius, they subsisted but a short time; but Tertullian says, that they only changed their name, and that their heresies passed into the sect of the Caunitans.
St. NICOLAS, a town of Lorrain, ten miles south-east of Nancy, at the mouth of the river Divin.

St. Nicholas is also a port-town of Russia situated on the White sea, six miles below Archangel.

St. Nicholas's Day, a festival of the Roman church, observed on the 6th of December.

NICOMEDIA, a city of Asia Minor, thirty miles south-east of Constantinople.

NICOPOLIS, a city of Europe, situated on the Danube, 100 miles north west of Adrianople: E. long. 23°, N. lat. 43°.

NICOPPING, a city of Sweden, in the province of Sunderland, fifty miles south of Stockholm.

Nicopling is also the capital of the island Hulfer, subject to Denmark, and forty-eight miles south-west of Copenhagen.

NICOSIA, the capital of the island of Cyprus: E. long. 33°, N. lat. 35°.

NICOTERA, a port town of the kingdom of Naples, thirty miles north east of Reggio.

NICOTIANA, in botany, a genus of the pentandria monogynia class. The corolla is funnel-shaped, with a plaited limbus; the stamens are inclined; and the capsule has two valves and two cells. There are 7 species, all natives of warm climates. The nicotiana tabacum, or tobacco, was first brought into Europe about the year 1560, from the island Tobago in America. It is cultivated in the following manner.

After sowing the tobacco seed, the ground is watered every day, and in hot weather covered to prevent its being scorched by the sun; and when the plants are grown to a convenient pitch, they are transplanted into a soil well prepared for their reception: care is also taken to keep this ground clear of weeds, and to pull off the lowest leaves of the plant, that ten or fifteen of the finest leaves may have all the nourishment. When these leaves are ripe, which is known by their breaking of a pinch in the air, and when the leaves are sufficiently dried, they are pulled from off the stalks, and made up in little bundles; which being steeped in seawater, or, for want thereof, in common water, are twisted in manner of ropes, and the twis formed into rolls, by winding them with a kind of string around a stick: in which condition it is imported into Europe, where it is cut by the tobacconists for smoking, formed into snuff, and the like. See Snuff.

Besides the tobacco of the West-Indies, there are considerable quantities cultivated in the Levant, the coasts of Greece and the Archipelago, the island of Malta and Italy.

The marks of good twist-tobacco, are a fine shining cut, an agreeable smell, and that it has been well kept. Tobacco is either taken by way of snuff, as a snuffitory; or as a medlar, by chewing it in the mouth; or by smoking it in a pipe. It is sometimes also taken in longish pellets put up the nose, where it is found to produce very good effects, to attract a deal of water or pituita, unload the head, resolve catarrhs, and make a free respiration; for the subtle parts of the tobacco in inspiration, are carried into the trachea and lungs, where they loosen the peccant humours adhering there-to, and promote expectoration. Some have left this tobacco in their noses all night; but this is found to occasion vomiting the next morning. Another thing charged on this way of application, is, that it weakens the sight. When taken in great quantities in the way of snuff, it is found to prejudice the smelling, greatly diminishes the appetite, and in time gives rise to a phthisis. That taken in the way of smoke, dries and damages the brain. Borrhii, in a letter to Bartholine, mentions a person who through excess of smoking had dried his brain to that degree, that after his death there was nothing found in his skull but a little black lump, consisting of mere membranes.

Some people use the infusion of tobacco as an emetic; but it is a very dangerous and unjustifiable practice, and often produces violent vomiting, sickness, and stupidity. Bates and Fuller give some receipts, in which tobacco is an ingredient, with mighty encomiums in aphthous cases. A strong decoction of tobacco, with proper carminatives and cathartics, given at the right time, sometimes proves of good effect in what is usually called the stomatitis, and also in the diac passions. A drop or two of the chymical oil of tobacco, being put on the tongue of a cat, produces violent convulsions, and death itself in the space of a minute; yet the same oil used in lint, and applied to the teeth, has been of service in the tooth-ache: though it must be to those that have been used to the taking of tobacco; otherwise, great sickness, reachings, vomitings, &c. happen; and even in no case is the internal use of it warranted by ordinary practice.

A strong decoction of the stalks, with sharp-pointed dock and alum, is said to be of good service, used externally, in cutaneous diseases, especially the itch: some boil them for that purpose in urine. The same is said to be infallible in curing the mange in dogs.

Beat into a mush with vinegar, or brandy, it has been found serviceable for removing hard tumours of the hypochondria.

NICOYA, or ST LUCAR, a port-town of Mexico, situated on a bay of the South Sea, in 98° W. long. and 10° 15' N. lat.

NICTITATING MEMBRANE, a thin membrane, chiefly found in the bird and fish kind, which covers the eyes of these animals, sheltering them from the dust or too much light; yet is so thin and pellucid, that they can see pretty well through it.

NIDUS, among naturalists signifies a nest, or proper repository for the eggs of birds, insects, &c., wherein the young of these animals are hatched and nurfed.

NIECE, a brother or sister's daughter, which in the civil law is reckoned the third degree of consanguinity.

NIEMEN, or BEREZINA, a river of Poland, which rises in Lithuania, and falls into a bay of the Baltic sea, near Memel.

NIEPER, or BorystheneS, a river which rises in the middle of Russia, and running south through Poland, enters...
enters the Russian Ukraine, separates Little Tartary from
Budziac Tartary, and falls into the Black Sea near
Oezkow.

NIFESTAT, a town of Lower Saxony, in the duchy of
Mecklenburg: E. long. 11° 26', N. lat. 53° 40'.

NIFESTAT is also a town of Upper Saxony, in the mar-
quarite of Brandenburg, 25 miles north-east of Berlin.

NIESTER, a river which rises in Poland, and running
south east divides Podolia in Poland from Moldavia
in Turkey; and afterwards, dividing Bessarabia from
Budziac Tartary, falls into the Black Sea near Bel-
gorod.

NIGELLA, in botany, a genus of the polyandria penta-
gynia class. The calix is wanting; the corolla con-
stitutes five petals; there are five trifid gynia within
the corolla; and there are five connected capsules. The
species are five, none of them natives of Britain.

NIGER, a great river of Africa, which runs from eaf
to west through the middle of Negroland, and dis-
charges itself into the Atlantic ocean by three channels,
called Rio Grande, Gambia, and the river Senega.

NIESTAT is also a town of Upper Saxony, in the mar-
quarite of Brandenburg, 25 miles north-east of Berlin.

NIGHT, that part of the natural day during which the
sun is underneath the horizon; or that space wherein
it is dark.

Night was originally divided by the Hebrews, and
other eastern nations, into three parts; or watchings.
The Romans, and afterwards the Jews from them,
divide the night into four parts, or watches, the first
of which began at sunset and lasted till nine at night,
according to our way of reckoning; the second lasted
till midnight; the third till three in the morning; and
the fourth ended at sunrife. The ancient Gauls and
Germans divided their time, not by days, but by nights;
and the people of Iceland, and the Arabs, do the fame
at this day. The like is also observed of our Saxons
ancestors.

Night-seat, in law. See Medicine, p. 157.

Night-walkers. See Noctambuli.

NIGHTINGALE, in ornithology. See Motacilla.

NIGRITIA, in onothology. See Motacilla.

NILE, a great river in Egypt, having its source in A-
byllia, or the Upper Ethiopia, in 12° north lat. It
generally runs from south to north through Abyssinia
into Egypt, and then continues its course north in one
stream till it comes below Cairo to the Delta, where
it divides; one branch discharging itself into the Me-
diterranean at Damietta, and another a hundred miles
above the weirward of it at Rosetta. There are great
rejoicings every year when the Nile rises to a certain
height, their future harvest depending upon it. The
just height of the inundation, according to Pliny, is
sixteen cubits; when it rises but to twelve or thir-
ten, a famine is dreaded; and when it exceeds six-
ten, there is also danger apprehended. The river
begins usually to rise in May or June, and is conveyed
by reservoirs, cisterns, and canals, to the fields and
gardens as they want it.

As to the Delta, it is all overflowed.

NIMBUS, in antiquity, a circle observed on certain
medals, or round the head of some emperors, answer-
ing to the circles of light, drawn around the images
of saints.

NIMEGUEN, a city of the united Netherlands, situ-
ated on the river Waal, in the province of Guelders,
52 miles north-east of Amsterdam.

NIMETULAHITES, a kind of Turkish monks, so
called from their founder Nimetulahi, famous for his
doctrines and the austerity of his life.

NIMO, a small Turkish island in the Archipelago, situa-
ted north-west of Santorini, remarkable for little but the
tomb of Homer, who is said to lie buried here.

NIORT, a town of France, in the province of Orlé-
ansois and territory of Poitou, situated on the river
Sevre, twenty eight miles north-east of Rochelle.

NIPHON, the largeft of the Japan islands, situatecl in
the Indian ocean about 130 miles east of Chiná; be-
ing 600 miles long, and 150 broad, and containing 55
provinces.

NIPPERS, in the menage, are four teeth in the fore-
part of a horse's mouth, two in the upper and two in
the lower jaw. A horse puts them forth between the
fecond and third year.

NIPPLES, in anatomy. See Anatomy, p. 277.

Nipple-wort, in botany. See Lapiana.

NISI PRIUS, in law, a judicial writ which lies in cafes
where the jury being impannelled and returned before
the juftices of the bank; one of the parties requests to
have such a writ, for the ease of the country, in or-
der that the trial may come before the juftices in the
fame county on their coming thither. The purport
of a writ of nisi prius is, that the sheriff is thereby
commanded to bring to Weftrinfter the men impa-
nelled, at a certain day, before the juftices, " nisi prius
jufticiarii domini regis ad affisas capitndas venerint."

NISMES, a fine city of France, in the province of Lan-
gu doc: E. long. 4° 26', N. lat. 45° 40'.

NISNA, or Nise Novogorod, the capital of the
province of Nise, or Little Novogorod, in Russia: E.
long. 45°, N lat. 56°.

NISNA, or Nise Novogorod, the capital of the
province of Nise, or Little Novogorod, in Russia: E.
long. 45°, N lat. 56°.

NISNA, or Nise Novogorod, the capital of the
province of Nise, or Little Novogorod, in Russia: E.
long. 45°, N lat. 56°.

NISUA, a city of European Turkish, in the province of
Servia: E. long. 23°, N. lat. 43°.

Nissa or Nizza, a town of Italy, in the duchy of
Montferrat: E. long. 8° 40', N. lat. 45° 45'.

NITHSDALE, a county of Scotland, bounded by
Clydesdale on the north, by Annandale on the east,
by Solway frith on the south, and by Galloway on the
west.

NITRACHT, or Nytrea, a town of Hungary, forty
miles north-east of Pestburg.

NITRE, or Salt-petre. See Chemistry, p. 73. 119.
N O E  ( 402 )  N O G

NIUCHE, a kingdom of Chinese Tartary, north of the province of Laotung.

NIVELLE, a town of the Austrian Netherlands, and province of Brabant, fourteen miles south of Brussels.

NISABOUR, or Nisabour, a city of Persia, in the province of Chorassan: E. long. 57° 32', N. lat. 33° 49'.

NOBILIARY, in literary history, a book containing the history of the noble families of a nation, or province: such as Chorier's Nobiliary of Dauphine, and Caumartin's Nobiliary of Provence. The Germans are said to be particularly careful of their nobiliaries, in order to keep up the purity of their families.

NOBILITY, a quality that ennobles, and raises a person to the rank of a commoner.

The origin of nobility in Europe is by some referred to the Goths; who, after they had feized a part of Europe, rewarded their captains with titles of honour, to distinguish them from the common people. In Britain the term nobility is referred to degrees of dignity above knighthood; but every where else nobility and gentility are the same. The British nobility consists only of five degrees, viz. that of a duke, marquis, earl or count, viscount, and baron, each of which fee under their proper articles.

NOBLE, a money of account containing six shillings and eight-pence.

The noble was anciently a real coin struck in the reign of Edward III. and then called the penny of gold; but it was afterwards called a rofe-noble, from its being stamped with a rofe: it was current at 6s. 8d.

Terra NOCERIANA, earth of Nocera, in the province of Chorassan; E. long. 57° 32', N. lat. 33° 49'.

NOCTAMBULI, or Nightwalkers, in medicine, nocturnal, Noctilucum, an instrument chiefly used at sea, to take the latitude or depression of some stars about the pole, in order to find the latitude and hour of the night.

Some nocturnals are hemispheres, or planispheres, on the plane of the equinoctial. Those commonly in use among seamen are two; the one adapted to the polar star, and the first of the guards of the little bear; the other to the pole-star, and the pointers of the great bear.

This instrument consists of two circular plates, (Plate CXXXIV. fig. 2.) applied to each other. The greater, which has a handle to hold the instrument, is about 1½ inches diameter, and is divided into twelve parts, agreeing to the twelve months; and each month subdivided into every fifth day; and so as that the middle of the handle corresponds to that day of the year wherein the star here regarded has the same right ascension with the sun. If the instrument be fitted for two stars, the handle is made moveable. The upper left circle is divided into twenty four equal parts for the twenty four hours of the day, and each hour subdivided into quarters. These twenty four hours are noted by twenty four teeth to be told in the night. Those at the hours 12, are distinguished by their length.

In the centre of the two circular plates is admitted a long index, A, moveable upon the upper plate. And the three pieces, viz. the two circles and index, are joined by a rivet which is pierced through the centre with a hole, through which the star is to be observed.

To use the Nocturnal, turn the upper plate till the long tooth, marked 12, be against the day of the month on the under plate; then, bringing the instrument near the eye, suspend it by the handle with the plane nearly parallel to the equinoctial, and viewing the pole-star through the hole of the centre, turn the index about till, by the edge coming from the centre, you see the bright star or guard of the little bear (if the instrument be fitted to that star; ) then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour circle, which may be known without a light, by counting the teeth from the longest, which is for the hour 12.

NODATED HYPERBOLA, a name given by Sir Isaac Newton, to a kind of hyperbola, which, by turning round, decussates or crosses itself.

NODE, a tumour arising on the bones, and usuallie proceeding from some venereal cause; being much the same with what is otherwise called exoftosis.

NODES. See Astronomy, p. 477.

NODUS, or Node, in dialling, a certain point or pole in the gnomon of a dial, by the shadow or light whereof either the hour of the day in dials without furniture, or the parallels of the sun's declination, and his place in the ecliptic, &c., in dials with furniture, are shown. See Dialling.

NOETIANS, in church history, Christian heretics in the IIIrd century, followers of Noetius, a philosopher of Ephesus, who pretended that he was another Moses, sent by God; and that his brother was a new Aaron. His heresy consisted in affirming that there was but one person in the Godhead; and that the Word and the Holy Spirit were but external denominations, given to God, in consequence of different operations; that as Creator, he is called Father; as Incarnate Son; and as ascending on the apostles, Holy Ghost.

NOGAIAN TARTARS, a nation which inhabits that part of Circasia, in Asiatic Turkey, that lies between the Palus Meotis and the Caspian sea.

NOGENT, a town of France, in the province of Champagne, situated on the river Seine, twenty five miles north-west of Troyes.
NOLA, a town of Italy, in the kingdom of Naples, situated 16 miles east of Naples.

NOLI, a town of Italy in the territory of Genoa, situated on the bay of Genoa, thirty-five miles south west of that city.

NOMARCHA, in Egyptian antiquity, the governor or commander of a nome. Egypt was anciently divided into several regions or quarters, called nomes.

NOMBRE DE DIO, a town of Mexico, in the province of Darien, a little to the eastward of Porto Bello: W. long. 83°, and N. lat. 10°.

NOMBREL POINT, in heraldry, is the next below the feast point, or the very centre of the escutcheon. See Point.

Supposing the escutcheon divided into two equal parts below the feast, the first of these divisions is the nombrel, and the lower the base.

NOME, or NAME, in algebra, denotes any quantity with a sign prefixed or added to it, whereby it is connected with some other quantity, upon which the whole becomes a binomial, trinomial, or the like. See Algebra.

NOMENCLATOR, in Roman antiquity, was dually the fes point, or the very centre of the escutcheon. See Point.

NOMENCLATURE, a catalogue of several of the more usual words in any language, with their significations, compiled in order to facilitate the use of such words to those who are to learn the tongue: such are our Latin, Greek, French, &c. nomenclatures.

NOMINALS, Nominalists, a sect of school philosophers, the disciples and followers of Occam, or Ocham, an English cordelier, in the XIVth century. They were great dealers in words, whence they were vulgarly denominated word-fellers; but had the denomination of nominalists, because that, in opposition to the realists, they maintained that words, and not things, were the object of dialectics.

NOMINATIVE, in grammar, the first case of nouns which are declinable. See Grammar.

NONAGE, in law, generally signifies all the time a person continues under the age of one and twenty; but in a special sense, it is all the time a person is under the age of fourteen.

NON-CAPES, in geography, a promontory on the west coast of Africa, opposite to the Canary islands.

NON-ENTRY, in Scots law. See Law, Tit. xii. 5.

NON-NATURALS, in medicine, so called because by their abuse they become the causes of diseases.

Physicians have divided the non-naturals into six classes, viz. the air, meats and drinks, sleep and watching, motion and rest, the passions of the mind, the retenions and excretions.

Vol. III. No. 86.

Non-suit, signifies the dropping of a suit or action, or a renouncing thereof by the plaintiff or defendant.

NONCONFORMISTS. See Dissenters.

NONE, one of the seven canonical hours in the Roman church, answering to three o'clock in the afternoon.

NONES, in the Roman calendar, the fifth day of the months January, February, April, June, August, September, November, and December; and the seventh of March, May, July, and October. March, May, July, and October, had six days in their nones; because these alone, in the ancient constitution of the year by Numa, had thirty-one days a-piece, and February thirty; but when Cæsar reformed the year, and made other months contain thirty-one days, he did not allot them six days of nones. See Calendar.

NORDEN, a port-town of Germany, in the circle of Weilphalia, and county of Embden, twelve miles north of Embden.

NORFOLK, a county of England, bounded by the German sea on the north and east; by Suffolk on the south, and by the fens of Lincolnshire and the isle of Ely on the west.

NORFOLK, a county of Virginia, north of Carolina, and contiguous to that province.

NORMANDY, a province of France, bounded by the east channel on the north, by Picardy and the isle of France on the west, by Britany and another part of the east channel on the west.

NORROY, the title of the third of the three kings at arms.

NORTH, one of the four cardinal points. See Navigation.

North Curry, a market-town of Somerfetshire, seven miles south-west of Wells.

North Foreland, a cape in the isle of Thanet, on the east coast of Kent, four miles east of Margate.

North Sea, a name given to all that part of the Atlantic Ocean which lies north of Terra Firma, in South America.

North-west Passage. A north-west passage by Hudson Bay, into the pacific ocean, has been more than once attempted of late years, but hitherto without success. Some greatly doubt of the practicableness of such an enterprise, and think the observations made by the Russians give us small hopes. Some general things may be seen in the Phil. Trans. N° 482. sect. 14. It appears from thence, that the Russians have passed between the land of Nova Zeltha, and the coast of Asia; and, as the Dutch did formerly discover the northern coasts of Nova Zelbha, we may now be well assured that that country is really an island.

NORTHALLERTON, a borough-town of the north riding of Yorkshire, twenty-two miles north-west of York. It sends two members to parliament.

NORTHAMPTON, the capital of Northamptonshire, situated on the river Nen: W. long. 55°, and N. lat. 52° 15'. It sends two members to parliament.

NORTHAMPTON, is also a county of Virginia, in North America.
America, which forms the south part of the peninsula on the eastern shore of Virginia.

NORTHUMBERLAND, a county of England, bounded on the north by Scotland, on the east by the German sea, on the south by Durham, and on the west by Cumberland and part of Scotland. Norfolk.

NORWICH, a large city of great trade in Norfolk.

NORTHUMBERLAND is also a county of Virginia, lying at the mouth of the river Patowmac.

NORTHWICH, a market town of Cheshire, sixteen miles north-east of Chester.

NORWAY, a kingdom of Europe, situated between 20° and 70° north latitude, bounded by the Atlantic ocean on the north and west, by Swedish Lapland and other provinces of Sweden on the east, and by the sea called the Cattegate and Schaggeric on the south. It is a cold barren country, subject to Denmark.

NOTATION, in arithmetic. See Arithmetic, p. 366.

NOTARY, signifies a person, usually some scrivener, who takes notes, or frames short drafts, of contracts, obligations, charter-parties, or other writings.

NOTATION, in musick, characters which mark the sounds, i.e. the elevations and fallings of the voice, and the swiftness and slowness of its motions. See Musick.

Note is likewise used for a mark made in a book or writing where there occurs something remarkable and worthy of particular notice: as also for an observation or explication of some passage in an author added in the margin, at the bottom of the page, or elsewhere, in which sense it stands contradistinguished to text.

Note, is also a minute, or short writing, containing some article of business, in which sense we say, promissory note, note of hand, bank note, &c.

NOTUS, signifies spurious or bastard; whence it is figuratively applied by physicians, &c. to such diseases as though in respect of a similitude of symptoms, &c. they have the same denomination as some others, yet are of a different origin, feat, or the like, from the same.

NOTION, in logic, an idea or representation of anything in the mind. See Logic and Metaphysics.

NOTITIA, in literary history, a book that gives an account of a particular country, city, or other place: such is the Notitia Imperii Romani, Notitia Romae Antique, &c.

NOTO, the capital of a province of the same name in Sicily, twenty miles south of Syracuse, E. long. 15°, N. lat. 37° 15'.

NOTONECTA, the Boat-fly a genus of insects belonging to the order hemiptera. The beak is inflecd; the antennae are shorter than the thorax; the four wings are plaited cross-ways; and the feet are hairy, and fitted for swimming. There are three species, distinguished by their colour.

NOTTEBURG, a city of Russia, situated on an island in the lake Lodoga, twenty five miles east of Peterburg.

NOTTINGHAM, the capital of Nottinghamshire, situated about a mile north of the river Trent; W. long. 1° 5', N. lat. 53°. It sends two members to parliament.

NOVA-SCOTIA. See Scotland.

NOVA-ZEMBLA, or Newland, called by the Dutch the island of Weygats, is situated in the frozen ocean, between 50° and 80° east longitude, and between 70° north latitude and the north pole: it is separated from the province of Samoidea, in Russia, by the straits of Weygats.

NOVARA, the capital of the Novarese, in the duchy of Milan.

NOVATION, or Innovation, in the civil law, denotes the change of one kind of obligation for another; as when a promise is accepted instead of a written obligation.

NOVATION, in Scots law. See Law, Tit. xxiii. 7.

NOVEL, in matters of literature, a fictitious history of a series of entertaining events in common life, wherein the rules of probability are or ought to be strictly preferred.

NOVELLARA, a town of Italy, in the duchy of Mantua, twenty miles south of the city of Mantua.

NOVEMBER, in chronology, the eleventh month of Romulus's year, which began with March.

NOVEMVIRI, the nine magistrates of Athens, more usually called archons.

NOVIGRAD, a town of Dalmatia, in 17° 30' E. long. and 44° 30' N. lat.

NOOUN, in grammar, a part of speech, which signifies things without any relation to time; as a man, a house, sweet, bitter, &c. See Grammar.

NOVOGOROD, the capital of a province of the same name in Muscovy, situated on the river Wolcoff, 130 miles...
miles south east of Petersburg; E. long. 34°, N. lat. 58°.
It is an archbishop’s see, and has 180 churches and monasteries.

**NOVOGRODECK**, a city of Lithuania, in Poland: E. long. 25° 20', N. lat. 53° 45'.

**NOURISHMENT.** See Nutrition.

**NOWED,** in heraldry, signifies knotted, from the Latin nodatus; being applied to the tails of such creatures as are very long, and sometimes represented in coat-armour, as if tied up in a knot.

**NUBIA,** a country of Africa, bounded by the desert of Barca, on the north; by Egypt and Abyssinia, on the east; by the Lower Ethiopia, on the south; and by the deserts of Africa, on the west.

**NUCHA,** the nape of the neck.

**NUCIFEROUS** trees, such as bear nuts.

**NUCHTA,** the nape of the neck.

**NUCLEUS,** in general denotes the kernel of a nut, or even any seed inclosed within a husk.

The term nucleus is also used for the body of a comet, otherwise called its head. See Astronomy, p. 444.

**NUDITIES,** in painting and sculpture, denotes those parts of an human figure which are not covered with any drapery; or those parts where the carnation appears.

**NULLITY,** in law, signifies anything that is null or void: thus there is a nullity of marriage, where persons marry within the degrees, or where infants marry without consent of their parents or guardians.

**NUMBER.** See Arithmetic.

**Golden Number.** See Astronomy, p. 495.

**Number,** in grammar, a modification of nouns, verbs, &c. to accommodate them to the varieties in their objects, considered with regard to number. See Grammar.

**Numbers,** in poetry. See Versification.

**Book of Numbers,** the fourth book of the Pentateuch, taking its denomination from its numbering the families of Israel.

A great part of this book is historical, relating to several remarkable passages in the Israelites march through the wilderness. It contains a distinct relation of their several movements from one place to another, or the two and forty stages through the wilderness, and many other things, whereby we are instructed and confirmed in some of the weightiest truths that have immediate reference to God and his providence in the world. But the greatest part of this book is spent in enumerating these laws and ordinances, whether civil or ceremonial, which were given to God, but not mentioned before in the preceding books.

**NOMENIUS,** in ornithology, a genus of birds of the order of the falcopaces; the beak of which is of a figure approaching to a cylindrical one; it is obtuse at the point, and is longer than the toes; the feet have each 4 toes, connected together. This genus comprehends the curlew, the woodcock, the great plover, and the snipe. See Curlew, &c.

**NUMERAL LETTERS,** those letters of the alphabet which are generally used for figures; as I, one; V, five; X, ten; L, fifty; C, a hundred; D, five hundred; M, a thousand; &c.

**NUMERATION,** or Notation, in arithmetic. See Arithmetic, p. 366.

**NUMERATOR of a fraction.** See Arithmetic, p. 287.

**NUMERICAL, NUMEROUS, or NUMERAL,** something belonging to numbers; as numerical algebra is that which makes use of numbers, instead of letters of the alphabet. Also, numerical difference, is the difference whereby one individual is distinguished from another. Hence a thing is said to be numerically the same, when it is so in the strictest sense of the word.

**NUMIDIA,** in ornithology, a genus belonging to the order of gallinac. On each side of the head there is a kind of coloured fleshy horn; and the beak is furnished with cere near the nostrils. There is but one species, a native of Africa.

**NUMIDIA,** the ancient name of Biledulgerid, in Africa.

**NUMISMATOGRA PHIA,** a term used for the description and knowledge of ancient medals and coins, whether of gold, silver, or brass.

**NUMMUS,** among the Romans, a piece of money otherwise called festeritus.

**NUN,** a woman, in several Christian countries, who devotes herself, in a cloister or nunnery, to a religious life.

There were women in the ancient Christian church who made public profession of virginity before the monastic life was known in the world, as appears from the writings of Cyprian and Tertullian. These, for distinction’s sake, are sometimes called ecclesiastical virgins, and were commonly enrolled in the canon or matricula of the church. They differed from the monastic virgin chiefly in this, that they lived privately in their father’s houses, whereas the others lived in communities: but their profession of virginity was not so strict as to make it criminal in them to marry afterwards if they thought fit. As to the consecration of virgins, it had some things peculiar in it; it was usually performed publicly in the church by the bishop. The virgin made a public profession of her resolution, and then the bishop put upon her the accustomed habit of sacred virgins. One part of this habit was a veil, called the facrum velamen; another was a kind of mitre or coronet worn upon the head. At present, when a woman is to be made a nun, the habit, veil, and ring of the candidate are carried to the altar; and since herself, accompanied by her nearest relations, is conducted to the bishop, who, after mass and an anthem, the subject of which is, “that she ought to have her lamp lighted, because the bridegroom is coming to meet her,” pronounces the benediction: then she rises up, and the bishop consecrates the new habit, sprinkling it with holy water. When the candidate has put on her religious habit, she proceeds herself before the bishop, and stands on her knees, Anella Christi fum, &c. then she receives the veil, and afterwards the ring, by which she is married to Christ; and lastly the crown of virginity.

**N U M ( 495 ) **

**NUN**
NUNCIATION, or Nuntiation, an ambassador from the pope to some Catholic prince or state; or a person who attends on the pope's behalf at a congress, or an assembly of several ambassadors.

NUNCUPATIVE, in the schools, something that is only nominal, or has no existence but in name.

NUNCUPATIVE TESTAMENT, in Scots law. See Law, Tit. xxviii. 2.

NUDINAL, Nundinalis, a name which the Romans gave to the eight first letters of the alphabet, used in their calendar.

This series of letters, A, B, C, D, E, F, G, H, is placed and repeated successively from the first to the last day of the year: one of these always expressed the market days, or the assemblies called nundinals, quasi novendine, because they returned every nine days. The country people, after working eight days successively, come to town the ninth, to sell their several commodities, and to inform themselves of what related to religion and government. Thus the nundinal day being under A on the first, ninth, seventeenth, and twenty-fifth days of January, &c. the letter day will be the nundinal letter of the year following. These nundinals bear a very great resemblance to the dominical letters, which return every eight days, as the nundinals did every nine.

NUPTIAL RITES, the ceremonies attending the solemnization of marriage, which are different in different ages and countries.

NURENBERG, the capital of a territory of the same name, in the circle of Franconia, in Germany; E. long. 11°, N. lat. 49° 30'.

NURSERY, in gardening, is a piece of land set apart for raising and propagating all sorts of trees and plants, to supply the garden and other plantations. See Gardening.

NUSANCE, in law, a thing done to the annoyance of another.

Nusances are either public or private. A public nuisance is an offence against the public in general, either by doing what tends to the annoyance of all the king's subjects, or by neglecting to do what the common good requires: in which case all annoyances and injuries to streets, highways, bridges, and large rivers, as also disorderly ale houses, bawdy-houses, gaming-houses, stages for rope-dancers, &c. are held to be common nuisances. A private nuisance is when only one person or family is annoyed, by the doing of anything; as where a person fops up the light of another's house, or builds in such a manner that the rain falls from his house upon his neighbour's.

NUT, among botanists, denotes a pericarpium of an extraordinary hardness, including a kernel or seed.

NUTATION, in astronomy, a kind of tremulous motion of the axis of the earth, whereby, in each annual revolution, it is twice inclined to the ecliptic, and as often returns to its former position.

NUTMEG, the kernel of a large fruit, not unlike the peach.

The nutmeg is separated from its invenient coat, the mace, before it is sent over to us; except that the whole fruit is sometimes imported in preference, by way of sweetmeat, or as a curiosity. See Mace.

The nutmeg, as we receive it, is of a roundish or oval figure, of a tolerably compact and firm texture, but easily cut with a knife, and falling to pieces on a smart blow. Its surface is not smooth, but furrowed with a number of wrinkles, running in various directions, though principally longitudinally. It is of a greyish brown colour on the outside, and of a beautiful variegated hue within, being marbled with brown and yellow variegations, running in perfect irregularity through its whole substance. It is very unctuous and fatty to the touch, when powdered; and is of an extremely agreeable smell, and of an aromatic taste.

There are two kinds of nutmeg in the shops, the one called by authors the male, and the other the female. The female is the kind in common use, and is of the shape of an olive; the male is long and cylindrical, and has less of the fine aromatic flavour than the other; so that it is much less esteemed, and people who trade largely in nutmegs will seldom buy it. The longer male nutmeg, as we term it, is called by the Dutch the wild nutmeg. It is always distinguishable from the others, as well by its want of fragrance, as by its shape: it is very subject to be worm-eaten, and is strictly forbid, by the Dutch, to be packed up among the other, because it will give occasion to their being worm-eaten too, by the insects getting from it into them, and breeding in all parts of the parcel.

The largest, heaviest, and most unctuous of the nutmegs are to be chosen, such as are of the shape of an olive, and of the most fragrant smell. The Dutch import them from the East-Indies.

Nutmeg is greatly used in our foods, and is of excellent virtues as a medicine; it is a good stomachic, it promotes digestion, and strengthens the stomach. It also stops vomiting; is an excellent remedy in flatulences; and is happily joined with rhubarb, and other medicines, in diarrhœas. It is observed to have a soporific virtue, and to exert it too strongly, if taken in immoderate quantities. It has a considerable degree of astringency; and given, after tasting before the fire till thoroughly dry and crumbly, it has been sometimes known alone to cure diarrhœas.

NUTRITION, in the animal economy, is the repairing the continual loss, which the different parts of the body undergo. The motion of the parts of the body, the friction of these parts with each other, and especially the action of the air, would destroy the body entirely, if the loss was not repaired by a proper diet, containing nutritive juices; which being digested in the stomach, and afterwards converted into chyle, mix with the blood, and are distributed throughout the whole body for its nutrition.

In young persons, the nutritive juices not only serve to repair the parts that are damaged, but also to increase them, which is called growth.

In grown persons, the cuticle is every where constantly desquamating, and again renewing; and in the same manner the parts rubbed off, or otherwise separated...
rated from the flabby parts of the body, are soon supplied with new flesh; a wound heals, and an emaciated person grows plump and fat.

Buffon, in order to account for nutrition, supposes the body of an animal, or vegetable, to be a kind of mould, in which the matter necessary to its nutrition is modelled and assimilated to the whole. But, continues he, of what nature is this matter, which an animal, or vegetable, assimilates to its own substance? What power is it that communicates to this matter the activity and motion necessary to penetrate this mould? and, if such a force exist, would it not be by a similar force that the internal mould itself might be reproduced?

As to the first question, he supposes that there exists in nature an infinite number of living organical parts, and that all organized bodies consist of such organical parts; that their production costs nature nothing, since their existence is constant and invariable; so that the matter which the animal, or vegetable, assimilates to its substance, is an organical matter, of the same nature with that of the animal, or vegetable, which consequently may augment its volume, without changing its form, or altering the quality of the substance in the mould.

As to the second question: There exist, says he, in nature, certain powers, as that of gravity, that have no affinity with the external qualities of the body, but act upon the most intimate parts, and penetrate them throughout, and which can never fall under the observation of our senses.

And, as to the third question, he answers, that the internal mould itself is reproduced, not only by a similar power, but it is plain that it is the very same power that causes the unfolding and reproduction thereof: for it is sufficient, proceeds he, that in an organized body that unfolds itself, there be some part similar to the whole, in order that this part may one day become itself an organized body, altogether like that of which it is actually a part.

NUX PISTACHIA. See PISTACHIA.

NYBURG, a town of Germany, twenty miles north of Cologne.

NYBURG, a town of Denmark, situated at the east-end of the island of Fynen, ten miles east of Odense: E. long. 10°, N. lat. 55° 30'.

NYCHTHEMERON, the natural day, or day and night, which together always make twenty-four hours.

NYCTALOPIA, in medicine, a two-fold disorder of the eye, one of which is opposite to the other. In the first, the sight is best in the night, and in obscure places; whereas in a clear light their fight fails, so that they can hardly see any thing. In the other sort of nyctalopia, the patient can see nothing at all except in a clear and bright light.

NYCTANTHES, Arabian Jasmine, in botany, a genus of the diandria monogynia class. The calyx and like-wise the corolla consist of eight segments. There are five species, none of them natives of Britain.

NYCTICORAX, in ornithology. See Ardea.

NYLAND, a province of Finland, situated on the gulf of Finland, west of the province of Carelia.

NYMPH, in mythology, an appellation given to certain inferior goddesses inhabiting the mountains, woods, waters, &c. See Mythology.

NYMPH, among naturalists, that state of winged insects between their living in the form of a worm, and their appearing in the winged or most perfect state.

NYMPHÆA, the water-lily, in botany, a genus of the polyandria monogynia class. The corolla consists of many petals, and the calyx of four or five leaves; and the berry has many cells. There are four species, two of which are natives of Britain, viz. the lutea, or yellow water-lily; and the alba, or white water-lily.

NYMPHEUM, in antiquity, a public hall, magnificently decorated, for entertainment, &c. and where those who wanted convenience at home held their marriage-feasts, whence the name.

NYONS, a town of Dauphine, in France: E. long. 5° 6', N. lat. 44° 28'.

NYPSLOT, a town of Sweden in the province of Finland, sixty miles north of Wyburg: E. long. 29°, N. lat. 62°.

OAK

OAK, in botany. See Quercus.

OAK OF JERUSALEM, in botany. See Chenopodium.

OAKAM, old ropes untwisted, and pulled out into loose hemp, in order to be used in caulking the seams, tree-nails, and bends of a ship, for stopping or preventing leaks.

OAKHAMPTON, a borough of Devonshire, twenty

Vol. III. No 86. 2 miles west of Exeter, which sends two members to parliament.

OAR, in navigation, a long piece of wood, made round where it is to be held in the hand, and thin and broad at the other end, for the easier cutting and refiling the water, and consequently moving the vessel, by rowing. Oars for ships are generally cut out of fir-timber; those for barges are made out of New-England, or Dantzick-rafters.
OBELISK, in architecture, a truncated, quadrangular, column, in which the persons sworn invoke the Almighty to witness that their testimony is true; renouncing all claim to his mercy, and calling for his vengeance, if it be false.

OBADIAH, or the Prophecy of Obadiah, a canonical book of the Old Testament, which is contained in one single chapter; and is partly an invective against the cruelty of the Edomites, who mocked and derided the children of Israel, as they puffed into captivity, and with other enemies, their confederates, invaded and oppressed those strangers, and divided the spoil amongst themselves; and partly a prediction of the deliverance of Israel, and of the victory and triumph of the whole church over her enemies.

OBELISKS, in architecture, a truncated, quadrangular, and slender pyramid, raised as an ornament, and frequently charged either with inscriptions or hieroglyphics. Obelisks appear to be of very great antiquity, and to be first raised to transmit to posterity precepts of philosophy, which were cut in hieroglyphical characters: afterwards they were used to immortalize the great actions of heroes, and the memory of persons beloved. The first obelisk mentioned in history was that of Ramesses king of Egypt, in the time of the Trojan war, which was forty cubits high. Phitus, another king of Egypt, raised one of forty-five cubits; and Ptolemy Philadelphus, another of eighty-eight cubits, in memory of Arsinoe. Augustus erected one at Rome in the Campus Martius, which served to mark the hours on a horizontal dial, drawn on the pavement. They were called by the Egyptian priests the fingers of the sun, because they were made in Egypt also to serve as styles or gnomons to mark the hours on the ground. The Arabs still call them Pharaoth's needles: whence the Italians call them anguilla, and the French aiguilles.

OBERSTEIN, the capital of the county of the same name, in the Palatinate of the Rhine, thirty miles east of Triers.

OBERWESEL, or WESSEL, a town of Germany, in the electorate of Triers, thirty-seven miles north east of the city of Triers.

OBJECT, in philosophy, something apprehended, or presented to the mind, by sensation or by imagination. See Metaphysics.

OBJECT-GLASS of a telescope. See Optics.

OBJECTION, something urged to overthrow a position, or a difficulty raised against an allegation or proposition of a person we are disputing withal. OBJECTIVE is used, in the schools, in speaking of a thing which exists no otherwise than as an object known. The existence of such a thing is said to be objective.

OBLATI, in church history, were secular persons, who devoted themselves and their estates to some monastery, into which they were admitted as a kind of lay brothers. The form of their admission, was, putting the bell-rope of the church round their necks, as a mark of servitude. They wore a religious habit, but different from that of the monks.

OBLATION, a sacrifice, or offering made to God.

OBLIGATION, in Scots law. See Law Tit. xx.

OBLIQUE, in geometry, something slant, or that deviates from the perpendicular. Thus an oblique angle is either an acute or obtuse one, i.e. any angle except a right one.

OBLIQUE CASES, in grammar, are all the cases except the nominative.

OBLIQUE LINE, that which falling on another line, makes oblique angles with it, viz. one acute, and the other obtuse.

OBLIQUE PLANES, in dialling, are those which recline from the zenith, or incline towards the horizon. See Dialling.

OBLIQUE SAILING, in navigation. See Navigation.

OBLIQUITY of the ecliptic. See Astronomy.

OBLIQUUS, in anatomy, a name given to several muscles, particularly in the head, eyes, and abdomen. See Anatomy, Part II.

OBLONG, in general, denotes a figure that is longer than broad: such is a parallelogram, ellipsis, &c.

OBLUS, in antiquity, an ancient Athenian coin.

OBREPTIOUS, an appellation given to letters patent, or other instruments, obtained of a superior by surprize, or by concealing from him the truth.

OBSCURE, something that is dark and reflects little light, or that is not clear and intelligible.

OBSECRATION, in rhetoric, a figure whereby the orator implores the assistance of God, or man.

OBSEQUIES, the fame with funeral solemnities. See Funeral.

OBSEVATION, among navigators, signifies the taking of the sun's or the star's meridian altitude, in order thereby to find the latitude.

OBSEVATORY, a place designed for observing the heavenly bodies; being generally a building erected on some eminence, covered with a terrace for making astronomical observations.

The more celebrated observatories are, 1. The Greenwich observatory, built in 1676, by order of Charles II. at the solicitations of Sir Jonas Moor and Sir Christopher Wren; and furnished with the most accurate instruments, particularly a noble sextant of fifteen feet radius, with telescopic sights.

2. The parish-observatory, built by the late Louis XIV. in the Fauxbourg St. Jaques.

It is a very singular, but useful very magnificent building; the design of monsieur Pernaut: It is eighty feet high; and at top is a terras.

The difference in longitude between this and the Greenwich observatory is 2° 20' west.

In it is a cave, or cellar, 170 feet descent, for experiments that are to be made far from the sun, &c., particularly such as relate to congelations, refrigerations, inducements, confirmations, &c.

3. Tycho Brahe's observatory, which was in the little
OCCUPANT, in law, the person that first seizes, or gets possession of a thing.

OCCUPATION, in a legal sense, is taken for use or tenure; as in deeds it is frequently said, that such lands are or lately were in the tenure or occupation of such a person. It is likewise used for a trade or mystery.

OCCUPIERS of wapping, a term in the salt-works for the persons who are the sworn officers that allot in particular places what quantity of salt is to be made, that the markets may not be overstocked, and see that all is carried fairly and equally between the lord and the tenant.

OCEAN, in geography, that vast collection of salt and navigable waters, in which the two continents, the first including Europe, Asia, and Africa, and the last America, are inclosed like islands.

OCHLORACY, that form of government wherein the populace has the chief administration of affairs.

OCHNE, in botany, a genus of the polyandria monogynia class. The corolla consists of five petals, and the calyx of five leaves; and the berry contains one seed. There are two species, both natives of the Indies.

OCHRE, in natural history, a genus of earths, slightly coherent, and composed of fine, smooth, soft, argillaceous particles, rough to the touch, and readily diffusible in water.

Ochres are of various colours, as red, yellow, blue, brown, green, &c.

OCYNUM, in botany, a genus of the didynamia angiosperma class. The superior lip of the calyx is round, and the inferior is divided into four segments.

There are eight species, none of them natives of Britain.

OCKER, a river of Germany, which rises in Kalmuck Tartary, and forms the boundary between Europe and Asia, till it falls into the frozen ocean, after it has run a course of above two thousand miles.

OCCIDENT, in geography, the westward quarter of the horizon, or that part of the horizon where the ecliptic, or the sun therein, descends into the lower hemisphere, in contradiction to orient. Hence we use the word occidental, for any thing belonging to the west; as, occidental beard, occidental pearl, &c.

OCCIPITAL, in anatomy, a term applied to the parts of the occiput, or back part of the skull. See Anatomy.

OCCIPITIS os, the occipital bone, in anatomy. See Anatomy, p. 156.

OCCULT, something secret, hidden, or invisible. The occult sciences, are magic, necromancy, cabbala, &c.

Occult, in geometry, is used for a line that is scarcely perceivable, drawn with the point of the compasses, or a leaden pencil. These lines are used in several operations, as the raising of plans, designs of buildings, pieces of perspective, &c. They are to be effaced when the work is finished.

OCCULTATION, in astronomy, the time a star or planet is hid from our sight, by the interpolation of the body of the moon, or of some other planet. See Astronomy.

OCTAGON, or Octogon, in geometry, is a figure of eight sides and angles; and this, when all the sides and angles are equal, is called a regular octagon, or one which may be inscribed in a circle.

OCTAGON, in fortification, denotes a place that has eight bastions. See Fortification.

OCTAHEDRON, or Octaedron, in geometry, one of the five regular bodies, consisting of eight equal and equilateral triangles.

OCTANDRIA, in botany, one of the classes of plants. See Botany.

OCTANT, or Octile, in astronomy, that aspect of two planets, wherein they are distant an eighth part of a circle, or 45° from each other.

OCTAPLA, in matters of sacred literature, denotes a polyglot bible, consisting of eight columns, and as many different versions of the sacred text; viz, the original
ODE ( 410 )

ODE, in poetry, a song, or a composition proper to be sung.

Among the ancients, odes signified no more than songs; but with us they are very different things. The ancient odes were generally composed in honour of their gods, as many of those of Pindar and Horace. These had originally but one stanza, or strophe; but afterwards they were divided into three parts, the prosthöme, the antistrophe, and the epode: The priests going round the altar singing the praises of the gods, called the first entrance, when they turned to the left, the strophe; the second, turning to the right, they called antistrophe, or returning; and, lastly, standing before the altar, they sung the remainder, which they called the epode.

Heroes and triumphs were also subjects for the odes; and in course of time love and entertainments were likewise thought very suitable to it. Here Anacreon and Sappho excelled, and Horace has left us some of both sorts with peculiar sweetness and elegance. Among the moderns, Dryden's ode on St Cecilia's day, and Pope's on the same subject, are justly allowed to exceed every thing of the kind, either in this, or in any of the modern languages.

ODENSEE, the capital of Funen, one of the largest of the Danish islands in the Baltic, situated forty-two miles west of Copenhagen.

ODER, a river which rises in the Carpathian mountains, on the confines of Hungary; runs through Silesia and Brandenburg; and then separating the eastern from the western Pomerania, divides itself into several channels, and falls into the Baltic sea.

ODYSSIE, a celebrated epic poem of Homer, wherein are related the adventures of Ulysses in his return from the siege of Troy.

OECONOMICS, the art of managing the affairs of a family, or community; and hence the person who takes care of the revenues and other affairs of churches, monasteries, and the like, is termed oeconomus.

OECONOMY, denotes the prudent conduct, or discreet and frugal management, whether of a man's own estate, or that of another.

Animal OECONOMY, comprehends the various operations of...
of nature, in the generation, nutrition, and preservation of animals. See Generation, Nutrition, &c.

The doctrine of the animal economy is nearly connected with physiology, which explains the several parts of the human body, their structure, use, &c. See Anatomy.

OECUMENICAL, signifies the same with general, or universal; as oecumenical council, bishop, &c.

OEDEMA, in medicine and surgery. See Medicine and Surgery.

OEDENBURG, or Edenburg, a town of Hungary, thirty miles south of Vienna.

OELFELD, a town in the duchy of Magdeburg and circle of Lower Saxony in Germany, twenty miles east of Brunswick.

OENANTHE, in botany, a genus of the pentandria digynia class. The flowers are sessile, diffimular, and barren in the disk; and the fruit is crowned with a calyx. There are five species, three of them natives of Britain, viz. the bifulosa, or water-dropwort; the pimpinelloides, or pimpernel-dropwort; and the crocata, or yellow dropwort.

OENANTHE, in ornithology, a species of motacilla. See Motacilla.

OENAS. See Columba.

OENOPTAE, in Grecian antiquity, a kind of censors at Athens, who regulated entertainments, and took care that none drank too much or too little.

OENOTHERA, in botany, a genus of the oenanthia monogynia class. The calyx consists of four segments, and the corolla of four petals; the capsule is cylindrical, and the seeds are naked. There are seven species, none of them natives of Britain.

OESEL, an island at the entrance of the bay of Livonia, in the Baltic sea; situated in 22° 3' and N. lat. 48° 3'.

OESELD, a town in the duchy of Magdeburg and circle of Lower Saxony in Germany, twenty miles east of Brunswick.

OESELD, a town in the duchy of Magdeburg and circle of Lower Saxony in Germany, twenty miles east of Brunswick.

OESOPHAGUS, in anatomy. See Anatomy, p. 292.

OESTRUS, in zoology, a genus of insects belonging to the order of diptera. It has no mouth, but the point appears in place of it, without any probosces or snout. There are five species, distinguished by their colour.

OETING, the capital of the county of the same name, in the circle of Swabia, in Germany: E. long. 10° 25', and N. lat. 49'.

OFFENBURG, a free imperial city of the circle of Swabia, in Germany, situated on the river Kintzig: E. long. 7° 40', and N. lat. 48° 20'.

OFFENCE in law, an act committed against the law, or omitted where the law requires it.

OFFICE, a particular charge or trust, or a dignity attended with a public function. The word is primarily used in speaking of the offices of judicature and policy; as the office of a secretary of state, the office of a sheriff, of a justice of peace, &c.

OFFICE also signifies a place or apartment appointed for officers to attend in, in order to discharge their respective duties and employments: as the secretary's office, office of ordnance, excise-office, signet-office, paper-office, pipe-office, six-clerks office, &c.

OFFICE, in architecture, denotes all the apartments appointed for the necessary occasions of a palace or great house, as kitchens, pantries, confectionaries, &c.

OFFICE, in the canon-law, is used for a benefice that has no jurisdiction annexed to it.

OFFICER, a person possesséd of a post or office. See the preceding article.

Commission-OFFICERS are those appointed by the king's commission: such are all from the general to the cornet inclusive, who are thus denominated in contradistinction to warrant-officers, who are appointed by the colonel's or captain's warrant, as quarter-masters, sergeants, corporals, and even chaplains and surgeons.

Field OFFICERS are such as command a whole regiment, as the colonel, lieutenant-colonel, and major.

Flag OFFICERS. See Flag-officers, and Admiral.

General OFFICERS are those whose whole command is not limited to a single company, troop, or regiment; but extends to a body of forces, composed of several regiments; such are the general, lieutenant-general, major-general, and brigadiers.

OFFICERS of the house hold. See Household.

Staff-OFFICERS are such as, in the king's presence, bear a white staff, or wand; and at other times, on their going abroad, have it carried before them by a footman bare-headed: such are the lord steward, lord chamberlain, lord treasurer, &c.

The white staff is taken for a commission, and at the king's death each of these officers breaks his staff over the hearfe made for the king's body, and by this means lays down his commission, and discharges all his inferior officers.

Subaltern-OFFICERS are all who administer justice in the name of subjects; as those who act under the earl marshal, admiral, &c. In the army, the subaltern officers are the lieutenants, cornets, ensigns, sergeants, and corporals.

OFFICIAL, in the canon-law, an ecclesiastical judge, appointed by a bishop, chapter, abbot, &c. with charge of the spiritual jurisdiction of the diocese.

OFFICIAL, is also a deputy appointed by an archdeacon, as his assistant, who sits as judge in the archdeacon's court.

OFFICIAL, in pharmacy, an appellation given to such medicines, whether simple or compound, as are required to be constantly kept in the apothecaries' shops.

OFFIDA, a town of Italy subject to the pope, twenty-six miles south of Loretto.

OFFING, or Offin, in the sea language, that part of the sea a good distance from shore, where there is deep water, and no need of a pilot to conduct the ship: thus, if a ship from shore be seen falling out to seaward, they say, the stands for the offing: and if a ship having the shore near her, have another a good way without her, or towards the sea, they say, that ship is in the offing.

OFF-SETS, in gardening, are the young shoots, that spring.
spring from the roots of plants; which being carefully separated, and planted in a proper soil, serve to propagate the species.

Off sets, in surveying, are perpendiculars let fall, and measuring from the stationary lines to the hedge, fence, or extremity of an enclosure.

OGEE, or O. G. in architecture, a moulding consisting of two members, the one concave, and the other convex; or of a round and a hollow, like an S. See Architecture.

OGIVE, in architecture, an arch, or branch of a gothic vault; which, instead of being circular, passes diagonally from one angle to another, and forms a cross with the other arches.

OGLIO, a river which rises in the Alps, in the county of Verona, enters the Adriatic Sea, and is navigable eighty miles.

OHIO, a large river of North America, which, taking its rise in the mountains of Pennsylvania, runs south-west; and, after receiving many considerable branches, falls into the Mississippi.

OSIANS, a town of France, in the province of Dauphine, fifteen miles south-east of Grenoble.

OLDENBURG, the capital of the county of the same name in Westphalia: E. long. 7° 32', and N. lat. 52° 35'.

OLDENDORP, a town of Germany in the circle of Hanover.

OLDENLANDIA, a genus of the tetrandria monogynia class. The corolla consists of four leaves, and the calyx of four segments; and the capsule has two cells, and many seeds. There are four species, none of them natives of Britain.

OLDENZEL, a city of the United Netherlands, in the province of Overijssel: E. long. 6° 50', and N. lat. 52° 20'.

OLD-DIFFUSIA. See Balistes.

OLEA, in botany, a genus of the diandria monogynia class. The corolla has four segments, with oval lanceae; and the drupa contains one seed. There are two species.

This tree grows in the southern parts of France, in Spain, Italy, and other warm countries; with us it is usually preferved in the green-houses of the curious; though it will bear our ordinary winters in the open air, and produce very good fruit. Olives have an acrid, bitter, extremely disagreeable taste; pickled (as we receive them from abroad) they prove less disagreeable. The Lucca olives, which are smaller than the others, have the weakest taste; the Spanish, or larger, the strongest; the Provence, which are of a middling size, are generally the most esteemed.

The oil obtained from this fruit has no particular taste or smell; and does not greatly differ in quality from oil of almonds. Authors make mention of two sorts of this oil, one expressed from the olives when fully ripe, which is our common oil olive; the other, before it has grown ripe; this is called oleum immaturo, and omphacium. Nothing is met with in the shops under this name; and Lemery affirms, that there is no such oil, unripe olives yielding only a nauseous juice to the press. From the ripe fruit, two or three sorts are obtained, differing in degree of purity; the purest runs by light pressure; the remaining magmatic, heated and pressed more strongly, yields an inferior sort, with some dregs at the bottom, called amures. All these oils contain a considerable portion of aqueous moisture, and a mucilaginous substance; which subject them to run into a putrid state; to prevent this, the preparers add some sea salt, which imbibing the aqueous and mucilaginous parts, sinks with them to the bottom; by this means the oil becomes more homogene, and consequently less susceptible of alteration. In its passage to us, some of the salt, thrown up from the bottom by the shaking of the vessel, is sometimes mixed with and detained in the oil, which, in our colder climate, becomes too thick to suffer it freely to subside; and hence the oil is sometimes met with of a manifestly fatty tinge. Olive-oil is used in the simple balsam of sulphur, Locatelli's balsam, and several ointments. It is oftener employed in this last intention than the other expressed oils, but more rarely for internal medicinal purposes.

OLEAGINOUS, something that partakes of the nature of oil, or out of which oil may be expressed.

OLECRANUM, or Olecranon, in anatomy. See Anatomy, p. 178.

OLERON, an island of France, near the coast of Poitou, fourteen miles south-west of Rochelle, being about fifteen miles long, and six broad.

Sea-laws of Oleron, certain laws relating to maritime affairs, made in the time of Rich. I. when he was at the island Oleron.

These laws, being accounted the most excellent sea-laws in the world, are recorded in the black book of the admiralty.

OLESCO, a town of upper Volhina, in Poland: east longitude 24°, and north latitude 50°.

OLFATORY nerves. See Anatomy, p. 248.

OLIBANUM, Frankincense, in pharmacy, a dry resinous substance, brought to us in detached pieces, or drops as it were, like those of mastic; but larger, and of a less pure and pellucid texture.

It is of a pale yellowish white colour, but with some mixture of a brownish cast in it. It is moderately heavy; its smell is strong, but not disagreeable; and its taste bitter, acrid, and resinous.

Olibanum is to be chosen white, pure, dry, and as much approaching to pellucidity as may be.

Olibanum is greatly commended by many against disorders of the head and breast, and against diarrhœas and
and dysenteries, and profusia of the menes, and the fever albus. Its doe is from ten grains to a drachm. It is esteemed by many a specific in pleurises, especially when epidemic.

Externally it is used in fumigations for disorders of the head, and against catarrhs; and is an ingredient in some plasters. It is a noble balsam in confumptions, given in substancce, or dissolved with the yolk of an egg into the form of an emulsion. There is an oil made of it per deliquium, in the same manner as that of myrrh: this is done by putting the powder of it in the white of a boiled egg, in a cellar, till it runs into a liquor; this is esteemed a great cosmetic, and destroyer of pimples in the face.

OLIGAEDRA, in natural history, the name of a genus of crystals, and expresses that which is composed of only a few planes.

The bodies of this class are crystals of the imperfect kind, being composed of columns affixed irregularly to some solid body at one end, and the other terminated by a pyramid; but the column and pyramid being both pentangular, the whole consists only of ten planes, and not, as the common kind, of twelve.

OLIARCHY, a form of government, wherein the administration of affairs is lodged in the hands of a few persons.

OLINDA, a city and port-town of Brazil: west long. 35°, and south lat. 8°.

OLIO, in cookery, denotes a favoury dish composed of a great variety of ingredients, chiefly used by the Spaniards.

OLIVA, a port-town of Poland, in the province of regal Prussia, only six miles west of Dantzick.

OLIVARYA corpora, in anatomy. See Anatomy, p. 287.

OLIVE, in botany. See Olea.

Olive-colour, a yellow mingled with black. See Optics.

OLIVENZA, a town of Alentejo, in Portugal, ten miles south of Elvas.

OLMUTS, a city of Moravia, seventy-five miles north of Vienna.

OLYMPIA, a port-town of the Morea, at present called Longinico: east long. 21° 35', and north lat. 37° 40'.

OLYMPIAD, the space or period of four years, whereby the Greeks reckoned time. See Astronomy, p. 493.

OLYMPIC GAMES were solemn games, famous among the ancient Greeks, so called from Olympian Jupiter, to whom they were dedicated; and by some said to be first instituted by Jupiter, after his victory over the sons of Titan; others ascribe their institution to Hercules, not the son of Alcmena, but one of much greater antiquity; others, to Pelops; and others, to Hercules the son of Alcmena. These games were so considerable, that the Greeks made them their epocha, distinguishing their years by the return of the olympics.

The care and management of these games belonged, for the most part, to the Eleans, who, on that account, enjoyed their possessions without molestation, or fear of war or violence. They appointed a certain number of judges, who were to take care that those who offered themselves as competitors performed their preparatory exercises; and those judges, during the solemnity, fat naked, having before them a crown of victory, formed of wild-olive, which was presented to whomsoever they adjudged it. Those who were conquerors, were called Olympionices, and were loaded with honours by their countrymen. At these games women were not allowed to be present; and if any woman was found to have passed the river Alpheus, during the solemnity, she was to be thrown headlong from a rock.

OLYMPUS, the name of two mountains, the one in Bythinia in the Lesser Asia, and the other in the island of Cyprus.

OMAN, a province or kingdom in the south-east parts of Arabia Felix.

OMBRE, a celebrated game at cards, borrowed from the Spaniards, and played by two, by three, or by five persons, but generally by three.

OMBRE DE SOLEIL, Shadow of the sun, in heraldry, is when the sun is borne in armory, so as that the eyes, nose, and mouth, which at other times are represented, do not appear; and the colouring is thin, so that the field can appear through it.

OMBRIA, the ancient name of a province of Italy, in the territory of the pope, now called Spoletto and Perugia.

OMIRO, or LOMBO, a town of Italy, in the duchy of Tuscany, and territory of the Siennois, situated near the Tufcan sea, a little south of the lake of Castiglione, forty-five miles south-west of Sienna.

OMELET, or AMLET, a kind of pancake or fricaffee of eggs, with other ingredients, very usual in Spain and France.

OMEN, a certain accident and casual occurrence that was thought to presage either good or evil. There were three sorts of omens among the ancients. One was of things internal, or those which affected the persons themselves; the second, of things external, that only appeared to men, but did not make any impression on them; the third were ominous words. Of the first sort were those sudden conterations, called panic fears, that seized upon men without any visible cause, and were therefore imputed to the demons, especially the god Pan: of these panics there is frequent mention in history. The second sort of omens were of such things as appeared to men, but were not contained in their own bodies. Of these there were several sorts: the beginning of things were thought to contain something ominous: it was thought a direful omen, when any thing unusual befel the temples, altars, or statues of the gods. Under the head of external omens are to be placed those which offered themselves in the way; such were the meeting of an eunuch, a black, a bitch with whelps, a snake lying in the road, &c. Words were ominous; and as they were good or bad, were believed to presage accordingly.

OMENTUM, in anatomy. See Anatomy, p. 266.
OMERS, or St. Omer’s, a city of Artois, in the French Netherlands, twenty miles south of Dunkirk, and eighteen fourth-sail of Calais.

OMILANDS, a division of the province of Groningen, in the United Provinces.

OMMEN, a town of the United Netherlands, in the province of Overijssel, situated on the Ij river, seventeen miles north-east of Deventer.

OMOPHAGIA, an ancient Greek festival, in honour of Bacchus, surnamed Omophagos, i.e. eater of raw flesh. This festival was observed in the same manner with the other festivals of Bacchus, in which they counterfeited raw and bloody, in imitation of the god, who was supposed to do the same thing.

OMPLATE, in anatomy. See Anatomy, p. 176.

OMPHALO-MESENTERIC, in anatomy. All fetuses are wrapped up in at least two coats or membranes; most of them have a third, called allantois, or urinary.

Some, as the dog, cat, hare, &c. have a fourth, which has two blood-vessels, viz. a vein and an artery, called omphalo-mesenteric, because passing along the firing to the navel, and terminating in the mesentery.

ONANDAGOES, one of the tribes of the Iroquois, or Five Nations, situated on the lake Ontario, or Frontenac, in North America: they are allies of Great Britain.

ONANIA, or Onanism, terms which some late empirics have framed, to denote the crime of self-pollution, mentioned in scripture to have been practised by Onan, and punished in him with death.

ONEGA-LAKE, a lake upwards of an hundred miles long, and forty broad, situated in the empire of Russia between 61° and 63° of north lat. and 35° east longitude.

ONEGLIA, a port town of Italy, seventy miles south-west of Genoa, subject to the king of Sardinia: it is long 8° 30', and north lat. 44°.

ONEIROCRITICA, the art of interpreting dreams, or predicting future events from dreams.

ONGAR, a market town of Essex, ten miles west of Chelmsford.

ONGLÉ’E, in heraldry, an appellation given to the talons or claws of beasts or birds, when borne of a different colour from that of the body of the animal.

ONION. See Cepa.

ONISCUS, in zoology, a genus of insects, belonging to the order of aptera. It has 14 feet, bristly feelers, and an oval body. There are 17 species.

ONKOTOMY, in surgery, the operation of opening a tumour or abscess. See Surgery.

ONOCLEA, in botany, a genus of the cryptogamia, the fruit consists of several globular capsules, with five valves and one cell, in which are several tiny hairy seeds.

ONOCROTALUS, in ornithology. See Pelicanus.

ONOMANCY, a branch of divination, which foretells the good or bad fortune of a man, from the letters in his name.

From much the same principle the young Romans toasted their miltreaves as often as there were letters in their names: hence Martial says,

Novia sex cyathis, septem jujina bibatur.

ONOMATOPOEIA, in grammar and rhetoric, a figure where words are formed to resemble the sounds made by the things signified; as the buzz of bees, the cackling of hens, &c.

ONONIS, in botany, a genus of the diadelphie decandria class. The calyx has five segments; the vexillum is divided; and the pod is sepal and turgid. There are 19 species, three of them natives of Britain, viz. the spinoa, or reft-harrow; the arvenfis, or corn reft-harrow; and the repens, or creeping reft-harrow.

ONOPORDUM, a genus of the syngenesia polygama equalis class. The receptacle is naked, and the seeds of their calyx are sharp-pointed. There are four species, none of them natives of Britain.

ONTARIO, or Frontenac, a lake of North America: situated in W. long. 79°, and between 41° and 43° N. lat.

ONTOGY. See Metaphysics.

ONYX, in natural history, one of the semi-pellucid gems, with variously coloured zones, but none red; being composed of crystal, debased by a small admixture of earth; and made up either of a number of flat plates, or of a series of coats surrounding a central nucleus, and separated from each other by veins of a different colour, resembling zones or belts.

We have four species of this gem. 1. A bluish white one, with broad white zones. 2. A very pure onyx, with snow-white veins. 3. The jasperonyx, or boronyx, with green zones. 4. The brown onyx, with bluish white zones.

OOST, a kiln for drying hops after they are picked from the stalks.

OOSTERGO, the north division of West Friesland, one of the United Provinces.

OPACITY, in philosophy, a quality of bodies which renders them impervious to the rays of light. See Optics.

OPAL, in natural history, a species of gems.

The opal is a gem of a peculiar kind, and has been esteemed by many in all ages of very great value; though at present it is of less value, in proportion to its size, than any of the finer gems. It is softer than any other of the fine gems, and is difficult to polish to any degree of nicety. It is found of various shapes and sizes: its most frequent bignesses is between that of a pea and a horse-bean; but it is found as small as the head of a large pin, and has been seen of the size of a large walnut. Its figure is very various and uncertain, but it is never found in a crystalliform or columnar state; its most usual shape is an irregularly oblong one, convex above, flattened at bottom, and dented with various sinuosities at its sides. It is often found among the loofe earth of mountains, sometimes on the shores of rivers, and not unfrequently bedded in the coalier kinds of jasper.
OPHIDES, in church history, Christian heretics, so called both from the veneration they had for the serpent that tempted Eve, and the worship they paid to a real serpent.

OPHYXYS, in botany, a genus of the gynandria diandra class. The nektarium has a kind of carina on the under part. There are 18 species, eleven of which are natives of Britain.

OPHTHALMIA, in medicine, an inflammation of the membranes which invest the eye; especially of the adnata, or albugineous coat. See Medicine.

OPHTHALMIC NERVES. See Anatomy, p. 248.

OPHTHALMOSCOPY, a branch of physiognomy, which deduces the knowledge of a man's temper and manners from the appearance of his eyes.

OPiates, medicines of a thicker consistence than a syrup, prepared with opium scarcely fluid. They consist of various ingredients, made up with honey or syrup; and are to be used for a long time either for purgative, alternative, or corroborative intentions.

The word opiate is also used, in general, for any medicine given with an intention to procure sleep, whether in the form of electuaries, drops, or pills.

OPINION, is defined to be an assent of the mind to propositions not evidently true at first sight.

OPISTHOTONOS, in medicine, a kind of convulsion, wherein the body is bent backwards.

OPium, in the materia medica, is an inspissated juice, partly of the resinous, and partly of the gummy kind, brought to us in cakes from eight ounces to a pound weight. It is very heavy, of a dense texture, and not perfectly dry; but, in general, easily receives an impression from the finger: its colour is a brownish yellow, so very dark and dully that at first it appears black: it has a dead and faint smell, and its taste is very bitter and acrid. It is to be chosen moderately firm, and not too soft; its smell and taste should be very strong, and care is to be taken that there is no dirty or flaty matter in it.

Opium is the juice of the poppy album, or white poppy, with which the fields of Asia Minor are in many places sown, as ours are with corn. When the heads are near ripening, they wound them with an instrument that has five edges, which, on being stuck into the head makes at once five long cuts in it; and from these wounds the opium flows, and is next day taken off by a person who goes round the field, and puts it in a vessel which he carries fastened to his girdle; at the same time that this opium is collected, the opposite side of the poppy head is wounded, and the opium collected from it the next day. They distinguish, however, the produce of the first wounds from that of the succeeding ones; for the first juice afforded by the plant is greatly inferior to what is obtained afterwards. After they have collected the opium, they moisten it with a small quantity of water or honey, and work it long time upon a flat, hard, and smooth board, with a thick and strong instrument of the same wood, till it becomes of the consistence of pitch; and then work it up with their hands, and form it into cakes or rolls for sale.
Optics is in great esteem, and is one of the most valuable of all the simple medicines. Applied externally, it is emollient, relaxing, and diffusient, and greatly promotes suppuration: if long kept, upon the skin, it takes off the hair, and always occasions an itching in it; sometimes it exacerbates it, and raises little blisters, if applied to a tender part: sometimes, on external application, it allays pain, and even occasions sleep: but it must by no means be applied to the head, especially to the futures of the skull; for it has been known to have the most terrible effects in this application, and even to bring on death itself. Opium, taken internally removes melancholy, eases pain, and diffuses to sleep; in many cases removes hæmorrhages, provokes sweating. A moderate dose is commonly under a grain; though, according to the circumstances, two grains, or even three, may be within the limits of this denomination: but custom will make people bear a dram or more; though in this case nature is vitiates, and nothing is to be hence judged in regard to others. If given dissolved, it operates in half an hour; if in a solid form, as in pills, or the like, it is sometimes an hour and a half. Its first effect, in this case, is making the patient cheerful, as if he had drank moderately of wine, and at the same time bold and above the fear of danger; for which reason the Turks always take it when they are going to battle. A very immediate of opium brings on a fort of drunkenness, much like that occasioned by an immaterial quantity of strong liquors; cheerfulness and loud laughter at first, than a relaxation of the limbs, a loss of memory, and lightheadedness; then vertigo, dimness of the eyes, with a laxity of the corners and a dilatation of the pupils, a slowness of the pulse, redness of the face, relaxation of the under jaws, swelling of the lips, difficulty of breathing, painful erection of the penis, convulsions, cold sweats, and finally death. Those who escape are usually relieved by a great number of floors, or profuse sweats.

Prepared opium, commonly called extract of opium, is made by dissolving opium in a sufficient quantity of water with a gentle heat; then straining the solution from the faces, and evaporating it to the consistence of honey. Tincture of opium, or liquid laudanum, otherwise called the thebais tincture, is made as follows: Take of prepared opium, two ounces; of cinnamon and cloves, each one drachm; of white-wine, one pint; infuse them a week without heat, and then filter it through paper.

OPOCULAMUM, in the materia medica. See Bal-sam.

OPOXANAX, in the materia medica, is a gum resin of a tolerably firm texture, usually brought to us in loofe granules or drops, and sometimes in large masses, formed of a number of these connected by a quantity of matter of the same kind; but these are usually loaded with extraneous matter, and are greatly inferior to the pure loose kind. The drops or granules of the fine opopanax, are on the outside of a brownish red colour, and of a dusky yellowish or whisth colour within: they are of a somewhat mucuous appearance, smooth on the surface; and are to be chosen in clear pieces, of a strong smell and acid taste.

Opoppanax is attenuating and diffusient, and is gently purgative; it diffuses flatulencies, and is good in asthma, in inveterate coughs, and in disorders of the hand and nerves. It also promotes the menstrual, and is good against all obstructions of the viscer.

OPOSSUM, in zoology. See Didelphis.

OPPILATION, in medicine, the act of obstructing or stopping up the passageways of the body, by redundant or peccant humours. This word is chiefly used for obstructions in the lower belly.

OPPONENT, a person who withstands or opposes another.

OPPOSITION, in logic, the disagreement between propositions which have the same subject and the same predicate.

OPTATIVE mood, in grammar, that which serves to express an ardent desire or wish for something.

In most languages, except the Greek, the optative is only expressed by prefixing to the subjunctive an adverb of willing; as utinam, in Latin; plus a Dieu, in French; and would to God, in English.

OPTERIA, in antiquity, presents made by a bridegroom to his bride, when first conducted to him.
great, appears from the light of a candle; which, if there be no obstacle in the way to obstruct the passage of its rays, will fill all the space within two miles of the candle every way with luminous particles, before it has lost the least sensible part of its substance.

A ray of light is a continued stream of these particles, flowing from any visible body in a straight line, and those particles themselves are incomprehensible small, is manifest from the following experiment. Make a small pin-hole in a piece of black paper, and hold the paper upright on a table facing a row of candles shining by one another; then place a sheet of paleboard at a little distance behind the paper, and some of the rays which flow from all the candles through the hole in the paper, will form as many specks of light on the paleboard, as there are candles on the table before the plate; each speck being as distinct and clear, as if there was only one speck from one single candle; which shows, that the particles of light are exceedingly small, otherwise they could not pass through the hole from so many different candles without confusion.—Dr. Newenham has computed, that there flows more than 6,000,000,000,000 times as many particles of light from a candle in one second of time, as there are grains of sand in the whole earth, supposing each cubic inch of it to contain 1,000,000.

These particles, by falling directly upon our eyes, excite in our minds the idea of light. And when they fall upon our bodies, and are thereby reflected to our eyes, they excite in us the ideas of these bodies. And as every point of a visible body reflects the rays of light in all manner of directions, every point will be visible in every part to which the light is reflected from it. Thus the object ABC (Optical Plates, fig. 11.) is visible to an eye in any part where the rays Ac, Ab, Ac, Ad, Ae, Ba, Bb, Be, Bd, Be, and Ca, Cb, Ce, Cd, Ce, come. Here we have shown the rays as if they were only reflected from the ends A and B, and from the middle point C of the object; every other point being supposed to reflect rays in the same manner. So that, wherever a spectator is placed with regard to the body, every point of that part of the surface which is towards him will be visible, when no intervening object stops the passage of the light.

Since no object can be seen through the bore of a bented pipe, it is evident that the rays of light move in straight lines, whilst there is nothing to refract or turn them out of their rectilinear course.

Whilst the rays of light continue in any medium of an uniform density, they are straight; but when they pass obliquely out of one medium into another which is either more dense or more rare, they are refracted towards the denser medium: and this refraction is more or less, as the rays fall more or less obliquely on the refracting surface which divides the mediums.

To prove this by experiment, let the empty vessel ABCD (No. 2.) into any place where the sun shines obliquely, and observe the part where the shadow of the edge BC falls on the bottom of the vessel at E; then fill the vessel with water, and the shadow will reach no farther than F; which shows, that the ray aBE, which came straight in the open air, just over the edge of the vessel at B to its bottom at E, is refracted by falling obliquely on the surface of the water at B; and instead of going on in the rectilinear direction aBE, it is bent downward in the water from B to e, the whole bend being at the surface of the water: and so of all other rays abc.

If a stick be laid over the vessel, and the sun's rays be reflected from a glass perpendicularly into the vessel, the shadow of the stick will fall upon the same part of the bottom, whether the vessel be empty or full; which shows that the rays of light are not refracted when they fall perpendicularly on the surface of any medium.

The rays of light are as much refracted by passing out of water into air, as by passing out of air into water. Thus, if a ray of light flows from the point e, under water, in the direction eB; when it comes to the surface of the water at B, it will not go on thence in the rectilinear course Bd, but will be refracted into the line Ba. Therefore,

To an eye at e looking through a plane glass in the bottom of the empty vessel, the point a cannot be seen, because the side Be of the vessel interposes; and the point d will just be seen over the edge of the vessel at B. But if the vessel be filled with water, the point a will be seen from e; and will appear as at a, elevated in the direction of the ray eA. Hence a piece of money lying at e, in the bottom of an empty vessel, cannot be seen by an eye at a, because the edge of the vessel intervenes; but let the vessel be filled with water, and the ray ea being then refracted at B, will strike the eye at a, and so render the money visible, which will appear as if it were raised up to / in the line abc.

The time of sun-rising or setting, supposing its rays suffered no refraction, is easily found by calculation. But observation proves, that the sun rises sooner and sets later every day than the calculated time; the reason of which is plain, from what was said immediately above. For, though the sun's rays do not come part of the way to us through water, yet they do through the air or atmosphere, which being a grofer medium than the free space between the sun and the top of the atmosphere, the rays, by entering obliquely into the atmosphere, are there refracted, and thence bent down to the earth. And although there are many places of the earth to which the sun is vertical at noon, and consequently his rays can suffer no refraction at that time, because they come perpendicularly through the atmosphere; yet there is no place to which the sun's rays do not fall obliquely on the top of the atmosphere, at his rising and setting; and consequently, no clear day in which the sun will not be visible before he rises in the horizon, and after he sets in it; and the longer or shorter, as the atmosphere is more or less replete with vapours. For, let ABC (No. 3.) be part of the earth's surface, DEF the atmosphere that covers it, and EBGH the sensible horizon of an observer at B. As every point of the sun's surface sends out rays of light in all manner of directions, some of his rays will constantly fall upon, and enlighten, some half of our atmosphere; and

* Any thing through which the rays of light can pass, is called a medium; as air, water, glass, diamond, or even vacuum.
and therefore, when the sun is at \( I \), below the horizon \( H \),
thee rays which go on in the free space \( I K \) preserve a rectilinear course until they fall upon the top of the atmosphere; and those which fall so about \( K \), are refracted at their entrance into the atmosphere, and bent down in the line \( KmK \), above the horizon \( BGH \), when he is really below it at \( I \).

The angle contained between a ray of light, and a perpendicular to the refracting surface, is called the angle of incidence; and the angle contained between the same perpendicular, and the same ray after refraction, is called the angle of refraction. Thus (No. 4.) let \( LBM \) be the refracting surface of a medium (suppose water,) and \( ABC \) a perpendicular to that surface; let \( DB \) be a ray of light, going out of air into water at \( B \), and therein refracted in the line \( BH \); the angle \( ABD \), is the angle of incidence, of which \( DF \) is the line; and the angle \( KBH \) is the angle of refraction, whose sine is \( KI \).

When the refracting medium is water, the sine of the angle of incidence is to the sine of the angle of refraction as 4 to 3; which is confirmed by the following experiment, taken from Doctor Smith’s Optics.

Describe the circle \( DABC \) on a plane square board, and crofs it at right angles with the straight lines \( ABC \), and \( LBM \); then, from the intersection \( A \), with any opening of the compasses, let off the equal arcs \( AD \) and \( AE \), and draw the right line \( DEF \); then, taking \( Fa \), which is three quarters of the length \( FE \), from the point \( a \), draw \( ai \) parallel to \( ABK \), and join \( KI \) parallel to \( BM \): so \( KI \) will be equal to three quarters of \( FE \) or of \( DF \). This done, fix the board upright upon the leaden pedestal \( O \), and stick three pins perpendicularly into the board, at the points \( D \), \( B \), and \( I \); then set the board upright into the vessel \( TUV \), and fill up the vessel with water to the line \( LBM \). When the water has settled, look along the line \( DB \), so as you may see the head of the pin \( B \) over the head of the pin \( D \); and the pin \( I \) will appear in the same right line produced to \( G \), for its head will be seen just over the head of the pin at \( B \); which shews that the ray \( IB \), coming from the pin at \( I \), is so refracted at \( B \), as to proceed from thence in the line \( BD \) to the eye of the observer; the same as it would do from any point \( G \) in the right line \( DFG \), if there were no water in the vessel: and also shews, that \( KI \), the line of refraction in water, is to \( DF \), the line of incidence in air, as 3 to 4.

Hence, if \( DBH \) were a crooked stick put obliquely into the water, it would appear a straight one at \( DBC \). Therefore, as the line \( BH \) appears at \( BG \), so the line \( BC \) will appear at \( BG \): and consequently, a straight stick \( DBG \) put obliquely into water, will seem bent at the surface of the water in \( B \), and crooked, as \( DBC \).

When a ray of light passes out of air into glasses, the sine of incidence is to the sine of refraction as 3 to 2; and when out of air into a diamond, as 5 to 2.

Of Glasses.

Glass may be ground into eight different shapes at \( LBM \), for optical purposes, viz.

1. A plane glass, (No. 5,) which is flat on both sides, and of equal thickness in all parts, as \( A \).
2. A plano-convex, which is flat on one side, and convex on the other, as \( B \).
3. A double-convex, which is convex on both sides, as \( C \).
4. A plano-concave, which is flat on one side, and concave on the other, as \( D \).
5. A double concave, which is concave on both sides, as \( E \).
6. A meniscus, which is concave on one side, and convex on the other, as \( F \).
7. A flat plano-convex, whose convex side is ground into several little flat surfaces, as \( G \).
8. A prism, which has three flat sides; and when viewed endwise, appears like an equilateral triangle, as \( H \).

Glasses ground into any of the shapes \( B, C, D, E, F \), are generally called lenses.

A right line \( LIK \), (No. 6.) going perpendicularly through the middle of a lens, is called the axis of the lens.

A ray of light \( Gh \), falling perpendicularly on a plane glass \( EF \), will pass through the glass in the same direction \( hi \), and go out of it into the air in the same right course \( HF \).

A ray of light \( AB \), falling obliquely on a plane glass, will go out of the glass in the same direction, but not in the same right line: for in touching the glass, it will be refracted in the line \( BC \); and in leaving the glass, it will be refracted in the line \( CD \).

A ray of light \( CD \), (No. 7.) falling obliquely on the middle of a convex glass, will go forward in the same direction \( DE \), as if it had fallen with the same degree of obliquity on a plane glass; and will go out of the glass in the same direction with which it entered; for it will be equally refracted at the points \( D \) and \( E \), as if it had passed through a plane surface. But the rays \( CG \) and \( CF \) will be so refracted, as to meet again at the point \( F \). Therefore, all the rays which flow from the point \( C \), so as to go through the glass, will meet again at \( F \); and if they go farther onward, as to \( L \), they crofs at \( F \), and go forward on the opposite sides of the middle ray \( CDEF \), to what they were in approaching it in the directions \( HF \) and \( KF \).

When parallel rays, as \( ABC \), (No. 8.) fall directly upon a plano-convex glass \( DE \), and pass through it, they will be so refracted, as to unite in a point \( f \) behind it; and this point is called the principal focus; the distance of which, from the middle of the glass, is called the focal distance, which is equal to twice the radius of the sphere of the glass’s convexity. And,

When parallel rays, as \( ABC \), (No. 9.) fall directly upon a glass \( DE \), which is equally convex on both sides, and passes through it; they will be so refracted, as to meet in a point or principal focus \( f \); whose distance is equal to the radius or semidiameter of the sphere of the glass’s convexity. But if a glass be more convex on one side than on the other, the rule for finding the focal distance is this: As the sum of the semidiameters of both convexities is to the semidiameter of either, so is double the semidiameter.
OPTICS.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.

If another glass FG, of the same convexity as DE, be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc; and go on in the same manner FG, as they converged in the space DFE in coming to it.
there is a very great difference between the real object and all the parts of a distant prospect are painted upon the retina, they are all right with respect to one another, as well as the parts of the prospect itself; and we can only judge of an object's being inverted, when it is turned reverse to its natural position with respect to other objects which we see and compare it with.—If we lay hold of an upright stick in the dark, we can tell which is the upper or lower part of it, by moving our hand downward or upward; and know very well that we cannot feel the upper end by moving our hand downward. Just so we find by experience, that upon directing our eyes towards a tall object, we cannot see its top by turning our eyes downward, nor its foot by turning our eyes upward; but must trace the object the same way by the eye to feel it from head to foot, as we do by the hand to feel it; and as the judgment is informed by the motion of the hand in one case, so it is also by the motion of the eye in the other.

In (No. 13.) is exhibited the manner of seeing the same object ABC, by both the eyes D and E at once.

When any part of the image cba falls upon the optic nerve L, the corresponding part of the object becomes invisible. On which account, nature has wisely placed the optic nerve of each eye, not in the middle of the bottom of the eye, but towards the side next the nose, so that whatever part of the image falls upon the optic nerve of one eye, may not fall upon the optic nerve of the other. Thus the point a of the image cba falls upon the optic nerve of the eye D, but not of the eye E; and the point c falls upon the optic nerve of the eye E, but not of the eye D: and therefore, to both eyes taken together, the whole object ABC is visible.

The nearer that any object is to the eye, the larger is the angle under which it is seen, and the magnitude under which it appears. Thus to the eye D, (No. 14.) the object ABC is seen under the angle APC; and its image cba is very large upon the retina: but to the eye E, at a double distance, the same object is seen under the angle APC, which is equal only to half the angle APC, as is evident by the figure. The image cba is likewise twice as large in the eye D, as the other image cba is in the eye E. In both these representations, a part of the image falls on the optic nerve, and the object in the corresponding part is invisible.

As the sense of seeing is allowed to be occasioned by the impulse of the rays from the visible object upon the retina of the eye, and forming the image of the object thereon, and that the retina is only the expansion of the optic nerve all over the choroides; it should seem surprising, that the part of the image which falls on the optic nerve should render the like part of the object invisible; especially as that nerve is allowed to be the instrument by which the impulse and image are conveyed to the common fenory in the brain. But this difficulty vanishes, when we consider that there is an artery within the trunk of the optic nerve, which entirely obscures the image in that part, and conveys no sensation to the brain.

That the part of the image which falls upon the middle of the optic nerve is lost, and consequently the correspond-
Tall el to the eye after faffing through the glasses; and then, by entering the eye at C, they will be converged to as many different points on the retina, and form a large inverted picture AB upon it, as in the figure.

To find how much this glass magnifies, divide the least distance (which is about six inches) at which an object can be seen distinctly with the bare eye, by the focal distance of the glass; and the quotient will show how much the glass magnifies the diameter of the object.

The double or compound microscope, (No. 18.) consists of an object-glass cd, and an eye-glass ef. The small object ab is placed at a little greater distance from the glass cd than its principal focus, so that the pencils of rays flowing from the different points of the object, and passing through the glasses, may be made to converge and unite in as many points between g and h, where the image of the object will be formed; which image is viewed by the eye through the eye-glass ef. For the eye-glasses being so placed, that the image gh may be in its focus, and the eye much about the same distance on the other side, the rays of each pencil will be parallel, after going out of the eye-glasses, as at e and f; till they come to the eye at k, where they will begin to converge by the refractive power of the humours; and after having crossed each other in the pupil, and passed through the chrysaline and vitreous humours, they will be collected into point s on the retina, and form the large inverted picture AB thereon.

The magnifying power of this microscope is as follows. Suppose the image gh to be six times the distance of the object ab from the object-glass cd; then will the image be six times the length of the object: but since the image could not be seen distinctly by the bare eye at a less distance than six inches, if it be viewed by an eye-glass ef, of one inch focus, it would thereby be brought six times nearer the eye; and consequently viewed under an angle six times as large as before; so that it will be again magnified six times; that is, six times by the object-glass, and six times by the eye-glass; which multiplied into one another, makes 36 times; and so much is the object magnified in diameter more than what it appears to the bare eye; and consequently 36 times 36, or 1296 times, in surface.

But, because the extent or field of view is very small in this microscope, there are generally two eye-glasses placed sometimes close together, and sometimes in an inch asunder; by which means, although the object appears less magnified, yet the visible area is much enlarged by the interpolation of a second eye-glass, and consequently a much pleasanter view is obtained.

The solar microscope, (No. 19.) invented by Dr. Lieberkun, is constructed in the following manner. Having procured a very dark room, let a round hole be made in the window-flutter, about three inches diameter, through which the sun may cast a cylinder of rays AA into the room. In this hole, place the end of a tube, containing two convex glasses and an object, viz. 1. A convex glass as, of about two inches diameter, and three inches focal distance, is to be placed in that end of the tube which is put into the hole. 2. The object bb, being put between two glasses (which must be concave to hold it at liberty) is placed about two inches and a half from the glass cc. A little more than a quarter of an inch from the object is placed the small convex glasses cc, whose focal distance is a quarter of an inch.

The tube may be so placed, when the sun is low, that his rays AA may enter directly into it: but when he is high, his rays BB must be reflected into the tube by the plane mirror or looking glass CC.

Things being thus prepared, the rays that enter the tube will be conveyed by the glass ab towards the object bb, by which means it will be strongly illuminated; and the rays a which flow from it through the convex glass cc, will make a large inverted picture of the object at DD, which, being received on a white paper, will represent the object magnified in length, in proportion of the distance of the picture from the glass cc, to the distance of the object from the same glass. Thus, suppose the distance of the object from the glass to be 40 parts of an inch, and the distance of the distinct picture to be 12 feet or 144 inches, in which there are 1440 tenths of an inch; and this number divided by 3 tenths, gives 480; which is the number of times the picture is longer or broader than the object; and the length multiplied by the breadth, shews how much the whole surface is magnified.

Of Telescopes.

Before we enter upon the description of telescopes, it will be proper to shew how the rays of light are affected by passing through concave glasses, and also by falling upon concave mirrors.

When parallel rays, as abedegh, (No. 20.) pass directly through a glass AB, which is equally concave on both sides, they will diverge after passing through the glass, as if they had come from a radiant point C, in the centre of the glass's concavity; which point is called the negative or virtual focus of the glass. Thus the ray a, after passing through the glass AB, will go on in the direction d, as if it had proceeded from the point C, and no glass been in the way. The ray b will go on in the direction m; the ray c in the direction o, &c.—The ray C, that falls directly upon the middle of the glass, suffers no refraction in passing through it; but goes on in the same rectilinear direction, as if no glass had been in its way.

If the glass had been concave only on one side, and the other side quite plane, the rays would have diverged, after passing through it, as if they had come from a radiant point at double the distance of C from the glass; that is, as if the radiant had been at the distance of a whole diameter of the glass's concavity.

If rays come more converging to such a glass, than parallel rays diverge after passing through it, they will continue to converge after passing through it; but will not meet so soon as if no glass had been in the way, and will incline towards the same side, to which they would have diverged if they had come parallel to the glass. Thus the rays f and h, going in a converging line towards the edge of the glass at B, and converging more in their way to it than the parallel rays diverge after passing through it, they will go on converging after they pass through it, though
thougla In a lefs degree t’han they did before, and will upon a concave mirror AB (which is not transparent, but has only the surface AB of a clear polish,) they will be reflected back from that mirror, and meet in a point m, at half the distance of the surface of the mirror from C the centre of its concavity; for they will be reflected at as great an angle from a perpendicular to the surface of the mirror, as they fell upon it with regard to that perpendicular, but on the other side thereof. Thus, let C be the centre of concavity of the mirror AB; and let the parallel rays dfa, Cmb, and ecle, fall upon it at the points a, b, and c. Draw the lines Cia, Cmb, and Cche, from the centre C to these points; and all these lines will be perpendicular to the surface of the mirror, because they proceed thereto like fo many radii or spokes from its centre. Make the angle Cab equal to: the angle dac, and draw the line amb, which will be the direction of the ray dfa, after it is reflected from the point a of the mirror; so that the angle of incidence dac, is equal to the angle of reflection Cab; the rays making equal angles with the perpendicular Cia on its opposite sides.

Draw also the perpendicular Cche to the point c, where the ray ecle touches the mirror; and, having made the angle Cei equal to the angle Cce, draw the line cmi, which will be the course of the ray ecle, after it is reflected from the mirror.

The ray Cmb passing through the centre of concavity of the mirror, and falling upon it at b, is perpendicular to it; and is therefore reflected back from it in the same line bmc.

All these reflected rays meet in the point m; and in that point the image of the body which emits the parallel rays dfa, Cgb, and ecle, will be formed; which point is distant from the mirror equal to half the radius bmc of its concavity.

The rays which proceed from any celestial object may be esteemed parallel at the earth; and therefore, the images of that object will be formed at m, when the reflecting surface of the concave mirror is turned directly towards the object. Hence, the focus m of parallel rays is not in the centre of the mirror’s concavity, but half way between the mirror and that centre.

The rays which proceed from any remote terrestrial object, are nearly parallel at the mirror; not strictly so, but come diverging to it, in separate pencils, or, as it were, bundles of rays, from each point of the side of the object next the mirror; and therefore they will not be converged to a point at the distance of half the radius of the mirror’s concavity from its reflecting surface, but into separate points at a little greater distance from the mirror. And the nearer the object is to the mirror, the farther these points will be from it; and an inverted image of the object will be formed in them, which will seem to hang pendant in the air; and will be seen by an eye placed beyond it (with regard to the mirror) in all respects like the object, and as distinct as the object itself.

Let AEB, (No. 22.) be the reflecting surface of a mirror, whose centre of concavity is at C; and let the upright object DE be placed beyond the centre C, and send out a conical pencil of diverging rays from its upper extremity D, to every point of the concave surface of the mirror AEB. But to avoid confusion, we only draw three rays of that pencil, as DAB, DCE, DBF.

From the centre of concavity C, draw the three right lines CA, Ce, CB, touching the mirror in the same points where the forefaid rays touch it; and all these lines will be perpendicular to the surface of the mirror. Make the angle CAB equal to the angle DCA, and draw the right line Ad for the course of the reflected ray DA; make the angle CDa equal to the angle DCA, and draw the right line ed for the course of the reflected ray DB: make also the angle CBe equal to the angle DBC, and draw the right line Be for the course of the reflected ray DB. All these reflected rays will meet in the point d, where they will form the extremity d of the inverted image ed, similar to the extremity D of the upright object DE.

If the pencil of rays Esa, Esb, be also continued to the mirror, and their angles of reflection from it be made equal to their angles of incidence upon it, as in the former pencil from D, they will all meet at the point e by reflection, and form the extremity e of the image ed, similar to the extremity E of the object DE.

And as each intermediate point of the object, between D and E, sends out a pencil of rays in like manner to every part of the mirror, the rays of each pencil will be reflected back from it, and meet in all the intermediate points between the extremities e and d of the image; and so the whole image will be formed, not at i, half the distance of the mirror from its centre of concavity C; but at a greater distance, between i and the object DE; and the image will be inverted with respect to the object.

This being well understood, the reader will easily see how the image is formed by the large concave mirror of the reflecting telescope, when he comes to the description of that instrument.

When the object is more remote from the mirror than its centre of concavity C, the image will be less than the object, and between the object and mirror; when the object is nearer than the centre of concavity, the image will be more remote and bigger than the object: thus, if DE be the object, ed will be its image: for, as the object recedes from the mirror, the image approaches nearer to it; and as the object approaches nearer to the mirror, the image recedes farther from it; on account of the lesser or greater divergency of the pencils of rays which proceed from the object: for, the less they diverge, the sooner they are converted to points by reflection; and the more they diverge, the farther they must be reflected before they meet.

If the radius of the mirror’s concavity, and the distance of the object from it, be known, the distance of the image from the mirror is found by this rule: Divide the product of the distance and radius by double the distance made less by the radius, and the quotient is the distance required.

If the object be in the centre of the mirror’s concavity,
In a reflecting telescope, the glass which is nearest the object in viewing it is called the object-glass, and that which is nearest the eye is called the eye-glass. The object-glasses must be convex, but the eye-glasses may be either convex or concave: and generally, in looking through a telescope, the eye is in the focus of the eye-glass; though that is not very material, for the distance of the eye, as to distant vision, is indifferent, provided the rays of the pencils fall upon it parallel: only, the nearer the eye is to the end of the telescope, the larger is the scope or area of the field of view.

Let $cd$ (No. 23.) be a convex glass fixed in a long tube, and have its focus at $E$. Then, a pencil of rays $gh$, flowing from the upper extremity $A$ of the remote object $AB$, will be so refracted by passing through the glass, as to converge and meet in the point $e$; and the pencil of rays $klm$, flowing from the lower extremity $B$ of the same object $AB$, and passing through the glass, will converge and meet in the point $e$ and the images of the points $A$ and $B$ will be formed in the points $f$ and $e$. And as all the intermediate points of the object, between $A$ and $B$, send out pencils of rays in the same manner, a sufficient number of these pencils will pass through the object-glass $cd$, and converge to as many intermediate points between $e$ and $f$; and so will form the whole inverted image $EF$ of the distant object. But because this image is small, a concave glass $no$ is so placed in the end of the tube next the eye, that its virtual focus may be at $F$. And as the pencils of rays pass converging through the concave glass, but converge less after passing through it than before, they go on further, as to $b$ and $a$, before they meet; and the pencils themselves being made to diverge by passing through the concave glass, they enter the eye, and form the large picture $ab$ upon the retina, whereon it is magnified under the angle $bFa$.

But this telescope has one inconvenience which renders it unfit for most purposes, which is, that the pencils of rays being made to diverge by passing through the concave glass $no$, very few of them can enter the pupil of the eye; and therefore the field of view is but very small, as is evident by the figure. For none of the pencils which either from the top or bottom of the object $AB$ can enter the pupil of the eye at $C$, but are all slopt by falling upon the iris above and below the pupil: and therefore, only the middle part of the object can be seen when the telescope lies directly towards it, by means of those rays which proceed from the middle of the object. So that to see the whole of it, the telescope must be moved upwards and downwards, unless the object be very remote; and then it is never seen distinctly.

This inconvenience is remedied by substituting a convex eye-glass, as $gh$, (No. 24.) in place of the concave one; and fixing it so in the tube, that its focus may be coincident with the focus of the object-glass $cd$, as at $E$. For then, the rays of the pencils flowing from the object $AB$, and passing through the object-glass $cd$, will meet in its focus, and form the inverted image $mEp$: and as the image is formed in the focus of the eye-glass $gh$, the rays of each pencil will be parallel, after passing through that glass, but the pencils themselves will cross in its focus on the other side, as at $e$: and the pupil of the eye being in this focus, the image will be viewed through the glass, under the angle $gsh$: and being at $E$, it will appear magnified, so as to fill the whole space $CmEpD$.

But, as this telescope inverts the object with respect to the object, it gives an unpleasant view of terrestrial objects; and is only fit for viewing the heavenly bodies, in which we regard not their position, because their being inverted does not appear on account of their being round. But whatever way the object seems to move, this telescope must be moved the contrary way, in order to keep sight of it; for, since the object is inverted, its motion will be so too.

The magnifying power of this telescope is as the focal distance of the object-glass to the focal distance of the eye-glass. Therefore, if the former be divided by the latter, the quotient will express the magnifying power.

When we speak of the magnifying of a telescope or micro-

---

**OPTICS.** 423
the focal distance of the object-glass be ten times as great as the focal distance of the eye-glass; then, the object will be magnified ten times, both in length and breadth; and 10 multiplied by 10, produces 100; which shows, that the area of the object will appear 100 times as big when seen through such a telescope, as it does to the bare eye.

Hence it appears, that if the focal distance of the eye-glasses were equal to the focal distance of the object-glass, the magnifying power of the telescope would be nothing.

This telescope may be made to magnify in any given degree, provided it be of a sufficient length. For, the greater the focal distance of the object-glass, the less may be the focal distance of the eye-glasses; though not directly in proportion. Thus, an object-glass, of 10 feet focal distance, will admit of an eye-glass whose focal distance is little more than 2.5 inches; which will magnify near 48 times: but an object-glass, of 100 feet focus, will require an eye-glass somewhat more than 6 inches; and will therefore magnify almost 200 times.

A telescope for viewing terrestrial objects, should be so constructed, as to shew them in their natural posture. And this is done by one object-glass, (No. 25.) and three eye-glasses, ef, gb, ik. So placed, that the distance between any two, which are nearest to each other, may be equal to the sum of their focal distances; as in the figure, where the focus of the glasses ed and ef meet at F, those of the glasses ed and gb meet at I, and of gb and ik at m; the eye being at n, in or near the focus of the eye-glasses ik, on the other side. Then, it is plain, that these pencils of rays, which flow from the object AB, and pass through the object-glass cd, will meet and form an inverted image CFD in the focus of that glass; and the image being also in the focus of the glass ef, the rays of the pencils will become parallel, after passing through that glass, and cross at I, in the focus of the glass ef, from whence they pass on to the next glass gb, and by going through it they are converted to points in its other focus, where they form an erect image EnF of the object AB; and as this image is also in the focus of the eye-glasses ik, and the eye on the opposite side of the same glass; the image is viewed through the eye-glasses in this telescope, in the same manner as through the eye-glasses in the former one; only in a contrary position, that is, in the same position with the object.

The three glasses next the eye have all their focal distances equal; and the magnifying power of this telescope is found the same way as that of the last above; viz. by dividing the focal distance of the object-glass cd, by the focal distance of the eye-glasses ik, or gb, or ef, since all these three are equal.

When the rays of light are separated by refraction, they become coloured; and if they be united again, they will be a perfect white. But those rays which pass through a convex glass near its edges are more unequally refracted than those which are nearer the middle of the glass. And when the rays of any pencil are unequally refracted by the glass, they do not all meet again in one and the same point, but in separate points; which makes the image indistinct, and coloured, about its edges. The remedy is, to have a plate with a small round hole in its middle, fixed in the tube at m, parallel to the glasses.

For, the wandering rays about the edges of the glasses will be stoped, by the plate, from coming to the eye; and none admitted but those which come through the middle of the glass, or at least at a good distance from its edges, and pass through the hole in the middle of the plate. But this circumscribes the image, and lessens the field of view, which would be much larger if the plate could be dispensed with.

The great inconvenience attending the management of long telescopes of this kind, has brought them much into disuse ever since the reflecting telescope was invented. For one of this sort, six feet in length, magnifies as much as one of the other an hundred. It was invented by Sir Isaac Newton, but has received considerable improvements since his time; and is now generally constructed in the following manner, which was first proposed by Dr. Gregory.

At the bottom of the great tube TTTT, (No. 26.) is placed the large concave mirror DUUF, whose principal focus is at m; and in its middle is a round hole P, opposite to which is placed the small mirror L, concave toward the great one; and so fixed to a strong wire M, that it may be moved farther from the great mirror, or nearer to it, by means of a long screw on the outside of the tube, keeping its axis still in the same line Pn with that of the great one.—Now, since in viewing a very remote object, we can scarce see a point of it but what is as least as broad as the great mirror, we may consider the rays of each pencil, which flow from every point of the object, to be parallel to each other, and to cover the whole reflecting surface DUUF. But to avoid confusion in the figure, we shall only draw two rays of a pencil flowing from each extremity of the object into the great tube, and trace their progress, through all their reflections and refractions, to the eye f, at the end of the small tube tt, which is joined to the great one.

Let us then suppose the object AB to be at such a distance, that the rays B may flow from its lower extremity B, and the rays E from its upper extremity A. Then the rays C falling parallel upon the great mirror at D, will be thence reflected converging, in the direction DG, and by crossing at I in the principal focus of the mirror, they will form the upper extremity I of the inverted image IK, similar to the lower extremity B of the object AB: and passing on to the concave mirror L (whose focus is at n) they will fall upon it at g, and be thence reflected converging, in the direction gN, because gm is longer than gn; and passing through the hole P in the large mirror, they would meet somewhere about r, and form the lower extremity B of the erect image AB, similar to the lower extremity B of the object AB. But by passing through the plano-convex glass R in their way, they form that extremity of the image at b. In like manner, the rays E, which come from the top of the object AB,
AB, and fall parallel upon the great mirror at F, are then reflected converging to its focus, where they form the lower extremity K of the inverted image IK, similar to the upper extremity A of the object AB; and thence passing on to the small mirror L, and falling upon it at b, they are then reflected in the converging plane at H0; and going on through the hole P of the great mirror, they would meet somewhere about q, and form there the upper extremity a of the erect image ab, similar to the upper extremity A of the object AB: but by passing through the convex glass R in their way, they meet and cross sooner, as at a, where that point of the erect image is formed.—The like being understood of all those rays which flow from the intermediate points of the object between A and B, and enter the tube TT; all the intermediate points of the image between a and b will be formed; and the rays passing on from the image, through the eye-glasses S, and through a small hole e in the end of the latter tube tt, they enter the eye f, (which sees the image ab by means of the eye-glasses) under the large angle eed, and magnified in length under that angle from e to d.

In the best reflecting telescopes, the focus of the small mirror is never coincident with the focus n of the great one; where the first image IK is formed, but a little behind it (with respect to the eye) as at n: the consequence of which is, that the rays of the pencils will not be parallel after reflection from the small mirror, but converge to as to meet in points about q, r, s; where they would form a larger upright image than ab, if the glass R was not in their way; and this image might be viewed by means of a single eye-glass properly placed between the image and the eye; but then the field of view would be less, and consequently not so pleasant; for which reason, the glass R is still retained, to enlarge the scope or area of the field.

To find the magnifying power of this telescope, multiply the focal distance of the great mirror by the distance of the small mirror from the image next the eye, and multiply the focal distance of the small mirror by the focal distance of the eye-glasses; then, divide the product of the former multiplication by the product of the latter, and the quotient will express the magnifying power.

We shall here set down the dimensions of one of Mr. Short's reflecting telescopes, as described in Dr. Smith's optics.

The focal distance of the great mirror 0.6 inches, its breadth 2.3; the focal distance of the small mirror 1.5, its breadth 0.6; the breadth of the hole in the great mirror 0.5; the distance between the small mirror and the next eye-glass 1.4; the distance between the two eye-glasses 2.4; the focal distance of the eye-glasses next the metals 3.8; and the focal distance of the eye-glasses next the eye 1.1.

One great advantage of the reflecting telescope is, that it will admit of an eye-glass of a much shorter focal distance than a refracting telescope will; and, consequently, it will magnify so much the more: for the rays are not coloured by reflection from a concave mirror, if it be ground to a true figure, as they are by passing through a convex glass, let it be ground ever so true.

The adjusting screw on the outside of the great tube fits this telescopes to all sorts of eyes, by bringing the small mirror either nearer to the eye, or removing it farther; by which means, the rays are made to diverge a little for short-sighted eyes, or to converge for those of a long sight.

The nearer an object is to the telescope, the more its pencils of rays will diverge before they fall upon the great mirror, and therefore they will be the longer of meeting in points after reflection; so that the first image IK will be formed at a greater distance from the large mirror, when the object is near the telescope, than when it is very remote. But as this image must be formed farther from the small mirror than its principal focus n, this mirror must be always set at a greater distance from the large one, in viewing near objects, than in viewing remote ones. And this is done by turning the farew on the outside of the tube, until the small mirror be so adjusted, that the object (or rather its image) appears perfect.

In looking through any telescope towards an object, we never see the object itself, but only that image of it which is formed next the eye in the telescope. For if a man holds his finger or a flick between his bare eye and an object, it will hide part (if not the whole) of the object from his view. But if he ties a flick across the mouth of a telescope before the object-glass, it will hide no part of the imaginary object he saw through the telescope before, unless it covers the whole mouth of the tube: for, all the effect will be, to make the object appear dimmer, because it intercepts part of the rays. Whereas, if he puts only a piece of wire across the inside of the tube, between the eye-glass and his eye, it will hide part of the object which he thinks he sees: which proves, that he sees not the real object, but its image. This is also confirmed by means of the small mirror L, in the reflecting telescope, which is made of opaque metal, and stands directly between the eye and the object towards which the telescope is turned; and will hide the whole object from the eye at e, if the two glasses R and S are taken out of the tube.

Of the Multiplying Glass.

The multiplying glass is made by grinding down the round side bH (No. 27.) of a convex glass AB, into several flat surfaces, as bb, bb, dd, &c. An object C will not appear magnified when seen through this glass by the eye at H, but it will appear multiplied into as many different objects as the glass contains plane surfaces. For since rays will flow from the object C to all parts of the glass, and each plane surface will reflect these rays to the eye, the same object will appear to the eye in the direction of the rays which enter it through each surface. Thus, a ray gH, falling perpendicularly on the middle surface, will go through the glass to the eye without suffering any refraction; and will therefore shew the object in its true place at C; whilst a ray ab flowing from the same object, and falling obliquely on the plane surface bb, will be refracted in the direction aH, by passing through the glass; and upon leaving it, will go on to the eye in the direction dH; which will cause the same object C to appear also at E, in the direction of the ray Hc, produced in the right line Hen. And the ray cd, flowing from the
the object C, and falling obliquely on the plane of the surface at D, will be refracted (by passing through the glass and leaving it at f) to the eye at H; which will cause the same object to appear at D in the direction H/m. — If the glass be turned round the line gH, as an axis, the object C will keep its place, because the plane basis is not removed; but all the other objects will seem to go round C, because the oblique planes, on which the rays ab ed fall, will go round by the turning of the glass.

Of the Camera Obscura.

The camera obscura is made by a convex glass CD, (No. 28.) placed in a hole of a window-shutter. Then, if the room be darkened so, as no light can enter but what comes through the glass, the pictures of all the objects (as fields, trees, buildings, men, cattle, &c.) on the outside, will be shown in an inverted order, on a white paper placed at GH in the focus of the glass; and will afford a most beautiful and perfect piece of perspective or landscape of whatever is before the glass, especially if the fan shines upon the objects.

If the convex glass CD be placed in a tube in the side of a square box, within which is the plane mirror EF, receding backwards in an angle of 45 degrees from the perpendicular kq, the pencils of rays flowing from the outward objects, and passing through the convex glass to the plane mirror, will be reflected upwards from it, and meet in points, as I and K (at the same distance that they would have met at H and C, if the mirror had not been in the way,) and will form the aforesaid images on an oiled paper stretched horizontally in the direction IK; on which paper, the out-lines of the images may be easily drawn with a black-lead pencil; and then copied on a clean sheet, and coloured by art, as the objects themselves are by nature.—In this machine, it is usual to place a plane glass, unpolished, in the horizontal situation IK, which glass receives the images of the outward objects; and their outlines may be traced upon it by a black-lead pencil.

N. B. The tube in which the convex glass CD is fixed, must be made to draw out, or put in, so as to adjust the distance of that glass from the plane mirror, in proportion to the distance of the outward objects; which the operator does, until he sees their images distinctly pointed on the horizontal glass at IK.

The forming a horizontal image, as IK, of an upright object AB, depends upon the angles of incidence of the rays upon the plane mirror EF, being equal to their angles of reflection from it. For, if a perpendicular be supposed to be drawn to the surface of the plane mirror at e, where the ray A Ae falls upon it, that ray will be reflected upwards in an equal angle with the other side of the perpendicular, in the line edI. Again, if a perpendicular be drawn to the mirror from the point f, where the ray A/fs falls upon it, that ray will be reflected in an equal angle from the other side of the perpendicular, in the line fsI. And if a perpendicular be drawn from the point g, where the ray Aeg falls upon the mirror, that ray will be reflected in an equal angle from the other side of the perpendicular, in the line giI. So that all the rays of the pencil abc, flowing from the upper extremity of the object AB, and passing through the convex glass CD, to the plane mirror EF, will be reflected from the mirror, and meet at I, where they will form the extremity I of the image IK, similar to the extremity A of the object AB. The like is to be understood of the pencil gis, flowing from the lower extremity of the object AB, and meeting at K (after reflection from the plane mirror) the rays form the extremity K of the image, similar to the extremity B of the object; and so of all the pencils that flow from the intermediate points of the object to the mirror, through the convex glass.

Of the Opera-Glass.

If a convex glass, of a short focal distance, be placed near the plane mirror in the end of a short tube, and a convex glass be placed in a hole in the side of the tube, so as the image may be formed between the last mentioned convex glass and the plane mirror; the image being viewed through this glass, will appear magnified.—In this manner, the opera-glasses are constructed; with which a gentleman may look at any lady at a distance in the company, and the lady know nothing of it.

Of the Common Looking-Glass.

The image of any object that is placed before a plane mirror appears as big to the eye as the object itself; and is erect, distinct, and seemingly as far behind the mirror, as the object is before it; and that part of the mirror, which reflects the image of the object to the eye (the eye being supposed equally distant from the glass with the object) is just half as long and half as broad as the object itself. Let AB (No. 29.) be an object placed before the reflecting surface ghI of the plain mirror CD; and let the eye be at o. Let Ab be a ray of light flowing from the top A of the object and falling upon the mirror at b, and bm be a perpendicular to the surface of the mirror at b; the ray Ab will be reflected from the mirror to the eye at e, making an angle who equal to the angle Abm; then will the top of the image E appear to the eye in the direction of the reflected ray ob produced to E, where the right line ApE, from the top of the object, cuts the right line oBE, at E. Let Bi be a ray of light proceeding from the foot of the object at B to the mirror at i; and ni a perpendicular to the mirror from the point i, where the ray Bi falls upon it; this ray will be reflected in the line is, making an angle nis equal to the angle Bin, with that perpendicular, and entering the eye at o; then will the foot F of the image appear in the direction of the reflected ray si, produced to F, where the right line BF cuts the reflected ray produced to F. All the other rays that flow from the intermediate points of the object AB, and fall upon the mirror between b and i, will be reflected to the eye at o; and all the intermediate points of the image EF will appear to the eye in the direction of these reflected rays produced. But all the rays that flow from the object, and fall upon the mirror above b, will be reflected back above the eye at o; and all the rays that flow from the object, and fall upon the mirror below i, will be reflected back below the
duced to \( F \), beyond the glass. And a ray \( B D \), flowing intermediate rays from \( A \) to \( B \). Hence, if the man \( AB \) reflected ray \( AD \), produced to \( F \), where it is cut by the glass, is exactly equal to his own size. For, a ray \( BD \), flowing from his foot, and falling obliquely on the glass at \( D \), will be reflected as obliquely on the other side of the glass. And so, the eye of his image will appear at \( F \), in the same line produced to \( E \), beyond the glass. And a ray \( BE \), flowing from his eye at \( A \), and falling perpendicularly upon the surface of the glass at \( C \), is reflected back to his eye, in the same line \( CA \); and the image of his eye will appear at \( E \), in the same line produced to \( E \), beyond the glass. And a ray \( BE \), flowing from his eye at \( A \), and falling perpendicularly upon the glass at \( D \), will be reflected as obliquely on the other side of the glass. And so, the eye of his image will appear at \( F \), in the direction of the line \( ADF \).

If the glass be brought nearer the man \( AB \), as supposed to \( ob \), he will see his image as at \( C D F \) : for the reflected ray \( CA \) (being perpendicular to the glass) will shew the eye of the image as at \( C \); and the incident ray \( Bb \), being reflected in the line \( A \), will shew the foot of his image as at \( C \); the angle of reflection \( ab \), being always equal to the angle of incidence \( Bba \); and so of all the intermediate rays from \( A \) to \( B \). Hence, if the man \( AB \) advances towards the glass \( CD \), his image will approach towards it; and if he recedes from the glass, his image will also recede from it.

Of the Magic Lantern.

ABCD (No. 31.) is a tin lantern, with a tube \( nkkm \), fixed in the side of it. This tube consists of two joints, one of which slips into the other; and by drawing this joint out, or pushing it in, the tube may be made longer or shorter. At \( kl \) in the end of the moveable joint of the tube a convex lens is fixed, and an object painted with transparent colours upon a piece of thin glass is placed at \( de \) somewhere in the immovable joint of the tube; so that as the tube is lengthened or shortened, the lens will be either at a greater or a less distance from this transparent object. In the side of the lantern there is a very convex lens \( bhbc \), which serves to call a very strong light from the candle within the lantern upon the object \( de \). Now when the rays, which shine through the object \( de \), diverge from the several points as \( d, e, \&c. \) in the object, and fall upon the lens \( kl \), they will be made to converge to as many points \( f, g, \&c. \) on the other side of the lens, and will print an inverted picture of the object at \( fg \) upon a white wall, a sheet or a screen of white paper, provided the object is farther from the lens than its principal focus. To make this picture appear distinct and bright, it must have no other light fall upon it but what comes through the lens \( kl \); and for this reason the whole apparatus is to be placed in a dark room \( EFGH \). The lens \( kl \) must be very convex, so that the object \( de \) may be very near to it, and yet not be nearer than its principal focus: for by this means, as the object is near to the lens, the picture \( fg \) will be at a great distance from it, and consequently the picture will be much bigger than the object. Since the picture is inverted with respect of the object, in order to make the picture appear with the right end upwards, it is necessary that the object \( de \) should be placed with the wrong end upwards.

Of the Different Refrangibility of Light.

We have hitherto supposed that a particle of light, as it comes from the sun, is the least particle into which light can be separated. But we must now correct this supposition, by shewing, that a particle of light, as it comes from the sun, is, properly speaking, a bundle of rays, which may be separated from one another. Therefore, for the future, by a ray of light we must be understood to mean, not that collection of particles which we have hitherto called by this name, but the least particles into which light can be separated.

Rays of light are said to be differently refrangible, when at the same or equal angles of incidence some are more turned out of the ray than others.

Rays are said to be differently reflecting, if some are more easily reflected than others.

Light is called homogeneous, when all the rays are equally refrangible: it is called heterogeneous, when some rays are more refrangible than others.

The colours of homogeneous light are called primary or simple colours; and those of heterogeneous light are called secondary or mixed.

The rays of the sun are not all equally refrangible: and those rays, which have a different degree of refrangibility, have likewise a different colour.

If a beam of light \( SF \), (No. 32.) that comes from the sun, passes into a dark room through \( F \) a round hole in a window shutter \( EG \); this beam proceeding straight forwards, and falling upon a paper at \( Y \), would make a round picture of the sun. This picture would be a confused one indeed, if the hole is a large one and there is no lens in the hole. However, as this round spot of light is a picture of the sun, we shall hereafter, notwithstanding its confusion, call it by this name. Now if a glass prism \( ABC \) is placed between the hole in the window shutter and the paper at \( Y \), the rays of this beam, by the refraction which they suffer in the prism, will be bent from their straight course, and instead of going on so as to fall upon the paper at \( Y \), they will be turned upwards, and the picture of the sun produced by them will fall upon a paper \( MN \) that is placed above \( Y \). If all the rays were
were equally bent upwards, the picture would be a round one upon the paper MN, after the rays have been refracted, as well as when they passed straight forwards and fell upon a paper at Y. But this refracted picture PT is found to be oblong. The horizontal diameter or breadth of this oblong picture is equal to the diameter of the circular one Y, but the perpendicular diameter or height of the picture PT is much greater than its breadth. The refraction is made upwards, and not in a horizontal direction: therefore no alteration ought to be made in the breadth or horizontal diameter of the picture; because no refraction, that is not in the direction of that diameter, can make the picture either broader or narrower. And if all the rays were equally refracted upwards, such a refraction would not change the length of the picture; as it is round when it falls at Y, so it would be round when it is refracted upwards by the prism and falls at PT. This oblong picture consists therefore of rays, which are differently refrangible: they all fall at equal angles of obliquity upon BC the first side of the prism, but in the refraction some are more turned out of the way than others; those rays which go to P, the upper part of the picture, are the most refrangible; and those which go to T, the lower part of it, are least refrangible: the rest, which fall between P and T, have intermediate degrees of refrangibility.

This oblong picture is of different colours in different parts of it. The most refrangible rays at P are violet, the least refrangible at T are red; the rays of intermediate refrangibility from the violet downwards to the red are indigo-coloured, blue, green, yellow, and orange. So that the whole picture is made up of rays of these seven different colours. We may from hence see the reason why the coloured picture consisting of differently refrangible rays should be oblong, in such a manner that the two sides of it are right lines, and the two ends semicircles. For it consists (as in No. 33.) of seven circles, the highest of which PAGQ is violet, the lowest STN is red; the five intermediate ones, BH, CI, DK, EL, OM, are indigo coloured, blue, green, yellow, and orange. The white round picture Y, (No. 32.) is formed by heterogeneous rays, that are of seven different sorts, distinguished from one another by their different degrees of refrangibility and different colours. The refraction of the prism separates these rays from one another by refracting some of them more and others less. And consequently the refracted picture will consist of seven round pictures one below another. These round pictures are so near to each other, that the highest of them APGR will mix itself with some of those below it, as with BH and COI. This nearness of these several round pictures to each other will prevent their colours from being distinctly seen; it will likewise make the sides AS, GN, which are composed of small arcs of circles very close to one another, appear like right lines; but the two ends P and T will be semicircles.

If the centres of these circles continue at the same distance from one another, and the circles themselves are made less, as aep, bb, ei, dk, el, om, sn, they will then be distinct or will not mix with each other; and as the colours of the several parts will by this means be kept separate, so the refracted rays, instead of forming one continued oblong picture, will form seven small circular ones placed in a line perpendicular to the horizon. This separation of the several parts in the refracted picture from each other is brought about, (as in No. 34.) by making the hole F in the window-shutter very small, and by collecting the rays that come through it with a convex lens MN. For this will make a very small white picture of the sun at L, if there is no prism abc: but the refraction of this prism, if it is placed a little beyond the lens, will separate the heterogeneous rays by refracting them upwards; and instead of one small round and white picture at L, there will be seven small round pictures at PT, of which r will be violet, s indigo, t blue, u green, l yellow, y orange, z red.

That the prism ABC (No. 32.) does not make the rays diverge, so as to spread over the space PT, upon any other account but their different refrangibility, will be evident, if (as in No. 35.) a second prism DH is placed beyond the first abc. For if the rays that come from S and pass through the hole F of the window-shutter EG, were by the first prism abc made to diverge and form the oblong picture PT upon any other account besides their different refrangibility; then, supposing a second prism DH to be placed at right angles to the former, the effect must be this; the first prism abc makes the rays diverge from one another in a line PT perpendicular to the horizon, and consequently the second prism DH must make them diverge from one another in a line parallel to the horizon; so that the second prism would increase the breadth of the picture, as much as the first increased its length; and as one prism alone makes the picture a long one, both of them together would make it square, as Pst. But this second refraction does not alter the figure of the picture, but only the position of it: the second prism refracts the picture sideways; and those rays, which fell the highest at P after the first refraction, are refracted sideways the most by the second prism; those rays which fell the lowest at T are refracted sideways the least; by which means the picture, though it continues oblong, will not be perpendicular to the horizon as PT was, but will be inclined so as to lie in the position pt. This makes it evident, that the spreading of the rays by the first refraction was owing to their different refrangibility, and to no other cause. It must be owing to their different refrangibility, because those which were most refracted upwards by the first prism are most refracted sideways by the second. It cannot be owing to any other cause, because if it was, the second prism would spread the rays in breadth as much as the first prism spreads them in length, and both prisms would make the picture square.

Those rays of light, which are most refrangible, are likewise most reflexible.

When a beam of light is admitted into a dark chamber through the hole F in the window-shutter EG, (No. 36.) and this beam falls upon a prism ABC, the fides of which AC and AB are equal, and the angle at A a right one; when the obliquity of these rays, as they are to pass out of the prism at its base BC, is less than 40 degrees, the greatest part of the beam will pass out, but some few rays will
will be reflected at the surface BC. The rays, which pass through the base, form an oblong coloured picture HK, where MH is a more refrangible ray, and MK a less refrangible one. If the few rays of the beam, which are reflected from M in the direction MN, are made to pass through another prism XYV, they will likewise form an oblong coloured picture pt, where p is the most refrangible and t the least refrangible ray. This picture will be a very faint one, because there are but few rays reflected from M.

Now if the prism ACB is turned slowly round upon its axis in the direction ACB, the obliquity of the rays EM to the base BC will keep increasing, till at last this obliquity may become so great, that no rays will pass out at M, but all of them will be reflected. When this total reflection is made, the oblong picture pt, which was faint before, will become much brighter, because then not only a few rays, but all the beam, will be reflected thither. This total reflection will not be made all at once; but as the prism is turned slowly round upon its axis, the most refrangible rays MH will be first reflected, for the violet colour will disappear in the oblong picture HK, whilst all the other colours continue as bright as they were before; and when this colour disappears at HK, the same colour at p will become bright, and all the other colours at pt will continue as faint as they were before. When the prism is turned a little farther upon its axis, the indigo colour, which consists of rays that have the next greatest degree of refrangibility, will be reflected, so that this colour will disappear at HK and will become bright at pt. The same thing will happen to all the rays in their order; as the prism is turned round, each different sort of rays will be reflected sooner as the rays have a greater degree of refrangibility, or latter as they have a less degree. The red rays at K, which are the least refrangible of all, will be reflected last of all. From hence therefore it appears, that the rays of the sun are differently refrangible, and that those which are most refrangible are likewise most reflexible.

Homogeneous light is refracted regularly without any dilatation or scattering of the rays.

When the rays of any one particular colour in the oblong picture of the sun, as the green rays, for instance, are separated from one another; if some of these green rays which are homogeneous, or are all equally refrangible, are transmitted through a very small round hole in a stiff pasteboard, and are refracted by a prism on the other side of the hole, the picture formed by these green rays after refraction upon a white paper held beyond the prism will not be oblong, but circular, as the hole is through which they passed. Therefore this homogeneous light is not dilated, nor are the rays of it scattered by this refraction.

The confused appearance of objects, when they are seen through refracting bodies, is owing to the different refrangibility of light.

If flies, or the letters of a small print, or any other minute objects, are placed in heterogeneous light, such as a direct beam of the sun's, which has never been separated by any refraction into its homogeneous parts; these objects being viewed through a glass-prism will be seen confusedly, their edges will appear so misty that the smaller parts of minute animals cannot easily be distinguished from one another, and the letters of the small print cannot be read. But if the same objects are placed in a beam of homogeneous light, which is separated from all other rays of a different refrangibility in the manner already described, they will appear as distinct through a prism as if they were viewed with the naked eye. Therefore we may conclude, that this confusion is owing to the different refrangibility of those rays which come from the objects; since objects never appear confused when they are seen through refracting bodies, unless they are enlightened with several sorts of rays which have different degrees of refrangibility.

It is probable that any single ray of the least refrangible sort contains a greater quantity of matter than any single ray of the most refrangible sort.

We have already seen, that at the same angles of incidence violet rays will be more refracted or more turned out of the way than red rays. And we have likewise seen, that rays are refracted when they pass out of one medium into another, by being either more or less attracted in one medium than they are in the other. Now since, when all other circumstances are equal, red and violet rays fall at equal obliquities, and are to pass out of glass into air, so that the mediums, and consequently the attractive force or cause of refraction, is given; if the cause can turn the violet rays more out of the way, or refract them more, than it does the red rays, these rays must have different moments; the most refrangible rays, or those which are most easily turned out of the way, have the least moment; and the least refrangible rays, or those which are most difficult to turn out of the way, have the greatest moment. But if all sorts of rays have the same velocity, their respective quantities of matter will be as their moments; and consequently any single ray of the most refrangible sort contains a less quantity of matter than any single ray of the least refrangible sort.

It may be upon this account that a red colour, or a pale purple, is least pleasant to the eye than a blue, green, or a yellow. The red rays strike the eye with so great a force as to be offensive to it; and the small force of the pale purple ones will produce too faint a sensation to be agreeable. The intermediate colours are therefore more pleasant to the eye, as the force of the rays is neither too great to be offensive, nor too small to produce a quick and lively sensation.

The colours of homogeneous light are so invariable, that neither any refraction nor any reflection can alter them.

If a beam of homogeneous light passes through a round hole in a pasteboard, and then is refracted by a prism on the other side of the hole, this refraction will make no alteration in the colour of the rays; if they were red, or whatever was their colour, before they entered the prism, their colour will still be the same, when they have passed through it, and fall upon a white paper held beyond the prism. This proves the first part of the proposition, that the
the colours of homogeneous light are to be changed by any
refraction.

Red lead, when it is viewed in open day-light, or when
heterogeneous rays fall upon it, will likewise be red, if
it is placed in homogeneous red light: but red lead, when
it is placed in any other sort of homogeneous light, will
have the same colour with the rays that fall upon it and
are reflected from it: if it is placed in yellow homogeneous
light, it will be yellow; if in green light, it will be
green; or if in blue light, it will be blue. Consequentially
the reflection of the rays from the red lead make no alter-
tation in their colour; for if it did, rays of any sort re-
lected from the lead would be of the same colour, so that
it would appear red in whatever sort of light it was pla-
ted. The same that is here said of red lead, is true of
any other substance of any other colour. Grains, which
are green either in open day-light or in homogeneous green
light, will not change the colour of any homogeneous rays
by reflecting them, but will itself have the same colour
with the rays in which it is placed; it will be red in red
light, or blue in blue light, or yellow in yellow light.

From hence we may conclude, by the way, that a body
is of any particular colour, not because it reflects no other
rays but those of that particular colour, but because it re-
fects those more copiously and others more sparingly.
Red lead, as it appears red in red light, so in green light
it appears green; or in blue light it appears blue: con-
sequently it reflects rays of these sorts, and in the same
manner it might be shewn to reflect all other sorts of rays.
But then the red colour of red lead, when it is placed in
red light, is much brighter than any other colour will be
that it puts on by being placed in another sort of light;
consequently it reflects red rays more copiously than any
other sort of rays; and for this reason, when it is placed
in open day-light, where it reflects all sorts of rays at once,
the red rays are so much more numerous than the rest, as
to make the whole mixture of their own colour.

Colours may be produced by composition, which shall in
appearance be like the colour of homogeneous light:
but then these compound colours will be altered by re-
fration.

When, by means of two holes in the window-shutter
of a dark room and of two prisms, two oblong coloured
pictures are produced; if a circular piece of white paper
is so placed that the red light of one picture and the yel-
low light of the other may fall upon it, this mixture will
produce an orange colour, that in appearance will be like
the primary orange colour. But between the simple and
compound colour, though they are alike in appearance,
there will be this difference; if the circular piece of paper,
when it is enlightened with compound orange, is viewed
through a prism, the rays will be found to be differently
refrangible, and they will, by the refraction of the prism,
be so separated from one another, that the paper seen
through it will appear as two circles, one of which will
be red and the other yellow: whereas, if the same paper,
when it is enlightened with simple or primary orange, is
viewed in like manner through a prism, the rays will be
found to be equally refrangible, and the paper will appear
through the prism, as it does to the naked eye, to be one
orange coloured circle distinctly terminated all round.

The whiteness of the sun's light is compounded of all the
primary colours mixed in a due proportion.

Let the oblong coloured picture (No. 37.) fall upon
the convex lens MN; and then all the rays which are
separated from one another at PT will be collected to-
gether by passing through the lens, and will meet at its
focus G, in such a manner as to form a round picture of
the sun upon a white paper DE. This round picture, which
consists of rays of all sorts, of red, orange, yellow, blue,
green, indigo, and violet, is white. And this whiteness is
compounded of all the primary colours mixed together.

None of the rays change their colour by being mixed with
the rest; each retains the same colour after it is mixed
with the rest that it had before; neither the red rays, nor
the orange, nor the yellow, nor the blue, nor the green,
nor the indigo, nor the violet, are made white by being
mixed with the rest at the focus; but though none of the
parts are white, yet the whole mixture is white.

That the whiteness at the focus G arises from a mixture
of all the primary colours, is evident. For if any of the
colours are intercepted at the lens, the focus loses its
whiteness, and becomes of that colour which arises from a
mixture of those which are not intercepted. Thus if all the
rays at PT are intercepted except the yellow, the orange,
and the red, the focus will not be white, but will be or-
ange-coloured. If all the rays are intercepted at PT, ex-
cept the blue, the green, and the yellow, the focus will
then be green. The orange in one case, and the green in
the other case, is the compound colour arising from a mix-
ture of those rays which are not intercepted. And in
either case, if the rays that were intercepted are again
suffered to pass through the lens, the focus will recover
its whiteness.

It may be more difficult to shew that the rays, when
they are all of them mixed at the focus, retain their pro-
per colours, and are none of them white though the
compound mixture is white. To make this out, let the
paper be removed from DE, where all the rays are mix-
ed upon it at G, to ds, where it will receive the rays,
after they have crooked one another at the focus, and
having got beyond it diverge again. In this position of
the paper, because the rays that were mixed at the focus
have diverged from thence, and are again separated from
one another, the oblong coloured picture will appear a-
gain at tp, so that the red colour T, which was the low-
est at the lens, will be the highest at the paper dp. But
though the colours are thus inverted by passing the focus,
yet all of them appear at tp; which would have been
impossible, if each sort of rays, by being mixed with the
rest at the focus, had lost their colour, and had been made
white. Nor indeed is the colour of any sort of rays at all
changed by being mixed with the rest at the focus; but
the same rays that produced any particular colour in the oblong picture PT are the rays that produce the same colour in the inverted picture tp; as would be evident from intercepting any particular colour at PT: for if the green rays, for instance, are intercepted at PT, there will be no green at tp: or if the red are intercepted at PT, there will then appear no red colour at tp: and the same thing will happen upon intercepting the rays of any other colour at PT, for then that colour will vanish at tp.

Colours may be produced by composition that are neither exactly like any of the primary ones, nor fully white.

If the red rays of one coloured picture are mixed with the violet rays of another, according to the various proportions in which they are mixed, various purples will be produced, such as are not like in appearance to the colour of any homogeneous light; and of these purples, mixed with yellow and blue, may be made other new colours.

By mixing the coloured powders which painters use, though the powders themselves resemble the primary colours, yet the mixture may be grey, or dun, or rufset-brown, such as are the colours of a man's nail, of a moufe, of ashes, of ordinary tones, of mortar, of dust and dirt in the highways. Thus one part of red lead, and five of viride aris, compose a dun colour like that of a moufe. If to porpiment, which is yellow, a full bright purple powder used by painters is added, the mixture may be made of a pale red; and with the addition of a little viride aris, which, as the name imports, is green, and of a light blue bile, this pale red will change to grey or pale white, such as is the colour of ashes, or of wood newly cut, or of a man's skin.

These grey, dun, and rufset colours are only imperfect sorts of white. And we may understand, why the mixture of these coloured powders should produce an imperfect white, and not a full bright one, from the following observation. All coloured powders suppress and stop great part of the light that falls upon them: they reflect more of those rays from whence their colour arises than of any other sort; but they reflect even those more sparingly than white bodies do. Red lead, for instance, reflects fewer red rays than white paper does; for if red lead and white paper are both of them placed in homogeneous red light, the paper will appear of a brighter red than the lead. But if red lead suppresses many red rays, it may well be supposed to suppress many more rays of other colours; since its redness is owing to its reflecting red rays more copiously, and all other rays more sparingly. From hence it follows, that in a mixture of coloured powders, though they reflect rays of all sorts in a due proportion, so that the compound light will not be more of one colour than another, but will be white; yet the whiteness will be much less bright than that of paper; because the mixture of powders suppresses and stops many rays, whereas the paper reflects almost all the rays that fall upon it, and suppresses scarce any. Thus the whiteness in the mixture of powders, and the whiteness in the paper, are both of the same sort, and differ from one another only in degree, or in the quantity of light. Therefore, if some of this mixture of powders is placed in bright furnhine, and a piece of white paper is placed in the shade, the mixture by thus increasing the light, and the paper by thus diminishing it, may be made to appear equally white.

The colours of all bodies are either the simple colours of homogeneous light, or such compound colours as arise from a mixture of homogeneous light.

Each sort of light has a peculiar colour of its own, which no refraction or reflection can change. Therefore the colour of no natural body can be any other than either the colour of some sort of homogeneous light, or a compound colour arising from a mixture of the several sorts. For bodies appear coloured only by reflecting light; and no reflection can give any other colours to the rays but what they had before.

Of the Colours of thin transparent Plates.

Water, air, glass, or any other transparent substance, when drawn out into thin plates, become coloured.

Water, when it is made tenacious by having soap mixed with it, may be blown up into a bubble A, (No. 38.) such as children play with. If this bubble be filled under a glass, so that the motion of the air may not affect it, then as the water glides down the sides of it, and the top of it at A grows thinner, several colours will successively appear at A, and will spread themselves from thence in rings surrounding A, and descending farther and farther down the sides of the bubble, till they vanish at BC in the same order in which they appeared. Thus, for instance, the first colour that appears at A, the top of the bubble, is red: this red spot spreads itself into a circular ring round A, and then the top of the bubble A becomes blue: this blue spot spreads itself in the same manner round A, and then A becomes red a second time. Before we go on to consider what other colours arise at A, we will observe what becomes of those which arise first. The red, which first appeared at A, spreads itself into a circular ring round A: this ring grows larger, as the water glides down the sides of the bubble; so that the coloured ring glides down the bubble along with the water, till it sinks at last to BC, and there encompasses the bubble. In like manner the blue, which arises at A after the red, spreads itself and descends down the bubble, as the red ring did. The colour which arises next at A, is red a second time; this spreads itself in the same manner, and is succeeded by blue a second time. These are followed by a great variety of colours, which appear successively at A, and spread themselves from thence in this order: Red, yellow, green, blue, purple; then again red, yellow, green, blue, violet; and lastly, red, yellow, white, blue. This last blue colour is succeeded at A by a black spot, which reflects scarce any light: this spot dilates itself, but not into a circular ring as the colours had done; it becomes broader and broader, till the bubble breaks.

A thin plate of water of the same sort with this bubble, but more lasting, may be otherwise procured. If a piece of plane polished glass is placed upon the object-glass of a long telescope, as in (No. 39,) the plane surface of one glass, and the convex one of the other, will touch one another only at a single point; and if the interval between them is filled with water, as the glasses are pressed together, the same colours arise at the point of contact.
contact, and spread themselves in circular rings round it in the same order as in the soap-bubble. If BC (No. 40.) is a section of the plane glass, and DAE a section of the convex one; when they are pressed close together, the thin plate of water that fills the interval between them will have a black spot at A; and this spot will be encompassed with rings of colours, in the same order that they stand in that figure upon the line BC, on each side of A. If the colours are reckoned in the order in which they stand on the plate of water after the black spot appears at A, and we reckon them from the spot A towards the edges of the plate at B and C; then we must call blue the first colour. But if we reckon them in the order in which they arose at A, and spread themselves; then we must begin from B or C, the edges of the plate, and go on towards A, and in this reckoning we must call red the first colour.

If there is no water between the two glasses, then the interval will be filled with air, and this thin plate of air will have the same colours that the plate of water had; with this difference only, that each of the coloured rings is larger in the plate of air than in the plate of water.

When glass is blown very thin at a lamp-furnace, thin plates of it thus formed will exhibit colours; and fo likewise will thin plates of Muscovy-glass. Metals, when they are heated, send out to their surfaces scoria or vitrified parts, which cover the metals in form of a thin skin; and these scoria or thin plates cause colours upon the surface of the metal, such as are made to appear on polished steel by heating it, or on bell-metal by melting it first and then pouring it on the ground to cool in the air.

When the thin plate is denser than the medium that surrounds it, the colours are more vivid than they are when the plate is rarer than that medium.

A thin bubble is a plate of water encompassed with air; where the substance of the plate, which is water, is denser than the air, which is the medium that surrounds it. On the contrary, the plate of air between the two glasses BAC, DAE, (No. 40.) is encompassed with glass; and here the substance of the plate is rarer than that of the circumambient medium; and the colours on the bubble of water are more vivid than those on the thin plate of air.

When thin transparent plates reflect one sort of rays, they transmit the rest.

If the plate of air between the two glasses BAC, DAE, (No. 40.) is viewed by reflected light, the colours of it are those expressed on the upper part of the figure from B to C; but if we look through it, that is, if we view it by transmitted light, or if the transmitted light falls upon a white paper, the colours that we see through the plate, or that fall on the paper, are those expressed on the lower part of the figure. Now, any of the transmitted colours are what would arise from a mixture of all the remaining rays, after those of the reflected colour are separated from the sun's heterogeneous light. Thus, for instance, the fourth reflected colour from the black spot A inclusively is yellow, the transmitted colour is violet. The yellow rays, and some of the orange and green, are reflected here, so that the mixture of the reflected light will be yellow. The mixture of the transmitted light therefore will be violet, or rather such a purple as is not exactly like any of the primary colours; for we observed, that from red rays, violet, and blue, new purples may be produced.

This is the case in some natural bodies, as well as in these transparent artificial plates; for if leaf-gold, which is made thin enough to transmit light, is held against the strong light of the sun's rays, the gold, which is yellow when seen by the reflected light, will be blue when thus seen by transmitted light.

The seventh reflected colour inclusively from the black spot is blue, the seventh transmitted colour is yellow. When the rays which make the blue colour are taken out of the sun's heterogeneous light, the remaining rays will be yellow. Thus it happens likewise in some natural bodies; for an infusion of lignum nephriticum, which is blue when seen by reflected light, is yellow when seen by transmitted light.

The black spot A reflects scarce any light: and as rays of all colours are transmitted there, the transmitted colour is white; the third reflected colour from the black spot inclusively is white. Therefore, since all the rays are reflected there, no colour ought to be seen there, when we look through the plate; and accordingly that part of the plate is black.

Hence we see the reason why, if there be two liquors of full colours in two different glass vessels, supple red and blue; though each is transparent when we look thro' it separately, yet we should not be able to see through both of them together, if one was held behind the other. For if the blue liquor, for instance, is held towards the light, and the red towards the eye; since blue rays pass through the first liquor, and come to the second; and since the second liquor will transmit no blue rays, but only red ones; it follows, that no rays at all can come to the eye.

Indeed some transparent bodies appear of the same colour, whether we see them by reflected or transmitted light. Of this sort is most painted glass. But when this is the case, the coloured rays are reflected from the second surface of the body. Thus, if a piece of painted glass is yellow either when seen by reflected light, or when seen by transmitted light, all the rays but the yellow ones are suppressed as they pass through the glass: of the yellow rays, most are transmitted at the second surface; the few which are reflected from thence will be sufficient to tinge all the light yellow, which is reflected from the first surface. This will be evident from making the body thick, and pitching it on the backside: for by this means the reflected colour will be lost; whereas, if it had been reflected from the first surface, the pitch at the second surface could not have altered it.

The more dense the substance is out of which a thin plate is made, the less is the thickness of the plate where it reflects any certain colour.

The colours are the same whether there is air or water between the two glasses BAC, DAE, (No. 40.) only the coloured circles are smaller in the plate of water than in the plate of air. Thus the yellow, for instance, which is the fourth coloured circle from the black spot, is a less circle, or is nearer to the black spot, when there is a plate of water between the glasses, than when there is a plate...
plate of air between them. But the less the distance from the point of contact $A$, the clearer the glasses are to one another, and consequently the thinner will be the plate that lies between them; consequently that part of a plate of water where this yellow appears, is thinner than that part of a plate of water where the same colour appears. And the same holds good in any other colour. But water is more dense than air; therefore, the more dense the substance is out of which a thin plate is made, the less is the thickness of the plate where it reflects any certain colour.

The fort of colour, which is reflected from any part of a thin plate, depends only upon the thickness of the plate itself in that part: but the same colour will be made less vivid by increasing the density of the medium with which the plate is encompassed.

The colours upon any part of a thin plate of Muscovy glass are the same in fort, whether the plate is dry or wetted with water. Therefore the fort of colour in any part depends not upon the medium that encompasses the plate, but upon the thickness of the plate itself, since the colours are the same when the plate is dry and encompassed with air, or wet and fo encompassed with water. But the same colours are more faint when the plate is wet, than when it is dry; and consequently, the brightness of the colours does depend upon the medium that encompasses the plate; and the denser that medium is, the fainter will be the colours; they are more faint when the plate is covered with water than when it is dry and fo is surrounded with air.

The rays of light have alternate fits of easy reflection and easy transmission, which return at equal intervals.

Let $GF$, (No. 41.) be a beam of homogeneous light consisting all of one sort of rays, as suppose all the rays that compose the beam were red ones. Then, if these rays fall upon a thin plate of air between the two glasses $BAC$, $DAE$, at $A$ there will be a dark spot; and all the rays will be transmitted; round this spot there will be a red ring, where all the rays are reflected; round this red ring there will be a dark ring, where all the rays are transmitted. And if the thicknesses of the plate where all the rays are reflected in the ring nearest to $A$ is called 1, the thickness where the dark ring appears and all the rays are transmitted will be 2. Again, at that part of the plate where the thicknesses is 3, all the rays will be transmitted; at the thicknesses 4, they will be all reflected. And thus alternately, as expressed by the lines in the figure, the rays will be reflected in all parts of the plate where the thicknesses is expressed by any of the uneven numbers 1, 3, 5, 7, 9, &c. and will be transmitted where the thicknesses is expressed by any of the even numbers 2, 4, 6, 8, 10, &c.

Now as the plate is the same in all parts, the cause of this alternate reflection and transmission must be in the rays themselves; and their dispositions to be thus alternately reflected and transmitted, are what we call fits of easy reflection and easy transmission.

The rays that are in a fit of easy reflection penetrate as far as the second surface of the plate. For if the second surface of a thin plate of Muscovy glass is wetted, the colours caused by the alternate reflection grow fainter; whereas if the reflection was made at the first surface, wetting the second could not affect the colours. But since those rays which have passed from the first surface of the plate to the second where the thickness of it is 1, are reflected, and those which have passed from the first surface to the second where the thickness of it is 2, are transmitted; and then again those which have thus passed from one surface to the other, where the thicknesses is 3, are reflected; and those which have passed in the same manner, where the thicknesses is 4, are transmitted; it follows, that the fits of easy reflection and transmission return at equal intervals. So that, if a ray was to be set out from $A$ in the line $AB$, (No. 42.) and was to be in a fit of easy reflection when it had moved from $A$ to $c$, it would be in a fit of easy transmission when it had moved to twice that distance from $A$, or when it was got to $d$: at $e$, or the distance 3 from $A$, it will be in a fit of easy reflection; at $f$, or the distance 4, in a fit of easy transmission; at $g$, or 5, in a fit of easy reflection; at $h$, or 6, in a fit of easy transmission: and thus, in the farther progress of the ray, the same fits will return at equal intervals.

Thus if the thickness of the plate of air, where the rays of any homogeneous colour are all reflected, is equal to $Ac$ or 1, and the rays are in a fit of easy reflection when they come to the second surface of the plate; then, where the thicknesses of the plate is $Ad$ or 2, the rays will be in a fit of easy transmission when they come to the second surface, and consequently will all pass through that surface. Again, where the thicknesses is $Ac$ or 3, the rays, when they come to the second surface, will be in a fit of easy reflection, and will all be reflected; where the thicknesses is $Ad$ or 4, the fit of easy transmission will be returned when the rays come to the second surface, so that all of them will be transmitted. And in like manner, by such fits returning at equal intervals, the rays will be reflected where the thicknesses is expressed by the number 1, 3, 5, 7, 9, &c. and will be transmitted where it is expressed by 2, 4, 6, 8, 10, &c.

When a thin coloured plate is viewed obliquely, the colours of every part in the plate will be altered.

When a bubble of water or a plate of air between two glasses $BAC$, $DAE$, (No. 40.) is viewed obliquely, the coloured rings dilate themselves: and consequently a ring of any one colour, by being dilated, gets into that part of the plate where a ring of some other colour appeared when the plate was viewed directly.

If the plate is denser than the medium that encompasses it, the colours of it, when viewed obliquely, change less than they would if the plate was rarer than the medium that encompasses it.

A bubble of water is a thin plate denser than the air that encompasses it; and a plate of air between the two glasses $BAC$, $DAE$, (No. 48.) is rarer than the glass that encompasses it. Upon viewing each of these thin plates obliquely, the coloured rings on the plate of water dilate less than those on the plate of air. Therefore, since it is by this dilation of the rings that a ring of
one colour gets into a part of the plate where a ring of some other colour appeared when the plate was viewed directly; that is, since it by this dilatation of the rings that the several parts of the plates change their colours; it follows, that any part of a plate of water encompassed with air changes colour less upon being viewed obliquely, than any part of a plate of air encompassed with glass.

When the medium which encompasses a coloured transparent plate is given, the colours change less upon altering the situation of the eye, as the substance is more dense out of which that plate is made.

The matter out of which a bubble of water is made is not so dense as that out of which a bubble of glass is made, and glass is not so dense as the scoria or glassy skin thrown out by metals when they are heated. Now, any of these plates either of water, or glass, or metallic substance, when they are encompassed with the same medium air, will change their colour a little upon being viewed obliquely; but the plate of water changes the most, the plate of glass less than that, and the scoria of metals least of all.

Of the Opakesness, Transparency, and Colours of Natural Bodies.

The opakensness of bodies is owing to the many reflections and refractions which the rays of light suffer within those bodies.

The smallest parts of almost all natural bodies are transparent, as will readily be granted by those who have been used to look through microscopes. A piece of leaf-gold, is transparent if it is held up against the hole of a window-flutter in a dark room; and any other substance, however opaque it may seem in the open air, will appear transparent by the same means, when it is made of a sufficient thinness. Even metals become transparent, if they are dissolved in a proper menstruum, as gold in aqua regia, or silver in aqua fortis; and by being thus dissolved, are reduced to very small particles. But since even in opaque bodies every single particle transmits light, or is transparent, the whole would likewise transmit light, unless the rays, when they are to pass through all the particles which make up the whole, were so turned out of the way by innumerable refractions and reflections, as to be stopped and suppressed in their passage. That this is the reason why bodies that consist of transparent particles should be opaque, is evident; since opaque bodies, when they are reduced to a sufficient thinness, become transparent; for then there will be but few particles lying beyond another for the light to pass through; and as the rays will suffer fewer refractions and reflections, some of them may get through a thin plate, though all of them would be suppressed in a thicker mass of the same substance.

The medium, with which the pores of opaque bodies are filled, is not of the same density with the particles of those bodies.

Bodies consist of transparent particles, and their opakensness is owing to the many refractions and reflections which the light suffers within them. Now, if the interfaces between the particles of any body were filled with a medium of the same density with the particles, the light would neither be refracted nor reflected as it passed out of the particles into the interfaces and out of the interfaces into the pores, but would pass through the body, and the body would be transparent. Consequently, in an opaque body, where the light is suppressed by the refractions and reflections which it suffers, the particles that compose the body, and the medium that fills the pores or interfaces between the particles, must be of different densities.

Hence we may see the reason why paper, when it has been dipped in water or oil, is more transparent than when it is dry. For when the paper is thoroughly wetted with water or oil, the pores of it are filled with a medium that is nearly of the same density with its particles. On the contrary, though oil of turpentine and water are both of them transparent when they are separate; yet if they are shaken together so as to mix but imperfectly, the mixture becomes much less transparent, because the parts of each fluid are separated from one another, and those of the other fluid, which are of a different density, get in between them.

The parts of bodies, and their interfaces, must not be less than of a certain definite bigness to render them opaque and coloured.

The most opaque bodies become transparent when their particles are subtilly divided; as metals, such as gold or silver, which are opaque in large masses, become transparent when the former is dissolved in aqua regia, and the latter in aqua fortis. And we observed, that at the top of a bubble of water, where the water is extremely thin, there is a black spot, which reflects scarce any light at all; though the water is encompassed with air, which is a medium of a different density. Consequently, if the diameter of the particles of which any natural substance consists was no greater than the thickness of the bubble, where it reflects no light, but transmits all, such a body would be transparent, notwithstanding the interfaces that are between its particles were filled with a medium the density of which is different from theirs.

In like manner, we observed, that when a thin plate of air lies between two pieces of glass BAC, DAE, (No 40.) there is a dark spot, which reflects no light, and transmits all, not only at the point A where the glasses touch one another, but also round that point to some distance where the glasses are very near to one another. From hence we may conclude, that though the particles of any natural substance were as dense as glass, and the medium which fills their interfaces was as rare as air; yet if these interfaces were no bigger than the interval between the two glasses BAC, DAE, at that place where all light is transmitted, such a body would be transparent.

The transparency of water seems to be owing to the capes here mentioned, to the smallness of its parts, or of its pores; or of both. For we are sure that the pores of water are filled with air, because the air may be drawn out from the water in an air-pump; and consequently, as the pores are filled with a medium of a different density from the parts, the mixture ought to be opaque, like such a mixture of water and oil of turpentine as was mentioned above; But the smallness either of the parts,
or of the interfiles, or of both, will prevent the mixture from being opaque.

Since therefore all bodies will be transparent, if either their parts or their interfiles are too small, it follows that the parts, and likewise the pores, of such bodies as are not transparent but opaque and coloured, must not be less than of a certain and determinate bigness.

The colours of natural bodies depend upon the size of their particles.

Different parts of thin transparent plates, according to the different bignesses of them, are of different colours. Now if any part of such a thin plate of glass, for instance, where it appears of one uniform colour, should be split into threads, or broken into small particles, all these particles would make a heap of powder of the same colour. And the small particles of natural bodies, since they are transparent, like so many fragments of a thin plate, must exhibit colours in the same manner.

The parts of bodies, on which their colours depend, are much denser than the medium which fills their pores.

For where the transparent plate or particle consists of a rarer substance than the medium that encompasses it, the colours are less vivid than those of natural bodies commonly are. For this reason it is that the colours of silks or cloths, when they are wetted with oil or water, become more faint; because these liquors are more nearly of the same density with the particles, than the medium is which fills the interfiles when they are dry. Besides, the colours upon a transparent plate change very sensibly, unless the plate consists of a substance much denser than the medium that encompasses it; but most natural bodies are of the same colour in whatever position of the eye they are viewed. Therefore their transparent particles, upon which their colours depend, are much denser than the medium which encompasses those particles or fills the interfiles between them.

Nor is it otherwise even in those bodies which do change colour upon being viewed obliquely, such as changeable silks, or the feathers of a peacock's tail or of a pigeon's neck. For this change of colour, upon the situation of the eye being changed, is no reason for concluding that the medium which fills the interfiles or pores is more nearly of the same density with the particles, upon which the colours depend, in these bodies than in others; since the change of colour is plainly owing to our seeing a different part of the body in different positions of the eye. Thus, in changeable silks, the warp is of one colour, and the woof of another; and in one position of the eye more of the warp is seen, and in another position of it more of the woof is seen. In like manner, if a pigeon's neck appears blue in one position of the eye, and crimson in another, it is because in these different positions we see different parts of the same feathers.

We cannot from the colour of a body make any conjecture about the size of the particles upon which its colours depend.

Suppose, from the appearance of the colour in any yellow body, that we had determined its yellow to be of the same sort with that which is next to the black spot in a plate of air, or water, or glass. The thickness of a plate, where it appears of this colour, is different according to the different density of the substance out of which that plate is made; the thicknesses of a plate of air where it appears of this colour, is greater than that of a plate of water were it appears of the same colour, and much greater fill than that of a plate of glass. Suppose therefore farther, that we were able to determine exactly what is the thickness of a plate of air or water or glass, where each of them is tinged with the same yellow colour that any natural body exhibits; yet we cannot determine whether the diameter of the particles, upon which this body's colour depends, is equal to the thickness of the plate of air, or of water, or of glass, unless we could first determine whether the density of those particles is equal to the density of air, or to that of water, or to that of glass: since the particles must be larger, if their density is equal to the density of air, than if it is equal to the density of water; and larger, if it is equal to that of water than if it is equal to that of glass. And indeed we have good reason to conclude, that the density of the parts, upon which the colours of natural bodies depend, is greater even than that of glass; and consequently that the diameter of those parts is much less than the thickness of a plate of glass, where it appears of the same colour with the body. For, upon being viewed obliquely, thin plates of glass change colour, whereas natural bodies do not: and the colour of natural bodies is made more unchangeable than that of thin plates of glass, by their particles being more dense than glass.

Of the Rainbow.

When the rays of the sun fall upon a drop of rain and enter into it, some of them, after one reflection and two refractions, may come to the eye of a spectator who has his back towards the sun and his face towards the drop.

If XY (No. 43.) is a drop of rain, and the sun shines upon it in any lines $s_f$, $d_s$, $a_r$, &c. most of the rays will enter into the drop; some few of them only will be reflected from the first surface; those rays, which are reflected from thence, do not come under our present consideration, because they are never refracted at all. The greatest part of the rays then enter the drop, and those passing on to the second surface will most of them be transmitted through the drop; but neither do those rays which are thus transmitted fall under our present consideration, since they are not reflected. For the rays, which are described in the proposition, are such as are twice refracted and once reflected. However, at the second surface, or hinder part of the drop, at $p_g$ some few rays will be reflected, whilst the rays are transmitted; those rays proceed in some such lines as $v_r$, $q_t$, and coming out of the drop in the lines $r_v$, $q_t$, may fall upon the eye of a spectator, who is placed any where in those lines, with his face towards the drop, and consequently with his back towards the sun, which is supposed to shine upon the drop in the lines $s_f$, $d_s$, $a_r$, &c. These rays are twice refracted, and once reflected: they are refracted, when they pass out of the air into the drop; they are reflected from the second surface, and are refracted again, when they pass out of the drop into the air.

When
When rays of light reflected from a drop of rain come to the eye, those are called effectual which are able to excite a sensation.

When rays of light come out of a drop of rain, they will not be effectual, unless they are parallel and contiguous.

There are but few rays that can come to the eye at all; for the greatest part of those which enter the drop sy (No. 43.) between x and a, pass out of the drop through the hinder surface pg; only few are reflected from thence and come out through the nearer surface between a and y. Now such rays as emerge, or come out of the drop, between a and y, will be ineffectual, unless they are parallel to one another, as ru and qt are; because such rays as come out diverging from one another, will be so far at variance when they come to the eye, that all of them cannot enter the pupil; and the very few that can enter it will not be sufficient to excite any sensation. But even rays, which are parallel, as rv, qt, will not be effectual, unless there are several of them contiguous or very near to one another. The two rays ru and qt alone will not be perceived, though both of them enter the eye; for so very few rays are not sufficient to excite a sensation.

When rays of light come out of a drop of rain after one reflection, these will be effectual which are reflected from the same point, and which entered the drop near to one another.

Any rays, as sb and cd, (No. 44.) when they have passed out of the air into a drop of water, will be refracted towards the perpendiculars bl, dl; and as the ray sb falls farther from the axis sa than the ray cd, sb will be more refracted than cd; so that these rays, though parallel to one another at their incidence, may describe the lines be and de after refraction, and be both of them refracted from one and the same point e. Now all rays which are thus reflected from one and the same point, when they have described the lines eg, ef, and after refraction emerge at f and g, will be so refracted, when they pass out of the drop into the air, as to describe the lines fg, gi, parallel to one another. If these rays were to return from e in the lines eb, ed, and were to emerge at b and d, they would be refracted into the lines of their incidence bs, dc. But if these rays, instead of being returned in the lines eb, ed, are reflected from the same point e in the lines eg, ef, the lines of refraction eg and ef will be inclined both to one another and to the surface of the drop; just as much as the lines eb and ed are. First eb and eg make just the same angle with the surface of the drop; for the angle bex, which eb makes with the surface of the drop, is the complement of incidence; and the angle gey, which eg makes with the surface, is the complement of reflection; and these two are equal to one another. In the same manner we might prove that ed and ef make equal angles with the surface of the drop. Secondly, the angle bed is equal to the angle seg, or the reflected rays eg, ef, and the incident rays be, de, are equally inclined to each other. For the angle of incidence bel is equal to the angle of reflection gel, and the angle of incidence del is equal to the angle of reflection fed; consequently the difference between the angles of incidence is equal to the difference between the angles of reflection, or bel—del = gel—fed, or bed = ges. Since therefore either the lines eg, ef, or the lines eb, ed, are equally inclined both to one another and to the surface of the drop; the rays will be refracted in the same manner, whether they were to return in the lines eb, ed, or are reflected in the lines eg, ef. But if they were to return in the lines eb, ed, the refraction, when they emerge at b and d, would make them parallel. Therefore, if they are reflected from one and the same point e in the lines eg, ef, the refraction, when they emerge at g and f, will likewise make them parallel.

But though such rays, as are reflected from the same point in the hinder part of a drop of rain, are parallel to one another, when they emerge, and to have one condition that is requisite towards making them effectual; yet there is another condition necessary; for rays, that are effectual, must be contiguous, as well as parallel. And though rays, which enter the drop in different places, may be parallel when they emerge, those only will be contiguous which enter it nearly at the same place.

Let sy, (No. 43.) be a drop of rain, ag the axis or diameter of the drop, and sa a ray of light that comes from the fun and enters the drop at the point a. This ray sa, because it is perpendicular to both the surfaces, will pass straight through the drop in the line agb without being refracted; but any collateral rays that fall about sb, as they pass through the drop, will be made to converge to their axis, and passing out at n will meet the axis at b; rays which fall farther from the axis than sb, such as those which fall about sc, will likewise be made to converge; but then their focus will be nearer to the drop than b. Suppose therefore i to be the focus to which the rays that fall about se will converge, any ray sc, when it has described the line eo within the drop, and is tending to the focus i, will pass out of the drop at the point o. The rays that fall upon the drop about sd, more remote still from the axis, will converge to a focus still nearer than i, as suppose at k. These rays therefore go out of the drop at p. The rays, that fall still more remote from the axis, as se, will converge to a focus nearer than k, as suppose at l; and the ray se, when it has described the line eo within the drop, and is tending to the focus l, will pass out at the point o. The rays, that fall still more remote from the axis, will converge to a focus still nearer. Thus the ray sf will after refraction converge to a focus at m, which is nearer than l; and having described the line fn within the drop, it will pass out at the point n. Now here we may observe, that as any rays sb or sc, fall farther above the axis sa, the points n, or o, where they pass out behind the drop, will be farther above g; or that, as the incident ray rises from the axis sa, the arc gno increases, till we come to some ray sd, which passes out of the drop at p; and this is the highest point where any ray that falls upon the quadrant or quarter ax can pass out: for any rays se, or sf, that fall higher than sd, will not pass out in any point above p, but at the points o, or n, which are below it. Consequentially, though the arc gno increases, whilst the distance of the incident ray from the axis sa increases, till we come to the ray sd; yet afterwards, the higher the
OPTICS

rays fall above the axis sa, this arc ong will decrease.

We have hitherto spoken of the points on the hinder part of the drop, where the rays pass out of it; but this was for the sake of determining the points from whence those rays are reflected, which do not pass out behind the drop. For, in explaining the rainbow, we have no farther reason to consider those rays which go through the drop; since they can never come to the eye of a spectator placed any where in the lines rv or qr with his face towards the drop. Now, as there are many rays which pass out of the drop between g and p, so from some rays will be reflected from thence; and consequently the several points between g and p, which are the points where some of the rays pass out of the drop, are likewise the points of reflection for the rest which do not pass out. Therefore, in respect of those rays which are reflected, we may call gp the arc of reflection; and may say, that this arc of reflection increases, as the distance of the incident ray from the axis sa increases, till we come to the ray sd; the arc of reflection is gn for the ray sb, it is go for the ray sc, and gp for the ray sd. But after this, as the distance of the incident ray from the axis sa increases, the arc of reflection decreases; for sg less than pg is the arc of reflection for the ray se, and ng is the arc of reflection for the ray sf.

From hence it is obvious, that some one ray, which falls above sd, may be reflected from the same point with some other ray which falls below sd. Thus, for instance, the ray sb will be reflected from the point n, and the ray sf will be reflected from the same point; and consequently, when the reflected rays nr, nj are refracted as they pass out of the drop at r and q, they will be parallel, by what has been shewn in the former part of this proposition. But since the intermediate rays, which enter the drop between sf and sb, are not reflected from the same point n, these two rays alone will be parallel to one another when they come out of the drop, and the intermediate rays will not be parallel to them. And consequently these rays rv, qt, though they are parallel after they emerge at r and q, will not be contiguous, and for that reason will not be effectual; the ray sd is reflected from p, which has been shewn to be the limit of the arc of reflection; such rays, as fall just above sd, and just below sd, will be reflected from nearly the same point p, as appears from what has been already shewn. These rays therefore will be parallel, because they are reflected from the same point p; and they will likewise be contiguous, because they all of them enter the drop at one and the same place very near to d. Consequently, such rays as enter the drop at d, and are reflected from p the limit of the arc of reflection, will be effectual; since, when they emerge at the fore part of the drop between a and y, they will be both parallel and contiguous.

If we can make out hereafter that the rainbow is produced by the rays of the sun which are thus reflected from drops of rain as they fall whilst the sun shines upon them, this proposition may serve to shew us, that this appearance is not produced by any rays that fall upon any part and are reflected from any part of those drops: since this appearance cannot be produced by any rays but those which are effectual; and effectual rays must all...
g as upon a centre, till they became parallel to $ab$ the incidental ray. But if either of these lines or rays were refracted so much from $g$ as to become parallel to $ab$, the ray so much refracted would, after emergence, make no angle with $ab$, because it would be parallel to it. And consequently that ray which is most turned round upon the point $g$, or that ray which is most refrangible, will after emergence be nearest parallel to the incident ray, or will make the least angle with it. The same may be proved of all other rays emerging parallel to $gi$ and $gp$ respectively, or of all effectual rays; tho' which are most refrangible, will after emergence make a less angle with the incident rays, than those do which are least refrangible.

But since the effectual rays of different colours make different angles with $ab$ at their emergence, they will be separated from one another: so that if the eye was placed in the beam $gh$, it would receive only rays of one colour from the drop $xagy$; and if it was placed in the beam $fgnp$, it would receive only rays of some other colour.

The angle $sgh$, which the least refrangible or red rays make with the incident ones, when they emerge so as to be effectual, is found by calculation to be 42 degrees 2 minutes. And the angle $sgi$, which the most refrangible rays make with the incident ones, when they emerge so as to be effectual, is found to be 40 degrees 17 minutes.

The rays, which have the intermediate degrees of refrangibility, make with the incident ones intermediate angles between 42 degrees 2 minutes and 40 degrees 17 minutes.

If a line is supposed to be drawn from the centre of the sun through the eye of the spectator, the angle which any effectual ray, after two refractions and one reflection, makes with the incident ray, will be equal to the angle which it makes with that line.

Let the eye of the spectator be at $i$, (No. 44.) and let $qi$ be the line supposed to be drawn from the centre of the sun through the eye of the spectator; the angle $qis$, which any effectual ray makes with this line, will be equal to the angle $ski$, which the same ray makes with the incident $xay$ or $sk$. If $zh$ is a ray coming from the centre of the sun, then since $qi$ is supposed to be drawn from the same point, these two lines, upon account of the remoteness of the point from whence they are drawn, may be looked upon as parallel to one another. But the right line $ki$ crossing these two parallel lines will make the alternate angles equal. Eucl. b. i. prop. 29. Therefore $kit$ or $git$ is equal to $ski$.

When the sun shines upon the drops of rain as they are falling; the rays that come from those drops to the eye of a spectator, after one reflection and two refractions, produce the primary rainbow.

If the sun shines upon the rain as it falls, there are commonly seen two bows, as AFB, CHD, (No. 46.) or if the cloud and rain does not reach over that whole side of the sky where the bows appear, then a part of one or of both bows is seen in that place where the rain falls. Of these two bows, the innermost AFB is the more vivid of the two, and this is called the primary bow. The outer part TFY of the primary bow is red, the inner part VEX is violet; the intermediate parts, reckoning from the red to the violet, are orange, yellow, green, blue, and indigo. Suppose the spectator's eye to be at $O$, and let LOP be an imaginary line drawn from the centre of the sun through the eye of the spectator: If a beam of light $S$ coming from the sun falls upon any drop $F$; and the rays that emerge at $F$ in the line $FO$, so as to be effectual, make an angle $FOP$ of 42 degrees 2 minutes with the line $LP$; then these effectual rays make an angle of 42 degrees 2 minutes with the incident rays, by the preceding proposition, and consequently these rays will be red, so that the drop $F$ will appear red. All the other rays, which emerge at $F$, and would be effectual if they fell upon the eye, are refracted more than the red ones, and consequently will pass above the eye. If a beam of light $S$ falls upon the drop $E$; and the rays that emerge at $E$ in the line $EO$, so as to be effectual, make an angle $EOP$ of 40 degrees 17 minutes with the line $LP$; then these effectual rays make likewise an angle of 40 degrees 17 minutes with the incident rays, and the drop $E$ will appear of a violet colour. All the other rays, which emerge at $E$, and would be effectual if they came to the eye, are refracted less than the violet ones, and therefore pass below the eye. The intermediate drops between $F$ and $E$ will for the same reasons be of the intermediate colours.

Thus we have shewn why a set of drops from $F$ to $E$, as they are falling, should appear of the primary colours, red, orange, yellow, green, blue, and indigo, and violet. It is not necessary that the several drops, which produce these colours, should all of them fall at exactly the same distance from the eye. The angle $FOP$, for instance, is the same whether the distance of the drop from the eye is $OF$, or whether it is in any other part of the line $OF$ something nearer to the eye. And whilst the angle $FOP$ is the same, the angle made by the emerging and incident rays, and consequently the colour of the drop, will be the same. This is equally true of any other drop. So that although in the figure the drops $F$ and $E$ are represented as falling perpendicularly one under the other, yet this is not necessary in order to produce the bow.

But the coloured line $FE$, which we have already accounted for, is only the breadth of the bow. It still remains to be shewn, why not only the drop $F$ should appear red, but why all the other drops quite from $A$ to $B$ in the arc ATFYB should appear of the same colour. Now it is evident, that where-ever a drop of rain is placed, if the angle which the effectual rays make with the line $LP$ is equal to the angle $FOP$, that is, if the angle which the effectual rays make with the incident rays is 42 degrees 2 minutes, any of those drops will be red, for the same reason that the drop $F$ is of this colour.

If FOP was to turn round upon the line OP, so that one end of this line should always be at the eye, and the other be at P opposite to the sun; such a motion of this figure would be like that of a pair of compasses turning round upon one of the legs OP with the opening FOP. In this revolution the drop F would describe a circle, P would be the centre, and ATFYB would be an arc in this circle. Now since, in this motion of the line and drop OP, the angle made by FO with OP, that is, the angle FOP, continues the same; if the sun was to shine upon this drop as it revolves, the effectual rays would make the same angle
The primary rainbow is never a greater arc than a semicircle.

Since the line LOP is drawn from the sun through the eye of the spectator, and since P (No. 46.) is the centre of the rainbow; it follows, that the centre of the rainbow is always opposite to the sun. The angle FOP is an angle of 42 degrees 2 minutes, as was observed, or F the highest part of the bow is 42 degrees 2 minutes from P the centre of it. If the sun is more than 42 degrees 2 minutes high, P the centre of the rainbow, which is opposite to the sun, will be more than 42 degrees 2 minutes below the horizon; and consequently F the top of the bow, which is only 42 degrees 2 minutes from P, will be below the horizon; that is, when the sun is more than 42 degrees 2 minutes high, no primary rainbow will be seen. If the sun is something less than 42 degrees 2 minutes high, then P will be something less than 42 degrees 2 minutes from P, will be just above the horizon; that is, a small part of the bow at this height of the sun will appear close to the ground opposite to the sun. If the sun is 20 degrees high, then P will be 20 degrees below the horizon; and F the top of the bow, being 42 degrees 2 minutes from P, will be 22 degrees 2 minutes above the horizon; therefore, at this height of the sun, the bow will be an arc of a circle whose centre is below the horizon; and consequently that arc of the circle, which is above the horizon, or the bow, will be less than a semicircle. If the sun is in the horizon, then P, the centre of the bow, will be in the opposite part of the horizon; F, the top of the bow, will be 42 degrees 2 minutes above the horizon; and the bow itself, because the horizon passes thro' the centre of it, will be a semicircle. More than a semicircle can never appear; because if the bow was more than a semicircle, P the centre of it must be above the horizon; but P is always opposite to the sun, therefore P cannot be above the horizon, unless the sun is below it; and when the sun is set, or is below the horizon, it cannot shine upon the drops of rain, as they fall; and consequently, when the sun is below the horizon, no bow at all can be seen. The rays of the sun fall upon a drop of rain, some of them, after two refractions and two reflections, may come to the eye of a spectator, who has his back towards the sun and his face towards the drop.

If bgw, (No. 45.) is a drop of rain, and parallel rays coming from the sun, as xo, yw, fall upon the lower part of it, they will be refracted towards the perpendiculars vh, wa, as they enter into it, and will describe some such lines as vh, wa. At h and i great part of these rays will pass out of the drop; but some of them will be reflected from thence in the lines hs, ig. At f and g again, great part of the rays, that were reflected thither, will pass out of the drop. But these rays will not come to the eye of a spectator at o. However, here again all the rays will not pass out; but some few will be reflected from f and g, in some such lines as fcl, gh; and these, when they emerge out of the drop of water into the air at a and d, will be refracted from the perpendiculars, and, describing the lines dt, be, may come to the eye of a spectator who has his back towards the sun and his face towards the drop.

Those rays, which are parallel to one another after they have been once refracted and once reflected in a drop of rain, will be effective when they emerge after two refractions and two reflections.

No rays can be effective, unless they are contiguous, and parallel. From what was said, it appears, that when rays come out of a drop of rain contiguous to one another, either after one or after two reflections, they must enter the drop nearly at one and the same place. And if such rays as are contiguous are parallel after the first reflection, they will emerge parallel, and therefore will be effective. Let xo and yw be contiguous rays which come from the sun, and are parallel to one another when they fall upon the lower part of the drop bgw, (No. 45.) suppose these rays to be refracted at v and w, and to be reflected at h and i; if they are parallel to one another, as hs, gi, after this first reflection, then, after they are reflected a second time from f and g, and refracted a second time as they emerge at d and b, they will go out of the drop parallel to one another in the lines at and bo, and will therefore be effective.

The rays xo, yw, are refracted towards the perpendiculars vh, wa, when they enter the drop, and will be made to converge. As these rays are very oblique, their focus will not be far from the surface vw. If this focus is at k, the rays, after they have passed the focus, will diverge from thence in the directions kh, ki; and if ki is the principal focal distance of the concave reflecting surface hi, the reflected rays hs, ig, will be parallel. These rays hs, ig, are reflected again from the concave surface fg, and will meet in a focus at e, so that ge will be the principal focal distance of this reflecting surface fg. And because hi and fg are parts of the same sphere, the principal focal distances ge and ki will be equal to one another. When the rays have passed the focus e, they will diverge from thence in the directions ed, eb; and we are to shew, that, when they emerge at d and b, and are refracted there, they will become parallel.

Now if the rays ek, ek, when they have met at k, were to be turned back again in the directions kw, kw, and were to emerge at w and w, they would be refracted into the lines of their incidence zu, zu, and therefore would be parallel. But since ge is equal to ik, as has already been shewn, the
When rays that are effectual emerge from a drop of rain after two reflections and two refractions, those which are most refrangible will at their emergence make a greater angle with the incident rays than those do which are least refrangible; and by this means the rays of different colours will be separated from one another.

If rays of different colours, which are differently refrangible, emerge at any point B, (No. 45.) these rays will not be all of them equally refracted from the perpendicular. Thus, if Bo is a red ray, which is of all others the least refrangible, and BM is a violet ray, which is of all others the most refrangible; when these two rays emerge at B, the violet ray will be refracted more from the perpendicular BX than the red ray, and the refracted angle XBM will be greater than the refracted angle XBO. From hence it follows, that these two rays, after emergence, will diverge from one another. In like manner, the rays that emerge at D will diverge from one another; a red ray will emerge in the line DP, a violet ray in the line DT. So that though all the effectual red rays of the beam BDMP are parallel to one another, and all the effectual red rays of the beam BDOP are likewise parallel to one another, yet the violet rays will not be parallel to the red ones, but the violet beam will diverge from the red beam. Thus the rays of different colours will be separated from one another.

This will appear farther, if we consider what the proposition affirms, That any violet or most refrangible ray will make a greater angle with the incident rays, than any red or least refrangible ray makes with the same incident rays. Thus if YW is an incident ray, BM a violet ray emerging from the point B, and BO a red ray emerging from the same point; the angle which the violet ray makes with the incident one is YRM, and that which the red ray makes with it is YRO. Now YRM is a greater angle than YRO. For in the triangle BRS the internal angle BRS is less than BSY the external angle at the base. Euc. b. I. prop. 16.

But YRM is the complement of BRS or of BSY to two right ones, and YRO is the complement of BSY to two right ones. Therefore, since BSY is less than BSY, the complement of BSY to two right angles will be greater than the complement of BSY to two right angles; or YRM will be greater than YRO.

Or otherwise: Both the rays BO and BM, when they are refracted in passing out of the drop at B, are turned round upon the point B from the perpendicular BX. Now either of these lines BO or BM might be turned round in this manner, till it made a right angle with YW. Consequently, that ray which is most turned round upon B, or which is most refracted, will make an angle with YW that will be nearer to a right one than that ray makes with it which is least turned round upon B, or which is least refracted. Therefore that ray which is most refracted will make a greater angle with the incident ray than that which is least refracted.

But since the emerging rays, as they are differently refrangible, make different angles with the same incident ray YW, the refraction which they suffer at emergence will separate them from one another.

The angle YMR, which the most refrangible or violet rays make with the incident ones, is found by calculation to be 54 degrees 7 minutes; and the angle YRO, which the least refrangible or red rays make with the incident ones, is found to be 50 degrees 57 minutes: the angles, which the rays of the intermediate colours, indigo, blue, green, yellow, and orange, make with the incident rays, are intermediate angles between 54 degrees 7 minutes and 50 degrees 57 minutes.

If a line is supposed to be drawn from the centre of the sun through the eye of the spectator; the angle, which, after two refractions and two reflections, any effectual ray makes with the incident ray, will be equal to the angle which it makes with that line.

If YW, (No. 45.) is an incident ray, BO an effectual ray, and QN a line drawn from the centre of the sun through the eye of the spectator; the angle YNO, which the effectual ray makes with the incident ray, is equal to SON the angle which the same effectual ray makes with the line QN. For YW and QN, considered as drawn from the centre of the sun, are parallel; BO crosses them, and consequently makes the alternate angles YNO, SON, equal to one another. Euc. b. I. prop. 29.

When the sun shines upon the drops of rain as they are falling; the rays that come from these drops to the eye of a spectator, after two refractions and two reflections, produce the secondary rainbow.

The secondary rainbow is the outermost CHD, No. 46. When the sun shines upon a drop of rain H; and the rays HO, which emerge at H as to be effectual, make an angle HOP of 54 degrees 7 minutes with LOP a line drawn from the sun through the eye of the spectator; the same effectual rays will make likewise an angle of 54 degrees 7 minutes with the incident rays S, and the rays which emerge at this angle are violet ones, by what was observed above. Therefore, if the spectator's eye is at O, none but violet rays will enter it; for as all the other rays make a less angle with OP, they will fall above the spectator's eye. In like manner, if the effectual rays that emerge from the drop G make an angle of 50 degrees 57 minutes with the line OP, they will likewise make the same angle with the incident rays S; and consequently, from the drop G to the spectator's eye at O, no rays will come but red ones; for all the other rays, making a greater angle with the line OP, will fall below the eye at O. For the same reason, the rays emerging from the intermediate drops between H and G, and coming to the spectator's eye at O, will emerge at intermediate angles, and therefore will have the intermediate colours. Thus, if there are seven drops from H to G inclusively, their colours will be violet, indigo, blue, green, yellow, orange and red. This coloured line is the breadth of the secondary rainbow.

Now, if HOP was to turn round upon the line OP, like a pair of compasses upon one of the legs OP with the opening HOP, it is plain from the supposition, that, in such a revolution of the drop H, the angle HOP would be the same.
fame, and consequently the emerging rays would make the same angle with the incident ones. But in such a revolution the drop would describe a circle of which P would be the centre and CNHRD an arc. Consequently, since, when the drop is at N, or at R, or any where else in that arc, the emerging rays make the same angle with the incident ones as when the drop is at H, the colour of the drop will be the same to an eye placed at O, whether the drop is at N, or at H, or at R, or any where else in that arc. Now, though the drop does not thus turn round as it falls, and does not pass through the several parts of this arc, yet, since there are drops of rain falling every where at the same time, when one drop is at H, there will be another at R, another at N, and others in all parts of the arc; and these drops will all of them be violet-coloured, for the same reason that the drop H would have been of this colour if it had been in any of those places. In like manner, as the drop G is red when it is at C, it would likewise be red in any part of the arc CWGQD; and so will any other drop, when, as it is falling, it comes to any part of that arc. Thus as the sun shines upon the rain, whilst it falls, there will be two arcs produced, a violet coloured one CNHRD, and a red one CWGQD; and for the same reason the intermediate space between these two arcs will be filled up with arcs of the intermediate colours. All these arcs together make up the secondary rainbow.

The colours of the secondary rainbow are fainter than those of the primary rainbow; and are ranged in the contrary order.

The primary rainbow is produced by such rays as have been only once reflected; the secondary rainbow is produced by such rays as have been twice reflected. But at every reflection some rays pass out of the drop of rain without being reflected; so that the oftener the rays are reflected, the fewer of them are left. Therefore the colours of the secondary bow are produced by fewer rays, and consequent-

OPTIMATES, in Roman antiquity, were, according to Tully, the best citizens, who defined their actions might be approved of by the better sort; and the populares, those who, out of a thirst of vain-glory, did not consider so much what was right, as what would please the populace.

OPUNTIA, in botany. See Cactus.

OR, in heraldry, denotes yellow, or gold colour. See Colour and Metal.

In the coats of noblemen, it is blazoned topaz; and in those of sovereign princes, fol.

It is represented in engraving by small points or dots, scattered all over the field or bearing. See Pl. 134. fig. 5.

ORACLE, among the heathens, was the answer which the gods were supposed to give to those who consulted them upon any affair of importance; it is also used for the god who it was thought gave the answer, and the place where it was given.

The credit of oracles was so great, that in all doubts and disputes their determinations were held sacred and inviolable: whence vast numbers flocked to them for advice about the management of their affairs; and no business of any consequence was undertaken, scarce any

ly will be fainter, than the colours of the primary bow.

In the primary bow, reckoning from the outside of it, the colours are ranged in this order; red, orange, yellow, green, blue, indigo, violet. In the secondary bow, reckoning from the outside, the colours are violet, indigo, blue, green, yellow, orange, red. So that the red, which is the outermost or highest colour in the primary bow, is the innermost or lowest colour in the secondary one.

Now the violet rays, when they emerge so as to be effective after one reflection, make a less angle with the incident rays than the red ones; consequently the violet rays make a less angle with the lines OP (No. 46.) than the red ones. But in the primary rainbow the rays are only once reflected, and the angle which the actual rays make with OP is the distance of the coloured drop from P the centre of the bow. Therefore the violet drops or violet arc in the primary bow will be nearer to the centre of the bow, than the red drops or red arc; that is, the innermost colour in the primary bow will be violet, and the outermost colour will be red. And, for the same reason, through the whole primary bow, every colour will be nearer to the centre P, as the rays of that colour are more refrangible.

But the violet rays, when they emerge so as to be effective after two reflections, make a greater angle with the incident rays than the red ones; consequently the violet rays will make a greater angle with the line OP, than the red ones. But in the secondary rainbow the rays are twice reflected, and the angle which the actual rays make with OP is the distance of the coloured drop from P the centre of the bow. Therefore the violet drops or violet arc in the secondary bow will be farther from the centre of the bow than the red drops or red arc; that is, the outermost colour in the secondary bow will be violet, and the innermost colour will be red. And, for the same reason, the whole secondary bow, every colour will be farther from the centre P, as the rays of that colour are more refrangible.

ORA
ORATORY. See Rhetoric.

ORATORIO, in the Italian music, a sort of sacred drama of dialogues; containing recitatives, duettos, trios, ritornelli, chorufes, &c.

The subjects of these pieces are usually taken from the Scriptures, or from the life of some saint, &c.

The music for the oratorio should be in the finest taste, and best chosen strains. These oratorios are greatly used at Rome, in time of lent; and of late, in England.

ORATORY. See Rhetoric.

Oratory, among the Romanists, an closet or like apartment near a bed-chamber, furnished with an altar, crucifix, &c. for private devotion.

ORB, in astronomy, &c. denotes an hollow globe or sphere.

ORBICULARIS, in anatomy. See Anatomy, p. 306.

ORBIS, in ichthyology, a name given to two species of ostracion, nearly as broad as long, and covered with spines. See Ostracion.

ORBIS MAGNUS, in astronomy, denotes the earth’s orbit, in its annual revolution round the sun.

ORBIS, in astronomy, the path of a planet or comet, or the curve that it describes in its revolution round its central body: thus the earth’s orbit is the curve which it describes in its annual course, and usually called the eccliptic. See Astronomy.

ORCADIEN, ORKNEY-ISHANDS. See Orkney.

ORCHARD, a plantation of fruit-trees. See Garden-ING.

ORCHESTRA, in the ancient theatres, a place in the form of a semi-circle, where the dancing was performed.

In the Greek theatres, the orchestra made part of the stage; but, among the Romans, it answered nearly to our pit; only that in it were disposed the seats for the patroners, magnificates, vulgares, and other persons of distinction.

ORCHIS, in botany, a genus of the gynandria diandria class. The nectarium is shaped like a horn behind the flower. There are 32 species, 12 of them natives of Britain. The root of the morio, or female foal-foanes, has been celebrated as an aphrodisiac, but without any solid foundation.

ORDER, in architecture, is a system of the several members, ornaments, and proportions of columns and pilasters; or a regular arrangement of the projecting parts of a building, especially the column, so as to form one beautiful whole. See Architecture.

ORDER is also used for a division or class of any thing: thus, the tribe of animals called birds is subdivided into orders. See Natural History, and Botany.

Holy orders, a character peculiar to ecclesiastics, whereby they are set apart for the ministry. See Ordination.

Military orders, are companies of knights, instituted by kings and princes; either for defence of the faith, or to confer marks of honour, and make distinctions among their subjects.

Religious orders, are congregations or societies of monastics, living under the same superior, in the same manner, and wearing the same habit.

ORDINAL, a book containing the order or manner of performing divine service.

ORDINANCE, or Ordonnance, a law, statute, or command of a sovereign or superior: thus the acts of parliament are sometimes termed ordinances of parliament.

ORDINARY, in civil law, is any judge invested with authority to take cognizance of causes in his own right, and not by deputation.

ORDINARY, or honourable Ordinary, in heraldry, a denomination given to certain charges properly belonging to that art. The honourable ordnaries are ten in number; viz. the chief, pale, bend, fesse, bar, crois, falter, chevron, bordure, and orle. For which see the articles Chief, Pale, &c.

ORDINATES. See Conic Sections.

ORDINATION, the act of conferring holy orders, or of initiating a person into the priesthood by prayer—and the laying on of hands.

ORDINANCE, a general name for all sorts of great guns used in war. See Gunery.

Office of Ordinance, an office kept within the tower of London, which superintends and dispenses of all the arms, instruments, and utensils of war, both by sea and land,
OREGRUND, a port-town of Sweden, in the province OREBRO, the capital of the province of Nericia, in Sweden: E. long. 15°, N. lat. 59° 30'.

ORE, in natural history, the compound mineral glebe, territory of Otranto, situated thirty miles north-west of the city of Otranto.

ORIFICE, the mouth or aperture of a tube, pipe, or other cavity.

ORGAL, among dyers, denotes the lees of wine dried.

ORGAN, in general, is an instrument or machine designed for the production of some certain action or operation; in which one or more of the mechanic powers, machines, and engines are used to perform the work desired. St. Jerome mentions one with twelve pair of bellows, which might be heard a thousand paces, or a mile; and another at Jerusalem, which might be heard at the mountain of Olives.

There is one in the cathedral church of Ulm, in Germany, that is sixty-three feet high, and twenty-eight feet broad; the biggest pipe is thirteen inches in diameter; and it has sixteen pair of bellows.

The modern organ is a buffet, containing several rows of pipes. The size of the organ is generally expressed by the length of its biggest pipe; thus we say an organ of thirty-two feet, of sixteen, of eight, and of two feet.

Hydraulic Organ, denotes a musical machine that plays by means of water instead of wind. Of these there are several in Italy in the grottoes of vineyards. Ctesebeus of Alexandria, who lived in the time of Ptolemy Euergetes, is said to have first invented organs that played by compressing the air with water, as is still practiced. Archimedes and Vitruvius have left us descriptions of the hydraulic organ.

ORGASM, an ecstacy, or impetuous desire of coition, occasioned by a turgescency of the seminal vesicles.

ORGLA, in antiquity, feasts and sacrifices performed in honour of Bacchus, instituted by Orpheus; and chiefly celebrated on the mountains by wild drugged women, called Bacchinae. See Bacchanalia, and Dionysia.

ORGIVA, a town of Spain, in the province of Granada, twenty-five miles south of Granada.

ORGUES is also used for a machine, composed of several harquebuffs or musquet-barrels bound together, by means whereof several explosions are made at the same time, used to defend breaches and other places attacked.

ORION, in astronomy. See Astronomy, p. 487.

ORLEA, or Orlo, in architecture, a fillet under the ovolo or quarter round of a capital. When it is at the top or bottom of the shaft, it is called cincture.

ORLON, in fortification, is a small rounding of earth faced with a wall; raised on the shoulder of those bastions that have camedes, to cover the cannon in the retired flank, and prevent their being dismounted by the enemy. See Fortification.

ORIOLUS, in ornithology, a genus belonging to the order of picce. The bill is conical, convex, very sharp, and fhrapt, the superior mandible being much longer than the under one; and the tongue is forked and sharp. There are 20 species, principally distinguished by their colour.

ORKNEY ISLANDS, certain islands on the north of Scotland, from which they are separated by a frith twenty miles in length, and ten in breadth. These islands are forty in number, and together with the island of Zetland send one member to parliament, and another for the burghs of Kirkwall, &c.
Orle, in heraldry, an ordinary, in form of a fillet, drawn round the shield, near the edge or extremity thereof, leaving the field vacant in the middle. Its breadth is but half that of the trefoir or bordure, which contains a sixth part of the shield; and the orle, only a twelfth, besides that the orle is its own breadth distant from the edge of the shield, whereas the bordure comes to the edge itself. The form of the orle is the same with that of the shield, whence it resembles an escutcheon. See Plate CXXXIV. fig. 6, which represents an orle argent in a field gules.

Orleans, a province or government of France, bounded by Normandy and the Isle of France, on the north; by Champaign and Burgundy, on the east; by Lyonois and Guienne, on the south; and by Brittany and the bay of Biscay, on the west.

Orleans, a city of France, capital of Orleans, situated on the river Loire, in E. long. 2°, N. lat. 47° 55'.

Orleans is also the name of an island and town on the river of St. Laurence, in Canada: W. long. 73°, N. lat. 47°.

Orlope, in the sea-language, the uppermost space or deck in a great ship, reaching from the main-mast to the mizen. In three-deck ships, the second and lowest decks are sometimes called orlopes.

Ormond, the north division of the county of Tipperary in Ireland.

Ormus, an island at the entrance of the gulf of Persia, situated opposite to Gombron on the continent, in E. long. 56°, N. lat. 29° 30'. This island is thirty miles in circumference.

Ornithogalum, in botany, a genus of the hexandria monogynia class. The corolla consists of six erect petals; and the filaments are alternately wider at the base. There are 11 species, three of them natives of Britain, viz. the luteum, or yellow star of Bethlehem; the pyrenaicum, or spiked star of Bethlehem; and the umbrellatum, or common star of Bethlehem.

Ornithology, that branch of natural history which treats of birds. See Natural History.

Ornithomancy, a species of divination, performed by means of birds; being the same with augury. See Divination and Augury.

Ornithopus, in botany, a genus of the diadelphia decandria class. The pod is jointed, cylindrical, and arcuated. There are four species, only one of which, viz. the perpusillus, or birds-foot, is a native of Britain.

Orobanche, in botany, a genus of the didynamia angiospermia class. The calix is bifid, and the corolla is gent; the capsule has two valves, and contains many seeds. There are seven species, two of them natives of Britain, viz. the major, or broom-rape; and the ramosa, or branched broom-rape.

Orobus, in botany, a genus of the diadelphia decandria class. The stylus is linear; the calix is blunt at the base, the superior segments of it being shorter. There are nine species, two of them natives of Britain, viz. the tuberosus, or wood-pease; and the sylvaticus, or bitter vetch.

Oronoque, a river of South America, which falls into the Atlantic ocean in 8° N. lat. almost opposite to the island of Trinity.

Orontium, in botany, a genus of the hexandria monogynia class. The spadix is cylindrical, and covered with filacles; the corolla consists of six petals; it has no styles; and the capsule has three cells. There is but one species, a native of Virginia.

Orphan, a fatherless child, or minor; or one that is deprived both of father and mother.

Orphus, in ichthyology. See Sparus.

Orpiment, in natural history, a fossilizable substance usually found in copper-mines, composed of thin flakes, like the talc; which easily split, and are flexible, and not elastic, fusible in oil, fusible in a moderate fire, and yielding in burning an offensive smell like garlic.

Orsano, the uppermost space or deck in a great ship, reaching from the main-mast to the mizen. In three-deck ships, the second and lowest decks are sometimes called orlopes.

Orsolo, a vessel of war of the Turkish dominions, and in Germany. And, 3. Red-orpiment, which is of a fine bright red: this is a very beautiful substance of a fine bright red, very glozzy, and a little transparent, and is found in the Turkish dominions, in the islands of the Archipelago, and even in Cornwall, where it is known under the name of red mandric.

Geoffroy declares it a corrosive and poisonous mineral; on the other hand, Boerhaave declares orpiment an innocent and harmless medicine; and Hoffman, who has been at more pains than any body to examine into its nature, declares the same, and even gives instances of its being given to dogs without any harm.

It is an excellent depilatory, mixed with lime, and made into a pafte with water. The painters are fond of it as a golden colour; and a lixivium of it, with quick-lime, makes sympathetic ink.

Orpine, in botany. See Sedum.

Orrey, a curious machine, or movement, for representing the motions and appearances of the heavenly bodies. See Astronomy, p. 495.

Orrice. See Iris.

Ortegal castle and cape, the most northerly promontory of Spain, thirty miles north-east of Ferrol: W. long. 8° 22', N. lat. 44°.

Ortega, in botany, a genus of the triandria monogynia class. The calix consists of five leaves; the corolla is wanting; and the capsule has one cell, and many seeds. There is but one species, a native of Spain.

Orthodox, in church-history, an appellation given to those who are found in all the articles of the Christian faith.

Orthographic projection of the sphere, that where-in the eye is supposed at an infinite distance; so called, because the perpendiculars from any point of the sphere will all fall in the common intersection of the sphere, with the plane of the projection.

Ortho-
ORTHOGRAPHY, that part of grammar which teaches the nature and affections of letters, and the just method of spelling or writing words with all the proper and necessary letters, making one of the four greatest divisions or branches of grammar. See GRAMMAR.

ORTHOGRAPHY, in geometry, the art of drawing or delineating the fore-right plan of any object, and of expressing the heights or elevations of each part. It is called orthography, from its determining things by perpendicular lines falling on the geometrical plane.

ORTHOGRAPHY, in architecture, the elevation of a building.

ORTHOGRAPHY, in perspective, is the fore-right side of any plane, i.e., the side or plane that lies parallel to a straight line, that may be imagined to pass through the outward convex points of the eyes, continued to a convenient length.

ORTHOPNOEAE, in medicine, a species or degree of asthma, where there is such a difficulty of respiration, that the patient is obliged to sit or stand upright, to be able to breathe. See MEDICINE.

ORTON, a market town of Westmoreland, situated ten miles south-west of Appleby.

ORVALA, in botany, a genus of the didynamia gymnospermae class. The superior lip of the corolla is divided into three segments, each being toothed; and the inferior or lip is cordated and crenated. There is but one species, a native of Italy.

ORVIETTO, a city of Italy, in the pope's territories, capital of the province of Orvietto, situated at the confluence of the Tiber and the Chiane: E. long. 13°, N. lat. 43°.

ORWELL, a river of Suffolk, which, rising in the middle of that country, runs south-east by Ipswich, and falls into the German sea at Languard-fort.

ORYZA, RICE, in botany, a genus of the hexandria digynia class. The calyx is a double-valved glume, with one flower; and the corolla consists of two equal valves. There is but one species.

This plant is cultivated in vast abundance in the East, as also in Carolina, for food. It is said to be good in dymenteries, diarriheas, &c.

OSACA, a great city and port-town of Japan, situated on a bay of the sea, on the east side of the island: in E. long. 135°, N. lat. 35°.

OSBECKIA, in botany, a genus of the oenandra monogynia class. The calyx consists of four segments, and the corolla of four petals: and the capsule has four cells. There is but one species, a native of India.

OSCHEOCELE, in surgery, a hernia of the ferotum. See SURGERY.

OSCILLATION, in mechanics, the vibration, or reciprocal ascent and descent of a pendulum. See MECHANICS.

OSMUNDA, in botany, a genus of the cryptogamia filicium class. The spike is full of branches, and the fructification is round. There are 17 species, none of them natives of Britain.

OSNAPBURG, the capital of the bishopric of the same name, in the circle of Westphalia: E. long. 7° 40', N. lat. 52° 31'. The territories of this bishopric, which are forty miles long, and thirty broad, are subject to its bishop; and this bishopric is alternately held by a protestant and papist, the protestant being always a prince of the house of Brunswick.

OSORNO, a town of Chili in South America: W. long. 80°, S. lat. 41°.

OSPREY. See FALCO.

OSSEIFICATION, the formation of bones, but more particularly the conversion of parts naturally soft to the hardness and consistence of bones. See ANATOMY, p. 148.

OSSORY, the west division of Queen's county in Ireland.

OSSUNA, a town of Spain, in the province of Andalusia, forty miles east of Seville.

OSTAGIO, a town of Italy in the territory of Genoa, fifteen miles north-west of Genoa.

OSTEND, a city and port-town of the Austrian Netherlands, in the province of Flanders, situated twelve miles west of Bruges: E. long. 2° 45', N. lat. 51° 15'.

OSTEOSPERMUM, in botany, a genus of the syngenesia class. The receptacle is naked; it has no pappus; the calyx consists of many leaves; and the seeds and the number of spines near the tail.

OSTEOLOGY, that branch of anatomy which treats of the bones. See ANATOMY, Part I.

OSTEOSPERMUM, in botany, a genus of the syngenesia polygamia necessaria class. The receptacle is naked; it has no pappus; the calyx consists of many leaves; and the seeds are round and hard. There are five species, none of them natives of Britain.

OSTIA, a port-town of Italy, in the pope's territories, situated at the mouth of the Tiber: E. long. 13°, N. lat. 41° 30'.

OSTRACION, in zoology, a genus of the amphibia nantes class. It has ten long, cylindrical, obtuse teeth in each jaw; the aperture is linear; the body is covered with a bony substance; and it has no belly-fins. There are nine species, principally distinguished by the angles of their bodies and the number of spines near the tail.

OSTRACISM, in Grecian antiquity, denotes the banishment of such persons whose merit and influence gave umbrage to the people of Athens, lest they should attempt anything against the public liberty. It was so called, because the people...
OTLEY, a market-town, twenty-one miles west of York.

OSTRACITES, in natural history, the name by which authors call the soluble oyster-shell.

Ostracites has the same medicinal virtues with the belemnites, and lapis judaicus, only in a higher degree; being accounted by Dr. lifter one of the greatest known medicines in nephritic cases: the dose, in powder, is from half a dram to a dram; in white-wine; and to prevent a sickness at the stomach, that sometimes attends the taking it, one third part of the quantity of powdered chamomile-flowers may be mixed with it.

OSTREA, the oyster, in zoology, a genus belonging to the order of vermes testacea. The shell has two unequal valves; the cario has no teeth, but a small hollow pit, with transversal lateral breaks. There are 31 species, principally distinguished by peculiarities in their shells. The common oyster is used both raw, and variously prepared as food.

OSTRICH, in ornithology. See Struthio.

OSTROGANOFF, a town of the Russian empire, on the river Volga, between the Black Sea and the Caspian, thirty-three miles west of Kazan.

OSTROGANOFF, a town of the Russian empire, on the Volga, between the Black Sea and the Caspian, thirty-three miles west of Kazan.

OSTRICH, in ornithology. See Struthio.

OSTWEGO, a town of the Iroquois, in North America, three hundred miles west of Albany, in New-York.

OSTWERY, a market-town in Shropshire, fifteen miles north-west of Shrewsbury.

OTIS, in botany, a genus of the dicotyledonous class, the calix of both male and female consists of three segments; neither of them has any corolla; the female has no style, but a roundish stigma; and the drupa has but one cell. There is only one species, a native of Italy.

OTONNA, in botany, a genus of the commelinaceae class. The receptacle is naked; it has no pappus; and the calix is somewhat cylindrical, and consists of many leaves. There are two species, two of them natives of Britain, viz. the palustris, or marsh fleabane; and the integriolia, or mountain ragwort.

OTOQUE, an island situated in the bay of Panama, from whence the city is furnished with provisions: W. long. 83°, N. lat. 70°.

OTRANTO, a city and archbishop's see of the kingdom of Naples, situated at the entrance of the gulph of Venice: E. long. 19° 15', N. lat. 40° 12'.

OTTEN, in zoology. See Mustela.

OTTOMAN, or Ottoman, an appellation given to the Turkish empire, from Othomannus, or Olmahanus, the first emperor of the present family.

OTTONA, or Ostona, a city of the kingdom of Naples, situated on the gulph of Venice: in E. long. 15° 30', N. lat. 42° 22'.

OVAL, an oblong curvilinear figure, otherwise called eclipis. See Conic Sections.

OVARIES, in anatomy. See Anatomy, p. 275.

OVATION, in the Roman antiquity, a lesser triumph, allowed to commanders for victories won without the effusion of much blood; or for defeating a mean and insignificant enemy. The show generally began at the Albanian mountain, whence the general with his retinue made his entry into the city on foot, with many flutes or pipes sounding in concert as he passed along, and wearing a garland of myrtle as a token of peace. The term ovation, according to Servius, is derived from ovis, sheep, because on this occasion the conqueror sacrificed a sheep, as in triumph he sacrificed a bull.

OVEDENARDE, a town of the Austrian Netherlands, in the province of Flanders, situated on the river Scheld, thirteen miles south of Ghent.

OUDENBURG, a town of the Austrian Netherlands, in the province of Flanders, five miles south-east of Odend.

OVERHALE, in the Fea-language. A rope is laid to be overhaled wben drawn too tight, or haled the contrary way.

OVER-RAKE, among seamen: When a ship, riding at anchor, so overrakes herself into an high sea, that she is washed by the waves breaking in upon her, they say the waves over-rake her.

OVERMAN, in Scots law; a person named by arbiters, or by the parties submitters, to determine the matter submitted, in case the parties disagree in their opinion.

OVERT, the same with open: thus an overt act signifies an act which, in law, must be clearly proved; and such is to be alleged in every indictment for high treason.

OVER-TURE, or Overture, opening or preluding; a term used for the solemnities at the beginning of a public act or ceremony; an opera, tragedy, concert of music, &c.

The overture of the theatre, or scene, is a piece of music usually ending with a fugue: the overture of a juvenile is a general prelucion, &c.

OVERYSCHE, a town of the Austrian Netherlands, in the province of Brabant, situated on the river Ysche, nine miles north-east of Brussel.

OVERYSEL, one of the united provinces, bounded by Groningen on the north, by Westphalia on the east, by Zutphen on the south, and by Gelderland, the Zuyder-see, and Friesland, on the west.

OVIEIDA, in botany, a genus of the didynamia angiospermia class. The calix consists of five segments; the corolla is a long cylindrical tube; and the berry is round, containing two seeds. There are two species, none of them natives of Britain.

OVIEDO, a city of Spain, capital of the province of Asturias; situated on the river Afia, fifty miles north of Leon, in W. long. 6° 40', N. lat. 43° 30'.

OVIAN, or Septa, in ancient Rome, a place the vilia was not by stairs, but by pontes, or narrow boards, laid there for the occasion; on which account de ponte desjicivis to be denied the privilege of voting; and persons thus dealt with, were called deponenti.

Oviparous, a term applied to such animals as bring forth their young from eggs; as birds, insects, &c.

OVIS, in zoology, a genus of the mammalia class, and of the order of pecora; the characters of which are these: The horns are concave, turned backwards, twisted, and full of wrinkles; there are eight teeth, first and second incisors, and eight others.

OVIPAROUS, a term applied to such animals as bring forth their young from eggs; as birds, insects, &c.
OVID

Aries, or ram and sheep, the horns of which are shaped like a half moon, and compressed. This animal is perhaps the most gentle and inoffensive, and at the same time the most timid and stupid, of all quadrupeds. In a flock of sheep, there is always a leader, whose feet the rest implicitly and blindly follow. If he runs over a precipice, the whole flock follow his example, and cannot be restrained though evident destruction be the consequence. The smallest noise, if uncommon, makes them run precipitately, against each other, without knowing the cause of their danger, or being able to extricate themselves. In snow, they remain fixed in the same spot; and continue obstinately in that situation, unless they are forced to move by the shepherd or his dog. But though daftardly in itself, though almost devoid of sentiment and mental qualities, this animal is of the most extensive utility to man. It affords us both food and clothing, besides the advantages we derive from its milk, its skin, and its tallow.

Love, the liveliest sentiment in all animals, is the only passion which inspires the ram with any degree of vivacity; when under the influence of this passion, he becomes petulant, runs against his neighbours, and sometimes even attacks the shepherd himself. But the ewe, or female, though in the same situation, does not appear to be in the least affected; the seems to have no other instinct than that of simply admitting the embraces of the ram, eating her food, and recognizing her offspring; the lamb, on the other hand, is endowed with the same instinct of distinguishing its mother from the rest of the flock.

This animal, so soft and so simple in its nature and disposition, is likewise extremely weak and feeble in its constitution: They can endure but little fatigue; whenever they run, their hearts palpitate, and their wind fails them; they are equally incapable of bearing heat or cold, snow or rain: They are subject to many diseases, most of which are contagious: They bring forth their young with pain and difficulty, and require more care and attention than any other domestic animal.

The ram is capable of generation at the age of 18 months; and the ewe can be impregnated when a year old. One ram is sufficient for 30 or 40 ewes. He ought to be strong, well proportioned; his head should be thick and strong, his front large, his eyes black, his nose flat, his neck thick, his body long and tall, his testicles firm, and his tail long. White is the best colour for a ram. The horns of which are shaped like a half moon, and compressed. The ram, ewe, and weather, when one year old, lose the two foreteeth of the under jaw; six months afterwards, they lose the two foreteeth next to these; and at the age of three years, the teeth are all replaced. The age of a ram may likewise be discovered by their horns, which always appear the first year, and frequently as soon as they are brought forth. These horns uniformly acquire an additional ring every year as long as the creature lives. The ewes commonly have no horns, but a kind of long protuberances in place of them; however, some of them have two, and some four horns.

In Spain, and the southern parts of Europe, the flocks are kept in shades or stables during the night: but in Britain, where there is now no danger from wolves, they are allowed to remain without, both night and day; which makes the animals more healthy, and their flesh a more wholesome food. Dry and mountainous grounds, where thyme and sheep's fefca graze abound, are the best for the pasturing sheep.

The Guineenfis, or Guinea sheep, has pendulous ears, lax hairy dew laps, and a prominence on the hind part of the head. The wool is short, like that of a goat. It is a native of Mount Iola.

OULNEY, a market-town of Buckinghamshire, situated nine miles south-east of Northampton.

OULZ, a town of Italy, in the province of Piedmont, situated in E long. 6° 30', N. lat. 45'.

OUNCE, a little weight, the sixteenth part of a pound avoirdupois, and the twelfth part of a pound troy.

OUCHE, in zoology. See Loxo.

OUNDLE, a market-town of Northamptonshire, situated on the river Nen, twenty-two miles north-east of Northampton.

OVOLO, or Ovum, in architecture, a round moulding, whose profile, or sweep, in the Ionic and Corinthian capitals, is usually a quadrant of a circle; whence it is also commonly called the quarter-round. It is usually cut with the representation of eggs and anchors or arrows heads placed alternately.

OUSE, a river, which, rising in the north of Yorkshire, runs south-east by York; and, continuing that course, falls into the Trent.

OUSTIACH, or OUSTIACH Country, is a part of Asiatic Russia, extending along the river I trauma to its confluence with the river Obi; and from thence north-west along the banks of the Oby and Jenifa, into the gulf of the Mandrake, or the frozen ocean; and extending also along the

Vol. III. No. 88. 2
OXUS, a river which rises in the mountains on the north of India; and running north-west, through Ufbc Tartary, afterwards separates from Ufbc Tartary, and falls into the Caspian sea, in 45° N. lat.

OXUS, in botany. See Vaccinium.

OXUS, in zoology. See Mus.

OXYCROCEUM, in pharmacy, &c. A preparation much used in plasters for fractures, &c. made as follows: Take yellow wax, one pound; pitch and galbanum, each half a pound; melt them over a gentle fire; and then add of Venice-turpentine, myrrh, and olibanum, each three ounces; saffron, two ounces; make them into a plaster.

OXYGLYCU, a species of drink prepared of the sweetest honey combs, macerated and boiled. The combs from which all the honey has been expressed, are put into a pot with pure water, and boiled till they seem to have deposited all their contained honey in the water. This liquor is to be kept, and, when diluted with cold water, is to be drank in the summer-time, in order to remove thirst.

OXYMELO, in pharmacy, a composition of vinegar and honey.

There are several sorts of oxymel, whereof the simplest kind is made by boiling, in a glazed earthen vessel, and with a gentle fire, two pounds of clarified honey, in a pint of vinegar, to the confidence of a syrup.

OYER, in law-books, seems to have been anciently used for what is now called assizes.

OYER AND TERMINER, a commission directed to the judge of assize, and other gentlemen, empowering them to hear and determine all criminal causes, and to try all offenders, whether for treason, felony, or trespass.

OYES, or OYER, signifies Hear ye; and is frequently used by the clerks in our courts, on making proclamations, or to enjoin silence.

OYSTER, in zoology. See Ostrea.

OZAI, a foul and malignant ulcer of the nose, distin-

guished by its fetor, and often accompanied with a caries of the bones of the nose.

PABULUM. See Fuel and Fire.

PACA, in zoology. See Mus.

PACE, a measure taken from the space between the two feet of a man, in walking; usually reckoned two feet and a half, and in some men a yard or three feet.

The geometrical pace is five feet; and 60000 such paces make one degree of the equator.

PACE, in the manege, is of three kinds, viz. walk, trot, and gallop; to which may be added an amble, because some horses have it naturally.

PACIFIC
PACIFIC OCEAN, that vast ocean which separates Asia from America: it is called Pacific, from the moderate weather the first mariners who failed in it met with between the tropics; and it was called fourth-sea, because the Spaniards crossed the illusium of Darien from north to south, when they first discovered it; though it is properly the Western ocean, with regard to America.

PACK, in commerce, denotes a quantity of goods, made up in loads, or bales, for carriage.

A pack of wool is seventeen stone and two pounds, or a horse’s load.

PACKAGE, is a small duty of one penny in the pound, paid for all goods not particularly rated.

PACOS, in zoology. See Camelus.

PACTOLUS, a river of Lydia in the lesser Asia, celebrated by the ancient poets for its golden sands.

PADDOC, or Paddock-course, a piece of ground encompassed with pales or a wall, and taken out of a park for exhibiting races with grey-hounds, for plates, wagers, or the like.

PADDERBORNE, the capital of the bishopric of the same name in Westphalia: E. long. 8° 25’, N. lat. 51° 45’.

PADSTOW, a market town of Cornwall, thirty miles west of Launceston.

PADUA, the capital of the Paduan, in Italy, a city of a circular form, situated twenty-two miles west of Venice: E. long. 12° 15’, N. lat. 45° 30’.

PADUAN, a province of Italy, in the territories of Venice, thirty-five miles long, and almost as much in breadth; bounded by the Trevifane on the north, by the duchy of Venice on the east, by the Polesin de Rovigo on the south, and by the Vicentin on the west.

PADUAN, among the medals, a modern medal struck in imitation of the antique; or a new medal struck with all the marks and characters of antiquity.

PADUS, in botany. See Prunus.

PAEAN, among the ancient pagans, was a song of rejoicing sung in honour of Apollo, chiefly used on occasions of victory and triumph.

PAEAN, in the ancient poetry, a foot consisting of four syllables; of which there are four kinds, the pean primus, secundus, &c.

The pean primus consists of one long syllable and three short ones, or a trochus and pyrrhichius, as temporibus; the pean secundus consists of a short syllable, a long, and two short, or an iambus and a pyrrhichius, as potentia; the pean tertius consists of two short syllables, a long and a short one, or a pyrrhichius and a trochus, as animatus; the pean quartus consists of three short syllables and a long one, or a pyrrhichius and iambus, as cellatar.

PAEDEROTA, in botany, a genus of the diandria monogynia class, of which there are two species, none of them natives of Britain.

PAEDO-BAPTISM, infant-baptism, or that conferred on children.

PAEONIA, in botany, a genus of the polyandria digynia class. The calix consists of five leaves, and the corolla of five petals; the stylus is wanting; and the capsule contains many seeds. There are two species, none of them natives of Britain.

The root of this plant is a very celebrated medicine in nervous cases.
Oil to the eye, as a good piece of musick to the ear. By this means the picture is not only more delightful, but better seen and comprehended. 4. The drawing must be firm; nothing must be flat, lame, or ill proportioned; and these proportions should vary according to the characters of the persons drawn. 5. The colouring, whether gay or fold, must be natural, beautiful, and clean, and what the eye is delighted with, in shadows, as well as lights and middle tints; and whether the colours are laid on thick, or finely wrought, they must appear to be done by a light and accurate hand. Lastly, Nature must be the foundation that must be seen at the bottom; but nature must be raised and improved, not only from what is commonly seen, to what is but rarely met with, but even yet higher, from a judicious and beautiful idea in the painter’s mind, so that grace and greatness may shine throughout: more or less according to the subject.

Painting is of various kinds, according to the materials used, the matter upon which they are applied, and the manner of applying them; as painting in oil, in water-colours, fresco, &c.

Painting in oil. The whole secret of painting in oil consists in grinding the colours with nut oil, or linseed-oil, but the manner of working is very different from that in fresco, or in water, by reason the oil does not dry near so fast, which gives the painter an opportunity of touching and re-touching all the parts of his figures as often as he pleases; which in the other methods of painting is a thing impracticable. The figures done in oil are also capable of more force and boldness; inasmuch that the black becomes blacker, when ground with oil, than with water; besides, all the colours mixing better together, makes the colouring the swifter, more delicate and agreeable, and gives an union and tenderness to the whole, invincible in any of the other manners.

Painting in oil is performed on canvas, on walls, wood, stone, and all sorts of metals. 1. Painting on cloth or canvas is done as follows: The canvas being stretched on a frame, give it a layer of size, or paste-water, and then go over it with a mince or flone to smooth off the knots. By means of the size, the little threads and hairs are all laid close on the cloth, and the little holes filled up, so that no colour can pass through. When the cloth is dry, lay on oker in oil, which may be mixed with white-lead to make it dry the sooner. When dry, go over it again with the pumice-stone, to make it smooth. After this a second couch is sometimes applied, composed of white-lead and a little charcoal-black, to render the ground of an ash colour. Others prime the canvas in the following manner: They first smooth the canvas with a pumice- or flone, fix it over with a good size and a little honey, and let it stand to dry, after which they lay it over with whitening and size, mixed with a little honey: the use of the honey is to prevent it from cracking, peeling, and breaking out; on this they first draw the picture with a coal, and then lay on the colours. 2. Painting on walls: When the wall is dry, they give it two or three washes with boiling oil; till the plaster remains quite greasy, and will imbibe no more; upon this they lay drying colours, such as white-charcoal, red-oker, or other chalks beaten pretty stiff. When this couch or layer is well dried, the subject or design is sketched out, and afterwards painted over, mixing a little varnish with their colours, to save the varnishing afterwards. In order the better to fortify the wall against moisture, some cover it with a plaster of lime, marble-dust, or a cement made of burnt tiles mixed in linseed-oil; and at last prepare a composition of green-pitch, mastic, and thick varnish boiled together, which they apply hot over the former plaster; and when dry, lay on the colours as before. Others, in fine, make their plaster with lime-mortar, tile-cement, and sand; and this being dry, they apply another of lime, cement, and iron scorze, which being well beaten, and incorporated with linseed-oil and whites of eggs, makes an excellent plaster. When this is dry, the colours are laid on as before. 3. In painting on wood, they usually give their ground a couch or layer of white tempered with size, and then proceed as in painting on walls. 4. In painting on stone or metals, it is not necessary to lay them over with size, but only to add a light couch of colours before the design is drawn on it; nor even is this done on stones, where you would have the ground appear, as in certain marbles and agates of extraordinary colours.

All the colours used in fresco are good in oil, except white of lime and marble dust. Thosse chiefly used are white-lead, or cerufa, yellow and white mastic, orniment, vermilion, lacca, blue and green athes, verdigris, indigo, fmal, black-lead, ivory-black, lamp-black, &c. As to oils, the best are those of linseed, walnuts, spike, and turpentine. The drying oils are nut-oil, boiled with thyme and sandarach, and otherwise with spirit of wine, mastic, and gum-lacca.

In the preparation of oil-colours, care must be taken that they be ground fine; that in putting them on a pallet, those which will not dry of themselves may be mixed with drying oil, or other ingredients of a dying quality, and that the tinged colours be mixed in as small quantities as possible. As to the situation of the colours, the purest and strongest must be placed in the front of the piece, and the colouring varied according to the subject, time, and place. If the subject be grave, melancholy, or terrible, the general tint of the colouring must incline to brown and black, or red and gloomy; but it must be gay and pleasant in subjects of joy and triumph.

PALÆSTRA, in Grecian antiquity, a public building, where the youth exercised themselves in wrestling, running, playing at quoits, &c.

PALÆSTROPHYLAX, was the director of the palaistra and the exercises performed there.

PALS, a town of France, in the province of Gascony, capital of the lower Navarre, situated in W. long. 1° 8', N. lat. 43° 23'.

PALAMBOANG, or Palambang, the capital of a kingdom at the east end of the island of Jave, in the East Indies, situated on the straits of Bally, in E. long. 114°, S. lat. 7° 30', and separated from the island of Bally by a narrow strait.

PALAMEDIA, in ornithology, a genus belonging to the order of grallie. The bill is conical, the superior mandible being crooked; and the feet have three divided toes. There are two species, both natives of Brazil.

PALARIA, among the Romans, a kind of exercize, performed at a stake by the soldiers. The stake being fixed in the ground, and six feet high above it, the young undisciplined soldiers advanced against it, armed with a hurdle and cudgel, instead of a shield and sword, and went through all the rules of attack and defence, as if actually engaged.
engaged with an adversary. Sometimes they flood at a distance, and attacked with misive weapons, at the same time using all the requisite motions for defending themselves, and warding off what might be thrown against them.

PALATE, in anatomy. See Anatomy, p. 162, 303.

PALATINATE, a province, or signiory, possessed by a palatine.

PALATINE, or Count Palatine, a title anciently given to all persons who had any office or employment in the prince's palace; but afterwards conferred on those delegated by princes to hold courts of justice in the provinces; and on such among the lords as had a palace, that is, a court of justice, in their own houses.

At present the word palatine is restricted to a prince of Germany, or a lord of Poland, possessed of a palace.

PALATO-salpingæus. See Anatomy, p. 303.

PALATO-staphylinus, in anatomy. See Anatomy, p. 303.

PALE, a little pointed flake or piece of wood, used in making inclosures, separations, &c. The pale was an instrument of punishment and execution among the ancient Romans, and still continues so among the Turks. Hence impaling, the passing a sharp pale up the fundament through the body.

PALE, in heraldry, one of the honourable ordinaries of an escutcheon; being the representation of a pale or flake placed upright, and comprehending the whole height of the coat from the top of the chief to the point. When the pale is single, it is to contain one third of the breadth of the shield. See Plate CXXXIV. fig. 7.

Palermo, the capital of the island of Sicily, situated on the north coast of that island, on a bay of the Mediterranean sea: in E. long. 13°, S. lat. 38° 30'.

Palestine, a part of Asiatic Turkey, situated between thirty-six and thirty-eight degrees of east longitude, and between thirty-one and thirty-four degrees of north latitude; it is bounded by Mount Libanus, which divides it from Syria, on the north; by Mount Hermon, which separates it from Arabia Deserta, on the east; by the mountains of Seir and the Deserts of Arabia Petraæa, on the south; and by the Mediterranean sea, on the west.

It was called Palestine, from the Philistines who inhabited the sea-coasts. It was also called Judaæa, from Judah; and the Holy Land, from our Saviour's residence and sufferings in it; and it is called Canaan, and the Promised Land, in the scriptures.

It is 150 miles in length, and 80 in breadth; and in the time of Solomon it seems to have extended from the Mediterranean sea to the river Euphrates.

Palestrina, a city of Italy, in the pope's territory and Campania of Rome, situated thirty miles east of Rome.

Palimbam, a town on the island of Sumatra, in the East-Indies, situated in E. long. 103°, S. lat. 3°.

Palindromus, a verse or sentence which runs the same when read either backwards or forwards; such is the verse,

Roma bibi stabit mutatis ibit amor.

Palining, a sort of fencing for fruit-trees planted in fields, wherein three small posts are erected at a foot and a half distance one from another, and near the top nailed to each other with crofs-bars.

Vol. III. N°. 87. 2

PALINGENESIA, among divines, signifies the same with regeneration.

Among chemists, it denotes the producing a body from its principles.

PALINODY, a discourse contrary to a preceding one; hence the phrase palinodiam canere was taken for a recantation.

Palisade, in fortification, an inclosure of stakes or piles driven into the ground, each six or seven inches square, and eight feet long, three whereof are hid under ground.

Palisse, in heraldry, a bearing like a range of palisades before a fortification, represented on a feffe, rising up a considerable height, and pointed a-top, with the field appearing between them. See Plate CXXXIV. fig. 8.

Paliurus, in botany. See Rhamnus.

Pall, in heraldry, denotes a kind of cross representing the pallium, or archiepiscopal ornamental fent from Rome to the Metropolitans. See Plate CXXXIV. fig. 9.

Palla, in Roman antiquity, a mantle which women wore over the gown called stola. It was borne on the left shoulder; whence palling to the other side, under the right arm, the two ends were bound under the left arm, leaving the breast and arm quite bare.

Palladium, in antiquity, a statute of the goddes Pal. las, supposed to have dropped down from heaven; preferred in Troy, whereon the fate of that city is said to have depended.

Pallet, among painters, a little oval table, or piece of wood, or ivory, very thin and smooth; on and round which the painters place the several colours they have occasion for, to be ready for the pencil. The middle serves to mix the colours on, and to make the tints required in the work. It has no handle, but instead thereof, a hole at one end to put the thumb through to hold it.

Pallet, in heraldry, is nothing but a small pale, consisting of one half of it in breadth, and therefore there are sometimes several of them upon one shield.

Pallet, in ship-building, is a room within the hold, close parted from it, in which by laying some pigs of lead, &c. a ship may be sufficiently balasted, without losing room in the hold; which, therefore, will serve for the flowing the more goods.

Palliation, or a palliative cure, in medicine, is when, in desperate and incurable diseases, after predicting the fatal event, the physician prescribes some remedies for mitigating the pain or some other urgent symptoms, as in ulcerated cancers, or cancerous fistulas, and the like.

Pallium, or Pall, an archiepiscopal vestment, of white woollen cloth, about the breadth of a border, made round, and thrown over the shoulders.

Palm-sunday, in the Christian church, the Sunday next before Easter; being so called in memory of our Saviour's triumphal entry into Jerusalem when the multitude that attended him fireweld palm-branches in his way.

Palm-tree, in botany. See Phoenix.

Palm isle, one of the Canary-islands, sixty miles north-west of Teneriff.

Palmaris, in anatomy. See Anatomy, p. 159.

Palimated, something resembling the shape of the hand: thus we say palmated leaves, roots, stiles, &c.

Palmipeedes, among ornithologists, the same with web-footed birds.
PALMISTRY, a kind of divination, or rather a deceitful art practised by gypsies, who pretend to forestall events by looking upon the lines and marks of the hand.

PALMYRA, the ruins of a magnificent city, in the province of Syria, two hundred miles south-east of Aleppo.

PALOS, a port-town of Spain, situated on the bay of Cadiz: W. long. 7° 15', N. lat. 37°.

PALPABLE, something perceivable by the senses, particularly that of feeling.

PALPITATION, a spastic contraction of the heart, when it leaps and beats violently.

PALS, in medicine. See Medicine, p. 97.

PALUDAMENTUM, in Roman antiquity, a habit that differed in little from the chlamys, except that this last belonged chiefly to the lower classes of people. See Chlamys.

PALUMBUS. See COLUMBIA.

PALLY, or PALL, in heraldry, is when the shield is divided into four or more equal parts, by perpendicular lines falling from the top to the bottom. See Plate CXXXIV. fig. 1c.

Pally bendy is when the escutcheon is divided by perpendicular lines, which is pally; and also by diagonals, which is called bendy. See the article Bendy.

PAMPULUNA, the capital of Spanish Navarre, is the seat of a bishop, and an university: W. long. 1° 30', N. lat. 43° 15'.

PANACEA, among physicians, denotes a universal medicine, or a remedy for all diseases; a thing impossible to be obtained.

PANADA, a diet consisting of bread boiled in water to the taste of a bishop, and an university: W. long. 1° 30', N. lat. 43° 15'.

PANACEA, among physicians, denotes an universal medicine, or a remedy for all diseases; a thing impossible to be obtained.

PANAMA, the capital city of the province of Darien, in South America, where the treasures of gold and silver, and the other rich merchandise of Peru, are lodged in magazines till they are sent to Europe: W. long. 82°, N. lat. 43° 15'.

PANARO, a river of Italy, which rising in the Appenine mountains, on the confines of Tuscany, divides Modena into the Gulph of Venice.

PANTHERA, the Scorpion-fly, in zoology, a genus of the hexandria monoelemma order. There are four species, distinguished by the colour of their wings.

PANCRATIUM, among the ancients, a kind of exercise, which consisted of wrestling and boxing. In these contests it was customary for the weaker party, when he found himself pressed by his adversary, to fall down, and fight rolling on the ground.

PANCREAS, in anatomy. See Anatomy, p. 263.

PANDESCTS, in the civil law, collections made by Justinian's order, of five hundred and thirty-four decisions of the ancient lawyers, on so many questions occurring in the civil law: to which that emperor gave the force and authority of law, by an epistle prefixed to them. The pandects consist of fifty books, and make the first part of the body of the civil law.

PANDICULATION, a stretching, or that violent and tense motion of the solids, which usually accompanies the act of yawning.

PANEYRIC, an oration in praise of some extraordinary thing, person, or virtue.

PANEYRICUM, in church-history, an ecclesiastical book, used by the Greek church, containing the panegyrical orations of various authors on the folemnities of Jesus Christ and the saints.

PANGONIA, in natural history, the name of a genus of crystal, consisting of such as are composed of many angles.

PANIC, denotes an ill-grounded terror or fright.

PANICLE, in botany, denotes a sheaf woolly beard, on which the seeds of some plants, as millet, reeds, etc., hang.

PANICUM, in botany, a genus of the triandria digynia clafs. The calix consists of three valves, the inmost of which is leafy. There are 28 species, four of which are natives of Britain, viz. the viride, or green panic-grass; the crusgalli, or loose panic-grass; the fangiuinale, or cock's-foot panic-grass; and the dactylon, or creeping panic-grass.

PANNEL, in law, signifies the prisoner at the bar, or person who takes his trial before the court of judiciairy, for some crime. See Law, Tit. xxxiii. 47.

PANNELS of a saddle, are two cushions or bolsters, filled with cow's, deer's, or horse-hair, and placed under the saddle, on each side, to prevent the bows and bands from galling the horse.

PANNICULUS CARNOSUS, in comparative anatomy, a robust fleshy tunic, situated in beasts, between the tunic and the fat; by means of which they can move their skin in whole or part: it is altogether wanting in mankind.

PANOPTRA, the Scorpion-fly, in zoology, a genus of insects belonging to the order of neuroptera. The rostrum is horned and cylindrical; there are two pappi, and three flomenta; the feelers are longer than the thorax; and the tail of the male is furnished with a forceps. There are four species, distinguished by the colour and shape of their wings.

PANTALOON,
PANTALOON, a sort of garment, consisting of breeches and stockings all of one piece; said to have been first introduced by the Venetians.

PANTHEON, in Roman antiquity, a temple of a circular form, dedicated to all the gods: It was built by Agrippa, son-in-law to Augustus; but is now converted into a church, and dedicated to the Virgin and all the martyrs.

PANTHÉON, in zoology. See Leo.

PANTOMIME, a person who imitates all sorts of actions and characters, by mere gestures, without speaking a word.

PANTOMIMA, a peperian who imitates all sorts of actions and characters, by mere gestures, without speaking a word.

PANTHER, in zoology. See Leo.

PANTHEON, in Roman antiquity, a temple of a circular form, dedicated to all the gods: It was built by Agrippa, son-in-law to Augustus; but is now converted into a church, and dedicated to the Virgin and all the martyrs.

PAP (453)

PAP, sheets of a thin matter, made of the same vegetable substance, as the range, or the reed kind. The second skin of the bark, which is soft and white, is ordinarily made use of for paper; this is beat in fair water to a pulp, which they take up in large moulds, so that some sheets are above twelve feet in length; they are completed, by dipping them sheet by sheet, in alum-water, which serves instead of the size among us, and not only hinder the paper from imbibing the ink, but makes it look as if varnished over. This paper is white, soft, and clothe, without the leaf roughness; though it cracks more easily than European paper, is very subject to be eaten by the worms, and its thinness makes it liable to be soon worn out.

Cotton-paper is a sort of paper which has been in use upwards of six hundred years. In the French king's library are manuscriptos on this paper, which appear to be of the Xth century; and from the XIth century, cotton manuscripts are more frequent than parchment ones. Cotton paper is still made in the East Indies, by beating cotton rags to a pulp.

Linen or European paper appears to have been first introduced among us towards the beginning of the XIVth century; but by whom this valuable commodity was invented, is not known. The method of making paper of linen or hempen rags, is as follows. The linen rags being carried to the mill, are first sorted, then washed very clean in wash-boards, whose sides are grated with strong wires, and the bottoms bored full of holes. After this they are fermented, by laying them in heaps clothe covered with flocking, till they sweat and rot, which is commonly done in four or five days. When duly fermented, they are twisted into handfuls, cut small, and thrown into oval mortars, made of well-seasoned oak, about half a yard deep, with an iron-plate at bottom, an inch thick, eight inches broad, and thirty long; in the middle is a washing-block, grooved, with five holes in it, and a piece of hair left on the inside; this keeps the hammers from touching it, and prevents anything going out except the foul water. These mortars are continually supplied with water, by little troughs from a cistern, fed by buckets fixed to the several floats of a great wheel, which raises the wooden hammers for pounding the rags in the mortars. When the rags are beaten to a certain degree, called the first fluff, the pulp is removed into boxes, made like corn-channers bins, with the bottom board affixed, and a little separation on the front for the water to drain away. The pulp of the rags being in; they take away as many of the front boards, as are needful, and piles the masts hard down with their hands; the next day they put on another board, and add more pulp, till the box is full; and here it remains mellowing a week, more or less, according to the weather. After this, the fluff is again put into clean mortars, and is beaten afresh, and removed into boxes, as before, in which flate it is called the second fluff. The masts is beat a third time, till some of it being mixed with fair water, and brewed to and fro, appears...
appears like flour and water, without any lumps in it: it is then fit for the pit-mortar, where it is perfectly dissolved, and is then carried to the vat, to be formed into sheets of paper. But lately, instead of pounding the rags to a pulp with large hammers, as above, they make use of an engine, which performs the work in much less time. This engine consists of a round solid piece of wood, into which are fastened several long pieces of steel, ground very sharp. This is placed in a large trough with the rags, and a sufficient quantity of water. At the bottom of the trough is a plate with steel bars, ground sharp like the former; and the engine being carried round with prodigious velocity, reduces the rags to a pulp in a very short time. It must be observed, that the motion of the engine causes the water in the trough to circulate, and by that means constantly returns the fluff to the engine. The trough is constantly fed with clean water at one end, while the dirty water from the rags is carried off at the other, through a hole, defended with wire gratings, in order to hinder the pulp from going out with the dirty water.

When the fluff is sufficiently prepared as above, it is carried to the vat, and mixed with a proper quantity of water, which they call priming the vat. The vat is rightly primed, when the liquor has such a proportion of the pulp, as that the mould, on being dipped into it, will just take up enough to make a sheet of paper of the thickness required. The mould is a kind of sieve exactly of the size of the paper to be made, and about an inch deep, the bottom being formed of fine brass wire, guarded underneath with sticks, to prevent it bagging down, and to keep it horizontal; and further, to strengthen the bottom, there are large wires placed in parallel lines, at equal distances, which form those lines visible in all white paper when held up to the light: the mark of the paper is also made in this bottom, by interweaving a large wire in any particular form. This mould the maker dips into the liquor, and gives it a shake as he takes it out, to clear the water from the pulp. He then slides it along a groove to the coucher, who turns out the sheet upon a felt laid on a plank, and lays another felt on it; and returns the mould to the maker, who by this time has prepared a second sheet in another mould: and thus they proceed, laying alternately a sheet and a felt, till they have made six quires of paper, which is called a poll, and this they do, with such swiftness, that, in many forts of paper, two men make twenty polls or more in a day. A poll of paper being made, either the maker or coucher whistles; on which four or five men advance, one of whom draws it under the press, and the rest press it with great force, till all the water is squeezed from it; after which it is separated sheet by sheet from the felts, and laid regularly one sheet upon another; and having undergone a second pressing, it is hung up to dry. When sufficiently dried, it is taken off the lines, rubbed smooth with the hands, and laid by till sized, which is the next operation. For this they chose a fine temperate day; and having boiled a proper quantity of clean parchment, or vellum shavings, in water, till it comes to a size, they prepare a fine cloth, on which they flew a due proportion of white vitriol and roch-alum finely powdered, and strain the size through it into a large tub; in which they dip as much paper at once as they can conveniently hold, and with a quick motion give every sheet its share of the size, which must be as hot as the hand can well bear it. After this, the paper is pressed, hung up sheet by sheet to dry; and being taken down, is sorted, and what is only fit for outside-quires laid by themselves; it is then told into quires, which are folded and pressed. The broken sheets are commonly put together, and two of the worst quires are placed on the outside of every ream or bundle; and being tied up in wrappers, made of the settling of the vat, it is fit for sale.

Paper is of various kinds, and used for various purposes; with regard to colour, it is principally distinguished into white, blue, and brown; and with regard to its dimensions, into atlas, elephant, imperial, super-royal, royal, medium, demy, crown, foolscap, and pot-paper.

Paper-office, an office in the palace of Whitehall, in which all the public writings, matters of state and council, proclamations, letters, intelligences, negotiations abroad, and generally all dispatches that pass through the offices of the secretaries of state, are lodged, by way of library.

Paphlagonia, an ancient province of the Jiffer Asia, situated on the Euxine-sea, now part of the province of Amasia in Turkey.

Paphos, once an elegant city at the west end of the island of Cyprus; but the little town of Baffo is now all that remains of it.

Papilio, the butterfly, in zoology, a genus of insects belonging to the order of lepidoptera. It has four wings, imbricated with a kind of downy scales; the tongue is convoluted in a spiral form; and the body is hairy. There are 273 species, principally distinguished by the colour of their wings.

Papilionaceous, among botanists, an appellation given to the flowers of plants belonging principally to the diadelpia clafs; from their resembling the figure of a butterfly.

Papous, or New Guinea, a large continent in the Pacific ocean, a little south of the equator; situated east of the Spence islands, in 130° east long. but how far it extends farther to the eastward or southward, is uncertain.

Pappus, in botany, a soft downy substance, that grows on the seeds of certain plants, as thistles, hawkweed, &c. serving to scatter and buoy them up in the air.

Par in commerce, signifies any two things equal in value. See Commerce.

Parable, a fable, or allegorical instruction, founded on something real or apparent in nature or history, from which a moral is drawn, by comparing it with something in which the people are more immediately concerned; such are the parables of Dives and Lazarus, of the Prodigal Son, of the Ten Virgins, &c.

Papoulce, made of paper, and called tapping. See Surgery.

Papula. See Conic Sections.

Paracentesis, an operation in surgery, commonly called tapping. See Surgery.

Paraclet, the Comforter, a name given to the Holy Ghost.

Paradisaea, in ornithology, a genus belonging to the order of pheas. The beak is covered with a belt or collar of downy feathers at the base; and the feathers on the sides are very long. There are three species, viz. 1. The spada, has the feathers on the sides longer than the body, and two long brilfully feathers in the tail. It is the greater bird of paradise, and feeds upon butterflies. They are
PARADISE, a term principally used for the garden of Eden, in which Adam and Eve were placed immediately upon their creation.

As to this terrestrial paradise, there have been many inquiries about its situation. It has been placed in the third heaven, in the orb of the moon, in the moon itself, in the middle region of the air, above the earth, under the earth, in the place poofled by the Capfian sea, and under the artice pole. The learned Huetius places it upon the river that is produced by the conjunction of the Tigris and Euphrates, now called the river of the Arabs, between this conjunction and the division made by the same river before it falls into the Perian sea. Other geographers have placed it in Armenia, between the sources of the Tigris, the Euphrates, the Araxis, and the Phafis, which they suppose to be the four rivers described by Moses.

The celestial paradise is that place of pure and refined delight, in which the souls of the bleffed enjoy everlasting happiness.

Bird of Paradise. See Paradisea.

PARADOX, in philosophy, a proposition seemingly absurd, as being contrary to fome received opinion, but yet true in fact.

No science abounds more with paradoxes than geometry: thus, that a right line fhould continually approach to the hyperbola, and yet never reach it, is a true paradox; and in the fame manner, a spiral may continually approach to a point, and yet not reach it, in any number of revolutions, however great.

PARÆA, in zoology. See Coluber.

PARAGOGOGE, in grammar, a figure whereby a letter or syllable is added to the end of a word; as med, for me; dicier, for dici, &c.

PARAGUAY, or La Plata, a province of South America, subject to Spain, lies between 12° and 35° S. lat. and between 50° and 75° W. long.

PARALIPOMENA, in matters of literature, denotes a supplement of things omitted in a preceding work.

PARALLACTIC, in general, fomething relating to the hyperbola, and yet never reach it, is a true paradox; and in the same manner, a spiral may continually approach to a point, and yet not reach it, in any number of revolutions, however great.

PARALLELA, in zology. See Coluber.

PARAPHRASE, an explanation of some text, in clearer and more ample terms, whereby is supplied what the author might have said or thought on the subject; such are esteemed Erasmus's paraphrase on the New Testament, the Chaldee paraphrase on the Pentateuch, &c.

PARALLELOPIPED, in geometry, a regular solid comprised under six parallelograms, the opposite ones whereof are similar, parallel, and equal.

PARALLELLOGRAM, in geometry, a quadrilateral right-lined figure, whose opposite sides are parallel and equal to each other.

PARALLELOPIPEDIA, in natural history, the name of a genus of spars, thus called, because regularly of a paralleloped form.

They are pellucid crystalline spars externally of a determinate and regular figure, always found loose, detached, and separate from all other bodies, and in form of an oblique paralleloped, with six parallelogram sides and eight solid angles, easily fitlfe either in an horizontal or perpendicular direction, being composed of numbers of thin plates, and those of very elegantly and regularly arranged bodies, each of the same form with the whole mass, except that they are thinner in proportion to their horizontal planes; and naturally fall into these and no other figures, on being broken with a light blow.

PARALOGISM, in logic, a false reasoning, or a fault committed in demonstration, when a consequence is drawn from principles that are false, or, though true, are not proved; or when a proposition is passed over that should have been proved by the way.

PARALYSIS, the Palsy. See Medicine, p. 97.

PARAMECIA, in natural history, a name given to fuch animalcules as have no visible limbs or tails, and are of an irregularly oblong figure.

PARAMETER, in conic fections, a conftant line, otherwise called latus rectum. See Conic Sections.

PARAMOUNT, in law, signifies the supreme lord of the fee.

PARANYMPH, among the ancients, the perfon who waited on the bridegroom, and directed the nuptial solemnities; called allo prounus, and auffpex, because the ceremonies began by taking auspícia. As the paranymp officiated only on the part of the bridegroom, a woman called prouna officiated on the part of the bride.

PARAPET, in fortification, an elevation of earth designed for covering the soldiers from the enemies cannon or small shot. See Fortification.

PARAPHERNAL goods in Scots law. See Law, Tit. vi. 8.

PARAPHIMOSIS, in medicine, a disorder in the penis, wherein the prepuce is shrunken, and withdrawn behind the glans, so as not to be capable of being brought to cover the same; which generally happens in venereal disorders. See Medicine.

PARAPHRASE, an explanation of some text, in clearer and more ample terms, whereby is supplied what the author might have said or thought on the subject; such are esteemed Erasmus's paraphrase on the New Testament, the Chaldee paraphrase on the Pentateuch, &c.

PARAPHERNIALIS, in medicine, an inflammation of the diaphragm. See Medicine.

PARAPHROSYNE, a word used by medical writers to express a delirium, or an alienation of mind in fevers, or from whatever cause.

VOL. III. No. 58. 2
PARAPLEGIA, a species of palsy. See Medicine.

PARASELENE, in physiology, a mock moon, a meteor, or phenomenon, encompassing, or adjacent to, the moon, in form of a luminous ring; wherein are sometimes observed, sometimes two, apparent images of the moon.

PARASITE, among the Greeks, was originally a very reputable title; the parasites being a kind of priests, at least ministers, of the gods, in the same manner as the Epulones were at Rome. They took care of the sacred corn, or the corn defined for the service of the temples, and the gods, viz. sacrifices, feasts; &c. they had even the intention over sacrifices, and took care that they were duly performed. At Athens, there was a kind of college of twelve parasites; each people of Attica furnishing one, who was always chosen out of the best families. Polybios adds, that a parasite was also an honourable title among the ancient Gauls, and was given to their poets; but of late it has been made a term of reproach, and used for a flatterer and mean dependant.

PARASITES, or parasitical plants, in botany, such plants as are produced out of the trunk or branches of other plants, from whence they receive their nourishment, and will not grow upon the ground, as the misleto.

PARASTATÆ, in anatomy. See Anatomy, p. 270.

PARASYNANCHE, in medicine, a kind of angina, or quinsy. See Medicine, p. 83.

PARATHENAR, in anatomy. See Anat. p. 212.

PARBUNCLE, in a ship, the name of a rope almost like a pair of strings: it is seizing both ends together, and then put double about any heavy thing that is to be hoisted in or out of the ship; having the hook of the runner hitched into it, to hoist it up by.

PARCE, in the heathen mythology, goddesses, who were supposed to preside over the accidents and events, and to determine the date or period, of human life. See Mythology.

PARCHMENT, the skins of sheep or goats prepared after such a manner as to render it proper for writing upon, covering books, &c.

The manufacture of parchment is begun by the skinner, and finished by the parchment-maker.

The skin having been stripped of its wool, and placed in the lime pit, the skinner flretches it on a kind of frame, and pares off the flesh with an iron instrument: this done, it is moistened with a rag; and powdered chalk being spread over it, the skinner takes a large pumice-stone, flat at bottom, and rubs over the skin, and thus scours off the flesh: he then goes over it again with the iron instrument, moistens it as before, and rubs it again with the pumice-stone without any chalk underneath: this smooths and softens the flesh-side very considerably. He then drains it again, by pausing over it the iron instrument as before. The flesh-side being thus drained, by foraping off the moisture, he in the same manner pales the iron over the wool or hair side: then stretches it tight on a frame, and scographs the flesh-side again; this finishes its draining; and the more it is drained, the whiter it becomes. The skinner now throws on more chalk, sweeping it over with a piece of lamb skin that has the wool on; and this smooths it still farther. It is now left to dry; and when dried, taken off the frame, by cutting it all round. The skin, thus far prepared by the skinner, is taken out of his hands by the parchment-maker: who first, while it is dry, pares it on a summer (which is a calf skin stretched in a frame) with a sharper instrument than that used by the skinner, and, working with the arm from the top to the bottom of the skin, takes away about one half of its thickness. The skin, thus equally pared on the flesh-side, is again rendered smooth, by being rubbed with the pumice-stone on a bench covered with a sack stuffed with flocks, which leaves the parchment in a condition fit for writing upon. The prings thus taken off the leather, are used in making glue, size, &c.

What is called vellum, is only parchment made of the skins of abortives, or at least fucking calves. This has a much finer grain, and is whiter and smoother than parchment; but is prepared in the same manner, except its not being passed through the lime-pit.

PARDALUS. See Leo.

PAREGORICS in pharmacy, medicines that affwage pain, otherwise called analogues.

PAREIRA BRAVA, in the materia medica, a kind of oblong and large root, brought from the Brazilis.

It is certainly a diuretic of no mean character, and has done great service in nephritic cases; and in pleurises and quinteys it has been attended with more success than almost any medicine we know of singly.

PARELCON, in grammar, a figure by which a word or syllable is added to the end of another.

PAREMOBLE, in rhetoric, a figure wherein something relating to the subject is inferred in the middle of a period. All the differences between the parembole and parenthesis, according to Voilius, is, that the former relates to the subject in hand, whereas the latter is foreign to it.

PARENCHYMA, in anatomy, a term introduced by Eratitrus, signifying all that substance which is contained in the interstices between the blood vessels of the vifeera, which he imagined to be extravaated and concreted blood.

PAREMBOLE. See Agriculture.

PARENTHESIS, in grammar, certain intercalary words, inserted in a discourse, which interrupt the sense, or thread, but seem necessary for the better understanding of the subject.

PARENT, a term of relation applicable to those from whom we immediately receive our being.

PARENTALIA, in antiquity, funeral obsequies, or the last duties paid by children to their deceased parents.

PARENTHESES, in grammar, certain intercalary words, inserted in a discourse, which interrupt the sense, or thread, but seem necessary for the better understanding of the subject.

PARENZO, or PIRENZO, a port-town of Ilflia, in the territory of Venice, situated on a bay of the gulph of Venice, twenty-five miles south of Cabo de Ilfria.

PARESIS, in medicine, is defined to be a palsy of the bladder, wherein the urine is either suppressed, or discharged involuntarily.

PARETONIUM, in natural history, the name of an earth

PARESIS, in medicine, is defined to be a palsy of the

PARENZO, or PIRENZO, a port-town of Ilfria, in the territory of Venice, situated on a bay of the gulph of Venice, twenty-five miles south of Cabo de Ilfria.
PARHELION, or PARHELUM, in physiology, a mock sun, or meteor, in form of a very bright light, appearing on one side of the sun.

The parhelia are formed by the reflection of the sun's beams on a cloud properly poised. They usually accompany the corona, or luminous circles, and are placed in the same circumference and at the same height. Their colours resemble that of the rainbow, the red and yellow are on the side towards the sun, and the blue and violet on the other. There are corona sometimes seen without parhelia, and vice versa.

Parhelia are double, triple, &c. and in 1629 a parhelion of five suns was seen at Rome, and in 1666 another at Arles of six.

M. Mariotta accounts for parhelia from an infinity of little particles of ice floating in the air, that multiply the image of the sun by refraction or reflection; and by a geometrical calculus he has determined the precise figure of these little icicles, their situation in the air, and the size of the corona of circles which accompany the parhelia, and the colours wherewith they are painted.

PARIA, a lake of Peru, in South America, in the province of Los Charcas, situated in 67° W. long. and 22° S. lat.

PARIETALIA ossa, in anatomy. See Anatomy, p. 154.

PARIETARIA, in botany, a genus of the polygama mo-nocla glass. The calix, both in the female and hermaphrodite, consists of four segments; none of them have any corolla; the hermaphrodite has four flamina; and both have one style, and one long seed. There are six species, only one of them, viz. the officinalis, or pellicaria, of London.

PARIETARIA, or PARHELION, in botany, a genus of the polygama monogna glass. The calix consists of four leaves, and the corolla of four narrow petals; and the berry has four cells. There is but one species, viz. the quadrifolia, herb-paris, or true-love, a native of Britain. It is esteemed an excellent and abortifacient.

PARIS, in botany, a genus of the octandria trigynia glass. The calyx consists of four leaves, and the corolla of four narrow petals; and the berry has four cells. There is but one species, viz. the quadrifolia, herb-paris, or true-love, a native of Britain.

Paris, in geography, the metropolis of the kingdom of France, and of the principality or government of the Isle of France, situated in E. long. 20° 25', N. lat. 48° 50', two hundred miles south-east of London, six hundred and eighty north-east of Madrid, five hundred and fifty west of Vienna, one thousand three hundred north-west of Conflantinople, and seven hundred north-west of Rome.

PARISH, the precinct of a parochial church, or a circuit of ground inhabited by people who belong to one church and are under the particular charge of its minister.

PARK, a large inclosure privileged for wild beasts of chase, either by prescription or the king's grant.

PARKINSONIA, in botany, a genus of the decandria monogynia glass. The calix consists of four segments, and the corolla of four oval petals, the lowest being kidney-shaped; it has no style; and the pod is cylindrical.

PARLEY, a conference with an enemy. Hence to beat or found a parley, is to give a signal for holding such a conference by beat of drum or sound of trumpet.

PARLIAMENT, is the grand assembly of the three estates of this kingdom, summoned together, by the king's authority, to consult of matters relating to the public welfare, and particularly to enact and repeal laws. It consists of the king, the lords spiritual and temporal, and the commons, and is at once the seat of the legislative authority, and the highest court of justice in Great Britain. In the house of lords, criminal causes are tried on the impeachment of the commons; and this house has an original jurisdiction for the trial of peers upon incriminations found by a grand jury; the lords likewise try such causes as come thither on appeals from the court of chancery, and all their decrees are as judgments. The house of commons examine the right of elections; regulate disputes concerning them; may expel their own members, and commit them to prison. They are the grand inquest of the nation; and present public grievances or delinquents to the king and lords, in order to their being punished. In short, they are the representatives of all the commons in the kingdom; and in them their constituents have placed the highest confidence, by inveting them with the power of making laws, and entrusting them with all their liberties and privileges.

Originally, new parliaments were called every year; but by degrees their term grew longer. In the reign of king Charles II. they were held a long time, with great interruptions between: but both methods were found of such ill consequence, that, in the beginning of the reign of king William III. an act was passed, by which the term of all parliaments was restrained to three sessions, or three years; this was hence called the triennial act; but since that time, from other views, the period of parliaments has been lengthened to seven years. A parliament is called by the king's writ or letter directed to each lord, commanding him to appear; and by other writs, directed to the sheriffs of each county, to summon the people to elect two knights for each county, and one or two burgesses for each borough. The number of the members in the house of lords is uncertain, as increasing at the king's pleasure. The members of the house of commons, when full, are five hundred and fifty-three; viz. ninety-two knights of the shires; fifty-two deputies for twenty-five cities, London having four; sixteen for the eight cinque-ports; two for each university; three hundred and thirty-two for an hundred and eighty boroughs; twelve for the boroughs in Wales, and forty-five members for Scotland. If three hundred of these members are not, it is reckoned a full house; and forty may compose a house for the dispatch of business.

Upon the holding of a parliament, the king, the first day, sits in the upper-house, under a canopy, with the crown on his head, and dressed in his royal robes; and there, by himself, or the lord chancellor, declares the reasons of their meeting, in the presence of both the lords and commons; and then the commons are required to chuse a speaker, who is presented to the king, and being approved by his majesty, the buifiness of the parliament goes on.

The lords and commons sit each in a distinct apartment: in the house of lords, the princes of the blood fit by themselves on the sides of the throne; the wall, on the king's right hand, the two archbishops sit by themselves on a form. Below them, the bishops of London, Durham, and Winchester, and all the other bishops, sit according to the priority of their consecration. On the king's left hand the lord-treasurer, lord president, and lord privy-seal, sit upon forms above all dukes, except the royal blood; then the dukes, marquisses, and earls, according...
Anciently all the people had votes in elections, till it was enacted by Henry VI. that none but freeholders, who had a yearly revenue of forty shillings, should be admitted to vote for knights of the shire.

The manner of debating upon, and passing bills in parliament, is as follows: Any member may move to have a bill brought in, which, upon a question put, being agreed to by the majority, this person, with others, is ordered to prepare and bring in the same. When it is ready, a time is appointed for its being read; and after the clerk's reading it, the speaker reads an abstract of it, and puts the question whether or no it shall have a second reading; and after a second reading, the question is put whether or no it shall be committed, which is either to a committee of the whole house if it be of importance, or to a private committee, any member naming the persons. The committee being appointed, and a chairman chosen, the chairman reads the bill paragraph by paragraph, puts every clause to the question, fills up the blanks, and makes amendments, according to the opinion of the majority. The bill thus gone through, the chairman makes his report at the side-bar of the house, reads all the additions and amendments, &c. and moves for leave to bring up the report to the table; which granted, he delivers it to the clerk, who reads the amendments, &c. The speaker then puts the question whether they shall be read a second time; and, if agreed to, he reads them himself. To so many of the amendments as the house acquiesces in, the question is now put. Whether the bill, thus amended, shall be ingrossed and written fair upon parchment, and read a third time? and the bill being ingrossed, the speaker puts the question whether or no it shall be committed, which is either to a committee of the whole house if it be of importance, or to a private committee, any member naming the persons. The committee being appointed, and a chairman chosen, the chairman reads the bill paragraph by paragraph, puts every clause to the question, fills up the blanks, and makes amendments, according to the opinion of the majority. The bill thus gone through, the chairman makes his report at the side-bar of the house, reads all the additions and amendments, &c. and moves for leave to bring up the report to the table; which granted, he delivers it to the clerk, who reads the amendments, &c. The speaker then puts the question whether they shall be read a second time; and, if agreed to, he reads them himself. To so many of the amendments as the house acquiesces in, the question is now put. Whether the bill, thus amended, shall be ingrossed and written fair upon parchment, and read a third time? and the bill being ingrossed, the speaker holds it in his hand, and asks if it shall pass. If the majority be for it, the clerk writes on it, Soit bâlie aux seigneurs, "Let it be delivered to the lords;" or if in the house of lords, Soit bâlie aux communes, "Let it be delivered to the commons." If a bill be rejected, it cannot be any more proposed during that session. A bill for a general pardon has but one reading.

When a member of the house of commons speaks, he stands up uncovered, and directs his speech to the speaker only. If what he says be answered by another, he is not allowed to reply the same day, unless personal reflections have been cast upon him: but when the commons, in order to have a greater freedom of debate, have resolved themselves into a committee of the whole house, every member may speak to a question as often as he thinks necessary. In the house of lords they vote, beginning at the pulpit, or lowest baron and so upwardsly to the highest, every one answering Content or Not content. In the house of commons they vote by yes and nays; and if it be dubious which are the greater number, the house divides. If the question be about bringing any thing into the house, the yes go out; but if it be about any thing the house already has, the nays go out. In all divisions the speaker appoints four tellers, two of each opinion. In a committee of the whole house, they divide by changing sides, the yes taking the right and the nays the left of the chair; and then there are but two tellers. If a bill passes one house, and the other demur to it, a conference is demanded in the painted chamber, where certain members are deputed from each house; and here the lords sit covered, and the commons stand bare and debate the case. If they disagree, the affair is null; but if they agree,
Parliaments of France, are sovereign courts, established by the king, finally to determine all disputes between particular persons, and to pronounce on appeals from decisions given by inferior judges. There are ten of these parliaments in France, of which that of Paris is the chief, its privileges and jurisdiction being of the greatest extent. It consists of six chambers, viz. the grand chamber, where causes of audience are pleaded; and five chambers of inquiry, where processe are adjudged in writing. This parliament enjoys the privileges of verifying and registering the king's arrests or edicts, without which those edicts are of little or no value.

There are ten of these parliaments in France, of which that of Paris is the chief, its privileges and jurisdiction being of the greatest extent. It consists of six chambers, viz. the grand chamber, where causes of audience are pleaded; and five chambers of inquiry, where processes are adjudged in writing. This parliament enjoys the privileges of verifying and registering the king's arrests or edicts, without which those edicts are of little or no value.

Parliaments of Sweden, consists of four estates, with the king at their head: these estates are, 1. The nobility and representatives of the gentry; with whom the colonels, lieutenant-colonels, majors, and captains of every regiment, sit and vote. 2. The clergy; one of which body is elected from every rural deanery of ten parishes; who, with the bishops and superintendents, amount to about two hundred. 3. The burghers, elected by the magistrates and council of every corporation as their representatives, of whom there are four for Stockholm, and two for every other town, amounting in the whole to about an hundred and fifty. 4. The peasants, chosen by the peasants out of every district; who chuse one of their own rank, and not a gentleman, to represent them: these amount to about two hundred and fifty.

All these generally meet at Stockholm; and after the state-affairs have been represented to them from the throne, they separate, and sit in four several chambers or houses, in each of which affairs are carried on by majority of votes; and every chamber has a negative in the passing any law.

Parma, the capital of the duchy of Parma, in Italy, sixty miles north-east of Genoa, is pleasantly situated on a river to which it gives name: E. long. 11°, N. lat. 44° 45'.

Parnassia, in botany, a genus of the pentandria tetraclase. The calix consists of five segments, and the corolla of five petals; it has five coccid nectaria, with round buttons on their points; and the capsule has four valves. There is but one species, viz. the palustris, or grass of Parnassus, a native of Britain.

Parnassus, a mountain of Greece, much celebrated by ancient poets, situated near Calipso in Livadia.

Parody, a popular maxim, adage, or proverb. Parody is also a poetical pleasantry, consisting in applying the verses written on one subject, by way of ridicule to another; or in turning a serious work into a burlesque, by affecting to observe, as nearly as possible, the same rhymes, words, and cadences.

Paronomasia, in rhetoric, a pun; or a figure whereby words nearly alike in sound, but of very different meanings, are affectedly or designedly used.

Paros, one of the smallest islands of the Cyclades, famous for its marble, situated in E. long. 25° 30', N. lat. 36° 30'.

Parotides, in anatomy. See Anatomy, p. 270.

Paroxysm, in medicine, the severe fit of a disease, unburdeous for its marble, situated in E. long. 25° 30', N. lat. 36° 30'.

Parotides, in anatomy. See Anatomy, p. 270.

Parody is also a poetical pleasantry, consisting in applying the verses written on one subject, by way of ridicule to another; or in turning a serious work into a burlesque, by affecting to observe, as nearly as possible, the same rhymes, words, and cadences.

Parotides, in anatomy. See Anatomy, p. 270.
an assemblage of which constitute all natural bodies.

It is the various arrangement and texture of these particles, with the difference of cohesion, &c. that constitute the various kinds of bodies. The smallest particles cohere with the flongest attraction, and compose bigger particles of weaker cohesion; and many of these cohering compose bigger particles, whose vigour is still weaker; and hereunto the operations in chemistry, and the colours of natural bodies, depend, and which, by cohering, compose bodies of sensibles bulk. The cohesion of the particles of matter, the Epicureans imagined, was effected by means of hooked atoms; the Aristotelians, by rest; but Sir Isaac Newton shews, that it is done by means of a certain power, whereby the particles mutually attract and tend towards each other. By this attraction of the particles, he shews, that most of the phenomena of the lesser bodies are affected, as those of the heavenly bodies are, by the attraction of gravity.

Particle, in grammar, a denomination for all those small words that tie or unite others together, or that express the modes or manners of words. See Grammar.

Partner, and Partnership. See Arithmetic, p. 386.

Partridge, in ornithology. See Tetrao.

Parturition. See Delivery.

Parulides, in surgery, tumours and inflammations of the gums, commonly called gum-boils.

They are to be treated with diffuents, like other inflammatory tumours.

Parus, in ornithology. See Certhia.

Paschal, something belonging to the passover or easter. See Passover, and Easter.

Paisley, a town of Scotland, in the county of Renfrew, six miles west of Glasgow.

Pasquin, a mutilated statue at Rome, in a corner of the palace of the Ursini: it takes its name from a cobbler of that city called Pasquin, famous for his screeers and gibes, and who diverted himself with paffing his jokes on all the people who went through that street. After his death, as they were digging up the pavement before his shop, they found in the earth the statue of an ancient gladiator, well cut, but maimed, and half spoiled: this they set up as they were digging up the pavement before his shop, six miles west of Glasgow.

Pasquinade, a satirical libel fastened to the statue of Pasquin: these are commonly short, merry, and pointed; and from hence the term has been applied to all other lampoons of the same cast.

Passade, in the menage, is a turn or course of a horse backwards or forwards, on the same spot of ground.

Birds of Passage, a name given to those birds which at certain stated seasons of the year remove from certain countries, and at other stated times return to them again, as our quails, woodcocks, storks, nightingales, swallows, and many other species. Among the birds of passage, the fieldfare, the redwing, the woodcock, and the snipe, come to us in the autumn, at the time when the summer-birds are leaving us, and go from us again in spring, at the time when these return; and of these the two last often continue with us through the summer, and breed: so that the two first seem the only kinds that certainly leave us at the approach of spring, retiring to the northern parts of the continent, where they live during the summer, and breed; and at the return of winter, are driven southerly from these frigid climates, in search of food, which there the ice and snow must deprive them of.

Passant, in heraldry, a term applied to a lion, or other animal, in a shield, appearing to walk leisurely: for most beasts, except lions, the term trippant is frequently used instead of passant.

Passao, or Cape Passao, a promontory of Peru, just under the equator: W. long. 81°.

Passau, the capital of the bishopric of the same name, in the circle of Bavaria, situated on the confluence of the rivers Danube, Inn, and Ills: E. long. 13° 30', N. lat. 48° 30'.

Passerina, in botany, a genus of the gynia class. It has no calix; the corolla consists of four segments, and the filament lie upon the tube. There are eight species, none of them natives of Britain.

Passiflora, in botany, a genus of the gynandria pentagyna class. It has three filii; the calix consists of five leaves, and the corolla of five petals; and the nectarium is a corona; and the berry is supported on a pedicle. There are 26 species, none of them natives of Britain, but are cultivated in gardens for the beauty of their flowers.

Passions, in medical philosophy, make one of the non-naturals, and produce very sensible effects. Joy, anger, and fear,
are the principal. In the two first, the spirits are hurried with too great vivacity; whereas, in fear or dread, they are is it we were curb'd and concentrac'd: whence we may conclude, that they have a very bad effect upon health; and therefore it will be best to keep them within bounds as much as possible, and to preferve an inward serenity, calmness, and tranquillity.

Passions, in painting, are the external expressions of the different dispositions and affections of the mind; but particularly their different effects upon the several features of the face: for though the arms, and indeed every part of the body, serve likewise, by their quick, languid, and variously diversified motions, to express the passions of the soul; yet, in painting, this difference is moft conspicuous in the face.

In sorrow, joy, love, shame, and compassion, the eyes swell all of a sudden, are covered with a superabundant moisture, and drop tears; and in grief especially, the corners of the mouth hang down, the eye-lids are half shut, and the pupil of the eye is elevated and half covered; and all the other muscles of the face are relaxed, so that the visage appears longer than ordinary.

In fear, terror, fright, and horror, the eye-brows are greatly elevated; the eye-lids are expanded as wide as possible, so as to discover the white of the eye; and the pupil is depressed, and half covered by the lower eye-lid; the hair stands an end; the mouth is at the same time wide open; and the lips so far drawn back, that the teeth both of the upper and under jaw appear.

Contempt is expressed by raising one side of the upper lip, so as to discover the teeth, whilst the other side has a movement like that in laughter; the eye, on that side where the teeth appear, is half shut, whilst the other remains open; however, both the pupils are depressed.

In jealousy, envy, hatred, and malice, the eye brows are knit; and, in laughter, all the parts agree, tending as it were towards the centre of the face.

Passion, or cross of the Passion, in heraldry, is so called, because resembling the shape of that on which our Saviour is thought to have suffered; that is, not crossed in the middle, but a little below the top, with arms short in proportion to the length of the shaft. See plate CXXXIV. fig. 12.

Passion-flower, in botany. See Passiflora.

Passion-week, the week immediately preceding the festival of Easter: so called, because in that week our Saviour's passion and death happened.

The Thursday of this week is called MaundayThursday; the Friday, Good Friday; and the Saturday, the great Sabbath.

Passive, in general, denotes something that suffers the action of another called an agent or active power.

In grammar, the verb or word that expresses this passion, is termed a passive verb: which, in the learned languages, has a peculiar termination, as amor, doreor, &c. in Latin.

Passover, a solemn festival of the Jews, celebrated on the fourteenth day of the month next after the vernal equinox, and instituted in commemoration of their coming out of Egypt; because on the night before their departure the destroying angel, who put to death the first born of the Egyptians, pass'd over the houses of the Hebrews; which were sprinkled with the blood of a lamb. The whole transaction is related in the twelfth chapter of Exodus.
P A T  ( 462 )

PATAGONIA, the most southern part of South America, extending from the mouth of the River di la Plata, in 36° of S. lat. to Cape Horn, in 55° 30'.

PATAGONULA, or Patagonica, in botany, a genus of the pteridaria monogynia class. The corolla is rotated; and the stylus is dichotomous. There is but one species, a native of America.

PATAVITY, among critics, denotes a peculiarity of Livy's diction, derived from Patavium, or Padua, the place of his nativity; but wherein this patavity consists, they are by no means agreed.

PATH, in general, denotes the course or track marked out; or run over by a body in motion. For the path of the moon, &c. see Astronomy, p. 465.

PATHETIC, whatever relates to the passions, or that is proper to excite or awake them.

PATHOGENOMONIC, among physicians, an appellation for a symptom, or concourse of symptoms, that are inseparable from a distemper, and are found in that only, and in no other.

PATHOLOGY, that part of medicine, which explains the nature of diseases, their causes and symptoms.

PATHOS, a Greek term, literally signifying passion, is sometimes used for the energy of a discourse, or its power to move the passions.

PATMOS, one of the isle of the islands of the Archipelago, subject to the Turks: E. long. 27°; and N. lat. 37°.

PATNA, a city of the hither India, the capital of the territory of the same name, in the province of Bengal: E. long. 85°; and N. lat. 26°.

PATANCE, in heraldry, is a cross, florid at the ends; from which it differs only in this, that the ends, instead of turning down like a fleur-de-lis, are extended somewhat in the pattee-form. See FLOWERY.

PATOMAC, a great river of Virginia, which arises in the Apalachian mountains, and after separating Virginia from Maryland falls into the bay of Chesapeake.

PATRAS, a city and port-town of European Turkey, in the province of the Morea: E. long. 21° 30'; and N. lat. 38° 20'.

PATURE PATRATUS, in Roman antiquity, the principal place of his nativity; but wherein this patavity consists, they are by no means agreed.

PATER NOSTER, the Lord's prayer, so called from the author and head of the Sabellians, and others. The author and head of the patripassians was Praxeas, a philosopher of Phrygia.

PATEGUA, or Patiique, a city of Mexico, W. long. 103°; N. lat. 21°; subject to Spain.

PATE, in fortification, a kind of platform, resembling what is called a horse-shoe.

PATEE, or Patte'e, in heraldry, a cross, small in the centre, and widening to the extremities, which are very broad. See Plate CXXXIV. fig. 13. which is a cross patee, argent, upon a field sable.

PATELLA, in anatomy. See Anatomy, p. 185.

PATELLA, the LIMPET, is a genus of invertebrates belonging to the order of vermes telesaeae. It is an animal of the final kind; the shell consists of one conical valve, without any spiral. There are 36 species, principally distinguished by peculiarities in their shells.

PATENT, in general, denotes something that stands open or expanded: thus a leaf is said to be patent when it stands almost at right angles with the stalk.

PATENT, or LETTERS-PATENT. See LETTER.

PATER PATRATUS, in Roman antiquity, the principal person among the seculae or college of heralds.

PATER NOSTER, the Lord's-prayer, so called from his ancestors.

PATTERINGTON, a market-town of Yorkshire, situated at the mouth of the Humber, fifty miles east of York.

PATRIPASSIANS, in church-history, a Christian sect, which appeared about the latter end of the IIth century; so called from their ascribing the passion to the Father: for they ascribed the unity of God in such a manner as to delireously all distinction of persons, and to make the Father and Son precisely the same; in which they were followed by the Sabellians, and others. The author and head of the patripassians was Praxeas, a philosopher of Phrygia in Asia.

PATROL, in war, a round or march made by the guards, or watch, in the night-time, to observe what passes in the streets, and to secure the peace and tranquility of a city or camp.

PATRON, among the Romans, was an appellation given to a master who had freed his slave. As soon as the relation of master expired, that of patron began; for the Romans, in giving the slaves their freedom, did not deprive themselves of all right and privileges in them; the law still subjected them to considerable services and duties towards their patrons, the neglect of which was very severely punished.

PATRON, in the church of Rome, a saint, whose name a perfon bears, or under whose protection he is put, and whom he takes particular care to invoke; or a saint, in whose name a church or order is founded.

April, and the last in August and September; and the more rain there falls in the year, the more plentiful are these fisheries. At the beginning of the season there are sometimes two hundred and fifty barks on the banks; the larger barks having two divers, and the smaller one. As soon as the barks arrive at the place where the fish lie, and have cast anchor, each diver binds a stone fix inches thick, and a foot long, under his body; which serves him as ballast, prevents his being driven away by the motion of the water, and enables him to walk more steadily under the waves. They also tie another very heavy stone to one foot, by which they are very speedily sent to the bottom of the sea: and as the oysters are usually firmly fixed, they arm their hands with leather mittens to prevent their being wounded in pulling them violently off; but this talk some perform with an iron rake. In the last place, each diver carries down with him a large net in the manner of a sack, tied to his neck by a long cord, the other end of which is fastened to the side of the bark. This net is to hold the oysters gathered from the rock, and the cord is to pull up the diver when his bag is full, or he wants air.

In this equipage he sometimes precipitates himself sixty feet under water; and as he has no time to lose, he no sooner arrives at the bottom, than he begins to run from side to side tearing up all the oysters he meets with, and cramming them into his budget.

At whatever depth the divers are, the light is so great, that they easily see whatever passeth in the sea: and to their great conformation sometimes perceive monstrous fishes, from which all their address in mudding the water, &c. will not always save them, but they unhappily become their prey: and of all the dangers of the fishery, this is one of the greatest and most usual. The bell divers will keep under water near half an hour, and the rest do not stay less than a quarter. During this time they hold their breath without the use of oils, or any other liquors; only acquiring the habit by long practice. When they find themselves fastened, they pull the rope to which the bag is fastened, and hold fast by it with both hands; when those in the bark, taking the signal, heave them up into the air, and unload them of their fish, which is sometimes five hundred oysters, and sometimes not above fifty. Some of the divers need a moment's respite to recover breath; others jump in again instantly, continuing this violent exercise without intermission for several hours.

On the shore they unload their barks, and lay their oysters in an infinite number of little pits dug in the sand four or five feet square; raising heaps of sand over them to the height of a man; and in this condition they are left, till the rain, wind, and sun have obliged them to open, which soon kills them: upon this the flesh rots and dries, and the pearls, thus disengaged, fall into the pit, on their taking out the shells. After clearing the pits of the großer fish, they sift the sand several times in order to find the pearl: but whatever care they take, they always lose a great many. After cleaning and drying the pearls, they are puffed through a kind of sieve, according to their sizes: the smallest are then sold as feed-pearls, and the rest put up to auction, and sold to the highest bidder.

Artificial Pearls, are made by reducing feed-pearls to a paste, by means of a chemical preparation called mercurial water, making the beads in silver-moulds, boring them with a hog's bristle, and drying them in a closed glass in the sun.

Beads, in imitation of pearls, are also made of wax, and covered with the scales of several kinds of fishes.

Mother of Pearl, is the shell, not of the pearl-oyster, but of another sea-fish of the oyster-kind. This fish on the inside is extremely smooth, and of the whiteness and water of pearl itself; and it has the same lustre on the outside, after the first laminae or scales have been cleared off with aquafortis and the lapidaries mill. Mother of pearl is used in inlaid works, and in several toys, as suffices, &c.

Pearl islands, several small islands situated in the bay of Panama; W. long. 81°, and between 7° and 9° of north lat.

PEAT, a kind of turf used for fuel in several countries.

PEBBLES, the name of a genus of fossils, distinguished from the flints and homochroa by their having a variety of colours. These are defined to be stones, composed of a crystalline matter, debased by earths of various kinds in the same species, and then subject to veins, clouds, and other variegations; usually formed by incrustations round a central nucleus, but sometimes the effect of a simple concretion, and veined like the agates, by the disposition the motion of the fluid they were formed in gave their differently coloured substanices.

PECCANT, in medicine, a term used for those humours of the body which offend either by their quantity or quality.

PECK, a measure of capacity, four of which make a bushel.

PECORA, in natural history, the name of a class of quadrupeds. See Natural History.

PECTORAL, an epithet for medicines good for disorders of the breast and lungs.

PECTORALIS, in anatomy. See Anatomy, p. 194. 195.

PECTORIS os, in anatomy. See Anatomy, p. 175.

PECULIUM, the stock or estate which a person in the power of another, as a slave, may acquire by his industry, the discipline and direction of a scholar.

PEDANT, is used for a rough unpollished man of letters, who makes an impertinent use of the sciences, and abounds in unseasonable criticisms and observations.

PEDARIAN, in Roman antiquity, those senators who signified their votes by their feet, not their tongues; that is, such as walked over to the fide of those whose opinion they approved of, in divisions of the house.

PEDESTAL, in architecture. See Architecture, p. 356.

PEDICLE, among botanists, that part of a flalk which immediately sustains the leaf of a flower or a fruit, and is commonly called, a foot-flalk.

PEDICULARIS, in botany, a genus of the didynamia angio sperma clafs. The calix consists of five segments; the capsule is sharp-pointed, oblique, and has two cells; and the seeds are covered with a tunic. There are 14 species, two of which are natives of Britain, viz. the sylvatica, or common louf-e-wort; and the palustris, or marsh louf-e-wort.

This plant is of a cooling and drying nature, whence
PEER, in general, signifies an equal, or one of the same kind of vermin, is cleanliness.

PEDILUVIUM, a bathing of the feet. This bath may either consist of light pure water alone; or, to correct the qualities of heavy and hard water, a lixivium or bran of wheat or chamomile-flowers may be added.

PEDIMENT, in architecture. See Architecture, p. 287.

PEEK, in the sea-language, is a word used in various senses. Thus the anchor is laid to be a peek, when the ship being about to weigh comes over her anchor in such a manner that the cable hangs perpendicularly betwixt the haufe and the anchor. To heave a peek is to bring the peek so as that the anchor may hang a peek.

PEER, in general, signifies an equal, or one of the same rank and station. The term peer is now applied to those who are impanelled in an inquest upon a perfon for convicting or acquitting him of any offence laid to his charge; and the reason why the jury is so called, is, because by the common law, and the custom of this kingdom, every perfon is to be tried by his peers or equals, a lord by the lords, and a commoner by commoners.

PEER OF THE REALM, a noble lord who has a seat and vote in the house of lords, which is also called the house of peers. These lords are called peers, because, though there is a distinction of degrees in our nobility, yet in public actions they are equal, as in their votes in parliament, and in trying any nobleman or other person impeached by the commons, &c. See Parliament.

PEERS OF FRANCE, the twelve great lords of that kingdom, of which six are dukes, and six counts; and of thefe, five are ecclesiastics, and six laymen: thus, the archbishop of Rheims, and the bishop of Laon and Langres are dukes and peers; and the bishops of Chalon on the Marn, Noyon, and Beauvais, are counts and peers. The dukes of Burgundy, Normandy, and Aquitain, are lay peers and dukes; and the counts of Flanders, Champaign, and Toloufe, lay peers and counts. These peers still assist at the coronation of kings, either in person or by their representatives, where each performs the functions attached to his respective dignity: but as the five lay peers are all at present united to the crown except that of the count of Flanders, six lords of the first quality are chosen to represent them; but the ecclesiastical peers usually assist in person. At present the title of peer is bestowed on every lord whose estate is erected into a peerage, the number of which is uncertain, and it depends entirely on the king.

PEERESS, a woman who is noble by descent, creation, or marriage.

If a peeress, by descent or creation, marries a person under the degree of nobility, the title continues noble; but if she obtains that dignity only by marriage, the loss of it on her afterwards marrying a commoner; yet, by the courtesy of England, she always retains the title of her nobility.

PEEVIT, in ornithology. See Larus.

PEGANUM, in botany, a genus of the dodecanidia monogynia class. The corolla consists of five petals, and the calyx of five leaves; the capsule has three cells, and three valves, containing many seeds. There are two species, none of them natives of Britain.

PEGASUS, in astronomy. See Astronomy, p. 487.

PEGU, the capital of the kingdom of Pegu, and situated upon a river of the same name, in 97° E. long. and N. lat. 17° 30'.

PEGUSUS, in astronomy. See Astronomy, p. 487.

PEKIN, the metropolis of the empire of China, is situated in E. long. 111°, and N. lat. 40°.

It is about twenty miles in circumference, and is said to contain 2,000,000 of people.

PELAGIANS, a Christian sect who appeared about the latter end of the fourth, or the beginning of the fifth century. Pelagius, the author of this sect, was born in Wales, and his name was Morgan, which in the Welsh language signifies sea-born; from whence he had his Latin name Pelagius. Some of our ancient historians pretend that he was abbot of Bangor; but this is impossible, because the British monasteries were of a later date. St Aulfin gives him the character of a very pious man, and a Christian of no vulgar rank: according to the same father, he travelled to Rome, where he associated himself with persons of the greatest learning and figure, and wrote his commentaries on St Paul's Epistles, and his letters to Melania and Demetrias; but being charged with herefy, he left Rome, and went into Africa, and from thence to Jerusalem, where he died. He died somewhere in the east; but where, is uncertain. He was charged with maintaining the following doctrines: 1. That Adam was by nature mortal, and, whether he had sinned or not, would certainly have died. 2. That the consequences of Adam's sin were confined to his own person. 3. That newborn infants are in the same condition with Adam before the fall. 4. That the law qualified men for the kingdom of heaven, and was founded upon equal promises with the gospel. 5. That the general resurrection of the dead does not follow in virtue of our Saviour's resurrection. 6. That the grace of God is given according to our merits. 7. That this grace is not granted for the performance of every moral act, the liberty of the will, and information in points of duty being sufficient, &c.

PELICANUS, in ornithology, a genus belonging to the order of anfears. The bill is straight, without teeth, and crooked at the point; the face is naked; and the feet are palmed. There are eight species, principally distinguished by the shape of their tails.

PELICAN, in ornithology. See Pelicanus.

PELLETS,
PENICILLUS, among surgeons, is used for a tent to be put into wounds or ulcers.

PENINSULA. In geography, a portion or extent of land, joining to the continent by a narrow neck or isthmus, the rest being encompassed with water.

PENS, in anatomy. See Anatomy, p. 270.

PENSCOLA, a port town of Spain, in the province of Valencia, situated on the Mediterranean, under the meridian of London, and in N. lat. 40° 29'.

PENNY, an ancient silver coin, which, though now little used, was the only one current among our Saxon ancestors.

PENNY EARTH, in agriculture, denotes a hard loamy, or sandy earth, with a large proportion of sea-shells intermixed with it.

PENNY-WEIGHT, a Troy-weight, containing twenty-four grains, each of which is equal in weight to a grain of wheat, gathered out of the middle of the ear, and well dried.

PENRISE, a port-town of Wales, in the county of Glamorgan, situated on Bristol Channel, seventeen miles south of Carmarthen.

PENRYN, a borough-town of Cornwall, near a bay of the English Channel: W. long. 5° 35', N. lat. 50° 20'. It sends two members to parliament.

PENNSANCE, a market-town of Cornwall, eight miles east of the Land's end.

PENNSILVANIA, one of the English plantations in America, two hundred miles in length, and almost as much in breadth: situated between 74 and 78° of well longitude, and between 39 and 42° of north latitude; a fine fruitful country, bounded by the five nations of the Iroquois on the north, by New-Jersey and New-York on the east, and by Maryland on the south and west. It is a proprietary government, the heirs of Mr. Penn, a quaker, who settled this country, appointing the governor.

PENSION, a sum of money paid annually for services or considerations already past. The yearly payment of each member to the house of the inn of courts, are likewise termed pensions; and the yearly assembly of the members of the society of Gray's Inn, to consult on the affairs of the house, is also called a pension.

PENSIONER, in general, denotes a person who receives a pension, yearly salary, or allowance. Hence, the band of gentleman-pensioners, the noblest fort of guard to the king's person, confists of forty gentlemen, who receive a yearly pension of one hundred pounds. This honourable band was first instituted by King Henry VIII and their office is to attend the king's person, with their battle-axes, to and from his chapel-royal, and to receive him in the presence chamber, or coming out of his privy-lodgings; they are also told to attend at all great solemnities, as coronations, St. George's feast, public audiences of ambassadors, at the sovereign's going to parliament.

They are each obliged to keep three double horses and a servant, and so are properly a troop of horse. They wait half a year, quarterly; but on Christmas-day, Easter-day, Whitsunday, &c. and on extraordinary occasions, they are all obliged to give their attendance.

PENTACROSISTIC, in poetry, a set of verses so disposed as that there are always five acrostics of the same name, in five divisions of each verse.

PENTAEDESTYSTILCA, in natural history, the name of a genus of spars. See Spar.
The bodies of this genus are sparse, in form of pentagonal columns, terminated by pentagonal pyramids at one end, and irregularly affixed at the other to some solid body.

PENTAGON, in geometry, a figure of five sides and five angles. See Geometry.

PENTAGRAM, an instrument whereby designs of any kind may be copied in what proportion you please, without being skilled in drawing.

PENTAMETER, in ancient poetry, a kind of verse consisting of five feet or metres; whence the name.

The two first feet may be either dactyls or spondees, at pleasure; the third is always a spondee, and the last anapestis.

PENTANDRIA, in botany. See Botany, p. 635.

PENTAPETALOUS, an appellation given to flowers that consist of five petals or leaves.

PENTAPETES, in botany, a genus of the monadelphia decandria class. The calix is simple; the capsule has five cells, containing many membranaceous seeds. There are three species, none of them natives of Britain.

PENTASTYLE, in architecture, a building wherein there are five rows of columns.

PENTATEUGH, an appellation given to the first five books of the Old Testament, viz. Genesis, Exodus, Leviticus, Numbers, and Deuteronomy, &c.

PENTATHLON, in antiquity, a general name for the five exercices performed at the Grecian games, viz. wrestling, boxing, leaping, running, and playing at the discus.

PENTECOST, a solemn festival of the Jews, so called because it was celebrated on the fiftieth day after the departure of the Israelites came out of Egypt.

PENTHORUM, in botany, a genus of the decandria pentagnia class. The calix consists of five segments; the petals are from five to nine; and the capsule has five cells. There is but one species, viz. the sedoides, a native of Virginia.

PENULTIMA, or PENULTIMATE SYLLABLE, in grammar, denotes the last syllable but one of a word, and hence the anti-penultimate syllable is the last but two, or that immediately before the penultima.

PENUMBRA, in astronomy, a partial shade observed between the perfect shadow and the full light in an eclipse. It arises from the magnitude of the sun's body; for were he but a luminous point, the shadow would be all perfect; but by reason of the diameter of the sun, it happens that a place which is not illuminated by the whole body of the sun does yet receive rays from a part thereof.

PEPLIS, in botany, a genus of the hexandria monogynia class. The perianthium is bell-shaped, with twelve segments; the petals are fixed, inserted into the calyx; and the capsule has two cells. There are two species, none of them natives of Britain.

PEPO, in botany. See Cucurbita.

PEPPER, in botany. See Piper.

PERAMBULATOR, in surveying, an instrument for measuring distances, called also penambulator, way-writer, and surveying wheel.

It consists of a wheel AA (Plate CXXXIV. fig. 15. n° 1.) two feet seven inches and a half in diameter; consequently half a pole, or eight feet three inches, in circumference. On one end of the axis is a nut, three quarters of an inch in diameter, and divided into eight teeth; which, upon moving the wheel round, fall into the eight teeth of another nut (ibid. n° 2.) fixed on one end of an iron-rod Q., and thus turn the rod once round in the time the wheel makes one revolution. This rod, lying along a groove in the side of the carriage of the instrument, under the dotted line, has at its other end a square hole, into which is fitted the end 6 of a small cylinder P. This cylinder is disposed (ibid. n° 3.) under the dial-plate of a movement, at the end of the carriage B, in such a manner as to be moveable about its axis: its end a is cut into a perpetual screw, which falling into the thirty-two teeth of a wheel wheel having perpendicularly thereto, upon driving the instrument forward, that wheel makes a revolution each sixteenth pole. On the axis of this wheel is a pinion with fix teeth, which, falling into the teeth of another wheel of fixty teeth, carries it round ever hundred and sixtieth pole, or half a mile.

This last wheel, carrying a hand or index round with it over the divisions of a dial-plate, whose outer limb is divided into one hundred and sixty parts, corresponding to the one hundred and fifty poles, points out the number of poles passed over. Again, on the axis of this last wheel is a pinion, containing twenty teeth, which falling into the teeth of a third wheel which hath forty teeth, drives it once round in three hundred and twenty poles, or a mile. On the axis of this wheel is a pinion of twelve teeth, which, falling into the teeth of a fourth wheel having seventy-two teeth, drives it once round in twelve miles.

This fourth wheel, carrying another index over the inner limb of the dial-plate, divided into twelve miles, and each mile subdivided into halves, quarters, and furthons, serves to register the revolutions of the other hand, an it to keep account of the half miles and miles passed over as far as twelve miles.

The use of this instrument is obvious from its construction. Its proper office is in the surveying of roads and large distances, where a great deal of expedition, and not much accuracy, is required. It is evident, that driving it along, and observing the hands, has the same effect as dragging the chain, and taking account of the chains and links.

Its advantages are its handiness and expedition; its contrivance is such, that it may be fitted to the wheel of a coach, in which state it performs its office, and measures the road without any trouble at all.

PERCA, the PEACh, in ichthyology, a genus belonging to the order of thoracici. The head is furnished with scaly and serrated opercula; there are seven rays in the membrane of the gills; and the fins on the back are prickly. There are 38 species, principally distinguished by peculiarities in the back fins.

PERCEPTION, in logic, the first and most simple act of the mind, whereby it perceives or is conscious of its ideas. See Logic.

PERCH. See PERCA.
PERIHELIUM. In agronomy, that point of a planet's or moon's orbit wherein it is in its least distance from the sun; in which sense it stands opposed to aphelium.

PERICRANIUM. In anatomy. See Anatomy, p. 279.

PERIGUEUX, a city of France, in the province of Gironde, capital of the territory of Perigord, situated on the river Lisle; in E. long. 7° 5', N. lat. 45° 1'.

PERIGRAPHIC. A word usually understood to express the white lines or impressions that appear in the musculus rectus of the abdomen.

PERIGEE, in astronomy, that point of the moon's orbit wherein it is in its least distance from the earth, in which sense it stands opposed to apogee.

PERICARPIUM, among botanists. See Botany, p. 637.

PERICHORUS, in antiquity, a name given by the Greeks to their profane games and combats, that is, to such as were not consecrated to any of the gods.

PERICRANIAL, in botany, applied to those plants whose roots will abide many years, whether they retain their leaves in winter or not; those which retain their leaves are called evergreens; but such as cast their leaves, are called deciduous, or peridifols.

PERFORATUS manus, in anatomy. See Anatomy, p. 201.

PERFORATUS pedis, in anatomy. See Anatomy, p. 211.

PERFORATUS manus, in anatomy. See Anatomy, p. 201.

PERFORATUS pedis, in anatomy. See Anatomy, p. 211.

PERFORATUS manus, in anatomy. See Anatomy, p. 201.

PERFORATUS pedis, in anatomy. See Anatomy, p. 211.

PERISTYLE, in ancient architecture, a building encompassed with a row of columns on the inside.

PERIODIC, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, in grammar, denotes a small compass of discourse containing a perfect sentence, and distinguished at the end by a point, or full stop, thus (.); and its members or divisions marked by commas, colons, &c.

PERIODIC, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODIC, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIODICAL, or Periodical, something that terminates and comprehends a period; such is a periodic month, being the space of time wherein the moon dispatches her period.
it, are punishable by fine, imprisonment, pillory, transportation, &c. See Law, Tit. xxxii. 34.

PERMEABLE, a term applied to bodies of loose and porous a structure, as to let something pass through them.

PERMUTATION, in commerce, the same with bartering.

PERORATION, in rhetoric, the epilogue, or last part of an oration, wherein what the orator had insisted on through his whole discourse, is urged afresh with greater vehemence and passion.

PERSPECTIVE teaches how to represent objects on a plane superficies, such as they would appear at a certain distance and height, upon a transparent plane perpendicular to the horizon, placed between the objects and the eye. In order to understand this subject, a general knowledge of the principles of Optics is absolutely necessary. The foundation of perspective...
The eye, however, being all the while opposite to the object, as it were, presents to us two sides or faces. The point of direct view, or of the front, is when we have the object directly before us; in which case, the eye sees the object laterally, and it presents to us two sides or faces.

The point of oblique view is, when we see an object a-side of us, and as it were slant, or with the corner of the eye; the eye, however, being all the while opposite to the point of view; in which case, we see the object laterally, and it presents to us two sides or faces.

The business of perspective, therefore, is to lay down geometrical rules for finding the points a, b, d, e, f, upon the plane; and hence also we have a mechanical method of delineating any object very accurately.

Perspective is either employed in representing the iconographies or ground plots of objects; or the scenographies, or representations of the objects themselves.

But before we give any examples of either, it will be proper to explain some technical terms in regard to perspective in general: and first, the horizontal line is that which is supposed to be drawn parallel to the horizon through the eye of the spectator; or rather it is a line which separates the heaven from the earth, and which limits the sight. Thus, A, B, (ibid. fig. 2) are two pillars below the horizontal line, CD; by reason the line is elevated above them; in fig. 3, they are laid to be equal with it, and in fig. 4, raised above it. Thus, according to the different points in view, the objects will be either higher or lower than the horizontal line. The point of sight A (ibid. fig. 5) is that which makes the central ray on the horizontal line ab; or, it is the point where all the other visual rays DD unite. The points of distance, C, C, are points let off in the horizontal line at equal distances on each side of the point of sight A; and in the same figure BB represents the base line, or fundamental line: EE is the abridgment of the square; of which DD, are the sides; F, F, the diagonal lines, which go to the points of distance C, C. Accidental points are those where the objects end: these may be call negligently; because neither drawn to the point of sight, nor to those of distance, but meeting each other in the horizontal line. For example, two pieces of square timber G and H (ibid. fig. 6) make the points I, I, I, I on the horizontal line; but go not to the point of sight K, nor to the points of distance C, C; these accidental points serve likewise for callimeters, doors, windows, tables, chairs, &c.

The point of direct view, or of the front, is when we have the object directly before us; in which case, it shews only the foreside; and, if below the horizon, a little of the top; but nothing of the sides, unless the object be polygonal. Thus the plan ABCD, (ibid. fig. 7) is all in front, and if it were raised we should not see any thing of the sides AB or CD, but only the front AD: the reason is, that the point of view E being directly opposite thereunto, causes a diminution on each side; which however is only to be understood where an elevation is the object; for it be a plan, it shews the whole, as ABCD.

The point of oblique view is, when we see an object a-side of us, and as it were slant, or with the corner of the eye; the eye, however, being all the while opposite to the point of view; in which case, we see the object laterally, and it presents to us two sides or faces.
Plate CXLII.

Phasianus Gallus
or common Cock & Hen.

Pavo cristatus
or Peacock.

Hen.
or raise the angle \( B^\circ \), and falling perpendicularly on \( BD \).

This being continued as a base line, lay your ruler on the side of the square \( AD \) and \( DC \), and where the ruler cuts the terrestrial line make the points \( H \) and \( I \).

Then from \( H \) and \( B \) draw lines to the point of distance \( P \); and from \( I \) draw a line to the other point of distance \( G \); and in the intersection of those lines, make points, which will give you the square \( KLMB \).

To do without the plan: set off the diameter each way from the middle point \( B \), as to \( H \) and \( I \). But in either case no line is to be drawn to the point of sight \( O \).

To diminish a Circle. See Plate CXLIII. fig. 13.

Draw a square \( ABCD \) about it, and from the angles \( AD \) and \( CB \) draw diagonals, dividing the circle into eight parts, and through the points where they cut it, draw lines from the base line perpendicular to \( DEF \).

Then draw two diagonals \( QR \), \( SP \), intersecting each other at right angles in the centre \( G \).

Having thus disposed the plan, draw lines from all the perpendiculars to the point of sight \( H \); and where they are intersected by the diagonals \( AK \) and \( BI \), make points; the two last of which \( M, N \) give the square, which is to be divided into four by diagonals, intersecting each other in the point \( P \).

In the left place, from the extremes of this cross, draw curve lines through the said points, which will give the form of the circle in perspective.

Of the measures upon the base in perspective. Pl. CXLIV.

By the base line alone any depth may be given, and in any place at pleasure, without the use of squares; which is a very expeditious way.

As for example, suppose the base line \( BS \), (fig. 1.) the point of view \( A \), and the points of distance \( DE \); if now you would make a plan of a cube \( BC \), draw two occult or dotted lines from the extremes \( BC \) to the point of sight; then to give the breadth, take the same measure \( BC \), and set it off from \( A \), as for instance, to \( P \), and then from \( P \) drawing a line to \( H \); and where this cuts the other parallels, will be formed the plan required; which you may make either round or square.

To find the height and proportion of any objects, as they appear above the horizon on a suppositious plane. See Plate CXLIV. fig. 3.

First rule your horizontal line \( NO \), and fix your point of sight, as at \( M \); then make the place of your nearest pillar, by making a dot for the base or bottom, as at \( A \); and another for the summit or top, as at \( B \); rule a line from \( A \) to the point of sight \( M \), and another from \( B \) to \( M \), and these two lines will give the height of any number of pillars. As for example: Suppose you would have a pillar at \( C \), fix your dot for the base, and rule from thence a parallel line to meet the diagonal \( AM \) at \( D \); then rule the perpendicular \( DE \) to the diagonal \( BM \); which perpendicular is the height of your figure required at \( C \). Or, if you would place pillars at \( F \) and \( I \), observe the same method, ruling the parallels \( FG \) and \( IK \), and the perpendiculars \( GH \) and \( KL \) will give their heights at the distances required.

To find the diameter or thickness of pillars at any particular distances, you are also to be guided by that nearest the base. For instance: Suppose your nearest pillar \( AB \) to be ten feet high, and one foot in diameter: divide it from top to bottom into ten equal parts, and set off one of them upon the base of the pillar: then rule a line from the point of sight \( M \) to the diameter \( P \), and you will have the thickness of all your pillars on their respective parallels or bases.

The same rule exemplified in objects below the horizon. See Plate CXLIV. fig. 4.

If you would know the heights of a number of figures below the horizon, rule your horizontal line \( QR \), and fix your point of sight, as at \( P \); then place your nearest figure, or mark the dots for the head and feet, by the points \( A \) and \( B \), which answer the same purpose; and rule from these dots to the point of sight the lines \( AP \) and \( BP \); and if you would find the height of a figure to be drawn at \( c \), rule from thence the parallel \( cd \) to the diagonal \( BP \), and the perpendicular \( de \) will give the height required. The same directions will give the height of a figure at any other distance you have a mind to place it, as at \( f \), \( i \), and \( m \), by ruling the parallels \( fg \), \( ik \), and \( mn \); and from each of these their respective perpendiculars \( gb \), \( kl \), and \( no \); which perpendiculars will give the heights of the figures at \( f \), \( i \), and \( m \).

4. To draw a direct view. See Plate CXLIV. fig. 4.

To illustrate this example, suppose you were to draw the inside of a church, as represented in this figure: First take your station at the point \( A \), in the centre of the base line.

Vol. III. No. 88. 2
hues inferred, is the point of sight F. This perpendicular is divided by the perpendicular EA; and where these two lines intersect, is the point of sight F. This perpendicular will pass through the centres of all the arches in the dome or cupola; which centres may be found by any three given points. Next divide your base line into any given number of feet; and the visual lines, ruled from these divisions to the point of sight, will reduce all your objects to their just proportion, by setting off their height upon a perpendicular raised at their respective distances. The base, in the example here given, is divided into twelve equal parts of five feet each; from which (supposing your front column to be 35 feet high) take seven divisions from the base line of your drawing, and set them off upon the perpendicular GH; to be, 35 feet high) take seven divisions upon the parallel IK, which is the breadth required. So that, by proportioning this scale you may set off one of those divisions upon the parallel IK, which is (supposing this column to be five feet thick at the base) your horizon at any height you think proper, as at DE: then from this point of sight the lines FIF and KF; after which, rule the diagonals from D to C, and from E to E, and the perpendicular FG, raised through the point of their intersection, will shew the true centre of the roof, as will appear by ruling the lines GE and GC.

To find the centre for the roof of a house, in an oblique view.

See fig. 8. of Plate CXLIV.

Suppose from the point of sight A, the visual lines AB and AC be drawn, BC being one perpendicular given, and DE the other, rule the diagonals from D to C, and from E to E, and the perpendicular FG, raised through the point of their intersection, will shew the true centre of the roof, as will appear by ruling the lines GE and GC.

For want of being acquainted with this necessary rule, many who have been well versed in other parts of perspective, have spoiled the look of their picture, by drawing the roofs of their houses out of their true perpendicular.

We shall conclude by giving a few practical rules. 1. Let every line, which in the object, or geometrical figure, is straight, perpendicular, or parallel to its base, be so also in its iconographic delineation. 2. Let the lines, which in the object return at right angles from the fore-right side, be drawn iconographically from the visual point. 3. Let all straight lines, which in the object return from the fore-right side, run in an iconographic figure into the horizontal line. 4. Let the object you intend to delineate, standing on your right-hand, be placed also on the right hand of the visual point; and that on the left-hand, on the left-hand of the same point; and that which is just before, in the middle of it. 5. Let those lines which are (in the object) equidistant to the returning line be drawn in the iconographic figure, from that point found in the horizon. 6. In setting off the altitude of columns, piers, and the like, measure the height from the base line upwards, in the front or forearm side; and a visual ray down that point in the front shall limit the altitude of the column or pillar, all the way behind the fore-right side, or orthographic appearance, even to the visual point. This rule you must observe in all figures, as well where there is a front or forearm side, as where there is none. 7. In delineating ovals, circles, arches, croffes, spirals, and crofs arches, or any other figure in the roof of any room, first draw iconographically, and so with perpendiculars from the most eminent points thereof, carry it up unto the ceiling; from which several points, carry on the figure. 8. The centre in any iconographic regular figure is found by drawing lines from opposite angles: for the point where the diagonals cross, is the centre. 9. A ground-plane of squares is alike, both above and below the horizontal line; only the more it is distant above or beneath the horizon, the squares will be so much the larger or wider. 10. In drawing a perspective figure, where many lines come together, you may, for the directing of your eye, draw the diagonals in red; the visual lines in black; the perpendiculars in green, or other different colours, from that which you intend the figure shall be of. 11. Having considered the height, distance, and position of the figure, and drawn it accordingly, with side or angle against the base; raise perpendiculars from the several angles,
or projected points, from the figure to the base, and transfer
the length of each perpendicular, from the place where it
touches the base, to the base on the side opposite to the point
distance; so will the diameters drawn to the perpendiculars
in the base, by intersection with the diagonals, drawn
to the several transferred distances, give the angles of the
figures, and fo lines drawn from point to point will circumference
the inclosed figure. If in a landscape there
be any standing-waters, as rivers, ponds, and the like,
place the horizontal line level with the farthest height or appear ance of it. 13. If there be any house, or the like, in
the picture, consider their position, that you may find from
what point in the horizontal lines to draw the front and
sides thereof. 14. In describing things at a great distance,
observe the proportion, both in magnitude and distance, in
draught, which appears from the object to the eye. 15. In colouring and shadowing of every thing, you must do
the same in your picture, which you observe with your eye,
especially in objects lying near; but, according as the di-
distance grows greater and greater, so the colours must be
especially in objects lying near; but, according as the di-
grees, which also by the refracted beams is made and continued
on the other side of the same flat. 19. When these
faces on a crystal are returned towards a plane placed di-
rectly before it, they separate themselves at a good dis-
tance on the plane; because they are all directed to various far-
distant places of the same. See Optics.

The matter of sweat is separated from the blood by
the miliary glands, and is therefore much more gross than that of insensible perspiration; for as there are no
glands which serve for the excretion of this last fluid, it
is supposed to proceed from the extremities of the capill
ary arteries.

The use of perspiration is to preserve the suppleness of
the papilte of the skin; to carry the saline particles off
from the blood, and by this means to render it more pure;
to preserve the body from various diseases; and to contrib
ute to the cure of the most dangerous distempers. It
may be promoted by exercise, by dry frictions with a
coarse linen-cloth or a flint-brush, by warm baths, and
wathing the hands, feet, head, &c.

PERTH, the capital of the county of the same name in
Scotland, thirty miles north of Edinburgh.
PERTHAMBOY, a port-town of New-Jersey, in North
America: W. long. 74°. N. lat. 40° 45'.
PERTINENT OF LANDS, in Scots law. See Law, Tit.

PERU, formerly a powerful empire in South America, but
now a province of Spain, is situated between 60° and 81°
of west longitude, and between the equator and 25° of
south latitude, being near 2000 miles in length from
north to south, and from 200 to 500 broad: it is bounded
by Popayan, on the north; by the mountains of An-
des, on the eait; by Chili and La Plata, on the fouth;
and by the Pacific Ocean, on the weft.

PERUGIA, a city of Italy, in the territories of the pope :
E. long. 15° 16', N. lat. 43°.
PERUVIAN BARK. See CINCHONA.
PESARO, a city of Italy, in the province of Urbino, situ-
ated on the sulph of Venice: E. long. 14°, N. lat. 44°.
PESSARY, in medicine, a solid substance composed of
wool, lint, or linen, mixed with powder, oils, wax, &c.

PERUVIAN BARK. See CINCHONA.
PET, a city of upper Hungary, situated on the Danube:
E. long. 16° 15', N. lat. 47° 42'.

PESTILENCE, in medicine. See Medicine, p. 71.

PESTALOZZI, among botanists. See Botany, p. 657.

PETER, in the art of war. See Gunnery, p. 761.

PETACITES, in botany. See Tussilago.

PETECHIA, in medicine, denotes spots in the skin like fleabites, which come out in malignant fevers, hence called petechial or spotted fevers. See Medicine, p. 67.

PETER, or Epistles of St. Peter, two canonical books of the New Testament, written by the apostle St. Peter, and addressed to the Jewish converts who were scattered throughout Pontus, Galatia, &c. not only upon the perfection raised at Jerusalem, but upon former differences of the Jews into those places. The first of these epistles is principally designed to comfort and confirm them, under those fiery trials they were then subjected to; and to direct them how to behave in the several states and relations, both of the civil and the Christian life. In the second epistle, the apostle prosecutes the same subject, to prevent their apostasy from the faith, and guard them against the corrupt principles of the gnostics, and those who fecked at the promises of Christ's coming.

St. Peter's Day, a festival of the Christian church, observed on the twenty-eighth of June.

PETERBOROUGH, a city of Northamptonshire, situated on the river Nene, thirty-four miles north-east of Northampton; W. long. 15', N. lat. 52° 53'. It sends two members to parliament.

Peter-Pence, an ancient tax of a penny on each house, paid to the pope.

It was called peter-pence because collected on the day of St. Peter ad vindex, and sent to Rome; whence it was also called Rome-scot and Rome-penny.

PETERSBURG, the capital city of Russia, and one of the largest and most populous cities in the world, situated on both sides the river Neva, in the provinces of Carelia and Ingria, between the gulph of Finland and the lake of Ladoga; E. long. 31°, N. lat. 60°. There were no less than sixty-five thousand houses built within three or four years after the foundation was laid, which was in the year 1703.

PETERSFIELD, a borough-town of Hampshire, fifteen miles south-east of Winchester.

PETERSHAGEN, a town of Germany, in the circle of Westphalia, and duchy of Minden, thirty-seven miles west of Hanover; subject to Prussia.

PETHERTON, a market-town of Somersetshire, 16 miles south-west of Wells.

PETIOLE, in botany, the slender stalks that supports the leaves of a plant.

PETITJAVES, a port-town of Hispantia, situated on a bay at the west end of the island: W. long. 76°, N. lat. 18° 5': subject to France.

PETITIO PRINCIPIS, in logic, the taking a thing for true, and drawing conclusions from it as such; when it is really false, or at least wants to be proved, before any inferences can be deduced from it.

PETITORY ACTION, in Scots law. See Law, Tit. xxx. 15.

PETITIVERIA, in botany, a genus of the hexandria tricytosperms. The calyx consists of four segments; it has no corollas; but one seed with reflexed prickles at the point. There are two species, none of them natives of Britain.

PETRE, or SALT PETRE. See Chemistry, p. 73, 119.

PETREA, in botany, a genus of the didynamia angiospermous plants. The calyx is large, open, coloured, and divided into five segments; the corolla is open and rotated. There is but one species, a native of America.

PETRIDIA, in natural history, a genus of scrupul of a plane, uniform structure, of no great variety of colours, and emulating the external form of pebbles.

PETRIFICATION, in physiology, denotes the conversion of wood, bones, and other substances into stone.

The fossil bodies found petrified are principally either of vegetable or animal origin, and are more or less altered from their original state, according to the different substances they have lain buried among in the earth; some of them having suffered very little change, and others being so highly impregnated with crystalline, sparry, ptyitical, or other extraneous matter, as to appear more malleable of stone or lumps of the matter of the common pyrites; but they are generally of the external dimensions, and retain more or less of the internal figure of the bodies into the pores of which this matter has made its way.

The animal substances thus found petrified are shellfish; the teeth, bony palates, and bones of fish; the bones of land animals, &c. These are found variously altered, by the infinuation of fluid and mineral matter into their pores; and the substance of some of them is now wholly gone, there being only stone, sparry, or other mineral matter remaining in the shape and form.

PETROBRUSIANS, in church-history, a religious sect which arose in France and the Netherlands, about the year 1126, so called from their leader Peter Bruys. They denied that children, before the use of reason, can be justified by baptism. They also condemned all places of public worship, crosses, crucifixes; and are said to have rejected the sacrament of the eucharist, and prayers for the dead.

PETROLEUM, also called rock-oil, is an extremely subtle and penetrating fluid, and is much the thinnest of all the native bitumens. It is very light and very pellucid; but though equally bright and clear under all circumstances, it is liable to a very great variety in its colour. It is naturally almost colourless; and in its appearance greatly resembles the most pure oil of turpentine: this is called white petroleum, though it has no more colour than water; it is sometimes tinged of a brownish reddish, yellowish, or faint greenish tinge; but its most frequent colour is a mixture of the reddish and blackish, of such a degree that it looks black when viewed behind the light, but purple when placed between the eye and a candle or window. It is of a pungent and acrid taste, and of a very strong and penetrating smell, which very much approaches to that of the distilled oil of amber. The white
PHALEUCIAN VERSÉ, in ancient poetry, a kind of verse which consists of five feet, the first of which is a spondee, the second a dactyl, and the three last trochees.

PHANTASM, a term sometimes used in a synonymous sense with idea, or the notion retained in the mind of an object.

PHARISEES, a famous sect of the Jews, who distinguished themselves by their zeal for the traditions of the elders, which they derived from the same fountain with the written word itself; pretending that both were delivered to Moses from Mount Sinai, and were therefore both of equal authority. From their rigorous observance of these traditions, they looked upon themselves as more holy than other men, and therefore separated themselves from those whom they thought sinners or prophanes, so as not to eat or drink with them; and hence, from the Hebrew word pharis, which signifies to separate, they had the name of Pharisees or Separatists.

PHAROS, a small island in the Mediterranean sea, opposite to Alexandria, in Egypt.

PHAROS, or Pharos, a light-house, a pile raised near a port, where fire is kept burning in the night, to guide vessels near at hand.

PHASALUS, a town of ancient Thebais, situated in European Turkey, a little south of Larissa, in E. lon. 23°, and N. lat. 39°.
PHE (476) PHI

PHARYNX, in anatomy. See Anatomy, p. 302.

PHASCUM, in botany, a genus of the cryptogamia musci glads. The antheca are oculated, and the calyptra is wanting. There are four species, all natives of Britain.

PHASEOLOUS, in botany, a genus of the diadophia decandria class. The carina, flamina, and stylus, are twilled like a cirew. There are 13 species, none of them natives of Britain.

PHASES, in astronomy, the several appearances or quantities of illumination of the moon, venus, mercury, and the other planets. See Astronomy.

PHASIANUS, in ornithology, a genus belonging to the order of gallinae. The cheeks are covered with a smooth naked skin. There are six species, viz. 1. The sullus, or dunghill cock and hen, with a compressed caruncle or flitty-comb on the top of the head, and a couple of caruncles or wattles under the chin; the ears are naked; and the tail is compressed, and erected. This bird, though not one of the domestic fowls, was originally brought from the East-Indies. They feed upon grain, grass, seeds, and worms. The cock or male is perhaps the boldest and most heroic of all the feathered tribe. He claps his wings before he sings or crows. He begins to crow about midnight, and seldom ceases till break of day. He is so exceedingly Lucious, that one cock is sufficient for 10 hens. His flight is very piercing, and he never fails to cry in a peculiar manner when he discovers any bird of prey in the air. The hen is very proflic: she makes her nest on the ground; and the young, immediately after they are hatched, follow her, and pick up their food themselves. There are six or eight varieties of this species. 2. The motmot, or Guinea pheasant, is brownish, somewhat red below, with a wedge-like tail, and wants fperms. It is a native of Guiana and Brazil.

3. The colicius, is red, with a blue head, a wedge-shaped tail, and papillosus cheeks. It is a native of Asia.

4. The argus is yellowish, with black spots, a red face, and a blue crest on the back part of the head. It is found in Chincan Tartary.

5. The pittus, has a yellow crest, a red breast, and a wedge-shaped tail. It is a native of China. 6. The nycthemerus, is white, with a black comb and belly, and a wedge-shaped tail. It is a native of China. See Plate CXXII.

PHASMATA, in physiology, certain appearances arising from the various tinctures of the clouds, by the rays of the heavenly luminaries, especially the sun and moon. These are infinitely diversified by the different figures and situation of the clouds, and the appulses of the rays of light.

PHASSACHATES, in natural history, the name of a species of agate, which the ancients, in its different appearances, sometimes called also leucachates and penleucos. See Agate.

PHEASANT, in ornithology. See Phasianus.

PHELLANDRIUM, in botany, a genus of the pentan-dria digynia class. The fruit is oval and smooth. There are two species, one of them, viz. the aquaticum, or water hemlock, is a native of Britain.

PHELYPÆA, in botany. See Lathrea.

PHENICIA, a subdivision or province of Syria, situated on the Levant, or eastern part of the Mediterranean sea, on the confines of Palestine.

PHIONS, in heraldry, the barbed heads of darts, arrows, or other weapons, and usually represented as in Plate CXLI. fig. 1.

PHIDITIA, in Greek antiquity, feasts celebrated with great frugality at Lacedaemon. The phiditia were held in the public places, and in the open air: rich and poor attended them alike, and on the same footing; their design being to keep up peace, friendship, and a good understanding and equality among all the citizens, great and small. It is said, that they who attended this feast, brought each a bushel of flour, eight measures of wine named choras, five mine of cheese, and as much figs.

PHILADELPHIA, the capital of the province of Pennsylvania, in North America, situated on the rivers Delawar and Schuylkill: W long. 74°, N. lat. 40° 50'.

PHILADELPHIA is also the name of an ancient town of the Lefser Alfa, situated in E. long. 29°, N. lat. 38°.

PHILADELPHUS, in botany, a genus of the iofandria monogynia class. The calix consists of four or five segments, and the corolla of four or five petals; and the capsule has four or five cells, containing many seeds. There are two species, none of them natives of Britain.

PHILLIP-FORT, a fortress in Dutch Brabant, situated on the east side of the Scheldt, opposite to Pearl-fort, five miles north-west of Antwerp.

PHILIPPI, an ancient town of Macedonia, a province of European Turkey, situated in E. long. 25°, N. lat. 41°.

PHILIPPI, in literature, a name given to the orations of Demothenes against Philip king of Macedon; being esteemed the master pieces of that great orator.

Philippic is also a term applied to the fourteen orations of Cicero against Mark Anthony.

PHILIPPINE ISLANDS, situated in the Pacific ocean, in Asia, between 114° and 131° east longitude, and between 5° and 10° north latitude: there are a great number of them, and some very large.

PHILIPPINES, a religious society of young women, at Rome, so called from their taking St. Philip de Neri for their protector: they consist of an hundred poor girls, who are brought up till they are of age to be married, or become nuns, under the direction of some religious women, who teach them to read, write, and work; and instruct them in the duties of Chriftianity. They wear a white veil, and a black cross on their breasts.

PHILIPPOPOLE, a city of European Turkey, in the province of Perramian, situated on the river Mariza: in E. long. 8° 16', N. lat. 49° 8'.

PHILIPSBURGH, a city of Germany, in the palatinate of Gothland and territory of Wermeland, situated in E. long. 14°, N. lat. 59° 50'.

PHILLYREA, in botany, a genus of the diadria monogynia class. The corolla consists of four segments, and the berry contains four seeds. There are three species, none of them natives of Britain.

PHILOLOGY, a science, or rather assemblage of several sciences, confounding of grammar, rhetoric, poetry, antiquities, history, and criticism.

Phylogeny is a kind of universal literature, conversant about all the sciences, their rise, progress, authors, &c.

It makes what the French call the belles lettres.

PHILOMATHES, a lover of learning or science.

PHILONIUM,
PHILTRON, in pharmacy, a kind of sonorous ana-
dyce opiate, taking its name from Philo the inventor.

PHILOSOPHER, a person versed in philosophy; or one
who makes profession of, or applies himself to, the study
of nature and morality.

PHILOSOPHER'S STONE, the greatest object of alchymy,
is a long sought for preparation, which, when found, is
to convert all the true monearial part of metal into pure
gold, better than any that is dug out of the mines, or
perfected by the refiner's art; and this only by calling a
little quantity thereof upon metals in fusion, whiff that
part of the metal which was not mercury is immediately
burnt or blown away. But this like every other scien-
tific chimera, will for ever elude the researches of man-
kind.

PHILOSOBO, or PHILOSOBOICAL, something that
relates to philosophy. See Philosophy.

PHILOSOPHALICAL EGG, among chemills, a thin glafs-
body, or bubble, of the shape of an egg, with a long
neck or stem, used in digestions.

PHILOSOPHY, the knowledge or study of nature and mo-
rality, founded on reason and experience. See Mecha-
nics, Optics, Astronomy, Logic, Morals, &c.

PHILYCTENIUS, in medicine, small eruptions on the skin.

PHILYCTENIUS, in medicine, a genus of the pentandria monogy-

PHILOPHAGUS, in pharmacy, such medicines as

PHLISMAGOGUES, in pharmacy, such medicines as

PHLEGHISCIERIA, another clafs of foffils, which are

PHLEGMON, denotes an external inflammation and

PHLEGMATIC, among phyficians, an appellation given
to that temperament or habit of the body, wherein phlegm
is predominant; which gives rise to catarrhs, coughs,
and daughters, in their train. They copulate on the shore,
the female lying on their backs. They are hardly afraid
of men, and bite stones when thrown at them. Each has
a particular stone for his bed, which they seldom defert.
They often fight for their wives and beds; when one is
beaten, another makes a fresh attack, and thus succeed
alternately, two never attacking one, till the whole be
gathered, when they make a hideous wailing noise. They
are found in the northern seas. 2. The leonina, or sea-
lion, has a crest on his forehead. They are found near
the south pole. They swim in troops, and fight for their
wives. 3. The vitulina, or sea-calf, has a smooth head,
the nostrils are linear; and the feet are palmated, and
four-toed. There is but one species, native of Africa
and America.

PHOENICEA, a city of Odisis, on the west coast of the leffer
Asi, anciently so called.

PHOENICOPTERUS, or Flamingo, in ornithology,
a genus of birds belonging to the order of grallae. The
beak is naked, toothed, and bent as if it were broken;
the nostrils are linear; and the feet are palmated, and
four-toed. There is but one species, a native of Africa
and America.

PHOENIX, in astronomy. See Astronomy, p. 487.

PHOENIX, the great palm, or date-tree, in botany,
a genus of plants, the characters of which are not yet
perfectly ascertained: the male and female flowers are
on distinct plants, or on the same spadix.

PHOENIX, the great palm, or date-tree, in botany,
a genus of plants, the characters of which are not yet
perfectly ascertained: the male and female flowers are
on distinct plants, or on the same spadix.

PHOLAS, a genus of insects belonging to the order of
vernus tettaceae. The shell is double-valved and divari-
cated; the cardo is turned backwards, and connected by
a carillage. There are six species, distinguished by the
figure of their shells.

PHONICS, the doctrine or science of sounds, otherwise
called acoustics. See Pneumatica.

PHOSPHORUS, See Chemistry, p. 123.

PHRENES,
PHRENSY, in medicine, an inflammation of the membranes of the brain, attended with an acute fever and delirium. See Medicine, p. 88.

PHRYGIA, the Greater and Lesser, two provinces anciently of Asia Minor; having the Hellefront on the north.

PHTRHRIASE, in medicine, the pedicalaris morbus, or lousy disease, is most incident to children, though adults are not wholly exempt from it.

PHTHISIS, a species of consumption, arising from an ulcer of the lungs. See Medicine, p. 103.

PHYLLANTHUS, in botany, a genus of the monocotyledons. The calyx both of the male and female consists of eight segments; neither of them have any corolla; the female has three birti flowers; the capsule has three cells, and contains one seed. There are fix species, none of them natives of Britain.

PHYLLIS, in botany, a genus of the pentandria digynia class. The corolla is rotated; the seeds are connivent; and the berry has two cells, and is contained within an inflated calyx. There are ten species, none of them natives of Britain.

PHYSETER, in zoology, a genus belonging to the order of Cete. It has teeth in the under jaw, and a fillet in the head or snout. There are four species, viz. 1. The catodon, with a fillet in the snout, and having no back-fin. 2. The macrocephalus has a fillet in the neck, and no back-fin. The spermaceti is extracted from this species. 3. The microps, with a long fin on the back, and the upper jaw much longer than the under one. 4. The turbo, with a very high fin on the back; and the points of the teeth blunt. All the four species are inhabitants of the northern Ocean.

PHYSIC. See Medicine.

PHYSICAL, something relating to nature.

PHYSICIAN, a person who professes medicine, or the art of healing diseases.

PHYSICS, a denomination sometimes given to natural philosophy.

PHYSIOLOGY, properly denotes a discourse of nature, and natural bodies; or, it is that part of natural philosophy which treats of the various phenomena of nature in a scientific and speculative way.

Among physicians, the term physiology denotes the history of the human body and its several constituent parts, with their relations and functions.

PHYTOBMA, in botany, a genus of the pentandria monogyina class. The corolla is rotated, with linear laciniae; the stigmas are trifid; and the capsule has two or three cells. The species are fix, only one of them, viz. the orbiculata, or orbicularis, or horned ramboult, a native of Britain.

PHYTOLEACCA, in botany, a genus of the decandria deceragynia class. It has no calix; the petals are five; and the berry has ten cells, and ten seeds. There are four species, none of them natives of Britain.

PHYSIOLOGY, a discourse concerning the kinds and virtues of plants.

PICA, in ornithology. See Corvus.

PICA, in medicine, a depravation of appetite, which makes the patient long for what is unfit for food, or incapable of nourishing, as chalk, ashes, coals, plaster, lime, &c.

PICT, the name of a class of birds. See Natural History.

PICARDY, a province of France, bounded by the French Netherlands, and the Straits of Dover, on the north and east; by the Isle of France, on the south; and by Normandy, and the English channel, on the west.

PICKLE, a brine or liquor, commonly composed of salt, vinegar, &c., sometimes with the addition of spices; wherein meat, fruit, and other things are preserved and seasoned.

PICKERY, in Scotch law, petty theft, or stealing things of small value.

PICQUERING, a flying war or skirmish made by soldiers detached from two armies for pillage, or before a main battle begins.

PICRIS, in botany, a genus of the syngeneia polygamia class. The receptacle is naked; the calyx is calciculated; the pappus is feathery; and the seeds are rowed transversely. There are four species, two of them natives of Britain, viz. the echio, or ox's tongue, and the hieracoides, or yellow succory.

Picts wall, in antiquity, a wall begun by the emperor Adrian, on the northern bounds of England, to prevent the incursions of the Picts and Scots. It was first made only of turf, strengthened with palisadoes, till the emperor Severus coming in person into Britain built it with solid stone. This wall, part of which still remains, began at the entrance of Solway-frith in Cumberland, and running N. E. extended to the German ocean.

PICTURE, a piece of painting, or a subject represented in colours, on wood, canvas, paper, or the like.

PICUS, the Wood-pecker, in ornithology, a genus belonging to the order of picas. The beak is straight, and consists of many sides, and like a wedge at the point; the nostrils are covered with bristly feathers; the tongue is round like a worm, very long, sharp at the point, which is befe with bristles bent backwards. There are 21 species, distinguished by their colour.

PIECE, in heraldry, denotes an ordinary or charge. See Charge.

PIEDMONT, a principality of Italy, so called from its lying at the foot of the Alps. It is bounded by Savoy, from which it is separated by the Alps, on the north; by the duchies of Milan and Montferrat, on the east; by the territories of Genoa, and the county of Nice, on the south; and by France, on the west, being about 100 miles long, and 70 broad.

PIER, in building, denotes a mass of stone, &c. opposed by way of fortresses against the force of the sea, or a great river, for the security of ships that lie at harbour in any haven.

PIETISTS, a religious sect sprung up among the protestants of Germany, seemingly to be a kind of mean between the quakers of England, and the quietists of the Romish church.

PIG, in zoology. See Sus.

Guinea-Pig. See Mus.

Pig of head, the eighth part of a fother, amounting to two hundred and fifty pounds weight.

PIGEON, in ornithology. See Columba.

PIGMENTS, preparations used by painters, dyers, &c. to impart
PILOT, a person employed to condue ships over bars and
PIMENTO, in botany. See Myrtus, of which it is a
PIMPINELLA, in botany, a plant of the pentandria di-
PILLAR, in architecture. See Architecture, p. 333.
PILCHARD, in ichthyology. See Clupea.
PILE, in heraldry, an ordinary in form of a wedge, con-
PILL, in pharmacy, a form of medicine resembling a lit-
PILGRIMAGE, a kind of religious discipline, which con-
Piles, in medicine. See Medicine, p. 1. These deca-
PILGRIMAGE, a kind of religious discipline, which con-
PISTACHIO, in botany. See Spinacia.
PINE, in botany. See Pinus.
PINDARIC, in poetry, an ode formed in imitation of the
PINE, in botany. See Pinus.
PINEAPPLE. See Bromelia.
PINGUICULA, in botany, a genus of the diandria mon-
PINE, in botany. See Pinus.
PINCER, in mechanics, an arbor, or spindle, in the body
PIGNOL, in architecture, a kind of irregular column,
PILLAR, in architecture, the top or roof of a house,
PILLORY, was anciently a post erected in a cross road,
PILLOW, in pharmacy, a form of medicine resembling a
PILOT, a person employed to conduct ships over bars and
PIMENTO, in botany. See Myrtus, of which it is a
PIGUS, in ichthyology. See Cyprinus.
PIKE, in ichthyology. See Lucius.
PINK, a vessel used at sea, with a square stern,
PINK, in botany. See Dianthus.
PINIONS, in botany. See Diandria tri-
PINE, in botany. See Pinus.
PIN, in commerce, a little necessary implement made of
PINUS, in botany, a genus of the monoecia monadelphia
PIGIONS, in botany, the greatest numbers now refert to Loretto, in order to
PINDARIC, in poetry, an ode formed in imitation of the
PINEAPPLE. See Bromelia.
PINGUICULA, in botany, a genus of the diandria mon-
PINE, in botany. See Pinus.
PINCER, in mechanics, an arbor, or spindle, in the body
PIGNOL, in architecture, a kind of irregular column,
PILLAR, in architecture, the top or roof of a house,
PILLORY, was anciently a post erected in a cross road,
PILLOW, in pharmacy, a form of medicine resembling a
PILOT, a person employed to conduct ships over bars and
PIMENTO, in botany. See Myrtus, of which it is a
PIGUS, in ichthyology. See Cyprinus.
PIKE, in ichthyology. See Lucius.
PINK, a vessel used at sea, with a square stern,
PIRACY, in Scots law. See LAV/, Tit. xxxiii.

PIRATE, a person, or vessel, that robs on the high seas, without permission or authority of any prince or state.

PISA, a city of Italy, in the duchy of Tuscany, situated on the river Arno, four miles east of the sea, and ten miles north of Leghorn.

PISCARY, in our ancient statutes, the liberty of fishing in another man's waters.

PISCIAS, in astronomy, the twelfth sign or constellation of the zodiac. See ASTRONOMY, p. 487.

PISCINA, in antiquity, a large basin in a public place or square, where the Roman youth learned to swim, and which was surrounded with a high wall, to prevent calling of filth into it.

PISSAPHALTUM, earth pitch, a fluid, opaque, mineral body, of a thick consistence, of a strong smell, readily inflammable, but leaving a residuum of grayish ashes after burning. It arises out of the cracks of rocks, in several places in the island of Sumatra, and in some other parts of the East-Indies, and is much esteemed there, in paralytic disorders.

PISSALDEUM Indicum, Barbadoes tar, a mineral fluid, of the nature of the thicker bitumens, and of all others the most approaching in appearance, colour, and consistence, to the true pitchphaltum, though differing from it in other respects. It is very frequent in many parts of America, where it is found trickling down the sides of mountains in large quantities, and sometimes floating on the surface of the waters. It has been greatly recommended internally in coughs and other disorders of the breath and lungs.

PISTACIA, in botany, a genus of the dioecia pentandria class. The calyx of the amentum in the male consists of five segments; it has no corolla: The calix of the female consists of three segments; it has no corolla: there are three stili; and the drupa contains one seed. There are five species, all natives of warm climates.

Pistachia-nuts abound with a sweet and well-tasted oil, which they will yield in great abundance, on being pressed: they are reckoned wholesome and nutritious, and are very proper to be prescribed by way of restoratives, eaten in a moderate quantity, and to people emaciated with long sickness.

PISTIL, among botanists. See Botany, p. 637.

PISTOL, the smallest piece of fire-arms, born at the saddle bow, on the girdle, and in the pocket.

PISTOLE, a gold-coin, struck in Spain, and in several parts of Italy, Switzerland, &c.

The pistol has its augmentations and diminutions, which are quadruple pistols, double pistols, and half pistols.

PISTON, in pump-work, is a short cylinder of metal, or other solid substance, fitted exactly to the cavity of the barrel or body of the pump. See HYDROSTATICS.

PISUM, in botany, a genus of the diadelphia decandria class. The stylos is triangular, carinated and downy above; and the two upper laminæ of the calix are shorter than the rest. The species are four, only one of them, viz. the mariponum, or pea-pea, a native of Britain.

Pees are nutritious, and accordingly used for food; but rarely for any medicinal purposes, except to keep issues open; for which purpose they are rubbed with ballston, or linimentum Aretii.

PITCH, a tenaceous oily substance, drawn chiefly from pines and firs, and used in shipping, medicine, and various other arts: or it is more properly tar, inspired by boiling it over a slow fire.

The method of procuring the tar, is by clearing the trees into small billets, which are laid in a furnace that has two apertures, through one of which the fire is put, and through the other the pitch is gathered, which, oozing from the wood, runs along the bottom of the furnace into places made to receive it. When the smoke, which is here very thick, gives it blackness, this is called pitch; which, on being boiled, to consume more of its moisture, becomes pitch.

There is another method of drawing pitch, used in the Levants: a pit is dug in the ground, two ells in diameter at the top, but constricting as it grows deeper; this is filled with branches of pine, cloven into shivers; the wood at the top of the pit is then set on fire, and burning downwards, the tar runs from it out of a hole made in the bottom; and this is boiled, as above, to give it the confidence of pitch.

PITH, in vegetation, the soft spongy substance contained in the central parts of plants and trees. See AGRICULTURE, Part I.

PITUITARY GLAND, in anatomy. See Anatomy, p. 286.

PLACE, in war, a general name for all kinds of fortrsetes where a party may defend themselves.

Common Place. See Common Place.

PLACENTA, in anatomy and midwifery, a soft roundish mass found in the womb of pregnant women; which, from its resemblance to the liver, was called by the ancients hepar uterinum, the uterine liver. See Midwifery, p. 208.

PLACENTIA, a city of Spain, in the province of Estremadura; W long. 6º, N. lat. 39º 45'.

PLAGIARY, in philology, the purloining another person's works, and putting them off for a man's own. Among the Romans, plagius was properly a person who bought, sold or retained a freeman for a slave; and was so called, because by the Flavian law such persons were condemned, ad plagas, to be whipped.

PLAGIURI, among ichthyologists, a class of fishes comprehending all those which have the tails not perpendicular, but placed in an horizontal direction.

PLAGUE, Pestilence, or Pestilential fever. See Medicine, p. 71.

PLAISE, the English name of a species of the pleuronectes. See Pleuronectes.

PLAN, in general, denotes the representation of something drawn on a plane: such are maps, charts, ichnographies, &c.

The term plan, however, is particularly used for a draught of a building, such as it appears, or is intended to appear, on the ground; shewing the extent, division, and distribution of its area, or ground-plot, into apartments, rooms, passages, &c.

PLANE, in geometry, denotes a plain surface, or one that lies evenly between its bounding lines: and as a right line is the shortest extension from one point to another, so a plain
plain surface is the flattest extension from one line to another.

PLANE, in joinery, an edged tool, or instrument for parting and having of wood smooth.

It consists of a piece of wood, very smooth at bottom, as a flock or shift; in the middle of which is an aperture, through which a steel edge, or chisel, placed obliquely, passes; which being very sharp, takes off the inequalities of the wood it is split along.

PLANE-TREE, in botany. See PLATANUS.

PLANT, is defined to be an organical body, definite of an external action, and continually changing. In such a manner as to draw from it its nourishment, and having power of propagating itself by seeds. See Agriculture and Botany.

PLANTAGNATUM, a genus of the tetrandria monogynia class. The calyx and corolla has each four segments; the flamina are very long; and the capsule is bilocular. There are 21 species, eight of them natives of Britain.

The root, leaves, and seeds of plaintain, are reckoned cooling and astringent. It is likewise accounted a great healer of fresh wounds.

PLANTAIN. See RAMUNCULUS.

PLANTATION, in the Well-Indies, denotes a spot of ground which a planter or peron arrived in a new colony, pitches on to cultivate for his own use, or is assigned for that purpose. However, the term plantation is often used in a synonymous sense with colony.

PLASTER, in pharmacy, is defined to be an external application of a harder consistence than our ointments; these are to be spread according to the different circumstances of the wound, place, or patient, either upon linen or leather.

PLASTER, among builders, &c. The plaster of Paris is a preparation of several species of gypsums, dug near Mont Maitre, a village in the neighbourhood of Paris; whence the name.

The belf fort is hard, white, shining, and marly; known by the names of plaster-ite, or parget of Mount Maitre. It will neither give fire with steel, nor ferment with aqua fortis; but very freely and readily calcines in the fire, into a very fine plaster; the use of which in building, and making statues, is well known.

PLASTIC, denotes a thing endowed with a formative power, or a faculty of forming or fashioning a mass of matter, after the likeness of a living being; such a virtue as some of the ancients Epicureans, and perhaps the Peripateticians too, imagined to reside in the earth, or at least to have anciently resided therein, by means whereof, and without any extraordinary intervention of a creator, it put forth plants, &c. Some of them seem to be of opinion that animals, and even man himself, was the effect of this plastic power.

PLASTIC ART, a branch of sculpture, being the art of forming figures of men, birds, beasts, fishes, &c. in plaster, clay, flux, or the like.

PLATA, in botany, a genus of the monogynia class. The calyx and corolla is a roundestamentum; the male has no corolla; the corolla of the female consists of many petals; the stigma is bent backward; and the seeds are round.

The species are two, none of them natives of Britain.

PLATIBAND, in gardening, a border or bed of flowers on which cannon is placed, to fire on the enemy; such is made square or not much arched.

PLATIBAND, or spoon-bill, in ornithology, a genus belonging to the order of grallas. The beak is plain, and dilates toward the point into an orbicular form; the feet have three toes, and are half palmated. There are three species, distinguished by their colour.

PLATANUS, the Plane-tree, in botany, a genus of the monogynia class. The calyx both of the male and female is a roundestamentum; the male has no corolla; the corolla of the female consists of many petals; the stigma is bent backward; and the seeds are round.

The species are two, none of them natives of Britain.

PLATIBAND, in gardening, a border or bed of flowers on which cannon is placed, to fire on the enemy; such are the mounts in the middle of curtains.

PLATIBAND, in architecture, is a row of beams, which support the timber-work of a roof, and lie on the top of the wall, where the entablature ought to be raised.

PLATIBAND, or spoon-bill, in ornithology, a genus belonging to the order of grallas. The beak is plain, and dilates toward the point into an orbicular form; the feet have three toes, and are half palmated. There are three species, distinguished by their colour.

PLATANUS, the Plane-tree, in botany, a genus of the monogynia class. The calyx both of the male and female is a roundestamentum; the male has no corolla; the corolla of the female consists of many petals; the stigma is bent backward; and the seeds are round.

The species are two, none of them natives of Britain.

PLATIBAND, in gardening, a border or bed of flowers on which cannon is placed, to fire on the enemy; such are the mounts in the middle of curtains.

PLATIBAND, in architecture, is a row of beams, which support the timber-work of a roof, and lie on the top of the wall, where the entablature ought to be raised.

PLATIBAND, or spoon-bill, in ornithology, a genus belonging to the order of grallas. The beak is plain, and dilates toward the point into an orbicular form; the feet have three toes, and are half palmated. There are three species, distinguished by their colour.

PLATANUS, the Plane-tree, in botany, a genus of the monogynia class. The calyx both of the male and female is a roundestamentum; the male has no corolla; the corolla of the female consists of many petals; the stigma is bent backward; and the seeds are round.

The species are two, none of them natives of Britain.

PLATIBAND, in gardening, a border or bed of flowers on which cannon is placed, to fire on the enemy; such are the mounts in the middle of curtains.

PLATIBAND, in architecture, is a row of beams, which support the timber-work of a roof, and lie on the top of the wall, where the entablature ought to be raised.

PLATIBAND, or spoon-bill, in ornithology, a genus belonging to the order of grallas. The beak is plain, and dilates toward the point into an orbicular form; the feet have three toes, and are half palmated. There are three species, distinguished by their colour.

PLATANUS, the Plane-tree, in botany, a genus of the monogynia class. The calyx both of the male and female is a roundestamentum; the male has no corolla; the corolla of the female consists of many petals; the stigma is bent backward; and the seeds are round.

The species are two, none of them natives of Britain.

PLATIBAND, in gardening, a border or bed of flowers on which cannon is placed, to fire on the enemy; such are the mounts in the middle of curtains.

PLATIBAND, in architecture, is a row of beams, which support the timber-work of a roof, and lie on the top of the wall, where the entablature ought to be raised.
PLEDGE, in Scots law. See Law, Tit. xx. 13.
PLEDGET, Bolster, or Compress, in surgery, a kind of flat tent, laid over a wound, to imbibe the superfluous humours, and keep it clean.

PLEIADES, in astronomy, an assemblage of stars in the neck of the constellation taurus. See Astronomy, p. 237.

PLENARY, something complete or full.

PLENIPOFENTIARY, a person vested with full power to do any thing. See Embassador.

PLENITUDE, the quality of a thing that is full, or that fills another. In medicine, it chiefly denotes a redundancy of blood and humours.

PLENUM, in physics, denotes, according to the Cartesians, that state of things, wherein every part of space is suppos'd to be full of matter; in opposition to a vacuum.

PLEONASM, a figure in rhetoric, whereby we use words seemingly superfluous, in order to express a thought with the greater energy: such as, I saw it with my own eyes, &c.

PLETHORA, in medicine, a greater redundancy of laudable blood and humours than is capable of undergoing those changes which must necessarily happen for the purposes of life without inducing diseases.

PLEURISY, in medicine. See Medicine, p. 89.

PLEURONECITES, in ichthyology, a genus belonging to the order of thoracici. Both eyes are on the same side of the head; there are from four to seven rays in the gill-membrane; the body is compressed, the one side resembling the back and the other the belly. There are 17 species.

PLEXUS, among anatomists, a bundle of small vessels interwoven in the form of net-work.

PLIMOUTH, or Plymouth, a port-town of Devonshire, and a station for the building and laying up of ships of war belonging to the royal navy: W, long. 4° 27', N. lat. 50° 26'. It sends two members to parliament.

PLIMTON, a borough town of Devonshire, situated near the English Channel, thirty-six miles south-west of Exeter. It sends two members to parliament.

PLINIA, in botany, a genus of the polyandria monogynia class. The corolla consists of five petals, and the calyx of five segments; the berry is furrowed, and contains one seed. There is but one species, a native of America.

PLINTH, in architecture, a flat square member, in the form of a brick.

PLUCKNETIA, in botany, a genus of the monocotyledonous class. It sends two members to parliament.

PLUMBAGO, in botany, a genus of the pentandria monogynia class. The corolla is bell-shaped; the filaments are inserted into scales at the base of the corolla; the stigma is quinquelobate; and there is but one oblong truncate-sessil seed. The species are four, none of them natives of Britain.

PLUMBERY, the art of chasing and working lead, and using it in buildings, &c.

As this metal melts very easily, it is easy to cast it into figures of any kind, by running it into moulds of brass, clay, plaster, &c. But the chief article in plumbery is sheets and pipes of lead; and as these make the basis of the plumber's work, we shall here give the processes of making them. In casting sheet-lead, a table or mould is made use of, which consists of large pieces of wood well jointed, and bound with bars of iron at the ends, on the sides of which runs a frame constituting a ledge, or border of wood, two or three inches thick, and two or three inches high from the mould, called the shaps; the ordinary width of the mould, within these shaps, is from three to four feet; and its length is sixteen, seventeen, or eighteen feet. This should be something longer than the sheets are intended to be, in order that the end where the metal runs off from the mould may be cut off, because it is commonly thin or uneven, or ragged at the end. It must stand very even or level in breadth, and something falling from the end in which the metal is poured into, viz. about an inch, or an inch and a half, in the length of sixteen or seventeen inches. At the upper end of the mould stands the pan, which is a concave triangular prism, composed of two planks nailed together at right angles, and two triangular pieces fitted in between them at the ends. The length of this pan is the whole breadth of the mould in which the sheets are cast: it stands with its bottom, which is a sharp edge, on a form at the end of the mould, leaning with one side against it; and on the opposite side is a handle to lift it up by, to pour out the melted lead; and on that side of the pan next the mould, are two iron hooks to take hold of the mould, and prevent the pan from slipping, while the melted lead is pouring out of it into the mould. This pan is lined at the inside with moistened sand, to prevent it from being fired by the hot metal. The mould is also spread over, about two thirds of an inch thick, with sand sifted and moistened.
en, which is rendered perfectly level by moving over it a piece of wood called a strike, by trampling upon it with the feet, and smoothing it over with a smoothing plane, which is a thick plate of polished brass, about nine inches square, turned up on all the four edges, and with a handle fixed on to the upper or concave side. The land being thus smoothed, it is fit for calling sheets of lead: but if they would call a cistern, they measure out the bigger of the four sides; and having taken the dimensions of the front, or fo far, make mouldings by profiling long strips of wood, which contain the same mouldings, into the level land, and form the figures of birds, beasts, &c. by profiling in the same manner leaden figures upon it, and then taking them off, and at the same time smoothing the surface where any of the land is raised up, by making the impressions upon it. The rest of the operation is the same in calling either cisterns or plain sheets of lead: but before we proceed to mention the manner in which that is performed, it will be necessary to give a more particular description of the strike. The strike then is a piece of board about five inches broad, and something longer than the breadth of the mould on the inside; and at each end is cut a notch, about two inches deep, so that when it is used, it rides upon the sharps with those notches. Before they begin to call, the strike is made ready by backing on two pieces of an old hat on the notches, or by dipping a café of leather over each end. In order to raise the under side about one eighth of an inch, or something more, above the land, according as they would have the sheet to be in thickness; then they hollow the under edge of the strike, and lay it across the mould. The lead being melted, it is ladled into the pan, in which, when there is a sufficient quantity for the present purpose, the form of the metal is swept off with a piece of board to the edge of the pan letting it settle on the land, which is by this means prevented from falling into the mould at the pouring out of the metal. When the lead is cool enough, which is known by its beginning to harden with a shell or wall on the land round the pan, two men take the pan by the handle, or else one of them lifts it up by a bar and chain fixed to a beam in the ceiling, and pours it into the mould, while another man stands ready with the strike, and, as soon as they have done pouring in the metal, puts on the mould, sweeps the lead forward, and draws the overplus into a trough prepared to receive it. The sheets being thus cast, nothing remains but to planish the edges; in order to render them smooth and straight: but if it be a cistern, it is bent into four sides, so that the two ends may join the back, where they are folded together, after which the bottom is folded up.

The method of calling thin sheets of lead. Instead of land, they cover the mould with a piece of wooden stuff nailed down at the two ends to keep it tight, and over this lay a very fine linen cloth. In this process great regard is had to the just degree of heat, so as that the lead may run well, and yet not burn the linen. This they judge of by a piece of paper; for it takes fire in the liquid lead if it is too hot, and if it be not thick and forced a little, it is too hot enough. They have here a strike different from that described above: it is a wooden café, only closed on three sides; it is pretty high behind; but the two sides, like two acute angles, fill dim of the tip from the place where they are joined to the third or middle piece, where they are of the same height therewith, viz. seven or eight inches high, the width of the middle makes that of the strike, which again makes that of the sheet to the cistern. This strike is placed at the top of the mould, which in the part is first covered with a past-board that serves as a bottom to the café, and prevents the linen from beingburst while the lead is pouring in. The strike is now filled with lead, according to the quantity to be used; which done, two men, one at each side, draw the strike down the mould with a velocity greater or less, as the sheet is to be more or less thick.

The method of calling plates without folding. To make these pipes, they have a kind of little mill, with arms or levers to turn it withal. The moulds are of brass, and consist of two pieces, which open and shut by means of hooks and hinges, their inward calibers, or diameter, being according to the size of the pipe to be made, and their length is usually two feet and a half. In the middle is placed a core, or round piece of brass or iron, somewhat longer than the mould, and of the thickness of the inward diameter of the pipe. This core is past through two copper-rundles, one at each end of the mould, which they serve to cloe; and to these is joined a little copper-tube about two inches long, and of the thickness the leaden pipe is intended to be of. By means of these tubes the core is retained in the middle of the cavity of the mould. The core being in the mould, with the rundles at its two ends, and the lead melted in the furnace, they take it up in a ladle and pour it into the mould by a little aperture at one end, made in the form of a funnel. When the mould is full they pass a hook into the end of the core, and turning the mill, draw it out; and then opening the mould, take out the pipe. If they desire to have the pipe lengthened, they put one end of it in the lower end of the mould, and pass the end of the core into it; then shut the mould again, and apply its rundle and tube as before, the pipe just cast serving for rundle, &c. at the other end. Things being thus replaced, they pour in fresh metal, and repeat the operation till they have got a pipe of the length required.

For making pipes of sheet-lead, the plumbers have wooden cylinders of the length and thickness required; and on these they form their pipes by wrapping the sheet around them, and folding up the edges all along them. PLUMBUM, LEAD See CHEMISTRY, p. 84.

PLUMMFT, PLUMB RULE, or PLUMB LINE, an instrument used by carpenters, masons, &c. in order to judge whether walls, &c. be upright planes, horizontal, or the like. It is thus called from a piece of lead, (aliened to the like. It is thus called from a piece of lead, (aliened to the
is let to rest, and the exact point where it rests is marked with a pen; he then goes on farther in the line till he has passed the exact point where the needle stands in this second position. In this manner he proceeds, from turning to turning, marking down the points, and marking the line, till he comes to the intended place; this done, he ascends, and begins to work on the surface of the earth where he did in the adit, bringing the first knot in the line to a place where the mark of the point of the needle will again answer its pointing, and continues this till he come to the desired place above ground, which is certain to be perpendicular to the part of the mine into which the air-shaft is to be sunk.

PLUMOSE, something formed in the manner of a feather.

PLUVIALIS, in zoology. See Charadrius.

PNEUMATICS.

THIS science treats of the nature, weight, and pressure of the air, and the effects arising from it.

The air is that thin transparent fluid body in which we live and breathe. It encompasses the whole earth to a considerable height, and, together with the clouds and vapours that float in it, is called the atmosphere. The air is justly reckoned among the number of fluids, because it has all the properties by which a fluid is distinguished. (See Hydrostatics.) For it yields to the least force impressed, its parts are easily moved among one another, it presses according to its perpendicular height, and its pressure is everywhere equal.

That the air is a fluid, consisting of such particles as have no cohesion between them, but easily glide over one another, and yield to the slightest impression, appears from that ease and freedom with which animals breathe in it, and move through it without any difficulty or sensible resistance.

But it differs from all other fluids in the three following particulars. It can be compressed into a less space than what it naturally possesses, which no other fluid can. 2. It cannot be congealed or fixed, as other fluids may. 3. It is of a different density in every part, upward from the earth's surface, decreasing in its weight as the height increases; and therefore must also decrease in density. 4. It is of an elastic or springy nature, and the force of its spring is equal to its weight.

That air is a body, is evident from its excluding all other bodies out of the space it possesses; for, if a glass jar be plunged with its mouth downward into a vessel of water, there will but very little water get into the jar, because the air of which it is full keeps the water out.

As air is a body, it must needs have gravity or weight; and that it is weighty, is demonstrated by experiment. For, let the air be taken out of a vessel by means of the air-pump; then, having weighed the vessel, let in the air again; and upon weighing it, when re-filled with air, it will be found considerably heavier. Thus, a bottle that holds a wine quart, being emptied of air, and weighed, is found to be about 17 grams lighter than when the air is let into it again; which shows that a quart of air weighs 17 grams. But a quart of water weighs 14625 grains; this divided by 17, quotes 860 in round numbers; which shews, that water is 860 times as heavy as air near the surface of the earth.

As the air rises above the earth's surface, it grows rarer, and consequently lighter, bulk for bulk. Since it is an elastic or springy nature, and its lowermost parts are pressed with the weight of all that is above them, it is plain that the air must be more dense or compact at the earth's surface, than at any height above it; and gradually rare the higher up. For, the density of the air is always as the force that compresseth it; and therefore, the air towards the upper parts of the atmosphere being less pressed than that which is near the earth, it will expand itself, and thereby become thinner than at the surface of the earth.

Dr Cotes has demonstrated, that if altitudes in the air be taken in arithmetical proportion, the rarity of the air will be in geometrical proportion. For instance,

And hence it is easy to prove by calculation, that a cubic inch of such air as we breathe, would be 10,299 times as heavy as a cubic inch of the air at the altitude of 500 miles, that it would fill a sphere equal in diameter to the orbit of Saturn.
The weight or pressure of the air is exactly determined by the following experiment.

The Toricellian Experiment.

Take a glass tube about three feet long, and open at one end; fill it with quicksilver; and putting your finger upon the open end, turn that end downward, and immerse it into a small vessel of quicksilver, without letting in any air; then take away your finger, and the quicksilver will remain suspended in the tube 29.5 inches above its surface in the vessel; sometimes more, and at other times less, as the weight of the air is varied by winds and other causes. That the quicksilver is kept up in the tube by the pressure of the atmosphere upon that in the basin, is evident; for, if the basin and tube be put under a glass, and the air be then taken out of the glass, all the quicksilver in the tube will fall down into the basin; and if the air be let in again, the quicksilver will rise to the same height as before. Therefore the air's pressure on the surface of the earth, is equal to the weight of 29.5 inches depth of quicksilver all over the earth's surface, at a mean rate.

A square column of quicksilver, 29.5 inches high, and one inch thick, weighs just 15 pounds, which is equal to the pressure of air upon every square inch of the earth's surface; and 144 times as much, or 2160 pounds, upon every square foot; because a square foot contains 144 square inches. At this rate, a middle-sized man, whose surface is about 14 square feet, sustains a pressure of 30,240 pounds, when the air is of a mean gravity; a pressure which supports a greater quantity of mercury in one situation of the tube than in the other. We cannot say, that though in the inclined tube there is a greater quantity of mercury than in the erect one, yet a part of this greater weight will be supported by the side of the tube as by an inclined plane. The true answer is, that the column of air which supports the mercury in the inclined tube, is greater than the column which supports it in the erect one. The height of the column of air is indeed the same in both cases; for in either case it is equal to the height of the atmosphere. But the base of the column of air, and consequently its weight, is greater when the tube is inclined than when it is erect. For the base of the column of air which supports the mercury in the tube, is equal to as much of the flagrant mercury's surface as the base of the tube covers. Now, if the diameters of the tubes D and E are equal; the base of the inclined tube E will cover a greater part of the surface FG than the erect tube D covers, or the base of the tube E will be greater than the base of the tube D. For the contents of the inclined tube are greater than those of the erect one, as has been shown already. But the column of mercury in each of the tubes are cylinders of the same height. Therefore their bases are as their contents. Euc. b. XII. prop. 11.

Since then the contents or the weights of mercury in each tube are as their bases, when their heights are equal; and the base of the column of air, which supports the mercury, and consequently the weight of this column, is proportional to the base of the tube; it follows, that the weight of the air will always be proportional to the weight of the mercury when it stands at a given height, whether the tube is inclined or erect.

The mercury will stand at the same height either in an inclined barometer or in an erect one.

If the mercury at any time stands at the height of 30 inches in the barometer D, (Plate CXLV, fig. 6.) then by inclining this barometer into the position E, the perpendicular height of the mercury will not be altered; for it will still stand at the height of 30 inches; that is, if the level AB is 30 inches from the surface FG, the mercury will stand at this level, either in the erect tube D, or in the inclined one E. Now here it is evident, that if NL is the height of the mercury when the tube is erect, and NM is the height of the mercury in the same tube or an equal one when it is inclined, there must be more mercury in the inclined tube than in the erect one. For we may consider NL as the side, and NM as the diagonal, of a right angled parallelogram. But the diagonal of a right angled parallelogram is longer than the side. Therefore, though either L or M are at the same perpendicular distance from FG, yet NM will be longer than NL. Since then the column of mercury in the inclined tube is longer than in the erect tube, there will be more mercury in the inclined than in the erect one. The question therefore is, How the pressure of the atmosphere can support a greater quantity of matter in one situation of the tube than in the other. We cannot say, that though in the inclined tube there is a greater quantity of mercury than in the erect one, yet a part of this greater weight will be supported by the side of the tube as by an inclined plane. The true answer is, that the column of air which supports the mercury in the inclined tube, is greater than the column which supports it in the erect one. The height of the column of air is indeed the same in both cases; for in either case it is equal to the height of the atmosphere. But the base of the column of air, and consequently its weight, is greater when the tube is inclined than when it is erect. For the base of the column of air which supports the mercury in the tube, is equal to as much of the flagrant mercury's surface as the base of the tube covers. Now, if the diameters of the tubes D and E are equal; the base of the inclined tube E will cover a greater part of the surface FG than the erect tube D covers, or the base of the tube E will be greater than the base of the tube D. For the contents of the inclined tube are greater than those of the erect one, as has been shown already. But the column of mercury in each of the tubes are cylinders of the same height. Therefore their bases are as their contents. Euc. b. XII. prop. 11.

Since then the contents or the weights of mercury in each tube are as their bases, when their heights are equal; and the base of the column of air, which supports the mercury, and consequently the weight of this column, is proportional to the base of the tube; it follows, that the weight of the air will always be proportional to the weight of the mercury when it stands at a given height, whether the tube is inclined or erect.
the bafe of the inlined column we do not mean the bottom
of the inlined tube, but the lowest horizontal section of it.
Thus, if we consider the surface FG as a plane passing
through the two tubes D and E, this plane will cut the tube D
perpendicularly, and the tube E obliquely. But a perpendicu-
lar section of a cylinder is a circle, and an oblique section
of it is an ellipse. Therefore the bafe of the erect column
is circular, and the bafe of the inlined tube is elliptical.

Now, by the supposition, the two tubes have equal diam-
ters, and consequently the shorter axis of the elliptical bafe
will be equal to the diameter of the circular one.

There is another sort of inlined barometer, such as one
as ABR. (ibid. fig. 7.) which is erect for 28 inches from
A to B, and then is inclined from B to C. The mercury
will stand at the same height in this barometer, as if it had
been a flat one AS: for the column of air pressing at the
bafe A would be the same in both cases; and though there
is more mercury in the tube ABR than there would be in
the tube ABS; yet, supposing the mercury to stand at the
same level DC in either case, the pressure of the mercury
downwards will in either case be the same. For, the pre-
 pressure of fluids is as their base and perpendicular height:
and here the bafe A is the same, and the perpendicular height is
the same, whether the tube is erect all the way up as AS,
or is inclined at the top as ABR.

The advantage which is proposed by these diagonal ba-
rometers, as they are called, is to make the variation of
the mercury greater, and consequently more apparent, upon
a given change in the weather. Thus suppositio
AB or 23
inches to be the least height of the mercury, and AD or 31
inches to be the greatest height of it; then the whole varia-
tion will be within the compasses BD, or 3 inches. But if
the barometer, instead of being erect at the top, is incli
into the position BC; then, as the mercury stands at the
same perpendicular height in this diagonal barometer as in
an erect one, AB will be the least height, and ABC will
be the greatest height, since D and C are on the same le-
vel of the same perpendicular distance from A. Now
though BD, one side of the parallelogram, is but 3 inches
long; yet BC may be 30 inches long, or more; and con-
sequently since AB is the least height, and ABC is the grea-
est height, the variation of the mercury will be much greater
than in an erect barometer; in particular, if BC is 30 inches
long, the variation will be 30 inches instead of 3, or will
be 10 times greater in the diagonal barometer than it would
have been in an erect one.

The barometer stands at the same perpendicular height,
whether the tube is large or small.

If the mercury stands at the same height either in the
large tube C or in the small tube D, there must be more
mercury in the large one than in the small one. But since
the heights are equal, the quantities of mercury contained in
these tubes will be as their bases. Now since the columns
of air, by which the mercury is supported in these tubes,
are as the respective bases of the tubes, the columns of air
will be proportional to the weights in each tube, when the
perpendicular heights are equal.

But though the heights of the mercury would be the same
in small tubes as in large ones, if, as we must suppose in
the proposition, the mercury moved equally free in both;
yet in fact, upon any change of weather, the variation will
be greater in a large tube than in a small one: because, in

a large tube, the weight of mercury is so great, that the mo-
tion of it will not be hindered by any attraction or repul-
sion of the glass upon it; whereas, in a small tube, where
the weight of mercury is less, the action of the glass is con-
considered in proportion to that weight, and consequently
the variations will be less upon a given change of the weather.

The barometer will commonly be low in rainy weather.

From what has been said already about the barometer, it
appears, that the mercury will be low when the weight of
the atmosphere is diminished; and such a diminution of
the atmosphere will occasion rain. Therefore, since rain
is occasioned by the same cause that makes the mercury
fall, the barometer will commonly stand low in rainy weather.

The barometer is the lowest of all in violent storms of wind.

When the air moves horizontally with a great velocity,
as it does in violent storms of wind, its weight, or rather its
pressure downwards occasioned by its weight, will be dimin-
ished. For as any heavy body may have such a velocity
given it, when it is thrown down horizontally, as may ei-
ther carry it quite off from the earth's centre, or carry it a
velocity as will make it move round the earth in a circle with-
out either departing from the centre or approaching to it;
so every degree of velocity given to the air will make it
tend or pre tend, according to the situation of the air and the
height of it in the tube will be less in storms than it is at any
other time.

When a storm of wind is over, the mercury will rise very fast.

Because as the horizontal velocity of the air ceases, the
pressure downwards will be suddenly relaxed, and conse-

quently the mercury in the barometer will keep rising as this
pressure is relaxed.

Of the THERMOMETER.

The variations of different thermometers are seldom equal,
upon equal variations of heat or cold.

A THERMOMETER is a well known instrument for esti-
mating different degrees of heat or cold. It consists of a
tube or stem, with a hollow ball at one end of it. The ca-
vity of the ball, and part of the tube, is filled with spirits of
wine, or with liquid oil, or with mercury. The upper
end of the tube is commonly sealed hermetically. But in
fealing this end, the liquor in the thermometer is rareified
by heating it till it almost fills the tube; so that when it
is sealed, and the liquor contracts again as it cools, there
will be a vacuum left in the upper part of the tube. Any
of the fluids will rarely be heat; and will contract again
when they cool; and consequently in warm weather, the
spirits, or the oil, or the mercury, whichever the thermo-
meter is made of, will stand higher than in cold weather.

Thus far thermometers may be said to vary alike; they
will either rise or sink from the same cause. But then, up-
on an equal increase of heat, they seldom vary equally,
though they are made of the same liquor. One thermome-
ter made with spirits of wine may vary upon an equal in-
crease of heat much more than another that is made with
the same sort of spirits; so that if one riles an inch, an-
other may rise but ¼ or ½ inch.

The variation of a thermometer is directly as the capacity
of the ball; and inversely as the base of the item. First, If the base of the item or cylindrical tube is given, the variation, when the spirits are equally warmed, will be directly as the capacity of the ball. For when the spirits are equally warmed, and consequently are equally rarefied in the balls of two different thermometers, whatever proportion tlie bulk of the spirits in one ball bears to the bulk of the spirits in the other ball before they were rarefied, the same proportion those bulk will still bear to each other after they are rarefied. Thus, if one ball is double the other, and consequently the bulk of spirits in one is double the bulk of spirits in the other before they are warmed; then, upon being warmed equally, their densities will diminish equally. But if their densities diminish equally, their bulk will still have the same proportion to each other; or the bulk of spirits in one thermometer will still be double the bulk in the other. But if the bulbs continue in the same proportion to each other, after they are swelled as they were before; the spirits must swell in proportion to their respective bulbs, or the spirits in one must swell twice as much as in the other. But if the spirits swell in this proportion, and by swelling rise into equal tubes in each, they must rise twice as high in the tube of one of these thermometers as they do in the tube of the other. And so, in all other instances, the spirits, upon being equally warmed, will swell in proportion to their bulk, that is, in proportion to the capacity of the ball that contains them. But the heights, to which they rise in equal tubes, will be as the increase of their bulk. Therefore the heights to which they rise, or the variations in equal degrees of heat, will be as the capacity of the ball, when the tubes are equal. We have here supposed that the spirits in the balls of the thermometers are equally heated quite through. In sudden changes of heat and cold, it will be otherwise: for the spirits in a small ball will be sooner heated quite through than in a large one. And consequently, if the heat does not last long enough to warm the spirits in a large ball as much as they are warmed in a small one, the spirits will not be equally rarefied in both, and will not swell in proportion to their respective balls; but those in the small ball will swell more in proportion than those in the large one. Secondly, If the balls are equal, the variations will be inversely as the bases of the items. For if the balls are equal, then, upon being equally heated, the spirits contained in them will swell equally; and consequently equal quantities will rise into the items. Now the spirits which rise into a cylindrical item are a cylindrical column. But the heights of equal cylinders are inversely as their bases. Therefore, when the balls are equal, and equal cylinders of spirits rise into the items, the heights to which they rise, or the variations, will be inversely as the bases of the items.

A universal scale may be made, by which the variations of different thermometers may be compared with one another.

Let the ball of a thermometer be put into water when it is beginning to freeze, or, which is the same as to heat or cold, into snow when it is beginning to melt; and let the place where the fluid in the thermometer stands be marked. The place where the fluid stands in such a trial is the freezing point. Let the ball of the same thermometer be put into water just hot enough to let wax, that swims upon it, begin to coagulate. This again is another determinate degree of heat, and is to be marked upon the thermometer.

Divide the distance between these two points into 110 equal parts; and each of these parts we call a degree. Now a thermometer often sinks lower than the freezing point; because the cold is frequently more intense than what is just sufficient to make water freeze: for this reason, the scale must not begin from the freezing point. This point, therefore, should not be marked 0, nor should the point where melted wax begins to coagulate be marked 110. In this scale, which from the inventor is called Fahrenheit's scale, the freezing point is marked 32; and then the point, where melted wax begins to coagulate, being 110 degrees above it, must be marked 142. When the length of a degree is thus found in one part of the scale, 32 degrees of the same length are set off below the freezing point, and as many such degrees as we please are set off above the point where melted wax begins to coagulate. If the thermometer is made with spirits of wine, only 33 degrees need be set off or marked above 142; and then the scale will begin from 0; 32 degrees will be the freezing point; 142 will be the point where melted wax begins to coagulate; and 142-32 = 110 degrees will be the highest point marked in the scale. The reason why no higher degree need be marked in a scale applied to a thermometer made with spirits, is, that at this degree of heat the spirits will boil, and consequently the thermometer would burst. But if the thermometer is made with mercury, the scale should contain at least 212 degrees from the bottom to the top, or 32 degrees below the freezing point, and 180 above it. The heat of boiling water, at the middle height of the mercury in the barometer, or in the middle weight of the atmosphere, will raise the mercury in the thermometer to 212 degrees, or 180 degrees above the freezing point. A thermometer made with mercury will not burst in such a degree of heat as this; for mercury requires a greater degree to make it boil.

In thermometers with such a scale, or, as they are called, in Fahrenheit's thermometers, the greatest degree of heat in the external parts of the human body is commonly about 96. Boerhave imagined that air, if its heat exceeded 80 or 90 degrees at most, would be destructive to the life of animals: but in this he was mistaken. For in the year 1732 the thermometer in Pennsylvania was at the height of 96 or 97; and in the year 1734 the height of it at Petersburg was 98 degrees. The thermometer in our own climate is scarce ever higher than 78 degrees, and seldom lower than 18; so that we may reckon 48 degrees to be the middle temperature of our air.

The variations of different thermometers, though they are not equal, may be compared with one another by Fahrenheit's scale. For each degree upon different thermometers is proportional to their respective variations, and consequently, though in equal heats one may vary more than another, yet each will vary an equal number of degrees. Thus, if, upon any given increase of heat, one thermometer will vary twice as much as another, then the distance between the freezing point and the point where melted wax begins to coagulate will be twice as great, or 110 degrees will be twice as long, in one as in the other. Therefore each degree will be twice as long in the former thermometer as in the latter. But by the supposition, one of these thermometers in a given degree of heat will vary twice as much as the other does; and consequently, whatever heat raises the former one degree, will likewise raise the latter one degree.
If the ball of a thermometer is dipped into hot water, the fluid in the thermometer will sink a little before it begins to rise.

Not only fluids, such as spirits, oil, or mercury, but likewise glass or iron, or almost any hard bodies, will expand when they are heated, and will contract again when they grow cold. Now, when the ball of a thermometer is dipped into hot water, the heat will be communicated to the glass of which the ball is made, before it is communicated to the fluid contained in the ball. By this means the ball will be expanded, and the capacity of it will be increased, so that some of the fluid will sink out of the item into it. But when the ball has been long enough in the water for the fluid within it to be heated, this fluid will be expanded, and then it will rise into the item, and will continue to rise as the heat increases.

Of Sound.

Sound, in the body that produces it, is a trembling motion; this motion is communicated to the air, and conveys it to the ear.

When any elastic body is struck, so as to produce a sound, the body, or some part of it, is made to vibrate. This is evident to see in the strings of a violin or harpsichord; for either the eye may see, or the hand may feel, the trembling of the strings, when by striking them they are made to sound. See Music.

If a bell is struck by its clapper on the inside, the bell is made to vibrate. The base of the bell is a circle; but by striking any part of this circle on the outside, the part which is struck will fly out a little way, so that the diameter, which passes through this part of the circular base, will become longer than another diameter which crosses this at right angles. Therefore by the stroke the base will be changed into an ellipsis, whose longer axis will pass through the part against which the clapper struck. But the elasticity of the bell will restore the figure of the base, and will make the part which was forced out of its place return back. This part in returning will acquire velocity in the same manner as an elastic string would in the same circumstances. And since it acquires velocity in returning to its place, it will not stop at that place, but will continue to rise as the heat increases. Therefore by the stroke the base will be changed into an ellipsis again; only now the shorter axis will pass through the part that was first struck. If the bell was to be struck at first by a hammer on the outside, the part struck would move inwards; and such a motion would likewise change the base into an ellipsis: only in this case the short axis of the ellipsis would pass through that part where the blow was given. The elasticity of the bell will restore its figure; and as the part which was struck will acquire velocity in returning to its proper situation, the acquired velocity will not suffer it to rest there, but will carry it farther out from the opposite side, and the base will by this means be again changed into an ellipsis, having the longer axis at that part where the blow was given. Thus we have seen that wherever the bell is struck, the parts of it will perform one vibration; the part which is struck will yield to the blow; the elasticity of the bell will bring it back to its former situation; in returning, it will acquire velocity; and as far as the blow had driven it one way, so far the acquired velocity will carry it the other. But since, after one vibration is thus performed, the figure of the base will be elliptical; the parts of the bell will vibrate a second time; and so on, in the same manner that an elastic string vibrates.

The same stroke which makes a bell vibrate makes it found too, and as the vibrations decay, the sound grows weaker. Our senses may convince us that the parts of a bell are in a trembling or vibratory motion whilst the bell sounds: for if we lay our hand upon it, we may feel it jar; or if small straws or pieces of paper are thrown upon it, we may see that the jarring or trembling of the bell will put them in motion.

But the air must convey this vibratory motion to the ear: for otherwise, though the sounding body is made to vibrate, no sound will be heard. Thus if a bell is rung in the receiver of an air-pump, the sound will grow weaker as the air is exhausted; and when all the air is drawn out of the receiver, no sound at all will be heard. When the air is admitted again into the receiver, the sound will at the first entrance of the air begin to be heard, and will grow louder as more air returns. If the bell was to be rung in like manner in a vessel where the air is condensed, the sound of it would be much louder than it is in common air. And accordingly, when divers are let down to any great depth of water, because the air in the diving-bell is much condensed, they seem to one another to speak much louder than usual.

The intensity of sound, at different distances from the sounding body, is inversely as the squares of the distances.

Sounds may differ from one another, both in respect of their tone, and in respect of their intensity or strength. In respect of their tone, they are distinguished into grave and acute; in respect of their intensity, they are distinguished into loud or strong, and low or weak. The tone of any sound depends upon the time that an impression continues, and is not altered by the distance of the ear from the sounding body. But the intensity or strength of any sound depends upon the force with which the particles of air, as they are condensed, strike the ear; and this force is found to be different at different distances, so that a sound which is very loud if we are near the body that produces it, would be weaker if we were farther from it, and our distance from it may be so great that we cannot hear it at all.

The proportion in which the intensity of sound decreases, as the distance of the ear from the sounding body increases, is this: If the different distances at which the ear is placed are to one another as 1, 2, 3, 4, 5; then the squares of those distances are 1, 4, 9, 16, 25; and the intensity of sound will be inversely as the squares, or as the reciprocals of the squares; that is, the strength of the sound will decrease in the same proportion with the fractions, \( \frac{1}{1}, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5} \), which are the reciprocals of 1, 4, 9, 16, 25. This is what we mean when we say that the intensity of sound is inversely as the squares of the distances, or that it decreases in the departure of the ear from the sounding body in the same proportion that the squares of the distances increase.

The intensity of sound decreases as the vibrations in the sounding body grow weaker.

If an elastic string was to stop all at once, the sound produced by it would cease immediately. But if the vibrations of
of the string decay gradually, the sound will likewise keep growing weaker, till it becomes too weak to be heard. The string performs all its vibrations from the first to the last in equal times, and consequently each pulse that the string produces is produced in an equal time, and upon that account each pulse from the first to the last will have the same thickness. But when the thickness of the pulse is given, the quantity of air, or number of particles, by which the ear is struck, will likewise be given; and the moment with which it is struck, or the intensity of the sound, will be as the velocity with which the particles move. Now the velocity of the string is successively communicated to the particles of air, as they are made to vibrate. Therefore, as the velocity of the string decays, the velocity of the particles, and consequently the intensity of the sound, will likewise decay.

The intensity of sound is increased by a speaking-trumpet.

When a man speaks without such a trumpet, the pulses, as they are produced, dilate themselves in all directions, or the motion is immediately communicated to the air all round him. But if he speaks in a trumpet, his voice, that is, the motion produced by his voice, is confined to the small portion of air contained in the trumpet. For this reason, as there are fewer particles to be moved than there are when the motion dilates itself immediately in all directions, the motion that is communicated will be greater, and consequently, when the voice comes out of the trumpet, its intensity or strength will be greater, than it would have been if it had been propagated in all directions at first.

Sound moves with the same velocity at all distances from the sounding body.

The sound of a cannon, or of a bell, moves at the rate of 1142 feet in a second at all distances from the gun or the bell. If it moves at this rate for the first mile, it would move just at the same rate for the second mile; so that a person who is within one mile of the cannon when it is discharged, will hear the report just as soon again as another who is at the distance of two miles. The velocity of the sound does not decrease as it is propagated forwards, but continues the same from the first to the last. This property of sound has been proved by repeated experiments.

When sound strikes against an obstacle, it will be reflected.

By sound we here mean the pulses in the air, which are, properly speaking, the cauſes of sound. If these pulses in their progress strike upon any obstacle, fuch as a rock, a thick wood, or the side of a building, the air, which is condensed at the obstacle, is prevented from expanding itself forwards, or from propagating the sound beyond the obstacle. Therefore, in expanding itself, the motion, which would otherwise have been propagated forwards, will be returned from the obstacle; and a person, who is placed so as to receive the pulses in their return, will hear the sound by reflection. Such a reflected sound is called an echo.

The number of syllables which an echo repeats distinctly depends upon the distance of the obstacle from whence the sound is reflected. The syllables that we hear distinctly repeated are those which are returned after we have done speaking. Therefore, if the obstacle is so near to us, that the first syllable we speak will be returned before we can speak a second, no reflected sound at all can be heard distinctly; because the direct and reflected sound, or the voice and the echo, will be confounded with one another. If the obstacle is at such a distance, that five syllables may be spoken before one will be returned; then if we speak a sentence consisting of ten syllables, the first five will be reflected whilst we are speaking the five last, so that in speaking the five last syllables the voice will be confounded with the echo of the five first, and we shall hear the echo of only the five last syllables distinctly, because the other will be returned after we have done speaking. But if the obstacle is at such a distance, that we may speak ten syllables before the first of them will return to the speaker; then if we speak a sentence consisting of only ten syllables, we shall have done speaking before the echo begins, and consequently we may hear the whole sentence distinctly repeated by the echo.

Sometimes the same sound is frequently repeated by an echo. This happens when there are several obstacles at different distances. For though there are several obstacles, yet if all of them are at the same distance, the sound will be returned from them all at one and the same time; and consequently the several reflected sounds will be heard together, and will make but one echo. But if the obstacles are at different distances, each will return the sound at a different time, and as many echoes will be heard as there are obstacles that produce them.

The Diving Bell.

The air in a diving-bell is compressed by the weight of the atmosphere before the bell is let down into the water. But when it has sunk 35 feet below the surface, the air contained in it is compressed by the weight of the atmosphere as before, and by the weight of 35 feet of water besides, which is equivalent to another atmosphere. Therefore the compressing force at this depth is doubled, and consequently the air in the bell will then be twice as dense as the common air that we breathe. As much air, likewise, as just fills the bell, when it is at the surface of the water, will, at the depth of 35 feet, only fill half of it; for as the compressing force is doubled, the same quantity of air will be reduced to half its usual dimensions. For this reason, the water would rise into the bell through the bafe or bottom of it, which is always open, and would fill the other half of it, if there was not a contrivance for bringing down additional air enough to force out this water, and to keep the whole capacity of the bell full of air. However, the air which fills it will, at the depth of 35 feet, have twice the density that common air has; and at the depth of 70 feet, where it will be compressed by the weight of another atmosphere, it will have three times the density of common air.

We shall here give a short account of the contrivance for bringing down additional air to the diving-bell; because it will serve to shew, that if a vessel full of air is sunk into water, and the water communicates with the air in the vessel, then the pressure upon that air will be so much the greater as the vessel is sunk farther below the surface of the water. The contrivance is this. A barrel is made use of, which has one bung-hole in the lower part of it, and another in the upper part. A leather pipe is fastened to the hole in the upper part; and this pipe is so long, that, when it hangs down on the outside of the barrel, its orifice reaches below the bung hole in the lower part. If this barrel, by the help of weights fastened to it, is made to sink with its bottom downwards, the water, by pressing against the lower bung-
bung hole, will condense the air contained in the barrel: for, notwithstanding this pressure, none of the air can escape through the upper hole, because it is kept in by a greater pressure against the orifice of the leathern pipe which hangs below the bottom of the barrel, and consequently, being deeper in the water, sustains a greater pressure than what acts against the lower bung-hole. If the barrel is let down in this manner, till it gets below the bell, and then the end of the leathern pipe is lifted up into the bell; the lower bung-hole will then be more pressed than the orifice of the pipe; and therefore the air contained in the barrel will be driven up through the pipe, and will be received into the bell. And because the barrel is deeper in the water than the bell is, the water will press more against the base of the barrel to force the air out of it than it does against the base of the bell: for which reason the air will rush out of the barrel with force enough to drive out any water which had risen into the bell whilst it was descending.

By the same contrivance, fresh air is brought down to the bell as often as there is occasion for it. The air, which has been heated by frequently breathing it, is let out through a flap cock in the top of the bell and rises in bubbles to the surface of the water, whilst fresh air is received from the leathern pipe of a barrel contrived in the manner already described.

**AIR necessary for the LIFE of ANIMALS.**

All common air is impregnated with a certain kind of vivifying spirit or quality, which is necessary to continue the lives of animals: and this, in a gallon of air, is sufficient for one man during the space of a minute, and not much longer.

This spirit in air is destroyed by passing through the lungs of animals; and hence it is, that an animal dies soon, after being put under a vessel which admits no fresh air to come to it. This spirit is also in the air which is in water; for fishes when they are excluded from fresh air, as in a pond that is closely frozen over, and the little eggs of fish swim up in a glass, do not produce their young, though suffered by a kindly warmth. The seeds also of plants mixed with good earth, and enclosed in a glass, will not grow.

This enlivening quality in air is also destroyed by the air's passing through fire; particularly charcoal fire, or the flame of sulphur. Hence smoking chimneys must be very unwholesome, especially if the rooms they are in be small and close. See Smokes.

Air is also vitiated, by remaining closely pent up in any place for a considerable time; or perhaps, by being mixed with malignant fumes and particles flowing from the neighbouring bodies; or lastly, by the corruption of the vivifying spirit, as in the holds of ships, in oil-cisterns, or wine-cellar, which have been shut up for a considerable time. The air in any of them is sometimes so much vitiated, as to be immediate death to any animal that comes into it.

Air that has lost its vivifying spirit is called damp, not only because it is filled with humid or moist vapours; but because it deadens fire, extinguishes flame, and destroys life. The dreadful effects of damp are sufficiently known to such as work in mines.

The atmosphere is the common receptacle of all the effluvia or vapours arising from different bodies: of the fumes and smoke of things burnt or melted; the fogs or vapours proceeding from damp watery places; and of effluvia from sulphurous, nitrous, acid, and alkaline bodies. In short, whatever may be called volatile, rises in the air to greater or less heights, according to its specific gravity.

When the effluvia which arise from acid and alkaline bodies meet each other in the air, there will be a strong conflict or fermentation between them; which will sometimes be so great, as to produce a fire; then if the effluvia be combustible, the fire will run from one part to another, just as the inflammable matter happens to lie.

Any one may be convinced of this, by mixing an acid and an alkaline fluid together, as the spirit of nitre and oil of cloves; upon the doing of which, a sudden fermentation, with a fine flame, will arise; and if the ingredients be very pure and strong, there will be a sudden explosion.

Whoever considers the effects of fermentation, cannot be at a loss to account for the dreadful effects of thunder and lightnings: (see Electricity:) For the effluvia of sulphurous and nitrous bodies, and others that may rise into the atmosphere, will ferment with each other, and, take fire very often of themselves; sometimes by the assistance of the sun's heat.

If the inflammable matter be thin and light, it will rise to the upper part of the atmosphere, where it will flash without doing any harm; but if it be dense, it will lie nearer the surface of the earth, where taking fire, it will explode with a surprising force; and by its heat rarefy and drive away the air, kill men and cattle, split trees, walls, rocks, &c. and be accompanied with terrible claps of thunder.

The heat of lightening appears to be quite different from that of other fires; for it has been known to run through wood, leather, cloth, &c. without hurting them, while it has broken and melted iron, steel, silver, gold, and other hard bodies. Thus it has melted or burnt afunder a sword, without hurting the scabbard; and money in a man's pocket, without hurting his fingers: the reason of this seems to be, that the particles of the fire are so fine, as to pass through soft loose bodies without difolving them; whilst they spend their whole force upon the hard ones.

It is remarkable, that knives and forks which have been struck with lightening have a very strong magnetical virtue for several years after.

Much of the same kind with lightening, are those explovions, called fulminating or fire-damps, which sometimes happen in mines; and are occasioned by sulphureous and nitrous, or rather oleaginous particles, rising from the mine, and mixing with the air, where they will take fire by the lights which the workmen are obliged to make use of. The fire being kindled will run from one part of the mine to another, like a train of gunpowder, as the combustible matter happens to lie. And as the elascity of the air is increased by heat, that in the mine will consequtely swell very much, and so, for want of room, will explode with a greater or less degree of force, according to the density of the combustible vapours. It is sometimes so strong as to blow up the mine; and at other times so weak, that when it has taken fire at the flame of a candle, it is easily blown out.

Air that will take fire at the flame of a candle may be produced thus. Having exhausted a receiver of the air-pump; let the air run into it through the flame of the oil of turpentine; then remove the cover of the receiver; and holding a candle to that air, it will take fire, and burn quicker or slower, according to the density of the oleaginous vapour.

When such combustible matter, as is above-mentioned, kindles...
kindles in the bowels of the earth, where there is little or no vent, it produces earthquakes, and violent storms or hurricanes of wind when it breaks forth into the air.

An artificial earthquake may be made thus. Take 10 or 15 pounds of sulphur, and as much of the filings of iron, and knead them with common water into the confections of a paste; this being buried in the ground, will, in 8 or 10 hours time, burst out in flames, and cause the earth to tremble all around to a considerable distance.

From this experiment we have a very natural account of the fire of Mount Etna, Veluvius, and other volcanos, they being probably fed on fire at first by the mixture of such metals: the fire of Mount Etna, Veluvius, and other volcanos, they being probably fed on fire at first by the mixture of such metals.

Of the Air-Pump.

The air-pump being in effect the same as the water-pump, (see Hydrostatics,) whoever understands the one will be at no loss to understand the other.

Having put a wet leather on the plate LL of the air-pump, (Plate CXLV. fig. 8.) place the glass receiver M upon the leather, so that the hole i in the plate may be within the glass. Then, turning the handle F backward and forward, the air will be pumped out of the receiver; which will then be held down to the plate by the pressure of the external air or atmosphere. For, as the handle (fig. 9.) is turned backwards, it raises the piston de in the barrel BK, by means of the wheel F and rack DD; and as the piston is levered so tight, as to fit the barrel exactly, no air can get between the piston and barrel; and therefore, all the air above d in the barrel is lifted up towards B, and a vacuum is made in the barrel from e to b; upon which, part of the air in the receiver M (fig. 8.) by its spring, rushes through the hole i, in the brass plate LL, along the pipe CG (which communicates with both barrels by the hollow trunk I HK (fig. g) and, pulling up the valve b, enters into the vacant place be of the barrel BK. For, where-ever the resistance or pressure is taken off, the air will run to that place, if it can find a passage. — Then, as the handle F will be turned forward, the piston de will be depressed in the barrel; and, as the air which had got into the barrel cannot be pushed back through the valve b, it will ascend through a hole in the piston, and escape through a valve at d; and be hindered by that valve from returning into the barrel, when the piston is again raised. At the next raising of the piston, a vacuum is again made in the same manner as before, between b and e; upon which more of the air, which was left in the receiver M, gets out thence by its spring, and runs into the barrel BK, through the valve B. The same thing is to be understood with regard to the other barrel AI, and as the handle F is turned backwards and forwards, it alternately raises and depresses the pistons in their barrels, always raising one whilst it depresses the other. And, as there is a vacuum made in each barrel when its piston is raised, every particle of air in the receiver M pushes out another, by its spring or elasticity, through the hole i and pipe CG, into the barrels, until at last the air in the receiver comes to be so much diluted, and its spring so far weakened, that it can no longer get through the valves; and then no more can be taken out. Hence there is no such thing as making a perfect vacuum in the receiver: for the quantity of air taken out at any one stroke, will always be as the density thereof in the receiver: and therefore it is impossible to take it all out, because, supposing the receiver and barrels of equal capacity, there will be always as much left as was taken out at the last turn of the handle.

There is a cock k below the pump-plate, which being turned lets the air into the receiver again; and then the receiver becomes loose, and may be taken off the plate. The barrels are fixed to the frame Eee by two srew-nuts ff, which press down the top piece E upon the barrels; and the hollow trunk H (in fig. 9.) is covered by a box, as GH in fig. 8.

There is a glass tube lmmn open at both ends, and about 34 inches long; the upper end communicating with the hole in the pump-plate, and the lower end immersed in quicksilver at n in the vessel N. To this tube is fitted a wooden ruler mm, called the gage, which is divided into inches and parts of an inch, from the bottom at n (where it is even with the surface of the quicksilver) and continued up to the top, a little below l, to 30 or 31 inches.

As the air is pumped out of the receiver M, it is likewise pumped out of the glass tube lmn, because that tube opens into the receiver through the pump-plate; and as the tube is gradually emptied of air, the quicksilver in the vessel N is forced up into the tube by the pressure of the atmosphere. And if the receiver could be perfectly exhausted of air, the quicksilver would stand as high in the tube as it does at that time in the barometer: for it is supported by the same power or weight of the atmosphere in both.

The quantity of air exhausted out of the receiver on each turn of the handle, is always proportionable to the ascent of the quicksilver on that turn; and the quantity of air remaining in the receiver, is proportionable to the defect of the height of the quicksilver in the gage, from what it is at that time in the barometer.

EXPERIMENTS WITH THE AIR-PUMP.

1. To shew the resistance of the air.

1. There is a little machine, consisting of two mills, a and b, (ibid. fig. 10.) which are of equal weights, independent of each other, and turn equally free on their axes in the frame. Each mill has four thin arms or fail fixed into the axis; those of the mill a have their planes at right angles to the axis, and those of b have their planes parallel to it. Therefore, as the mill a turns round in common air, it is but little resisted thereby; because its sides cut the air with their thin edges; but the mill b is much resisted, because the broad sides of its slats move against the air when it turns round. In each axle is a pin near the middle of the frame, which goes quite through the axle, and stands out a little on each side of it; upon these pins, the slider d may be made to bear, and so hinder the mills from going when the strong spring c is set on bend against the opposite ends of the pins.

Having set this machine upon the pump-plate LL (fig. 8.) draw up the slider d to the pins on one side, and let the spring c at bend upon the opposite ends of the pins; then push down the slider d, and the spring acting equally strong on each mill, will let them both along with equal forces and velocities: but the mill a will run much longer than the mill b, because the air makes much less resitance against the edges of its slats than against the sides of the fails of b.
Draw up the slider again, and set the spring upon the pins as before; then cover the machine with the receiver \( M \) (fig. 8.), upon the pump-plate, and having exhausted the receiver of air, push down the wire \( PP \) (through the collar of leathers in the neck \( q \)) upon the slider; which will diffuse it from the pins, and allow the mills to turn round by the impulse of the spring; and as there is no air in the receiver to make any sensible resistance against them, they will both move a considerable time longer than they did in the open air; and the moment that one stops, the other will do so too. This shows that air resists bodies in motion, and that equal bodies meet with different degrees of resistance, according as they present greater or less surfaces to the air, in the planes of their motions.

2. Take off the receiver \( M \) (fig. 11.) and the mills; and having put the guinea \( a \) and feather \( b \) upon the brass flap \( c \), turn up the flap, and shut it into the notch \( d \). Then, putting a wet leather over the top of the tall receiver \( AB \) (it being open both at top and bottom) cover it with the plate \( C \) from which the guinea and feather tongs \( ed \) will then hang within the receiver. This done, pump the air out of the receiver; and then draw up the wire \( f \) a little, which by a square piece on its lower end will open the tongs \( ed \); and the flap falling down, as at \( e \), the guinea and feather will descend with equal velocities in the receiver; and both will fall upon the pump-plate at the same instant. N.B. In this experiment, the observers ought not to look at the top, but at the bottom of the receiver; in order to see the guinea and feather fall upon the plate; otherwise, on account of the quickness of their motion, they will escape the sight of the beholders.

II. To shew the weight of the air.

1. Having fitted a brass cap, with a valve tied over it, to the mouth of a thin bottle or Florence flask, whose contents are exactly known, screw the neck of this cap into the hole \( i \) of the pump-plate; then, having exhausted the air out of the flask, and taken it off from the pump, let it be suspended at one end of a balance, and nicely counterpoise it by weights in the scale at the other end; this done, raise up the valve with a pin, and the air will rush into the flask with an audible noise; during which time, the flap will descend, and pull down the end of the beam. When the noise is over, put as many grains into the scale as will restore the equilibrium; and they will shew exactly the weight of the quantity of air which has got into the flask, and filled it. If the flask holds an exact quart, it will be found, that 17 grains will restore the equipoise of the balance, when the quicksilver stands at 29½ inches in the barometer; which shews, that when the air is at a mean rate of density, a quart of it weighs 17 grains; it weighs more when the quicksilver stands higher, and less when it stands lower.

2. Place the small receiver \( O \) (fig. 8.) over the hole \( i \) in the pump-plate; and upon exhausting the air, the receiver will be fixed down to the plate by the pressure of the air on its outside, which is left to act alone, without any air in the receiver to act against it; and this pressure will be equal to as many times 15 pounds, as there are square inches in that part of the plate which the receiver covers; which will hold down the receiver so fast, that it cannot be got off, until the air be let into it by turning the cock \( k \); and then it becomes loose.

3. Set the little glass \( AB \) (fig. 12.) (which is open at both ends) over the hole \( i \) upon the pump-plate \( LL \), and put your hand close upon the top of it at \( B \); then, upon exhausting the air out of the glass, you will find your hand precluded with a great weight upon it; so that you can hardly release it, until the air be re-admitted into the glass by turning the cock \( k \); which air, by acting strongly against the hand as the external air acted in pressing it downward, will release the hand from its confinement.

4. Having tied a piece of wet bladder \( b \) (fig. 13.) over the open top of the glass \( A \) (which is also open at bottom) let it to dry, and then the bladder will be tight as a drum. Then place the open end \( A \) upon the pump-plate, over the hole \( i \), and begin to exhaust the air out of the glass. As the air is exhausting, its spring in the glass will be weakened, and give way to the pressure of the outward air on the bladder, which, as it is precluded, will put on a spherical concave figure, which will grow deeper and deeper, until the strength of the bladder be overcome by the weight of the air; and then it will break with a report as loud as that of a gun—If a flat piece of glass be laid upon the open top of this receiver, and joined to it by a flat ring of wet leather between them; upon pumping the air out of the receiver, the pressure of the outward air upon the flat glass will break it all to pieces.

5. Immerse the neck \( cd \) (fig. 14.) of the hollow glass ball \( eb \) in water, contained in the phial \( aa \); then set it upon the pump-plate, and cover it and the hole \( i \) with the clothe receiver \( A \); and then begin to pump out the air. As the air goes out of the receiver by its spring, it will also by the same means go out of the hollow ball \( eb \), through the neck \( de \), and rise up in bubbles to the surface of the water in the phial: from whence it will make its way, with the rest of the air in the receiver, through the air-pipe \( GG \) and valves \( a \) and \( b \), into the open air. When it has done bubbling in the phial, the ball is sufficiently exhausted; and then, upon turning the cock \( k \), the air will get into the receiver, and press upon the surface of the water in the phial, as to force the water up into the ball in a jet; through the neck \( cd \), and will fill the ball almost full of water. The reason why the ball is not quite filled, is because all the air could not be taken out of it; and the small quantity that was left in, and had expanded itself so as to fill the whole ball, is now condensed into the same article, as the outer air, and remains in a small bubble at the top of the ball; and so keeps the water from filling that part of the ball.

6. Pour some quicksilver into the jar \( D \) (fig. 15.), and set it upon the pump-plate near the hole \( i \); then set on the tall open receiver \( AB \), so as to be over the jar and hole; and cover the receiver with the brass plate \( C \). Screw the open glass tube \( fg \) (which has a brass top on it at \( h \)) into the syringe \( H \); and putting the tube through a hole in the middle of the plate, so as to immerse the lower end of the tube \( e \) in the quicksilver at \( D \), screw the end \( h \) of the syringe into the plate. This done, draw up the piston in the syringe by the ring \( L \), which will make a vacuum in the syringe below the piston; and as the upper end of the tube opens into the syringe, the air will be dilated in the tube, because part of it, by its spring, gets up into the syringe; and the spring of the undilated air in the receiver acting upon the surface of the quicksilver in the jar, will force part of it up into the tube: for the quicksilver will follow the piston in the syringe, in the same way, and for the same reason, that wa-
The weight of the column in the tube is the same as the very near as high as it lands at that time in the barometer. quicksilver, and reaching from the earth to the top of the ported in the barometer by the pressure of the air on its jiilver will rise into it, because there is no air left in the receiver, and it will also come out of the tube, because the tube is close at top. When the gauge moves, the receiver is well exhausted, pull down the tube, so as to immerse its lower end into the quicksilver in the jar. Now, although the tube be exhausted of air, none of the quicksilver will rise into it, because there is no air left in the receiver to press upon its surface in the jar. But let the air into the receiver by the cock k, and the quicksilver will immediately rise in the tube; and stand as high in it, as it was pumped up in the last experiment.

Both these experiments shew, that the quicksilver is supported in the barometer by the pressure of the air on its surface in the box, in which the open end of the tube is placed; and that the more dense and heavy the air is, the higher does the quicksilver rise; and, on the contrary, the thinner and lighter the air is, the more will the quicksilver fall. For, if the handle P be turned ever so little, it takes some air out of the receiver, by raising one or other of the pistons in its barrel; and consequently, that which remains in the receiver is so much the rarer, and has so much the less spring and weight; and therefore, the quicksilver falls a little in the tube; but upon turning the cock, and admitting the air into the receiver, it becomes as weighty as before, and the quicksilver rises again to the same height. Thus we see the reason why the quicksilver in the barometer falls before rain or snow, and rises before fair weather; for, in the former case, the air is too thin and light to bear up the vapours, and in the latter too dense and heavy to let them fall.

N. B. In all mercurial experiments with the air-pump, a short pipe must be screwed into the hole i, so as to rise about an inch above the plate, to prevent the quicksilver, from getting into the air-pipe and barrels, in case any of it should be accidentally spilt over the jar; for if it once gets into the pipes or barrels, it spoils them, by loosening the folder, and corroding the brass.

8. Take the tube out of the receiver, and put one end of a bit of dry hazel-branch, about an inch long, tight in the hole, and the other end tight into a hole quite through the bottom of a small wooden cup; then pour some quicksilver into the cup, and exhaust the receiver of air; and the pressure of the outward air, on the surface of the quicksilver, will force it through the pores of the hazel, from whence it will descend in a beautiful shower into a cup placed under the receiver to catch it.

9. Put a wire through the collar of leathers in the top of the receiver, and fix a bit of dry wood on the end of the wire within the receiver; then exhaust the air, and pull the wire down, so as to immerse the wood into a jar of quicksilver on the pump-plate: this done, let in the air; and upon taking the wood out of the jar, and splitting it, its pores will be found full of quicksilver, which the force of the air, upon being let into the receiver, drove into the wood.

10. Join the two brass hemispherical cups A and B (fig. 17.) together, with a wet leather between them, having a hole in the middle of it; then screw the end D of the pipe CD into the plate of the pump at i, and turn the cock E; so the pipe may be open all the way into the cavity of the hemispheres; then exhaust the air out of them, and turn the cock a quarter round, which will shut the pipe CD, and keep out the air. This done, unscrew the pipe at D from the pump, and screw the piece Fh upon it at D; and let two strong men try to pull the hemispheres asunder by the rings g and h, which they will find hard to do; for if the diameter of the hemispheres be four inches, they will be pressed together by the external air with a force equal to 188 pounds. And to shew that it is the pressure of the air that keeps them together, hang them by either of the rings upon the hook P of the wire in the receiver M (fig. 8.) upon exhausting the air out of the receiver, they will fall asunder of themselves.

11. Place a small receiver O (fig. 8.) near the hole i on the pump-plate, and cover both it and the hole with the receiver M; and turn the wire so by the top P, that its hook may take hold of the little receiver by a ring at its top, allowing that receiver to stand with its own weight on the plate. Then, upon working the pump, the air will come out of both receivers; but the large one M will be forcibly held down to the pump by the pressure of the external air; whilst the small O, having no air to press upon it, will continue loose, and may be drawn up and let down at pleasure, by the wire PP. But, upon letting it quite down to the plate, and admitting the air into the receiver M, by the cock k, the air will press so strongly upon the small receiver O, as to fix it down to the plate; and at the same time, by counterbalancing the outward pressure on the large receiver M, it will become loose. This experiment evidently shews, that the receivers are held down by pressure, and not by suction, for the internal receiver continued loose whilst the operator was pumping, and the external one was held down: but the former became fast immediately, by letting in the air upon it.

12. Screw the end A (fig. 18.) of the brass pipe ABF into the hole of the pump-plate, and turn the cock e until the pipe be open; then put a wet leather upon the plate cd, which...
which is fixed on the pipe, and cover it with the tall receiver $GH$, which is close at top; then exhaust the air out of the receiver, and turn the cock $e$ to keep it out; which done, unscrew the pipe from the pump, and set its end $A$ into a basin of water, and turn the cock $e$ to open the pipe; on which, as there is no air in the receiver, the pressure of the atmosphere on the water in the basin will drive the water forcibly through the pipe, and it will play up in a jet to the top of the receiver.

13. Set the square phial $A$ (fig. 21.) upon the pump-plate; and having covered it with the wire-cage $B$, put a clofe receiver over it, and exhaust the air out of the receiver; in doing of which, the air will also make its way out of the phial through a small hole in its neck under the valve $b$. When the air is exhausted, turn the cock below the plate, to re-admit the air into the receiver; and as it cannot get into the phial again, because of the valve, the phial will be broke into some thousands of pieces by the pressure of the air upon it. Had the phial been of a round form, it would have sustained this pressure like an arch, without breaking; but as its sides are flat, it cannot.

To prove the elasticity or spring of the air.

14. Tie up a very small quantity of air in a bladder, and put it under a receiver; then exhaust the air out of the receiver, and the small quantity which is confined in the bladder (having nothing to act against it) will expand itself so by the force of its spring, to fill the bladder as full as it could be blown of common air. But upon letting the air into the receiver again, it will overpower the air in the bladder, and press its sides almost close together.

15. If the bladder so tied up be put into a wooden box, and have 20 or 30 pounds weight of lead put upon it in the box, and the box be covered with a clofe receiver; upon exhausting the air out of the receiver, that air which is confined in the bladder will expand itself so, as to raise up all the lead by the force of its spring.

16. Take the glass-ball mentioned in the fifth experiment, (fig. 14.), which was left full of water all but a small bubble of air at top, and having set it with its neck downward into the empty phial $aa$, and covered it with a clofe receiver, exhaust the air out of the receiver, and the small bubble of air in the top of the ball will expand itself, so as to force all the water out of the ball into the phial.

17. Screw the pipe $AB$ (fig. 18.) into the pump-plate, place the tall receiver $GH$ upon the plate $cd$, as in the twelfth experiment, and exhaust the air out of the receiver: then, turn the cock $e$, to keep out the air; unscrew the pipe from the pump, and screw it into the mouth of the copper vessel $CC$ (fig. 22.), the vessel having first been about half filled with water. Then turn the cock $e$ (fig. 18.) and the spring of the air which is confined in the upper vessel will force the water up through the pipe $AB$ in a jet into the exhausted receiver, as strongly as it did by its preffure on the surface of the water in a basin, in the twelfth experiment.

18. If a fowl, a cat, rat, a mouse, or bird, be put under a receiver, and the air be exhausted, the animal will be at first oppressed as with a great weight, then grow convulsed, and at last expire in all the agonies of a most bitter and cruel death.

19. If a butterfly be suspended in a receiver, by a fine thread tied to one of its horns, it will fly about in the receiver, as long as the receiver continues full of air; but if the air be exhausted, though the animal will not die, and continue to flutter its wings, it cannot remove itself from the place where it hangs in the middle of the receiver, until the air be let in again, and then the animal will fly about as before.

20. Pour some quicksilver into the small bottle $A$ (fig. 19.) and screw the brass collar $c$ of the tube $BC$ into the brass neck $b$ of the bottle, and the lower end of the tube will be immerfed into the quicksilver, so that the air above the quicksilver in the bottle will be confined there, because it cannot get out about the joinings, nor can it be drawn out through the quicksilver into the tube. This tube is also open at top, and is to be covered with the receiver $G$ and large tube $BP$, which tube is fixed by brass collars to the receiver, and is close at the top. This preparation being made, exhaust the air both out of the receiver and its tube; and the air will by the same means be exhausted out of the inner tube $BC$, through its open top at $C$; and as the receiver and tubes are exhausting, the air that is confined in the glass bottle $A$ will press its by its spring upon the surface of the quicksilver, as to force it up in the inner tube as high as it was raised in the ninth experiment by the pressure of the atmosphere; which demonstrates that the spring of the air is equivalent to its weight.

21. Screw the end $C$ (fig. 20.) of the pipe $CD$ into the hole of the pump-plate, and turn all the three cocks $d, G$, and $H$, so as to open the communications between all the three pipes $E, F, DC$, and the hollow trunk $AB$. Then, cover the plates $g$ and $b$ with wet leathers, which have holes in their middle where the pipes open into the plates; and place the clofe receiver $I$ upon the plate $g$: this done, flout the pipe $F$ by turning the cock $H$, and exhaust the air out of the receiver $I$. Then turn the cock $d$, to flout the air out; unscrew the machine from the pump; and having screwed it to the wooden foot $L$, put the receiver $K$ upon the plate $b$: this receiver will continue flooe on the plate as long as it keeps full of air; which it will do until the cock $H$ is turned to open the communication between the pipes $F$ and $E$, through the trunk $AB$; and then the air in the receiver $K$, having nothing to act against its spring, will run from $K$ into $I$, until it be so divided between these receivers, as to be of equal denfity in both; and they will be held down with equal forces to their plates by the pressure of the atmosphere, though each receiver will then be kept down but with one half of pressure upon it that the receiver $I$ had when it was exhausted of air; because it has now one half of the common air in it which filled the receiver $K$ when it was fet upon the plate; and therefore a force equal to half the force of the spring of common air will act within the receivers against the whole preflure of the common air upon their outsides. This is called transferring the air out of one vessel into another.

22. Put a cork into the square phial $A$, (fig. 21.) and fix it in with wax or cement; put the phial upon the pump plate with the wire-cage $B$ over it, and cover the cage with a clofe receiver. Then, exhaust the air out of the receiver; and the air that was corked up in the phial will break the phial outwards by the force of its spring, because there is no air left on the outside of the phial to act against the air within it.

23. Put a shrivelled apple under a clofe receiver, and exhaust the air; then the spring of the air within the apple will pump it out, so as to caufe all the wrinkles to disappear; but
but upon letting the air into the receiver again, to press upon the apple, it will instantly return to its former decayed and shrivelled state.

23. Take a fresh egg, and cut off a little of the shell and film from its smallest end; then put the egg under a receiver, and pump out the air; upon which, all the contents in the egg will be forced out into the receiver, by the expansion of a small bubble of air contained in the great end, between the shell and film.

24. Put some warm beer in a glass; and having set it on the pump, cover it with a close receiver, and then exhaust the air. Whilst this is doing, and thereby the pressure more and more taken off from the beer in the glass, the air therein will expand itself, and rise up in innumerable bubbles to the surface of the beer; and from thence it will be taken away with the other air in the receiver. When the receiver is near exhausted, the air in the beer, which could not disentangle itself quick enough to get off with the rest, will now expand itself so, as to cause the beer to have all the appearance of boiling; and the greatest part of it will go over the glass.

25. Put some warm water in a glass, and put a bit of dry wainscot or other wood into the water. Then, cover the glass with a close receiver, and exhaust the air; upon which, the air in the wood having liberty to expand itself, will come out plentifully, and make all the water to bubble about the wood, especially about the ends, because the pores lie lengthwise. A cubic inch of dry wainscot has so much air in it, that it will continue bubbling for near half an hour together.

Of WINDS.

As the air is a fluid, subject to the same laws of gravitation as other fluids, it necessarily has a constant tendency to preserve an equilibrium in every part; so that, if by any means whatever it is rendered lighter in any one place than another, the lighter air will rush in from every side towards this place, till as much be there accumulated as makes it of an equal weight with the rest of the atmosphere: It is these currents of air which are called winds.

Many are the causes which may vary the weight of the atmosphere, and occasion particular topical winds.

Although other causes may occasion winds in certain circumstances, yet their principal and most universal cause is the sun, which warmeth the air to a much greater degree in some places of the atmosphere than in others; and as the air is susceptible of a great degree of expansion by heat in those places where it is heated to any considerable degree, it is expanded so much as to become lighter than the air in those places where it is colder; so that the lighter cold air from all the circumjacent parts rushes towards this point to restore the equilibrium which had been destroyed. So that if there be any particular part upon the earth's surface where the sun acts contantly with greater force than on any other part, a current of air will constantly flow from these towards the warmer region; but the sun acts with greater force upon those parts of the earth which are nearest the Equator, than those which approach towards either Pole; so that we might naturally expect that a wind would constantly blow from the polar regions towards the Equator; which is really found to be the case in the Torrid Zone, where the influence of the sun overcomes almost all the other lesser causes which produce the variable winds in our more northerly regions. However, even in the Torrid Zone, these north and south winds are varied in different ways.

Although the heat of the equatorial region is greater than in any other: yet as the sun acts perpendicularly in his diurnal course upon one point of the earth only at one time, and immediately passes over it; and as the air retains the heat communicated to it by the sun but for a short time, cooling gradually as he retires, and continuing still to decrease till his influence again returns the following day; the degree of heat upon this great circle must be very different in different parts, and perpetually varying in every point; which must in some measure tend to disturb those winds coming from the polar regions, which we have already mentioned. To comprehend clearly what will be the effects of this rotation, let us consider what effect it would naturally produce upon the equator with regard to wind, supposing no other cause should interrupt it. And here we must observe, that as the point upon which the sun acts with the greatest power is constantly moving from east to west, the air to the east of that point over which the sun has more lately passed will be more rarified than that to the west, and will naturally flow towards that point from east to west with greater velocity than from west to east, as the cool air to the west of that point will be interrupted in its motion towards it by the motion of the sun meeting it. Hence therefore it follows, that from the diurnal motion of the earth from west to east a constant easterly wind would always be produced, were it not obstructed by other causes. But as there is a constant stream of air flowing from the polar regions towards the equatorial regions, a composition of these two currents of air acting at the same time will produce a north-easterly wind in all parts of the northern hemisphere, and a south-easterly wind in all parts of the southern one. These winds are known by the name of the general trade-winds.

If there were no inequalities on the surface of our globe, and if it were composed of a substance perfectly homogeneous, this wind would invariably take place at all times on every part of the earth's surface; but as this is not the case, it is liable to several very considerable variations. In all these regions towards the poles, as the influence of the sun is there but weak, other lesser causes occasion particular winds, and disturb that regularity which at first view we might expect, so that the general trade wind does not invariably take place beyond the 28th or 30th degree of latitude; and the regions between that and the poles have nothing but variable winds.

Even in the Torrid Zone, there are many causes which in particular places alter this direction of the wind; so that the genuine trade-winds do not take place except in the Atlantic and Pacific oceans on each side the equator to the distance of 28 or 30 degrees, and in the greatest part of the Indian ocean to the south of the Equator as appears, more distinctly upon the Map, see Plate CXLVI. where the course of the winds are marked by the direction of the arrows, the darts pointing in the same direction as the wind blows.

Having thus explained the nature and causes of the general trade wind, we now proceed to take notice of the principal deviations which take place in the Torrid Zone. The general trade-wind, when thus altered at particular stations, is known by the name of monsoons. There are other variations, which, although as general, are yet of smaller and more limited influence. These are known by the name of breezes; and as they blow periodically from the sea, they are denominated sea or land breezes, and take place more
or less in every sea coast within the tropics. As the causes of the monsoons will be more clearly comprehended after the nature of these breezes is explained, we shall first consider them.

The sea and land breezes of the Torrid Zone are gentle periodical winds regularly shifting twice every day, and blowing from the sea towards the land during the daytime, and from the land towards the sea in the night. These breezes do not blow with an equal degree of force throughout the whole day and night, but are perpetually varying, being always strongest about midday and midnight, and becoming gradually weaker till the time of change in the evening and morning; about which time the air continues for a short space perfectly calm; but in a little the breeze begins to be felt on the side opposite to that from which it blew last, so faint at first as hardly to be perceived; but by degrees acquiring greater strength, it goes on increasing for five or six hours, after which it again as gradually sinks and dies away. They always blow directly off or towards the shore, and never extend their influence to a great distance from it, although this is varied by particular circumstances in different places; as they never extend far from the points of capes and promontories, as in deep bays; nor upon the windward, as lee-shores.

These breezes are produced by the same cause which gives rise to the trade-wind, viz., the heat of the sun. In these warm regions the days and nights are nearly of an equal length throughout the whole year; the sun rising high in the daytime, and descending almost perpendicularly at night; which occasions a much greater variation between the heat of the day and night than is experienced in the more temperate climates; and it is this great difference between the heat of the night and day which produces the breeze. For the rays of the sun are reverberated from the land during the daytime, much more powerfully than from the sea, whose surface is constantly evaporating; and the air above the land is rendered much warmer, and consequently more rarified, than above the sea; so that a current of air necessarily takes place at that time from the sea towards the land, increasing and diminishing in strength as the heat increases or declines. But when the sun descends below the horizon, the evaporation from the surface of the sea is stopped, or greatly diminished, and the cold which it occasioned is of consequence removed: the reverberation of the sun’s rays from the surface of the earth is likewise removed, and the air above the land is quickly rendered its natural degree of cold, which is always greater than the sea, when the influence of the sun is withdrawn; so that the air above the sea becomes warmer during the night than that above the land, and a current of air is of course established from the land to the sea, which forms the land-breeze, which acts as uniformly, although less powerfully, than the sea-breeze; blowing at first gently as the air begins to cool, and gradually gathering strength as the sun retires below the horizon; till its influence begins to be felt again in the morning, when it gradually gives place to the more powerful influences of the sea-breeze. These breezes are not, however, entirely confined to the Torrid Zone. They are even felt in more northern regions: the sea-breeze in particular being almost perceptible during the summer season along the coasts of the Mediterranean and the Levant, both on the African, and European and Asiatic shores, as within the tropics. Even in our own colder climate, the effects of this are often distinctly felt during the summer season; although, from the length of the day and shortness of the night, the difference between the heat of these is far less than in warmer climates. And although the shortness of our nights prevents us from feeling a nocturnal breeze, similar to the land-breezes of the Torrid Zone; yet in every serene evening we have an opportunity of observing a phenomenon, proceeding from a similar cause with that which occasions them in warmer climates. For as the waters retain their heat longer than the earth after the sun withdraws, the moisture which was raised during the heat of the day to a small distance from the earth’s surface is quickly condensed by the cold of the evening, and falls down in copious dews; whereas that which is above the surface of the water is more slowly condensed, by reason of the heat which that element retains longer; and hovers at a small distance above it in the form of a dense vapour, which slowly subides as it loses its heat. This is the cause of those low mists which are so often seen hovering above the surface of rivers and other waters in the evenings towards the end of summer.

It was already observed, that in the Indian ocean the general trade-wind only took place in some parts to the south of the Equator. To the north of the line, and in some places to the south of it in that ocean, the general trade-wind only blows regularly for six months, and during the other six months the wind blows in a direction entirely opposite. It is these winds, which shift thus regularly, which are called Monsoons, although they are also sometimes called trade-winds.

At the Equator the days and nights are always of an equal length throughout the whole year; so that the heat being thus equally divided, it never arrives to such an intense degree as to be insupportable to the inhabitants. And as there is no vicissitude of seasons at the Equator, so at the Poles they never experience the more pleasing vicissitudes of day and night. The sun never setting during the summer season; and although the day decreases in length as we recede from the pole, from six months to twenty-four hours; yet in all high latitudes the sun descends for such a short space below the horizon, and in such an oblique direction, that the difference between the heat of the day and night is but very inconsiderable. From which it follows, that during this season, when the sun continues to act with such uninterrupted influence upon the surface of the earth, the air will then be rarified more above the dry land than upon the surface of the water; so that a wind would naturally set in at that time from the sea towards the land, similar to the diurnal sea-breezes in the warmer climates; and on the contrary, during the winter season, the air in these northern regions being colder above the land than the water, the winds will naturally blow from the land towards the sea, similar to the land-breezes of the Torrid Zone. But as the influence of the sun, although of longer continuance, is in general more languid in climates of a high latitude than in those near the line, it is not to be expected that these effects will follow with the same regularity as in the Torrid Zone: being more apt to be interrupted by leffer causes which affect the atmosphere and produce winds in different directions. Yet these are not so totally interrupted, but that we can easily trace their effects even in our own cold climate: For during the summer season, the large continent to the east of us, being more heated than the Atlantic ocean westward, produces...
A View of the General and

ations are wanting to confirm this.
Neither is it easy to ascertain, with precision,
to the south of the equator, extend west from
On the eastern part of this ocean, lying so much farther south than the kingdom of Arabia and Persia; so that these, being more heated than the ocean to the westward, naturally draw the winds towards them, and produce the easterly variation of the monsoon which takes place in this part of the ocean, while the warm and sandy deserts of Arabia draw the winds more directly northward near the African coasts.

In the eastern parts of the Indian ocean, beyond the island of Sumatra, and as far as the gulph of Siam, the bay of Tonquin, and along the southern parts of China, and among the Philippine islands, &c. to the north of the Equator, the monsoons observe a different direction, blowing nearly due south and north. Here the greatest part of the warm continent is to the west of this district, which makes the wind naturally assume this direction. A little to the east of this, among the Mariamne islands, the general trade-wind takes place, there being no continent to the north of them to occasion monsoons.

The monsoons are as regular in the eastern part of the Indian ocean to the south of the Equator, as they are to the north of it; as here a northern monsoon sets in from the month of October till April, and a southern from April till October. And here, as to the north of the line, we find the direction of the monsoons varying according to particular circumstances in different places: for about the island of Sumatra, and towards the west end of Java, the monsoons set in nearly from the north and south; but toward Celebes and Timur, they begin to tend a little more to the east and west, gradually declining as they approach the coast of New Guinea, near to which the northern monsoon from October till April blows from the N. W. and the opposite monsoon from the S. E. between October and April. The reader will easily perceive that these monsoons are occasioned by the continent of New Holland and Guinea, which being heated by the sun when in the southern signs, draws the wind towards that in the summer season, in the same manner as the continent of Asia produces the monsoons to the north of the line. And it is likewise sufficiently plain, that the influence of these periodical winds about Celebes and Timur is occasioned by that part of the continent called New Guinea, jutting out far to the north of the Equator, in which the wind is strong, and drawing the wind toward that quarter.

These are the most general and extensive monsoons which take place in our globe. But there are other periodical winds, which occur in particular places in the warm regions, that deserve particular attention.

In the Red-Sea, the monsoon shifts as regularly as in other places; but being influenced by the coasts, it tends a little more to the north and south than in the Indian ocean.

On the south coast of Africa, to the south of C. Corientes, and about the southern parts of the island of Madagascar, the regular trade-wind from the S. E. takes place between October and April; but from April till October the wind blows from the W. or N. W., and is at that season exceedingy cold. This is evidently occasioned by a cause already taken notice of: for, notwithstanding the high and cold nature of this continent, yet when the sun is to the south of the line, his powerful influence at that season so far abates their natural degree of cold, as not to interrupt the general trade-wind between the months of October and April. But when he returns to the northern hemisphere, the high mountains of Africa resume their native coldness, and repel the general trade-winds by their cold and more powerful

This being a general tendency of the current of air towards the east, inasmuch that westerly winds are observed to prevail more than any other, not only here, but in all the coasts of the ocean, the continental line, during the summer season. And easterly winds become again more prevalent in the winter and spring. On the contrary, it is observed in North America, that the easterly winds prevail more in summer than at any other time; and the westerly winds always prevail during the cold months of winter. The same effects take place with a greater degree of constancy in other parts of Europe, particularly in Greece, and the countries in that neighbourhood; as the ancient Greeks have particularly remarked, that the winds blew from the south during the heat of summer, particularly about the dog-days, and from the north during the colder weather of winter.

Any attentive reader, who has accompanied us thus far, will readily see, that the monsoons which take place in the Indian ocean proceed from the same general cause. For when the sun, in his annual course, has crossed the line, and comes to act very strongly upon the extensive countries of Arabia, Persia, China, and the other parts of India, these countries become heated to a much higher degree than the ocean to the south of them; and the air above these extensive countries being so much rarified, naturally draws the wind towards that place. which, by overcoming the general trade-wind, produces the southerly monsoons which take place in all those seas during the months of April, May, June, July, August, and September. But when the sun has again retreated towards the southern hemisphere, this great degree of heat in those countries subsides, and the genuine trade-wind again refumes its natural course; forming what they call the northerly monsoon, which blows in the months of October, November, December, January, February, and March: and as the continent of Asia now assumes a greater degree of cold than the Atlantic or Pacific oceans in the same latitude, it produces a brisker and more steady gale during the continuance of this monsoon, than is ever experienced in the general trade wind.

Having thus explained the nature of the monsoons in general, we shall proceed to consider the particular winds which influence the direction of these in those parts where they take place. In all that part of the Indian ocean which lies between the island of Madagascar and Cape Comorin, the wind blows constantly from the W. S. W. between the months of April and October; and in the opposite direction from the month of October till April, although with some variation in different places, as these winds are neither so strong nor constant in the Bay of Bengal as in the Indian ocean. And it is likewise remarkable, that the S. W. winds in these seas are generally more southerly on the African side, and more easterly on the Indian, as appears distinctly in the map. But these variations are not repugnant to the general theory. For it is sufficiently known, that high lands in every part of the globe are much colder than low and flat countries; and as that part of Africa is very high and mountainous, the cold in these regions is much greater than in the more flat countries of Arabia and India; so that the wind naturally blows from these cold regions, in the summer season, towards the warmer continent of Asia; which occasions those inflections of the wind to the easterly which take place in these seas during the summer months; and is still farther assisted by the peninsula of India, the kingdom of Siam, and the islands of Sumatra and Java, on the eastern part of this ocean, lying so much farther south than the kingdom of Arabia and Persia; so that these, being more heated than the ocean to the westward, naturally draw the winds towards them, and produce the easterly variation of the monsoon which takes place in this part of the ocean, while the warm and sandy deserts of Arabia draw the winds more directly northward near the African coasts.

In the eastern parts of the Indian ocean, beyond the island of Sumatra, and as far as the gulph of Siam, the bay of Tonquin, and along the southern parts of China, and among the Philippine islands, &c. to the north of the Equator, the monsoons observe a different direction, blowing nearly due south and north. Here the greatest part of the warm continent is to the west of this district, which makes the wind naturally assume this direction. A little to the east of this, among the Mariamne islands, the general trade-wind takes place, there being no continent to the north of them to occasion monsoons.

The monsoons are as regular in the eastern part of the Indian ocean to the south of the Equator, as they are to the north of it; as here a northern monsoon sets in from the month of October till April, and a southern from April till October. And here, as to the north of the line, we find the direction of the monsoons varying according to particular circumstances in different places: for about the island of Sumatra, and towards the west end of Java, the monsoons set in nearly from the north and south; but toward Celebes and Timur, they begin to tend a little more to the east and west, gradually declining as they approach the coast of New Guinea, near to which the northern monsoon from October till April blows from the N. W. and the opposite monsoon from the S. E. between October and April. The reader will easily perceive that these monsoons are occasioned by the continent of New Holland and Guinea, which being heated by the sun when in the southern signs, draws the wind towards that in the summer season, in the same manner as the continent of Asia produces the monsoons to the north of the line. And it is likewise sufficiently plain, that the influence of these periodical winds about Celebes and Timur is occasioned by that part of the continent called New Guinea, jutting out far to the north of the Equator, in which the wind is strong, and drawing the wind toward that quarter.

These are the most general and extensive monsoons which take place in our globe. But there are other periodical winds, which occur in particular places in the warm regions, that deserve particular attention.

In the Red-Sea, the monsoon shifts as regularly as in other places; but being influenced by the coasts, it tends a little more to the north and south than in the Indian ocean.

On the south coast of Africa, to the south of C. Corientes, and about the southern parts of the island of Madagascar, the regular trade-wind from the S. E. takes place between October and April; but from April till October the wind blows from the W. or N. W., and is at that season exceedingly cold. This is evidently occasioned by a cause already taken notice of: for, notwithstanding the high and cold nature of this continent, yet when the sun is to the south of the line, his powerful influence at that season so far abates their natural degree of cold, as not to interrupt the general trade-wind between the months of October and April. But when he returns to the northern hemisphere, the high mountains of Africa resume their native coldness, and repel the general trade-winds by their cold and more powerful...
ful blast, so as to produce the intertemporarv monsoon which here takes place between the months of April and October.

From Mozambique, to cape Guardafayo, at the mouth of the Red Sea, the monsoons are a little more irregular than in the other parts of the Indian ocean. For it is observed, that between October and January the winds are variable, although chiefly from the north. In January the N. E. monsoon sets in, and continues regular till the month of May. From May till October the winds again become variable, but blow chiefly from the southern points; but in the months of June, July, and August, there are frequent calms, especially about the bay of Melinda, which sometimes continue for several weeks together, and extend only about a hundred leagues from shore.

Before we can explain the cause of this irregularity clearly, it will be necessary to attend to the direction of the wind on each side of this track at each particular season. In the months of October, November, and December, the winds are here variable, but chiefly from the north. Now during these three months, the wind to the south of this beyond C. Corientes blows from the S. E. at the Red Sea, and all to the north of this the wind during this season of the year is from the N. E. And as the sun is then perpendicular to the bay of Melinda, those opposite winds here meeting and opposing one another, and being both of them frow in their course westward by the cold regions of Africa near the Mountains of the Moon, will naturally produce the variable winds here observed according as the one or the other of these three balancing powers shall predominate; although, as the coast here runs away towards the south-west, it is natural to expect that the northerly wind, which follows the same direction, should more frequently prevail than those which are opposed by it; especially when we consider, that the island of Madagascar, now beginning to be warmed by the influence of the sun, will concur in drawing the wind to the southward; and when the continent of Africa is more heated in the months of January and February, it does not oppose the easterly monsoon, so that the winds become then more fixed than before. But in the months of June, July, and August, the wind to the south of C. Corientes is from the N. W.; and near the Red Sea, and throughout the northern part of the Indian ocean, the S. W. monsoon is then in its greatest vigour; so that on each end of this district the wind is blowing in an opposite direction; from which results these calms about Melinda, which we just now mentioned.

This much may suffice for the shifting winds on the African and Asiatic coasts. As to America, the only places where the wind shifts regularly are, the bays of Honduras and Campeachy on the east, and that of Panama and some parts on the coast of Mexico on the west, with a small track upon the coast of Brazil. In the south part of the bay of Honduras, between C. Gratia de Dios and C. la Bela, the common trade-wind between E and NE blows between March and November; from October till March, there are westerly winds; not constant or violent, but blowing moderately sometimes two or three days, or a week; and then the easterly breeze may again prevail for an equal length of time. The reason of the peculiarity here observed is this. During the summer season, the high land on the Isthmus of Darien is so much warmed as not to interrupt the course of the general trade-winds. But when he retires to the southern hemisphere, the cold upon the Isthmus at that season becomes so great, as to condense the air to such a degree as to repel the trade-wind for some time: but not being cooled to such an intense degree as in some of the larger continents, the trade-wind at times overcomes and repels these land breezes in its turn, and produces the phenomena above described. And that this is really the case, appears evident from this circumstance, that the land-breezes are most prevalent and of longest duration in the colder months of December and January; before and after which two months, the trade-wind being generally checked, only a day or two about the full or change of the moon. As these western breezes on this coast take their rise from the same cause as the diurnal land breeze in warm climates, they may be considered as land-breezes of two or three days continuance, and forming an intermediate step between the land-breezes and monsoons. Although the influence of these breezes is felt farther off at sea than the common diurnal breeze, yet they do not extend a great way, being seldom felt above twenty or thirty or forty leagues from shore; and about C. La Vela, which is much exposed to the easterly wind, these breezes extend beyond eight or ten leagues from shore. Land breezes of the same nature, and proceeding from similar causes, are also experienced in the winter season in the bay of Campeachy which are there known by the name of Susamajenta winds. Beyond C. la Vela these western breezes are not felt, which is undoubtedly occasioned by the whole of that coast as far as C. St Augufine being so much exposed to the general trade-wind, which here sweeps along the coast with so much violence as almost totally to repel the weaker influence of the breezes. But between C. St Augufine and St Catharine's island, or a little farther, we again meet with a variation of the wind at different seasons, as it is here observed to blow in an E or NE direction from September till April; and from April till September from the SW. This variable wind, or monsoon, like the others on this coast, extends but for a very short way from shore, and is evidently occasioned by the same causes as the other periodical winds. For, in the summer-months, (which in this climate is between September and April, the land of the continent being heated by the sun, draws the trade-wind from its common course of SE, a little to the westward; and as the coast here tends towards the SW, the wind in some measure (as it always does) follows the same direction, and produces this ENE monsoon. But, in the winter, when this region becomes more cool, the easterly wind is repelled by the dense cold air from the mountains; by which means it is bent to the northward, and is forced along the coast to C. St Augufine; where meeting with no further hindrance, it again falls in with the general trade-wind, and is carried along with it in its proper direction.

We have purposely omitted mentioning the winds on the west coasts of Africa and America, till the others were explained, as the causes of the peculiarities here observed will be now more easily comprehended. On the coasts of Chili and Peru, in America, from 25° or 30° of south latitude to the line; and on the parallel coasts of Angola, &c. in Africa, the wind blows all the year from the south, varying in its direction a little in different places according to the direction of the coast, towards which it always inclines a little. But whatever is the direction at any one place, it continues the same throughout the whole year without
any variation, and always blows from some westerly point. But there is this difference between this wind upon the coasts of Chili and Angola, that it extends much farther out to sea upon the former than upon the latter.

In order to explain the cause of this singular phenomenon, it is necessary to recollect, that the general trade-wind is produced by the concurrence of two separate causes. One is the great heat of the equatorial region, by which alone would be produced a constant north or south wind. The other is the diurnal revolution of the earth, which would cause a perpetual tendency of the air in those warm regions from east to west. From the concurrence of these two causes result the general trade-wind, which would constantly blow from the SE or NE, as we have already demonstrated. But if any one of these two causes, in any particular place, is prevented from producing its full effect, while the other continues to exert its influence, the general direction of the wind will be varied, and it will assume another. Thus, if the east wind was prevented from acting in any particular place, while nothing interrupted the south or north wind, it is evident that the air would rush towards the equator in that direction which was nearest and easest, whether that should be pointing eastward or westward.

Now as the high mountains in the internal parts of Africa and America interrupt the course of the east wind near the surface of the earth, while these coasts of which we now treat are entirely open to the south, the wind naturally rushes along the coasts of Chili and Angola from north to south; and as the low lands near the shore, in those warm regions, is generally warmer than the sea, the wind will naturally point in towards the shore, as is generally observed to happen.

This, then, is the obvious cause of the south wind which always prevails upon the coasts of Chili and Peru, as well as along the shores of Angola, Leango, &c. But it is only near the shore that this can take place; nor can it extend to a great height above these low and fertile regions. For as the internal parts of these countries are exceedingly high; but more especially the Andes of America, which experience a perpetual degree of cold more intense than some polar regions ever experience; the air muri here be condensed to a very great degree, and send forth from these high regions a perpetual wind to every side, which occasions almost all the peculiarities that have been remarked in these climates: For by opposing the general current of the trade-wind upon the eastern part of these countries, they produce these deluges of rain which supply the immense rivers of the Amazon, La Plata, &c. thee do not, like the Nile and Gambia, swell only at a particular season, and then shrink into a diminutive size again, but continue throughout the whole year, with less variation of size, to pour their immense floods of water into the ocean. These cold winds likewise stretching to the westward, at a considerable distance above the warmer regions of the sea-coast, at length descend as low as the ocean, and form the general trade-wind, and occasion that unusual degree of cold which navigators have so often complained of even under the line to the westward of America. To the same cause also must we attribute the thick fogs so common upon the southern parts of Chili and along the coasts of Peru, with the other peculiarities of that singular climate about Lima and the kingdom of Valparaiso in South America; for the vapours which are exhaled in such great abundance in the warm regions on the

feashore, are, at a little height above the earth, condensed by the cold winds which come from the mountains, and form these thick mists which are so often observed in this climate. The same effects are felt in some degree on the similar coast of Africa. But as the mountains of Africa are not so high as the Andes of America, nor approach to near the western coast, the effects are less sensible here than in America. The great height of the Andes above the mountains of the similarly situated country of Africa, is the only reason why the effects on that coast are not felt to an equal degree, although similar in kind.

A more singular deviation from the general trade-wind is observed to take place on the African and American coasts to the north of the line, than those we have taken notice of to the south of it. For it is observed, that from California to the bay of Panama, all along the coasts of New Spain, the winds blow almost constantly from the west or SW, nearly directly opposite to the trade-wind; and on the coast of Africa from C. Bayador to C. Verde, they blow chiefly from the NW, standing in upon the shore; from thence the wind beads gradually more and more from the north to the west, and so round to the SW, all along the coast of Guinea, as will be distinctly seen by the map. After what we have said of the winds on the southern parts of those regions, it will be unnecessary to spend much time in explaining the cause of these peculiarities, as it will evidently appear that they are nearly the same, the variations here observed being occasioned by the particular direction of the coast. Thus, along the coast of New Spain, the wind blows nearly the same direction in every place, as there are no remarkable bendings on the coast; being uniformly drawn towards the shore, by the great heat of the low part of the continent near the sea; which in these regions is always more heated than the water of the ocean, and occasions that inflection. But as the coast of Africa is more irregular, the winds also are found to be more different in their direction. To the north of C. Verde, as the coast stretches nearly south and north, the wind, being drawn towards it a little, blows from the NW. But beyond that, the coast bends more eastward to C. Panama; from which it runs E or NE all along the coast of Guinea, the wind shifting gradually more and more to the west, still pointing in upon the coast. And as there is nothing to oppose the current of air, which comes from the south, along the coast of Angola, it stretches forward till it comes within the influence of the coast of Guinea, and is there drawn in towards the shore in a SW direction. But as it is only the lower regions of the coast of Guinea, which are so much warmed, the high mountains within continuing cold; the northerly wind coming from these meeting and opposing the southerly winds in the higher regions of the air, by their mutual conflicts occasion those incessant rains and tremendous thunder so remarkable along the whole of this uncomfortable coast.

It has been often observed by mariners, that there is a track of fea to the west of Guinea from five to ten degrees of north latitude, in which the trade-wind blows with less headiness than in any other part of that ocean, being almost constantly troubled with calms and tornadoes; the cause of which the reader will perceive by inspecting the map; as he will easily see that the winds are drawn from this quarter almost in every direction; so that there can be here no constant wind; but being exhausted of its air, it must become lighter than the circumjacent parts, and must then be expul-
plied from either side, as chance or occasional circumstances may direct, which occasions those sudden gales and typhoons here observed.

Before we take our leave of this subject, it is necessary to observe, that in the Bay of Panama, the winds between September and March are easterly; but from March till September they blow chiefly from the SSW; that is, during the winter months, while the sun is far from them, the winds are off shore, and during the summer months, the land being heated to a considerable degree, they are drawn towards the shore as usual. It is remarkable, however, that this is the only part on the east of a large continent where the wind shifts regularly at different seasons; which seems to be occasioned by the great height of the Isthmus of Darien, and the Terra Firna to the east of it, and the nearest of these to the sea, in comparison of the mountains near Benin on the similarly situated coast of Africa; which is greatly afflicted by the deepens of the bay, which, by bending too much to the eastward from C. Lorenzo, is in a great measure screened from the force of the former winds, which allows the winter breeze to extend itself upon the bay with more facility. We ought here also to remark, that along the coast of Mexico, between C. Pelanço and Guatimala, there are land winds which blow in the months of May, June, and July, called by the Spaniards Popogatzois. They greatly resemble the Summamontio winds in the Bay of Campeachy, as they blow both night and day a moderate breeze without intermission, sometimes three or four days or a week together. But as these blow from the land in summer only, whereas the Summamontio's blow only in winter, they must be occasioned by a different cause; which seems to be this: As the continent which divides the south sea from the Bay of Mexico and Gulf of Honduras, is but of very small breadth, and in many places very high ground, the heat which it receives from the sun in summer is not so great as on the similar coast of Africa; and as the trade-wind coming from the great Atlantic ocean sweeps along the eastern part of the American coast from C. St. Augufine to the Bay of Honduras with very great violence at that season, the small heat of this narrow continent, is not sufficient to stop it entirely during that season; so that at some times it blows for a short time quite across it, and occasions those winds called Popogatzois.

Besides these more general winds, there are likewise some particular winds which are only felt in particular places at certain times, whose effects are so singular as to merit attention; some of which we shall here take notice of. In the Gulf of Persia, particularly at Ormuz, during the months of June and July, there sometimes blows from the west, for a day or two together, a hot suffocating fiery wind, which scorcheth up and destroyeth any animal that may be exposed to it; for which reason, almost every body leave their habitations at Ormuz during these two months, and retire to the mountains near Ubirah in Persia, where they enjoy a more comfortable climate. To explain the cause of which, it is necessary to observe, that along all the coasts of Asia, to the north of the Indian ocean, the diurnal sea and land breezes take place, as in every part of the torrid zone, by means of which the monsoons are not felt close in upon the shores. But as the monsoon continues to blow regularly at a small distance from shore, so in all probability it continues its course without interruption at a small distance above the surface of the earth. Now when the monsoon is in its greatest vigour, its influence will sometimes de

execute even as low as the surface of the earth, and, interrupting the course of the breezes, hurry along with it these warm vapours, which ought to have ascended upwards, and produced the fatal sea-breeze; and as the earth is thus deprived of the refreshing influence and moisture of the sea-breeze, the air, by the strong reverberation of the sun's beams from such dry and sandy countries as Arabia, must soon be heated to an amazing degree, and produce these hot and suffocating winds. It is also remarkable, that these hot winds are more often experienced near headlands, where the sea-breezes are weakest, which seems to confirm this hypothesis. Winds similar to these in kind, though not in degree, are felt upon the coast of Coromandel during the months of June, July, and August, while the west monsoon reigns; and on the Malabar coast they are likewise felt in the months of December and January, while the east monsoon reigns; but these are much less powerful than either of the others. As these hot winds always come from the land, they are known upon these coasts by the name of Tornado's.

It has likewise been observed, that on the coast of Africa to the north of C. Verde, during the months of December, January, and February, there sometimes blows, for a day or two together, an easterly wind, so very intensely cold as to be almost as destructive as the warm winds at Ormuz. We have already in some measure explained the cause of this phenomenon. During these months, when the sun is far from them, his influence is less felt than at other seasons, and the northerly wind upon the coast is of course weakened. Infomuch that the cold produced by the mountains in the heart of the country being now in its greatest degree of force, bursts its usual confinement for a time, spreading to the west with great violence, and producing those uncommon effects already mentioned. Those who fail on these coasts, distinguish this particular wind by the name of Hermatan.

There are the principal winds, whether constant or periodical, that take place within the tropics; and thus simple are their causes.

The succession of sea and land breezes renders the Torrid Zone not only habitable but comfortable. Besides, as these currents of cold air, rushing from each side of the globe, and carrying along with them vast quantities of aqueous vapours which they collect from the surface of the earth in their course, meet and oppose one another at that part of the atmosphere where the influence of the sun is greatest at the time, the water is there forced from the clouds in such prodigious quantities, as to produce a diversity of feasons in the Torrid Zone, something similar to what is experienced in more temperate climates; with this difference however, that whereas, in temperate climates, the warmest and most comfortable season is when the sun approaches nearest perpendicular to them, in these warmer climates the heavy rains which fall upon them at that season moderate the heat, and prevents the sun from having such an effect as at other times; so that their coldest and most inconstant weather, which they call winter, is at that season, when without this cause, they would be exposed to the sun's most powerful influence.

We shall only take notice of one other instance of the happy effects produced on our globe, by the laws of nature with respect to winds. We have seen, that in the great Atlantic and Pacific oceans, the trade-wind blows constantly from the easterly points throughout the whole year, so that
nature are concerned we find, that what produceth the death, at the same time furnisheth a remedy: for that very same ships fail from east to west within the tropics with the utmost facility; but it is absolutely impossible in these seas to fail from west to east, as the wind would be constantly against them; so that ships bound for any part to the eastward in these regions, must hard to the north or south till they are beyond the limits of the trade-winds, where they meet with variable breezes, by the help of which they fail to the eastward. But if the same constant trade-wind had taken place in the northern part of the Indian Ocean, it would have been impossible to have failed to the eastward at all; because the continent of Asia would have prevented the ships from failing far enough north to find the variable winds. But here, as in almost every case in which the operations of nature are concerned, we find, that what produces the difficulty, at the same time furnishes a remedy: for that very same winds which separate it from Bessarabia and Moldavia, on the south-west; and by the province of Red-Russia, on the north and north-east; by Tartary, on the south-east, by the river Nieffer, where it receives the Doria; then passing north-east, it discharges itself by several channels into the gulf of Venice. Thus we see, that where-ever the sea is open to the south or north, near the tropics, so as that ships are at liberty to reach the variable winds, the trade-wind constantly blows in one direction; but where-ever there is any extent of continent within the verge of the Torrid Zone, so as that they could not be at liberty to reach the variable winds, there the course of the trade-wind is altered, being drawn towards it in summer, and from it in winter, forming that shifting wind called monsoons. From which we may naturally infer, that as there are no monsoons in the Pacific or Atlantic, or in the western part of the Indian ocean, to the south of the line, there are no extensive continents near the tropics in either of these places.

POE

PNEUMATOCELE. See Medicine and Surgery.

PNEUMONICS, in pharmacy, medicines proper in diseases of the lungs, in which respiration is affected.

PO, a great river of Italy, rising in the Alps, and running westward. But if the same constant trade-wind had taken place in the northern part of the Indian Ocean, it would have been impossible to have failed to the eastward at all; because the continent of Asia would have prevented the ships from failing far enough north to find the variable winds. But here, as in almost every case in which the operations of nature are concerned, we find, that what produces the difficulty, at the same time furnishes a remedy: for that very same winds which separate it from Bessarabia and Moldavia, on the south-west; and by the province of Red-Russia, on the north and north-east; by Tartary, on the south-east, by the river Nieffer, where it receives the Doria; then passing north-east, it discharges itself by several channels into the gulf of Venice. Thus we see, that where-ever the sea is open to the south or north, near the tropics, so as that ships are at liberty to reach the variable winds, the trade-wind constantly blows in one direction; but where-ever there is any extent of continent within the verge of the Torrid Zone, so as that they could not be at liberty to reach the variable winds, there the course of the trade-wind is altered, being drawn towards it in summer, and from it in winter, forming that shifting wind called monsoons. From which we may naturally infer, that as there are no monsoons in the Pacific or Atlantic, or in the western part of the Indian ocean, to the south of the line, there are no extensive continents near the tropics in either of these places.

POE

Voillis thinks that love was the first occasion of poetry; which is not improbable, considering that this affection is coeval with mankind, is universal, and naturally productive of poetry. Yet it undoubtedly owes its increase and progress to religion. Dacier indeed calls it the offspring of religion; and it is certain, in the earliest ages of the world, that it was usual to sing hymns to the honour of the gods upon solemn festivals. Du Bos thinks that poetry has been employed in all ages, even by the most unpollished nations, to preserve the memory of past events. Its principal aim is to flatter our senses and imagination: for, according to Plato, it awakes the spiritual empire of the soul. Every kind of poetry charms us in proportion to its object, says Du Bos; and to be very affecting, it ought to be very exact. It is not the same with poetry as with other arts; for an ignorant person may judge of poetry by the impression it makes on him: whence all men have a right to give their opinion concerning a piece of poetry; and this judgment ought to be founded on experience rather than on argumentation. Poetry is an art where every thing should please. It is not enough to exhibit nature, which in certain places and circumstances is rude and unpleasant; but the poet must chuse in her what is beautiful from what is not: whence a poet ought to chuse, for the subject of his imitation, something that is naturally affecting. There is a particular rhetoric for poetry, which consists in discerning very precisely what ought to be said figuratively, and what to be spoken simply; and in knowing where ornament is required, and where not: yet the style should be copious, and every species of writing in this art should have a distinction proper to itself. The qualifications, then, necessary for poetry, or those which form a good poet, are seldom found united in one person: he must have an extraordinary genius, great natural gifts, a wit just, piercing, solid, and universal; an understanding clear and distinct; an imagination neat and pleasing; an elevation of soul that depends not on art, or study, and which is purely a gift of heaven, and must be sustained by a lively fancy and vivacity, a great judgment to consider wisely of things, and a vivacity to express them with that grace and abundance which gives them beauty. In fine, to accomplish a poet, is required a temperature of wit and fancy, of strength and sweetness, of penetration and delicacy; but above all,
POLIANTHES, in botany, a genus of the hexandria monogynia class. The corolla is bell-shaped; and the stigma is trifid; and the capsule has three cells. There are three species, all natives of India.

POLE, in astronomy, one of the extremities of the axis on which the sphere revolves. There are principal points in an ecuetteon, as represented in Plate CXLV. fig. 2. where A shows the dexter chief; B, the precise middle chief; C, the sinister chief; D, the honour-point; E, the fels-point, called also the centre; F, the nombril-point, that is, the navel-point; G, the dexter base; I, the sinister base; H, the precise middle base.

POLE, or Polar star, is a star of the second magnitude, containing sixteen feet and a half. It is one hundred and fifty miles long, and seventy broad.

POLCIECK, the capital of the palatinate of the same name, in the duchy of Lithuania, in Poland: E. long. 29°, N. lat. 56° 20'.

POLICY, or Polity, in matters of government. See Polity.

POLIGNAC, in botany. See Carduus.

POLYANDRIA, in botany. See Botany, p. 635.

POLYANTHA, in botany. See Primula.

POLEX, in anatomy, denotes either the thumb or great toe, according as either manus or pedis is added to it. See Anatomy.

POLLY, a word used in ancient writings for the head: hence to poll, is either to vote or to enter down the names of those persons who give in their votes at an election.

POLLOCK, in ichthyology. See Gadus.

POLLY, or Polity, denotes the peculiar form and constitution of the government of any state or nation; or, the laws, orders, and regulations, relating thereto.

POLYCHREST, in pharmacy, signifies a medicine that serves for many uses, or that cures many diseases.

POLYCHREST, in pharmacy, a compound salt made of equal parts of salt-mercur and sulphur, laid on a red-hot crucible.

POLYCHREST, or POLYCHREST, a compound salt made of equal parts of salt-mercur and sulphur, laid on a red-hot crucible.

POLYCHREST, or Polyiemum, in botany, a genus of the diadelphia diandria monogynia class. The calix consists of five petals, and it has but one round seed. There is but one species, a native of Germany.

POLYCHREST, in botany, a genus of the triandria monogynia clasfs. The calix consists of three leaves, and the corolla of five petals; and it has but one round seed. There is but one species, a native of Britain.

POLYCYTIA, in botany. See Botany, p. 635.

POLYGANY, a plurality of wives or husbands, in the possession of one man or woman, at the same time.

POLYGAMY, a plurality of wives or husbands, in the possession of one man or woman, at the same time. Many arguments have been offered to prove the unlawfulness of polygamy; one of the principal of which is, that the males and females brought into the world are nearly on a balance; only abating for a small excess on the side of the males to make up for the extraordinary expense thereof in war and at sea: whence it evidently follows, that nature only intends one wife, or one husband, for the same person; since if they have more, some must go without any at all. Hence it is justly concluded, that
that the Christian law, which prohibits polygamy, is more
agreeable to the law of nature than the Mahometan, and,
we may add, than the Jewish law, by which polygamy
was tolerated.

POLYGLOTT, among divines and critics, chiefly denotes
a bible printed in several languages. See Bible.

POLYGON, in geometry, a figure with many sides, or
whose perimeter consists of more than four sides at least:
such are the pentagon, hexagon, heptagon, &c.

POLYGONATUM, in botany, See Contallaria.

POLYGONUM, in botany, a genus of the extandria tri-
gynia classis. It has no calyx; the corolla has five seg-
ments; and there is but one angular feed. The species
are 27, eleven of them natives of Britain.

POLYGYMIA, among botanists, See Botany, p. 635.

POLYHEDRON, in geometry, denotes a body or solid
comprehended under many sides or planes.

POLYHEDRON, in optics, is a multiplying glass or lens,
confifting of several plane surfaces disposed into a convex
form. See Optics.

POLYMATHY, denotes the knowledge of many arts and
sciences.

POLYMIA, in botany, a genus of the syngenia po-
gamia necessaria classis. The receptacle is paleaceous; it
has no pappus; and the calyx consists of ten leaves. There
are two species, both natives of America.

POLYPUS, in zoology, a species of the hydra, which,
although cut in a thousand pieces, and in every direction,
still exists, and each section becomes a complete animal.

POLYETALOUS, among botanists, an epithet applied
to such flowers as consist of several petals, or flower-leaves.

POLYPODIUM, in botany, a genus belonging to the cryp-
togamia filices classis. The fructifications are disposed in
round spots on the margin of the leaf. There are 65
species, 14 of them natives of Britain.

POLYPREMUM, in botany, a genus of the tetrandria mon-
gynia classis. The calyx consists of four leaves, and
the corolla, which is rotated, of four segments; the cap-

dule is compressed, and bilocular.

POLYPUS of the heart. See Medicine, p. 158.

POLYSYLLABLE, in grammar, a word consisting of more
yllables than three; for when a word consists of one,
two, or three syllables, it is called a monosyllable, dif-
yllable, and trisyllable.

POLYTEISM, in matters of religion, the doctrine or
belief of a plurality of gods.

POLYTRICHUM, in botany, a genus of the muci clasis.
The anthera is operculated, and the ca-

POLYTRICHUM, in botany, a genus of the cryptogamia
muci classis. The anthera is operculated, and the calyp-
ttra hairy. There are three species, one of them, viz.
the commune, or great golden maidenhair, a native of
Britain.

POMEGRANATE. See Punica.

POMMERANIA, a province of Upper Saxony, in the north
of Germany, bounded by the Baltic-see, on the north; by
Poland, on the east; by another part of Poland, and
Brandenburg, on the south; and by the dutch of Meck-
lenburg, on the west.

POMME, or Pommette, in heraldry, is a croix with
one or more balls or knobs at each of the ends.

POMMEL, or Pummel, in the menage, a piece of bract,
or other matter, at the top and in the middle of the fad-
dle-bow.

POND-WEED, in botany. See Potamogeton.
ware, is, that it is a half vitrified substance, or manufacture, in a middle state between the common baked earthen ware of our vulgar manufactures, and true glafs. This is the essential and distinctive character of porcelain; and it is only by considering it in this light, that we are to hope of arriving at the perfect art of imitating it in Europe. This attempt is to be made on these principles in two different manners. The one by finding some appropriated matter, on which fire acts with more than ordinary strength, in the time of its passing from the common baked state of earthen ware into that of glafs. The other is to compose a paste of two substances, reduced to a powder; the one of which shall be of force to refult a very violent fire, so as not to become vitrified in it; and the other a matter very easily vitrifiable. In the first case, the matter is to be taken out of the fire at the time when it is imperfectly vitrified; and in the other, the compound mass is to remain in the furnace, till the one substance which is the more easily vitrifiable is truly vitrified; and being then taken out, the whole will be what porcelain is, a substance in part vitrified, but not wholly so. The first method is that by which the European porcelain has been generally made, which though it may be very beautiful, yet it is always easy to distinguish even the line of it from the china-ware; and the nature of the two substances appears evidently different: these owing all their beauty to their near approach to vitrification, are made to endure a long and violent fire, and are taken from it at a time when a little longer continuance should have made them perfect glass; on the contrary, the china-ware being made of a paste, part of which is made of a substance in itself scarce possible to be vitrified, bears the fire in a yet more intense degree than ours, and is in no danger of running wholly into glafs from it.

The two substances used by the Chineses, are well known by the names of petunfe and kaolin; and on examining these, it appears very evident, that we have in Europe the very same substances, or at least substances of the very same nature, capable of being wrought into porcelain equally beautiful and fine.

Porcelain-shell. See Cypræa.

Porcupine, in zoology. See Histrix.

Pore, in anatomy, a little interstice or space between the parts of the skin, serving for perspiration.

Porella, in botany, a genus of mosses, the anthera of which is multilocular and foraminose. See Moss.

Poria, a genus of funguses, growing horizontally; but having its under side not formed into lamelle, but full of little holes or pores.

There are a great many species of poria, among which is the agaric of the shops. See Agaric, and Stypitic.

Porpesse, in ichthyology. See Delphinus.

Porphyry, in natural history, a kind of stone of a plain uniform grey, spotted with separate concrections, of great hardness, giving fire with fleel, not fermenting with acids, and very fluidly and difficultly calcining in a strong fire.

Porphyry is of several sorts; as, 1. The porphyry of the ancients, which is a most elegant mass of an extremely firm and compact structure, remarkably heavy, and of a fine strong purple, variegated more or less with pale, red, and white: its purple is of all degrees, from the cla-

Ret-colour to that of the violet; and its variegations are rarely disposed in veins, but spots, sometimes very small, and at others running into large blotches. It is less fine than many of the ordinary marbles; but it excels them all in hardness, and is capable of a most elegant polish. It is still found in immense llrata in Egypt. 2. The hard red lead-coloured porphyry, variegated with black, white, and green. This is a most beautiful and valuable substance. It has the hardnes, and all the other characters of the oriental porphyry; and even greatly excels it in brightness, and in the beauty and variegation of its colours. It is found in great plenty in the island of Minorca; and is extremely worth importing, for it is greatly superior to all the Italian marbles. 3. The hard pale-red porphyry, variegated with black, white, and green. This is of a pale flesh-colour; often approaching to white. It is variegated in blotches from half an inch to an inch broad. It takes a high polish, and emulates all the qualities of the oriental porphyry. It is found in immense llrata in Arabia Petraea, and in the Upper Egypt: and in separate nodules in Germany, England, and Ireland.

Porphyry-shell. See Murex.

Porrum, in botany. See Allium.

Port royal, the name of two monasteries of Cistercian nuns, in the diocese of Paris; the one near Chevreufe, and the other in Paris, in the suburbs of St James.

The nuns of the former of these monasteries, proving refractory, were dispersed; when many ecclesiastics, and others who were of the same sentiments as thefe religious, retired to Port Royal, took apartments there, and printed many books: hence the name of Port-Royalists was given to all of their party, and their books were called books of Port-Royal: from hence we say the writers of Port Royal, Mifsieurs de Port Royal, and the transla-

Port royal, in geography, a port-town, situated at the mouth of the river Blavet: W. long. 3° 15', N. lat. 47° 42'.

Port-louis, a port-town of Britain in France, situated in the bay of Bicay: W. long. 3° 6', N. lat. 47° 42'.

Port-mahon, a port-town of the island of Minorca, situated on a fine bay at the east end of the island, in E. long. 4° 6', N. lat. 39° 50'.

Port-royal, the name of two monasteries of Cistercian nuns, in the diocese of Paris; the one near Chevreufe, at the distance of five leagues from Paris, called Port-Royal of the fields; and the other in Paris, in the subburbs of St James.

The nuns of the former of these monasteries, proving refractory, were dispersed; when many ecclesiastics, and others who were of the same sentiments as these religious, retired to Port Royal, took apartments there, and printed many books: hence the name of Port-Royalists was given to all of their party, and their books were called books of Port-Royal: from hence we say the writers of Port Royal, Mefsieurs de Port-Royal, and the transla-

Port-royal, in geography, a port-town, situated in the extremity of a long point of land, in the south-east part of the island of Jamaica: W. long. 77°, N. lat. 17° 30'.

Port-royal, an island on the coast of South-Carolina, which, with the neighbouring continent, forms one of the most commodious harbours in the British plantations: W. long. 80°, N. lat. 31° 45'.

Porta, or vena porta, in anatomy. See Anatomy, p. 244.

Portate, or a cross portate, in heraldry, a crofs which does not stand upright, as crofes generally do, but lies across the escutcheon in bend, as if it were carried
carried on a man's shoulders. See Plate CXLV. fig. 4.

PORTRETRU, a city of Switzerland, in the bishopric of Basle: E. long. 7°, N. lat. 47° 30'.

PORTER, a kind of malt-liquor, which differs from ale and pale-beer, in its being made with high-dried malt. See Brewing.

PORTICO, in architecture, a kind of gallery on the ground, supported by columns, where people walk under covert.

PORTLAND, a peninsula in Dorsetshire, situated in the English channel, ten miles south of Dorchester, famous for producing the best free-stone.

PORTSMOUTH, a borough and port town of Hampshire, situated on a fine bay of the English channel; it has one of the most secure, capacious, and best fortified harbours in England: W. long. 1° 6', N. lat. 50° 48'. It sends two members to parliament.

PORTUGAL, the most westerly kingdom in Europe; it is about three hundred miles long, and one hundred broad; and is situated between 7° and 16° of W. long. and between 37° and 42° of N. lat. being bounded by Spain on the north and east, and by the Atlantic ocean on the south and west. This country is neither so hot nor so fruitful as Spain; it however produces plenty of grapes, olives, oranges and lemons.

PORTUGALLICA TERRA, earth of Portugal, the name of a fine allringent bole, dug in great plenty in the northern parts of Portugal, and esteemed a remedy against poisons and venomous bites, and malignant fevers.

PORTULACA, in botany, a genus of the dodecandria monogynia class. The corolla consists of five petals, and the calyx of two-segments. There are six species, none of them natives of Britain.

POSE', in heraldry, denotes a lion, horse, or other beast standing still, with all his four feet on the ground.

POSITIVE, a term of relation, opposed to negative. It is also used in opposition to relative or arbitrary: thus we say, beauty is no positive thing, but depends on the different tastes of people.

POSITIVE DEGREE, in grammar, is the adjective in its simple signification, without any comparison. See Grammar.

POSSE COMITATUS, in law, signifies the power of the county, or the aid and assistance of all the knights, gentlemen, yeomen, labourers, servants, apprentices, &c. and all others within the county that are above the age of fifteen, except women, ecclesiastical persons, and such as are decrepit and infirm.

This posse comitatus is to be raised where a riot is committed, a posse comitatus kept upon a forcible entry, or any force of rescue used, contrary to the king’s writ, or in opposition to the execution of justice; and it is the duty of all sheriffs to assist justices of the peace in the suppression of riots, &c. and to raise the posse comitatus, or to charge any number of men for that purpose.

POSSESSION, in Scots law. See Law, Tit. viii. 11.

POSSESSIVE, in grammar, a term applied to pronouns which denote the enjoyment or possession of any thing either in particular or in common: as meus, mine; and tuus, thine.

POSSESSORY action, in Scots law. See Law, Tit. xxx. 18.

POSSIBILITY, in law, is defined to be any thing that is altogether uncertain, or what may or may not be.

POSSIBILITY also denotes a non-repugnance to existing, in any thing that does not any way exist.

POSSIBLE, is sometimes opposed to real existence; and is understood of a thing which, though it does not actually exist, yet may exist; as a new star.

POST, a courier or letter-carrier, or one who frequently changes horses, posted or placed on the road, for quick delivery. The word is also applied to the houses where such a person takes up and lays down his charge.

In England, posts were first established by act of parliament in the twelfth year of the reign of Charles II. which enabled the king to settle a post-office, and appoint a governor.

Penny Post, a post established for the benefit of London and the adjacent parts, by which any letter or parcel not exceeding sixteen ounces weight, is speedily conveyed to and from all parts within ten miles of London.

POSTDAM, or POTS DAM, a town of Germany in the marquisate of Brandenberg, ten miles south-west of Berlin.

POSTHUMOUS, a child born after the death of his father, or taken out of the body of a dead mother; from whence it is frequently applied to the works of an author not published till after his decease.

POSTING, among merchants, the putting an account forward from one book to another, particularly in the journal or waite-book to the ledger. See Book-keeping.

POSTLIMINIUM, among the Romans, the return of one who had gone to sojourn elsewhere, or had been banished or taken by an enemy to his own country and state.

POSTULATE, in mathematics, &c is described to be such an easy and self-evident supposition, as needs no explication or illustration to render it intelligible; as, that a right line may be drawn from one point to another.

POTAMOGETON, in botany, a genus of the tetrandria tetracyania class. It has no calix, nor flylus; but has four petals, and four seeds. There are 12 species, to of them natives of Britain.

POTANCE, in heraldry, a cross like that represented in Plate CXLV. fig. 4.
POT-ASH, the lixivious-ashes of certain vegetables, used in the making of glass, soap, &c.

The method of making pot-ash is directed by Dr. Shaw, as follows. Burn a quantity of billet-wood to grey allies; this lye be strained through a coarse linen cloth, to keep out any black parts of the half-burnt wood, that might happen to remain in the allies: then evaporate this strained lye in an iron-pan over a quick fire almost to driness; then taking out the matter remaining at the bottom, and putting it into an iron-crucible, let it in a strong fire till the matter is melted, and then immediately pour it out upon an iron-plate, where it soon cools, and appears in the form of a solid lump of pot-ash. Much after this manner is pot-ash made in the large way of business, for the service of the soap-boiler; glass-maker, fuller, &c. but according to the difference of the wood or combustible matter employed, with the manner of turning it, and conducting the procures, different kinds of pot-ash are prepared.

POTATOES, in botany. See Convolvulus, of which it is a species.

POTENT, or Potence, in heraldry, a term for a kind of crutch. It is otherwise called the Jerusalem crufs, and is represented in Plate CXLV. fig. 5.

POTENTIA, Power, that whereby a thing is capable either of acting, or being acted upon.

POTENTIAL, in the schools, is used to denote and distinguish a kind of qualities, which are supposed to exist in the body in potentia only, by which they are capable in some manner of affecting and impressing on us the ideas of such qualities, though not actually inherent in themselves; in which fenie we say, potential heat, potential cold.

POTENTIAL, in medicine. Cauteries are distinguished into actual and potential. See CAUTERY.

POTENTIAL, in grammar, an epithet applied to one of the moods of verbs. The potential is the same in form with the subjunctive. See GRAMMAR.

POTENTILLA, in botany, a genus of the icofandria polygaenia class. The calix consists of five segments, and the corolla of five petals; the seeds are round, naked, and fixed to the receptacle. There are 27 species, 8 of them natives of Britain.

This plant is said to posses in a great measure the virtues of the peruvian bark.

POTERIUM, in botany, a genus of the monoecea polyandria class. The calyx of the male consists of five segments, that of the male has but one entire rough leaf. Neither of them have any corolla; the stamens of the male are from five to ten; and the hypan of the female are from two to five; and the seed is single and oval. There are three species, one of which, viz. the fanguiforba, or burnet, is a native of Britain.

POTHOS, in botany a genus of the gyandria polyandria class. The fpatha and fpatix are roundish; it has no calix; the corolla has four petals; and the berry contains many seeds. There are seven species, none of them natives of Britain.

POISON, a liquid medicine, consisting of as much as can be drank at one draught.

POTOSI, a city of Peru in South America, situate at the bottom of a mountain of that name, in which is the richest silver-mine ever discovered: W. long. 67°, S. lat. 29°.

POTTERY, the manufacture of earthen ware, or the art of making earthen vessels.

The wheel and lathe are the chief, and almost the only instruments used in pottery: the first for large works, and the last for small. The potter's wheel consists principally in the nut; which is a beam or axis, whose foot or pivot plays perpendicularly on the free-tome sole or bottom. From the four corners of this beam, which does not exceed two feet in height, arise four iron-bars, called the spokes of the wheel; which forming diagonal lines with the beam, descend, and are fastened at bottom to the edges of a strong wooden circle, four feet in diameter, perfectly like the felloes of a coach-wheel, except that it has neither axis nor radii, and is only joined to the beam which serves it as an axis by the iron-bars. The top of the nut is flat, of a circular figure, and a foot in diameter; and on this is laid the clay which is to be turned and fashioned. The wheel, thus disposed, is encompassed with four different pieces of wood fastened on a wooden frame. The hind-piece, which is that on which workman sits, is made a little inclining towards the wheel: on the side-pieces are placed the prepared earth: on the side-pieces he rests his feet; and these are made inclining, to give him more or less room. Having prepared the earth, the potter lays a round piece of it on the circular head of the nut; and sitting down turns the wheel with his feet, till it has got the proper velocity: then, wetting his hands with water, he presses his fist or his fingers-ends into the middle of the lump, and thus forms the cavity of the vessel, continuing to widen it from the middle; and thus turning the inside into form with one hand, while he proportion the outside with the other, the wheel constantly turn all the while, and he wetting his hands from time to time. When the vessel is too thick, he uses a flat piece of iron, somewhat sharp on the edge, to pare off what is redundant; and when it is finished, it is taken off from the circular head, by a wire passed underneath the vessel.

The potter's lathe is also a kind of wheel, but more simple and flight than the former. Its three chief members are an iron-beam or axis, three feet and a half high, and two feet and a half diameter, placed horizontally at the top of the beam, and serving to form the vessel upon; and another larger wooden wheel, all of a piece, three inches thick, and two or three feet broad, fastened to the fame beam at the bottom, and parallel to the horizon. The beam or axis turns by a pivot at the bottom in an iron-fland. The workman gives the motion to the lathe with his feet, by pulling the great wheel alternately with each foot, still giving it a greater or leffer degree of motion, as his work requires. They work with the lathe, with the same instruments, and after the fame manner as with the wheel. The mouldings are formed by holding a piece of wood or iron cut in the form of the moulding to the vessel, while the wheel is turning round; but the feet and handles are made by themselves, and set on with the hand; and if there be any sculpture in the work, it is usuallly done in wooden moulds, and stuck on piece by piece on the outside of the vessel.

POTTLE, an English measure containing two quarts.

POULTRY,
POULTRY, all kinds of domestic birds brought up in yards, as cocks, hens, capons, ducks, turkeys, &c.

POUND, a standing weight. See Money.

POUND also denotes a money of account; so called, because the ancient pound of silver weighed a pound troy. See Money.

POUNDAGE, a subsidy of 10d. in the pound granted to the crown on all goods and merchandise exported or imported; and if by aliens, one penny more.

POURRESTORE, in law, is a wrongfull inclosure, or encroachment upon another person's property.

POURSUIVANT, or Pursuivant, in heraldry, the lowest order of officers at arms.

The pursuivants are properly attendants on the heralds, when they marshal public ceremonies. Of these in England, there were formerly many, but at present there are only four, viz. blue mantle, rouge-cross, rouge dragon, and portcullise. In Scotland, there is only one king at arms, who is styled Lion; and has no less than six heralds, and as many pursuivants, and a great many messengers at arms, under him.

POURVEYANCE, or Purveyance, in law, the providing corn, fuel, victual, &c. for the king's household; and hence the officer who did so was termed pourveyor.

POWDER, in pharmacy, a dry medicine well broken, or reduced to a fine powder.

POWDER, in mechanics See Mechanics.

Power, in law, signifies, in general, a particular authority, and, when broken in upon, gives an action at law.

Power, in mechanics See Mechanics.

Power, in law, signifies, in general, a particular authority granted to any person to another to represent him, or act in his stead.

POWERS, in arithmetic and algebra, are nothing but the products arising from the continual multiplications of a number, or quantity, into itself. See Algebra, p. 81, and Arithmetic, p. 420.

POX, or small pox, in medicine. See Medicine, p. 75.

French: Pox See Medicine, p. 133.

PRACTICE, in arithmetic. See Arithmetic, p. 393.

PRACTICAL SANCTION, in the civil law, is defined by Hottonian to be a reascript, or answer of the sovereign, delivered by advice of his council, to some college, order, or body of people, upon consulting him on some case of their community: The like answer given to any particular person, is called simply reascript. The term practical sanction, is chiefly applied to a settlement of Charles VI. emperor of Germany, who, in the year 1722, having no sons, settled his hereditary dominions on his eldest daughter, the archduchess Maria Theresa which was confirmed by the diet of the empire, and guaranteed by Great Britain, France, the States general, and most of the powers in Europe.

PRACTICIO HEREDITATIS, in Scots law. See Law, Tit. xxvii. 33.

PRAGUE, the capital of Bohemia, situated on the river Molda, in E. long. 14° 20', N. lat. 50°. This is a strong fine city; and next to London, Paris, and Constantinople, the largest in Europe.

PRAMNION, in natural history, the name of a semi-pelucid gem.

This is a very singular stone, and of a very great con-

6 M
PREDESTINATION, in general, signifies a decree of God, whereby, from all eternity, he ordained such a concatenation of causes as must produce every event by a kind of necessity.

In this sense, the Turks are great predestinarians; and on this account are much more daring in battle, and willingly encounter greater dangers than they would otherwise do. See MAHOMETANISM.

Predestination, among Christians, is used, in a more limited sense, for a judgment or decree of God, whereby he has resolved, from all eternity, to save a certain number of persons, from thence called elect; so that the rest of mankind being left in a state of impotence, are said to be reprobated.

PREDICABLE, among logicians, denotes a general quality which may be predicated of or affected of several things; thus an animal is predicabie of mankind, beasts, birds, fishes, &c. See LOGIC.

PREDICAMENT, among logicians. See LOGIC.

PREDICATE, in logic, that part of a proposition which affirms or denies something of the subject. See LOGIC.

PREDICTION, in natural history, the action of birds dressing their feathers, to enable them to glide more readily through the air, &c.

For this purpose they have two peculiar glands on their neck, which secrete a viscid matter into a bag that is perforated, out of which the bird occasionally draws it with its bill.

PRE-EXISTENCE, the state of a thing actually in being before another.

PREFACE, something introductory to a book, to inform the reader of the design, method, &c. observed therein, and generally whatever is necessary to facilitate the understanding of a book.

PREFECT, in ancient Rome, one of the chief magistrates who governed in the absence of the kings, consuls, and emperors.

Prefect of the pretorium, the leader of the pretorian bands destined for the emperor's guards, confisting, according to Dion, of 10,000 men. This officer, according to Suetonius, was instituted by Augustus, and usually taken from among the knights.

PREGNANCY, the state of a woman who has conceived, or is with child. See MIDWIFERY.

PREJUDICE does not mean a judgment merely as prior to another in respect of time, but as being passed before the things were duly considered and fully understood. Hence prejudice is sometimes called anticipation, and a preconceived opinion.

PRESBYTER, in the primitive Christian church, an elder, and of the second order of ecclesiastics; the other two being bishops and deacons.

PRESBYTERIANS, protestants, so called from their maintaining that the government of the church appointed in the New Testament was by presbyters; that is, by ministers and ruling elders, associated for its government and discipline.

The presbyterians affirm, that there is no order in the church as established by Christ and his apostles superior to that of presbyters; that all ministers, being ambassadors of Christ, are equal by their commission; and that elder or presbyter, and bishop, are the same in name and office: for which they allege, Acts xx. 28, &c.

The only difference between them and the church of England, relates to discipline and church-government. Their highest assembly is a synod, which may be provincial, national, or ecumenical; and they allow of appeals from inferior to superior assemblies; according to Acts xx. 2, 6, 22, 23. The next assembly is composed of a number of ministers and elders, associated for governing the churches within certain bounds. This authority they found upon Acts xi. 30. Acts xv. 4, 6, &c. The lowest of their assemblies or presbyteries consists of the minister and elders of a congregation, who have power to cite before them any member, and to admonish, instruct, rebuke, and suspend him from the eucharist. They have also a deacon, whose office is to take care of the poor.

The ordination of their ministers is by prayer, laying on of hands, and imposition of the hands of the presbytery. This is now the discipline of the church of Scotland.

PRESCRIBED, in grammar. See Grammar.

PRESCRIPTION, in theology, foreknowledge, or the knowledge which God has of events before they come to pass.

PRESCRIPTION, in Scots. See Law, Tit. vi. 18.

PREPOSITION, in grammar. See Grammar.

PREPARE, in anatomy. See Anatomy, p. 274.

PREROGATIVE of the king, that power which the king hath, not only over other persons, but over the ordinary course of the common law, in right of his crown.

Such as, that he may pardon a person condemned to die, that the king's person is subject to no man's suit, his possessions cannot be taken from him by any violence, his goods are subject to no tribute, nor deductible, &c.

PRESAGE, in antiquity, denotes an augury, or sign of some future event; which was chiefly taken from the flight of birds, the entrails of victims, &c. See AUGURY, and AUSPICES.

PRESBURG, the capital of Hungary, a large city on the north side of the Danube; fifty miles east of Vienna: E. long. 17° 30', N lat. 49° 26'.

PRESBYTER, in the primitive Christian church, an elder, and of the second order of ecclesiastics; the other two being bishops and deacons.

PRESBYTERIANS, protestants, so called from their maintaining that the government of the church appointed in the New Testament was by presbyters; that is, by ministers and ruling elders, associated for its government and discipline.

The presbyterians affirm, that there is no order in the church as established by Christ and his apostles superior to that of presbyters; that all ministers, being ambassadors of Christ, are equal by their commission; and that elder or presbyter, and bishop, are the same in name and office: for which they allege, Acts xx. 28, &c.

The only difference between them and the church of England, relates to discipline and church-government. Their highest assembly is a synod, which may be provincial, national, or ecumenical; and they allow of appeals from inferior to superior assemblies; according to Acts xx. 2, 6, 22, 23. The next assembly is composed of a number of ministers and elders, associated for governing the churches within certain bounds. This authority they found upon Acts xi. 30. Acts xv. 4, 6, &c. The lowest of their assemblies or presbyteries consists of the minister and elders of a congregation, who have power to cite before them any member, and to admonish, instruct, rebuke, and suspend him from the eucharist. They have also a deacon, whose office is to take care of the poor.

The ordination of their ministers is by prayer, laying on of hands, and imposition of the hands of the presbytery. This is now the discipline of the church of Scotland.

PRESCRIBED, in grammar. See Grammar.

PRE:
PRESENTATION, in Scots law. See Law, Tit. v. 7.
PRESS, in the mechanic arts, a machine of wood, or iron, serving to squeeze any body very close, generally by means of a screw. See Mechanics.
PRESTER JOHN, or Jean, an appellation given to the king of Abyssinia or Ethiopia.
PRESTON, a borough-town, twenty miles south of Lancaster, which sends two members to parliament.
PRESS, in the mechanic arts, a machine of wood, or iron, serving to squeeze any body very close, generally by means of a screw. See Mechanics.
PRETEXTO, in the Italian music, intimates to perform very quick, as prestissimo does extremely so.
PRETEXT, a colour or motive, whether real or feigned, for doing something.
Toga PRETEXTA, among the ancient Romans, a long white gown, with a border of purple round the edges, and worn by children of quality till the age of puberty, vix. by the boys till seventeen, when they changed it for the toga virilis; and by the girls till marriage.
PRETOR, a magistrate among the ancient Romans, not unlike our lord chief justices, or lord chancellor, or both in one: as being vested with the power of distributing justice among the citizens. At first there was only one prætor; but afterwards another being created, the first or chief one had the title of prætor urbanus, or the city-prætor; the other was called peregrinus, as being judge in all matters relating to foreigners. But, besides these, there were afterwards created many provincial prætori; who were not only judges, but also shifted the confuls in the government of the provinces, and even were invested with the government of provinces themselves.
PRETORIAN GUARDS, in Roman antiquity, were the emperor’s guards, who at length were increased to ten thousand: they had this denomination, according to some, from their being stationed at a place in the palace called prætorium: their commander was called præfectus prætorii. See Prefect.
PRETORIUM, among the Romans, denoted the hall, or court wherein the prætor lived, and wherein he administered justice.
PREVENTION in Jurisdiction, in Scots law. See Law, Tit. ii. 5.
PRIAPISM, in medicine, a continual and painful erection of the penis.
PRIAPUS, in medicine, denotes the genital parts in men. It also denotes in antiquity, a fabulous deity, particularly adored at Lampacus, the place of his birth, who was revered very much for the extraordinary size of his parts.
PRIEST, a person set apart for the performing of sacrifice and other offices of religion.
PRIEST, in the Christian church, is a person invested with holy orders: in virtue whereof he has a power to preach, pray, administer the sacraments, &c.
PRIMA VERIS, among physicians, denote the whole alimentary duct; including the oesophagus, stomach, and intestines, with their appendages.
PRIMAGE, in commerce, a small duty at the water side, usually about twelve pence per ton, or six pence a bale, due to the master and mariners of a ship.
PRIMATE, in church polity, an archbishop, who is invested with a jurisdiction over other bishops.
PRIME, an appellation given to whatever is first in order, degree, or dignity, among several things of the same or like kind; thus we say the prime minister, prime coat, &c.
PRIMIPILUS, in antiquity, the centurion of the first cohort of a legion, who had charge of the Roman eagle.
PRIMITVAE, the first fruits gathered of the earth, whereof the ancients made presents to the gods.
PRIMITIVUS, in grammar, is a root or original word in a language, in contradistinction to derivative: thus, God is a primitive; godly a derivative, and god-like a compound.
PRIMULA, in botany, a genus of the pentandria monogynia class. The tube of the corolla is cylindrical, with an open mouth. There are eight species, three of them natives of Britain, viz. the vulgaris, or common primrose; the veris, or cows-lips; and the farinosa, or birds-eye.
PRINCIPAL, the chief and most necessary part of a thing.
PRINCIPATE, a province of the kingdom of Naples, situated on the Mediterranean, between the provinces of Lavoro and Calabria; and divided into the Hisber and Further Principate, with respect to the city of Naples.
PRINCIPLE, in general, is used for the cause, source, or origin of any thing.
PRINCIPES, is also sometimes used in a synonymous sense with axiom or maxim.
PRINOS, in botany, a genus of the hexandria monogynia class. The calix consists of six segments, and the corolla of one rotated petal; and the berry contains six seeds. There are two species, both natives of America.
PRINT, the impression taken from a copperplate. See Rolling-press Printing.
PRINTER, a person who composes and takes impressions from moveable characters ranged in order, or from plates engraved, by means of ink, and a press: or from blocks of wood cut in flowers, &c., and taken off in various colours on calicées, linens, silks, &c.

The most curious of these arts; and that which deserves the most particular explication, is the first; for to the printers of books are chiefly owing our deliverance from ignorance and error, the progress of learning, the revival of the sciences, and numerous improvements in arts, which, without this noble invention, would have been either lost to mankind, or confined to the knowledge of a few. The first printers were Gutenberg, Fütter, Scheffer, Mentel, and Koffer; and the first who practised this art in England was Fred Corelles, who brought it over from Haerlem, in the reign of king Henry VI. The great printers famous for the correctness and elegance of their works, were Aldus, and Paulus Manutius; the two Badi; William and Frederic Morel; Oporin; Frobenius; Robert, Henry, and Charles Stephens; Gryphius, Turnebus, Torres, Commelin, Plantin, Raphelengius, Vactofan, Bleau, Crifpin, and the two Elzevirs; and among these, the learned printers were the Manutii, the Stephens, the Bodii, Turnebus, Morel, &c. Plantin had the title of archigraphorus, or arch-printer, given him.
PRINTING, the art of taking impressions from characters or figures, moveable or immovable, on paper, linen, silk, &c. There are three kinds of printing; the one from moveable letters, for books; another from copper-plates, for pictures; and the last from blocks, in which the representation of birds, flowers, &c. are cut, for printing calicoes, linens, &c. The first called common-press printing, the second rolling-press printing, and the last calico, &c. printing. The principal difference between the three consists in this, that the first is cast in relief, in distinct pieces; the second engraved in creux; and the third cut in relief, and generally flamed, by placing the block upon the materials to be printed, and striking upon the back of it.

Progress of Printing. Who the first inventors of the European method of printing books were, in what city and what year it was set on foot, are questions long disputed among the learned. In effect, as the Grecian cities contended for the birth of Homer, so do the German cities for that of printing. Mentz, Haerlem, and Strafburg, are the warmest on this point of honour. John Guttenburg, and John Full of Mentz; John Mentel of Strafburg, and L. John Kofter of Haerlem; are the persons to whom this honour is severally ascribed, by their respective countrymen; and they have all their advocates among the learned. However, their first essays were made on wooden blocks, after the Chinese manner. The book at Haerlem, the vocabulary called Catholicon, and the pieces in the Bodleian library, and that of Bennet-college, are all performed in this way; and the impression appears to have been only given on one side of the leaves, after which the two blank sides were pasted together. But they soon found the inconveniences of this method; and therefore thought themselves of an improvement; which was by making single letters distinct from one another; and these being first done in wood, gave room for a second improvement, which was the making them of metal; and, in order to that, forming moulds, matrices, &c. for casting them.

From this ingenious contrivance we ought to date the origin of the present art of printing, contradistinguished from the method practised by the Chinese. And of this Schoffer, or Scheffer, first servant, and afterwards partner and son-in-law of Full, at Mentz, afo mentioned, is pretty generally allowed to be the inventor, so that he may properly be reckoned the first printer, and the Bible which was printed with moveable letters in 1450, the first printed book; the next was Auguiffine de civitate Dei, then Tully's offices, printed about the year 1461. In these books they left the places eof the initial letters blank, and gave them to the illuminers to have them ornamented and painted in gold and azure, in order to render the work more beautiful, and, as some think, to make their books pass for manuscripts.

Some authors tell us, that Full carrying a parcel of bibles with him to Paris, and offering them to sale as manuscripts; the French, upon considering the number of books, and their exact conformity to each other even to a point, and that it was impossible for the scribes to write to exact, concluded there was witchcraft in the cafe, and, by their actually indicting him as a conjurer, or threatening to do so, extorted from him the secret; and hence the origin of the popular story of Dr. Faulus.

From Mentz, the art of printing soon spread itself throughout a good part of Europe: Haerlem and Strafburg had it very early; which, as the current of authors represent it, occasioned their pretending to the honour of the invention. From Haerlem it passed to Rome in 1467; and into England in 1468, by means of Tho. Bouchier, archbishop of Canterbury, who lent W. Turner master of the robes, and W. Caxton merchant, to Haerlem to learn the art. These privately prevailing with Corfeilles, an under-workman, to come over, a press was set up at Oxford and an edition of Rufinus on the creed was printed the same year in octavo. From Oxford, Caxton brought it to London about the year 1470, and the same year it was carried to Paris. Hitherto there had been nothing printed but in Latin, and the vulgar tongues; and this first in Roman characters, then in Gothic, and at last in Italic: but in 1480, the Italians cast a set of Greek types; and they have also the honour of the first Hebrew editions, which were printed about the same time with the Greek.

Towards the end of the sixteenth century there appeared various editions of books in Syriac, Arabic, Persian, Armenian, Coptic or Egyptian characters; some to gratify the curiosity of the learned, and others for the use of the Christians of the Levant. Out of Europe, the art of printing has been carried into the three other parts of the world: for Asia, we fee impreffions of books at Goa, and in the Philippines; at Morocco, for Africa; at Mexico, Lima, Philadelphia, New York, Boston, &c. for America. The Turks, indeed, rigorously prohibit printing throughout their empire, as imagining that the too frequent communication with books might occasion some change in their religion and government; yet the Jews have several editions of their books printed at Jaffa, and even at Constantinople.

Method of Printing. The workmen employed in the art of printing are of two kinds: compositors, who range and dispose the letters into words, lines, pages, &c. according to the copy delivered them by the author; and pressmen, who apply ink upon the same, and take off the impression. The types being cast, the compositor distinguishes each kind by itself among the divisions of two wooden frames, an upper and an under one, called cafes; each of which is divided into little cells or boxes. Those of the upper cafe are in number ninety-eight; there are all of the same size; and in them are diposited the capitals, small capitals, accented letters, figures, &c. the capitals being placed in alphabetical order. In the cells of the lower cafe, which are fifty-four, are placed the small letters, with the points, spaces, &c. The boxes are here of different sizes, the larges being for the letters most used; and these boxes are not in alphabetical order, but the cells which contain the letter ofteneft wanted are nearest the compositor's hand. Each cafe is placed a little above, that the compositor may more easily reach the upper boxes. The instrument in which the letter are set is called a composing-flick, (ibid, n° 2) which commits
consists of a long and narrow plate of brass, or iron, &c.

To dress the chafe, or range and fix the pages therein, the compositor makes use of a fet of furniture, consisting of slips of wood of different dimensions, and about half an inch high, that they may be lower than the letters: some of these are placed at the top of the pages, and called head-flicks; others between them, to form the inner margin; others on the sides of the crofles, to form the outer margin, where the paper is to be doubled; and others in the form of wedges to the sides and bottom of the pages. Thus all the pages being placed at their proper distances, and secured from being injured by the chafe and furniture placed about them, they are all united, and fastened together by driving small pieces of wood called quoins, cut in the wedge-form, up between the flating side of the foot and side flicks and the chafe, by means of a piece of hard wood and a mallet; and all being thus bound fast together, so that none of the letters will fall out, it is ready to be committed to the the pressman.

Before the compositor proceeds to compose, he puts a rule, or thin flip of brass-plate, cut to the length of the line, and of the fame height as the letter, in the composing-flick, against the ledge, for the letter to bear against. Things thus prepared, the compositor having the copy lying before him, and his flick in his left-hand, his thumb being over the slider d; with the right, he takes up the letters, spaces, &c. one by one, and places them against the rule, while he supports them with his left thumb by prefling them to the end of the slider d. the other hand being conftantly employed in flitting in other letters: the whole being performed with a degree of expedition and address not eafy to be imagined.

A little being thus compos'd, if it end with a word or syllable, and exactly fill the measure, there needs no further care; otherwife, more spaces are to be put in, or else the distances leflened between the feveral words, in order to make the measure quite full, fo that every line may end even. The spaces here used are pieces of metal exactly shaped like the flakes of the letters: these are of various thicknefles, and serve to support the letters, and to prefler a proper distance between the words; but not reaching fo high as the letters, they myte no impression when the work is printed. The firft line being thus finifh'd, the compositor proceeds to the next; in order to which he moves the brass-rule from behind the former, and places it before it, and thus compofes another line againft it after the fame manner as before; going on thus till his flick is full, when he empties all the lines contained in it into the gally.

The compositor then fills and empties his composimg-flick as before, till a complete page be formed; when he ties it up with a cord or pack-thread, and letting it by, pro- ceeds to the next, till the number of pages to be contain- ed in a sheet is completed; which done, he carries them to the impofing-ftone, there to be ranged in order, and fastened together in a frame called a chafe, and this is termed impofing. The chafe is a reftangular iron-frame, of different dimensions, according to the size of the paper to be printed, having two crofle-pieces of the fame metal, called a long and short crofs, mortifed at each end fo as to be taken out occasionally. By the different situation of these crofles the chafe is fitted for different volumes: for quarto's and octavo's, one traverses the middle length- wise, the other broadwise, fo as to interfeft each other in the centre: for twelve's and twenty-fours, the short crofs is thifled nearer to one end of the chafe: for folios, the long crofs is left entirely out, and the short one left in the middle; and for broad-sides, both crofles are set aside.

As it is imposfible but that there mytle be fome mif- takes in the work, either through the oversight of the compositor, or by the casual tranfposition of letters in the cafes; a sheet is printed off, which is called a proof, and given to the corrector; who reading it over, and confuluming it by the copy, by making the alterations in the margin, it is delivered back to the compositor to be corrected.

The compositor then unlocking the form upon the cor- recting-ftone, by loofening the quoins or wedges which bound the letters together, rectifies the myfakes by picking out the faulty or wrong letters with a fender sharp-pointed steel-bodkin, and puts others into their places. After this another proof is made, fent to the author, and corrected as before; and laftly, there is another proof, called a re-vice, which is made in order to fee whether all the myfakes marked in the laft proof are corrected.

The preffman's businefs is to work off the forms thus prepared and corrected by the compositor; in doing which there are four things required: paper, ink, balls, and a preff. To prepare the paper for ufe, it is to be firft wetted by dipping several sheets together in water; these are afterwards laid in a heap over each other; and to make them take the water equally, they are all prefled clofe down with a weight at the top. The ink is made of oil and lamp-black; for the manner of preparing which, fee Printing Ink. The balls, by which the ink is applied on the forms, are a kind of wooden funnels with handles, the cavities of which are filled with wool or hair, as is also a piece of alum-leather or pelt nailed on the handle, the cavities of which are filled with wool or hair. The ink-block, daubs and works them together to diffuse the ink equally. To dress the compositor's hands, and applying one of them to the ink-block, daubs and works them together to distribute the ink equally, and then blackens the form which is placed on the preff, by beating with the balls upon the face of the letter. The printing-preff represented in Plate CXLVII. fig. 1.
The body consists of two strong checks, a, placed perpendicularly, and joined together by four cross-pieces; the cap b, the head c, which is moveable, being partly fastened by two iron-pins, or long bolts, that pass the cap; the shelves d, which serve to keep ready a part called the hoist; and the winter x, which bears the carriage, and sustains the effort of the press beneath. The spindle f is an upright piece of iron pointed with steel, having a male-crew which goes into the female one in the head about four inches. Through the eye g of this spindle is fastened the bar k, by which the pressman makes the impression. Part of the spindle is inclosed in a square wooden frame called the hoist b, and its point works into a brass pan supplied with oil, which is fixed to an iron plate let into the top of the platten. At each corner of the hoist, there is an iron-hook fastened with pack-thread to those at each end of the platten, in such a manner as to keep it perfectly level. The carriage l is placed a foot below the platten, having its fore-part supported by a prop called the fore-stay, while the other rests on the winter. On this carriage, which sustains the planks, are nailed two long iron-bars or ribs, and on the planks are nailed short pieces of iron or steel called cramp-irons, equally tempered with the ribs, and which slide upon them when the plank is turned in or out. Under the carriage is fixed a long piece of iron called the spit, with a double wheel in the middle, round which are fastened the planks; and to the outside of the spit is fixed a rounce m, or handle, to turn round the wheel. Upon the planks is a square frame or coffin, in which is inclosed a polished stone on which the form n is laid; at the end of the coffin are three frames, viz. the two tympan and ruffket; the tympan a are square, and made of three thick pieces of iron, equally tempered, and at the top a piece of iron still thinner; that called the outer tympan is fastened with hinges to the coffin: they are both covered with parchment; and between the two are placed blankets, which are necessary to take off the impression of the letters upon the paper. The ruffket p is a square frame of thin iron, fastened with hinges to the tympan; it is covered with paper cut in the necessary places, that the feet, which is put between the ruffket and the great or outward tympan, may receive the ink, and that nothing may hurt the margins. To regulate the margins, a sheet of paper is fastened upon this tympan, which is called the tympan-sheet; and on each side is fixed an iron point, which makes two holes in the sheet, which is to be placed on the same points, when the impression is to be made on the other side. In preparing the press for working, the parchment which covers the outer tympan is wetted till it is very soft, in order to render the impression more equal; the blankets are then put in, and secured from slipping by the inner tympan: then while one pressman is beating the letter with the balls q, covered with ink taken from the ink-block, the other person places a sheet of white paper on the tympan-sheet, turns down the ruffket upon it to keep the paper clean and prevent its slipping; then bringing the tympan upon the form, and turning the rounce, he brings the form with the stone, &c. weighing about 300 pounds weight, under the platten; pulls with the bar, by which means the platten presses the blankets and paper close upon the letter, whereby half the form is printed; then easing the bar, he draws the form still forward, gives a second pull; and letting go the bar, turns back the form, takes up the tympan and ruffket, turns out the printed sheet, and lays on a fresh one; and this is repeated till he has taken off the impression upon the full number of sheets the edition is to consist of. One side of the sheet being thus printed, the form for the other is laid upon the press, and worked off in the same manner.

Chinese Printing, is performed from wooden planks or blocks, cut like those used in printing of calico, paper, cards &c.

Rolling press Printing, is employed in taking off prints or impressions from copper-plates engraved, etched, or scaped as in mezzotint. See Engraving.

This art is said to have been as ancient as the year 1540, and to owe its origin to Finiguerra, a Florentine goldsmith, who pouring some melted brimstone on an engraved plate, found the exact impression of the engraving left in the cold brimstone, marked with black taken out of the strokes by the liquid sulphur. Upon this he attempted to do the same on silver-plates with wet paper, by rolling it smoothly with a roller; and this succeeded: but this art was not used in England till the reign of King James I when it was brought from Antwerp by Speed. The manner of the rolling-press, the composition of the ink used therein, and the manner of applying both off prints, are as follow.

The rolling-press AL (Plate CXLVII. fig. 2) may be divided into two parts, the body and carriage; the body consists of two wooden cheeks PP placed perpendicularly on a stand or foot LM, which sustains the whole press. From the foot likewise are four other perpendicular pieces c,c,c,c, joined by other cross or horizontal ones d,d,d, which serve to sustain a smooth even plank or table HIK, about four feet and a half long, two feet and a half broad, and an inch and a half thick. Into the cheeks go two wooden cylinders or rollers, DE, FG, about fix inches in diameter, borne up at each end by the cheeks, whose ends, which are leftened to about two inches diameter, and called trunnions, turn in the cheeks about two pieces of wood in form of half-moons, lined with polished iron to facilitate the motion. Lastly, to one of the trunnions of the upper roller is fastened a cross, consisting of two levers A,B, or pieces of wood, traversing each other, the arms of which cross serve instead of the bar or handle of the letter-presses, by turning the upper roller, and when the plank is between the two rollers, giving the fame motion to the under one, by drawing the plank forward and backward.

The ink used for copper-plates, is a composition made of the stones of peaches and apricots, the bones of sheep, and ivory, all well burnt, and called Frankfort black, mixed with nut-oil that has been well boiled, and ground together on a marble, after the same manner as painters do their colours.

The method of printing from copper-plates is as follows. They take a small quantity of this ink on a rubber made of linen-rags, strongly bound about each other, and therewith smear the whole face of the plate as it lies on a grate over a charcoal-fire. The plate being insufficiently inked, they first wipe it over with a foul rag, then with the
the palm of their left hand, and then with that of the right; and to dry the hand and forward the wiping, they subit from time time in whiting. In wiping the plate perfectly clean, yet without taking the ink out of the engraving, the address of the workman confines. The plate thus prepared, is laid on the plank of the press; over the plate is laid the paper, first well moistened, to receive the impression, and over the paper two or three folds of flannel. Things thus disposed the arms of the crofs are pulled by that means the plate with its furniture passed through between the rollers, which pinching very strongly, yet equally, presses the moistened paper into the strokes of the engraving, whence it licks out the ink.

PRIOR, the superior of a convent of monks, or the next under the abbot. See Abbots.

PRISCILLIANISTS, in church-history, Christian heretics, called from their leader Priscillian, a Spaniard by birth, and bishop of Avila. He is said to have practised magic, and to have maintained the principal errors of the Manichees; but his peculiar tenet was, that it is lawful to make false oaths, in order to support one's cause and interest.

PRISM, an oblong solid, contained under more than four planes whose bases are equal, parallel, and alike situated.

PRIVATEERS, in maritime affairs, a kind of private man of war, fitted out by private persons at their own expense; who have leave granted them to keep what they can take from the enemy, allowing the admiral his commission, or the king's prerogative; and that either by a man of war, a privateer, &c. having a commission for that purpose.

PROBATION, in the universities, is the examination and trial of a student who is about to take his degree.

PROBATIONER, in the church of Scotland, a student in divinity, who bringing a certificate from a professor in an university of his good morals, and his having performed his exercises to approbation, is admitted to undergo several trials.

PROBE, a surgeon's instrument for examining the circumstances of wounds, ulcers, and other cavities, searching for stones in the bladder, &c.

PROBLEM, in logic, a proposition that neither appears absolutely true nor false; and, consequently, may be affirmed either in the affirmative or negative.

PROBLEM, in geometry, is a proposition, wherein some operation or construction is required; as to divide a line or angle, erect or let fall perpendiculars, &c. See Geometry.

PROBOSCIDES, in natural history, is the trunk or snout of an elephant, and some other animals and insects.

PROCATEARCTIC CAUSE, in medicine, the preceding, or pre-dipping cause or occasion of a disease.

PROCELEUSMATICUS, in the ancient poetry, a foot consisting of four short syllables, or two pyrrhichiaules; as, hominibus, etc.

PROCELLARIA, in ornithology, a genus of birds, belonging to the order of anseres. The beak is somewhat compressed, and without teeth; the mandibles are equal, the inferior one being crooked at the point; the feet are palmated, the hind claw being feeril, without any toe. There are six species, principally distinguished by their colour.

PROCES, in law, denotes the proceedings in any cause, real or personal, civil or criminal, from the original writ to the end thereof.

PROCES, in chemistry, the whole course of an experiment or series of operations tending to produce something new.

PROCESSION, a ceremony in the Roman church, consisting of a formal march of the clergy and people, putting up prayers, &c. and in this manner visiting some church, &c. They have also processions of the host or sacrament. See Host.

PROCLAMATION, a public notice given of any thing of which the king thinks proper to advertise his subjects.

Proclamations are a branch of the king's prerogative; and no person can make them without the king's authority, except mayors of towns, &c. by custom of privilege. Proclamations which require the people to do or not to do certain things, have the force of laws; but then they are supposed to be consistent with the laws already in being, otherwise they are superceded.

PROCONSUL, a Roman magistrate, sent to govern a province with confular authority.

PROCUREMENT, the begetting and bringing forth children. See Generation and Midwifery.

PROCTOR, a person commissioned to manage another person's cause in any court of the civil or ecclesiastical law.

PROCURATION, an act or instrument by which a person...
PROFANE, a term used in opposition to holy; and, in general, applied to all persons who have not the sacred character, and to things which do not belong to the service of religion.

PROFESSION, among the Romanists, denotes the entering into a religious order, whereby a person offers himself to God by a vow of inviolably observing obedience, charity, and poverty.

PROFESSOR, in the universities, a person who teaches or reads public lectures in some art or science from a chair for the purpose.

PROFILE, in architecture, the draught of a building, fortification, &c. wherein are expressed the several heights, widths, and thicknesses, such as they would appear were the building cut down perpendicularly from the roof to the foundation.

PROFLUVIUM, in medicine, denotes a flux, or liquid evacuation, of any thing.

PROGNOSTICS, among physicians, signifies a judgment concerning the event of a disease; as, whether it shall end in life or death, be short or long, mild or malignant, &c.

PROGRESSION, in general, denotes a regular advancing, or going forward in the same course and manner. See Arithmetic, Algebra, and Geometry.

PROJECTION, in mechanics, the act of communicating motion to a body, from thence called projectile. See Mechanics.

PROJECTURE, in architecture, the out-jutting, prominence, or emboassing, which the moldings and other members have beyond the naked wall, column, &c. See Architecture.

PROLAPSUS, in surgery, a prolapsion, or falling out of any part of the body from its natural situation; thus we say prolapsus intellini, a prolapsion of the intestine, &c. See Surgery.

PROLATE, in geometry, an epithet applied to a spheroid produced by the revolution of a semi-ellipsoid about its larger diameter.

PROLEGOMENA, certain preparatory observations or discourses prefixed to a book, &c. containing something necessary for the reader to be apprised of, to enable him the better to understand the book, or to enter deeper into the science, &c.

PROLEPSIS, a figure in rhetoric, by which we anticipate or prevent what might be objected by the adversary.

PROLEPTIC, an epithet applied to a periodical disease which anticipates, or whose paroxysm returns sooner and sooner every time, as is frequently the case in agues.

PROLIFIC, something that has the qualities necessary for generating.

PROLIXITY, in discourse, the fault of entering into too great a detail, of being too long, precise, and circumstantial, even to a degree of tediousness.

PROLOGUE, in dramatic poetry, a discourse addressed to the audience before the drama or play begins. The original intention was to advertise the audience of the subject of the piece, and to prepare them to enter more easily into the action, and sometimes to make an apology for the poet.

PROMETHEUS, in the ancient astronomy, the name of the constellation now called Hercules. See Astronomy, p. 487.

PROMISE, in law, is when upon any valuable consideration one binds himself by word of mouth to another to perform a thing agreed on.

PROMONTORY, in geography, a high point of land or rock projecting out into the sea; the extremity of which towards the sea, is called a cape, or headland.

PROMULGATED, something published or proclaimed, and generally applied to a law, to denote the publishing or proclaiming to the people.

PRONATION. See Anatomy, p. 179.

PRONATORS, in anatomy. See Anatomy, p. 198.

PRONOUN, in grammar, a declinable part of speech used to evince the truth of any thing.

PRONUNCIATION, in grammar, the manner of articulating or sounding the words of a language. See Grammar.

PROOF, in law, &c. denotes the mediums or arguments used to evince the truth of any thing.

PROPAGATION, the act of multiplying the kind. See Generation.

PROPER, something naturally and essentially belonging to any thing.

PROPERTY, in a general sense, that which constitutes or denotes a thing proper; or it is a particular virtue or quality which nature has bestowed on some things exclusive of all others: thus colour is a property of light; extension, figure, divisibility, and impenetrability, are properties of body.

PROPERTY, in law, is described to be the highest right a person has, or can have, to any thing.

PROPHECY, a prediction made by divine inspiration.

PROPHET, in general, a person who foretells future events; but particularly applied to such inspired persons among the Jews as were commissioned by God to declare his will and purposes to that people. Among the canonical books of the Old Testament, we have the writings of sixteen prophets, four of which are denominated the greater prophets, viz. Isaiah, Jeremiah, Ezekiel, and Daniel, fo called from the length or extent of their writings, which exceed those of the others, viz. Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habbukuk, Zephaniah, Haggai, Zechariah, and Malachi, who are called the leffer prophets from the shortness of their writings. The Jews do not place Daniel among the prophets, because, they say, he lived the life of a courtier rather than that of a prophet.

PROPIATION, in theology, a sacrifice offered to God to atone for his wrath, and render him propitious. Among the Jews there were both ordinary and public sacrifices, as holocausts, &c. offered by way of thanksgiving; and extraordinary ones, offered by particular persons guilty of any crime, by way of propitiation. The Romish church believe the mass to be a sacrifice of propitiation for the living and the dead. The reformed churches allow of
PROTEA, in botany, a genus of the tetrandria monogynia class. The calyx consists of three segments; it has no corolla, and but one seed. There is only one species, a native of Virginia.

PROSODY, that part of grammar which treats of the quantities and accents of syllables. See Grammar.

PROSOPOPOEIA, a figure in rhetoric, whereby we raise qualities of things inanimate into persons.

PROTUBERANCE, is an eminence, whether natural or artificial.

PROTRACTOR, the name of an instrument used for projecting or laying down on paper the angles of a field, or other figure. See Geometry.

PROPOSITION, in logic, part of an argument wherein some quality, either negative or positive, is attributed to a subject. See Logic.

PROPORTION, when two quantities are compared one with another, in respect of their greatness or smallness, the comparison is called ratio, rate, or proportion. See Algebra, Arithmetic, and Geometry.

PROSURE, the dictionary of P票rse, comprising

PROTEM, in botany, a genus of the tetrandria monogynia class. The petal consists of four segments surrounding the germen; it has no proper calix; and the receptacle is paleaceous. There are two species, both natives of the Cape of Good Hope.

VOL. III. No. 90. 2

PROTECTOR, a person who undertakes to shelter and defend the weak, helpless, and distressed.

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther, because, in 1529, they protested against a decree of the emperor Charles V. and the diet of Spire, declaring that they appealed to a general council. The same name has also been given to those of the sentiments of Calvin, and is now become a common denomination for all those of the reformed churches.

PROTONOTARY, a term which properly signifies first notary, and which was anciently the title of the principal notaries of the emperors of Constantinople.

PROTOTYPE, is the original or model after which a thing was formed; but chiefly used for the patterns of things to be engraved, cast, &c.

PROTRACTOR, the name of an instrument used for projecting or laying down on paper the angles of a field, or other figure. See Geometry.

PROTUBERANCE, is an eminence, whether natural or artificial, that projects or advances out beyond the rest.

PROVEDITOR, an officer in several parts of Italy, particularly at Venice, who has the direction of matters relating to policy.

PROVENCE, a province or government of France, bounded by Dauphine on the north; by Piedmont on the east; by the Mediterranean on the south; and by the river Rhone, which separates it from Langedoc, on the west. It is about an hundred miles long, and near as many broad.

PROVERB, according to Camden, is a concise, witty, and wise speech, grounded upon experience, and for the most part containing some useful instructions. Book of Proverbs, a canonical book of the Old Testament, containing a part of the prophecies of Solomon the son of David king of Israel. The first twenty-four chapters are acknowledged to be the genuine work of that prince; the next five chapters are a collection of several of his prophecies, made by order of king Hezekiah; and the two last seem to have been added, though belonging to different and unknown authors, Agur the son of Jekiel, and King Lemuel.

In this excellent book are contained rules for the conduct of all conditions of life; for kings, courtiers, masters, servants, fathers, mothers, children, &c.

PROVIDENCE, the conduct and direction of the several parts of the universe, by a superior intelligent Being.

PROVIDENCE PLANTATION, a colony of New-England, which, with Rhode-Island, constitutes a charter government: its chief town is Newport.

PROVIDENCE is also one of the Bahamas islands, planted and fortified by the English: W. lond. 76°, N. lat. 29°.

PROVENCE, in Roman antiquity, a country of considerable extent, which, upon being entirely reduced under the Roman dominion, was new-modelled according to the pleasure of the conquerors, and subjected to the command of annual governors sent from Rome; being commonly obliged to pay such taxes and contribution as the Senate thought fit to demand.
comprising several cities, towns, &c. all under the same government, and usually distinguished by the extent either of the civil or ecclesiastical jurisdiction.

PROVINCIAL, something relating to a province. See the preceding article.

PROVOST, of a city or town, is the chief municipal magistrate in several trading cities, particularly Edinburgh, Paris, &c. being much the same with mayor in other places.

He presides in city-courts, and, together, with the bailies, who are his deputies, determines in all differences that arise among citizens.

The provost of Edinburgh, as well as of all the other considerable towns in Scotland, has the title of lord; and the former calls yearly conventions of the royal boroughs to Edinburgh by his missives.

PROW, denotes the head or fore part of a ship, particularly in a galley, being that which is opposite to the poop or stern.

PROXIMITY, denotes the relation of nearness, either in respect of place, blood, or alliance.

PROXY, a person who officiates as a deputy in the room of another.

PRUCH, or Bruch, a town of Austria, in Germany, twenty-two miles south-east of Vienna.

PRUCK, or Brugg, of Switzerland, in Germany, sixty miles south-west of Vienna.

PRUNES, are plums dried in the sun or in an oven.

PRUNING, in gardening and agriculture, is the lopping off the superfluous branches of trees, in order to make them bear better fruit, grow higher, or appear more regular.

PRUNUS, in botany, a genus of the icofandria monogynia class. The calyx consists of five segments, and the corolla of five petals; and the shell of the drupe is full of prominent futures. There are 13 species, five of them natives of Britain, viz. the infititia, or black bullace-tree; the pinifolia, or bloe-tree; the padus, or birds cherry; the avium, or common wild cherry; and the cerasus, or black cherry.

PRURITIS, denotes an itching sensation.

PRUSIA, a province of Poland, situated on the coast of the Baltic sea, and divided into regal and ducal Prussia, the first subject to Poland, and the last to the king of Prussia.

PRUSSIA, a province of Poland, situated on the coast of the Baltic sea, and divided into regal and ducal Prussia, the first subject to Poland, and the last to the king of Prussia.

PRYTANES, in Grecian antiquity, were the presidents of the senate, who formed the body of the ancients called the prytanes, or other herb of the same intention.

The prytanes of the tribes did not govern all at once, but ten to the hundred and fifty Psalms of David, a canonical book of the Old Testament.

Most of the Psalms have a particular title, signifying either the name of the author, the person who was to set it to music or sing it, the instrument that was to be used, or the subject and occasion of it. Some have imagined, that David was the sole author of the book of Psalms; but the titles of many of them prove the contrary, as Psalm xix. which appears to have been written by Moses. Many of the Psalms are inscribed with the names Korah, Judah, &c. from the persons who were to sing them.

PSALMODY, the art or act of singing psalms. See the preceding article.

PSALTER, the name with the book of Psalms. See Psalm.

Among the religious, in the Popish countries, the term psalter is also given to a large chaplet or rosary, consisting of an hundred and fifty beads, according to the number of psalms in the psalter.

PSALTERY, a musical instrument, much in use among the ancient Hebrews, who called it nebel.

We know little or nothing of the precise form of the ancient psaltery.

PSIDICM, in botany, a genus of the icofandria monogynia class. The calyx consists of five segments, and the corolla of five petals; the berry has but one cell, containing many seeds. There are two species, both natives of India.

PSITTACUS, in ornithology, a genus belonging to the order of picae. The beak is hooked, the superior mandible being furnished with a moveable wax; the nostrils are placed at the base of the beak; the tongue is fleshly, blunted, and entire; and the feet are fitted for climbing. There are 47 species, distinguished by their colour, and the length of their tails. This genus includes the parrot-kind, which are all natives of warm climates.

PSOAS, in anatomy. See Anatomy, p. 203.

PSORALIA, in botany, a genus of the diadelphia decandria class. The calyx consists of five segments, the corolla of five petals; the berry has but one cell, containing many seeds. There are 14 species, none of them natives of Britain.

PSOS, in anatomy. See Anatomy, p. 203.

PTERIS, in botany, a genus of the cryptogamia silicum class. The fructification is situate in lines near the margin. There are 19 species, only one of them, viz. the aquilina, or female fern, is a native of Britain.

PTERMÉUS, in botany. See Achillea.

PTERETAL, in botany, a genus of the tetrandria monogynia class. The calyx consists of four segments, and the corolla of four petals; the fruit is a roundish membrane, with one seed in the centre. The species are two, none of them natives of Britain.

PTERIS, in botany, a genus of the cryptogamia siliac claf. The fructification is situate in lines near the margin. There are 19 species, only one of them, viz. the aquilina, or female fern, is a native of Britain.

PTERYGOID, something resembling a wing.

PTERYGOID.EUS, in anatomy. See Anatomy, p. 221.

PTISAN, is properly barley decorticled, or deprived of its hulls, by beating in a mortar, as was the ancient practice, though the cooling potion, obtained by boiling such barley in water, and afterwards sweetening the liquor with liquorice-root, is what at present goes by the name of ptisani: and to render it laxative, some add a little fenna, or other herb of the same intention.

PTOLEMAIC System of Astronomy, is that invented by Claudius Ptolemaus, a celebrated al atronomer and mathematician of Pelusium, in Egypt, who lived in the beginning of the 2nd century of the Christian era.

This hypothesis supposes the earth immovable fixed in the centre, not of the world only, but also of the universe:
verse; and that the sun, the moon, the planets, and stars,
all move about it, from east to west, once in twenty-four
hours, in the order following, viz. the moon next to the
earth, then mercury, venus, the sun, mars, jupiter, fa-
turn, the fixed stars, the first and second crystalline heav-
vens, and above all the fiction of their primum mobile.
PTyalism, in medicine, a salivation, or frequent and
copious discharge of saliv.
Puberty, among civilians, &c. the age wherein a per-
son is capable of procreation, or begetting children. See
Law.
Pubes, among anatomists, &c. denotes the middle part
of the hypogastric region of the abdomen, lying between
the two inguina or groins. See Anatomy, p. 277.
Publican, among the Romans, one who farmed the
taxes and public revenues.
Publication, the act of making a thing known to the
world; the same with promulgation.
Pubenda, the parts of generation in both sexes. See
Anatomy, p. 270.
Puerility, he adds, is the common fault of
some longer than its body, a native of America.
Pugil, in physic, such a quantity of flowers, feeds,
or the like, as may be taken up between the thumb and
two fore-fingers.
It is esteemed to be the eighth part of the manipule or
handful.
Pulex, in zoology, a genus of insects belonging to the
order of aptera. It has six feet fixed for leaping, and
two eyes; the feelers are like threads; the rostrum is
inflated, fetectous, and armed with a sting; and the
belly is compresed. There are two species, viz. one of
defects, with a proboscis shorter than its body, a native
of Europe and America: and the penetrans, with a pro-
obscis longer than its body, a native of America.
Puleley, in mechanics, one of the mechanical powers.
See Mechanics.
Pulmo, the lungs, in anatomy. See Anatomy, p.
280.
Pulmonaria, in botany, a genus of the pentandria
monogynia clafs. The corolla is funnel-shaped; and the
calyx has five sides. There are seven species, two of
them natives of Britain, viz. the officinalis, or buglos-
cowflips, the leaves of which are reckoned pedoral and
cordiac; and the maritima, or sea-buglofls.
Pulmonary Vessels, in anatomy. See Anatomy,
Part III. and IV. and p. 280.
Pulp, in pharmacy, the fefhy and succulent part of fruits,
extracted by infusion or boiling, and passed through a
sieve.
Pulpit, an elevated place in a church, whence sermons
are delivered: the French give the same name to a read-
ing desk.
Pulsatilla, in botany. See Anemone.
Pulse, in the animal economy, denotes the beating or
throbhing of the heart and arteries.
With regard to motion, the pulses are reckoned only
four, great and little, quick and slow. When quicknfs
and greatnfs are joined together, it becomes violent;
and when it is little and slow, it is called a weak pulse,
They are also said to be frequent and rare, equal and un-
equal; but these are not the essential affections of motion.
Frequency and quickness are often confounded with each
other. A pulse is said to be hard or soft, with regard
to the artery, according as it is tenfes, resistent, and hard,
or flaccid. soft, and lax. Add to thefe, a convulsive pulse;
which does not proceed from the blood, but from the
state of the artery, and is known by a tremulous subful-
tory motion, and the artery seems to be drawn upwards:
this, in acute fevers, is the sign of death; and is said to
be the pulse in dying persons, which is likewise generally
unequal and intermitting. A great pulse shows a more
copious afflux of the blood to the heart, and from thence
into the arteries; a little pulse, the contrary.
Pulse is also used for the stroke with which any medium is
affected by the motion of light, found, &c. through it.
Pulse, in botany, a term applied to all those grains or
seeds which are gathered with the hand, in contradiftinc-
tion to corn, &c. which are reaped, or mowed: or it is
the seed of the leguminous kind of plants, as beans, vet-
ches, &c. but it is by some used for artichokes, alpar-
gus, &c.
Pulverization, the art of pulverizing, or reducing
a dry body into a fine powder; which is performed in
frangible bodies, by pounding or beating them in a mortar,
&c.
Pulvis, a powder. See Powder.
Pumice, in natural history, a flag or cinder of some fof-
fl, originally bearing another form, and only reduced to
this state by the action of the fire, though generally rank-
ed by authors among the native frones. It is a lax and
fponge matter, frequently of an obscure striated texture
in many parts, and always very cavernous and full of
holes; it is hard and harfh to the touch, but much light-
er than any other body that comes under the clafs of
fones. It is found in mafles of different fizes, and of
a perfectly irregular shape, from the bignefs of a pigeon’s
egg, to that of a bullfe. We have it from many parts of
the world, but particularly from about the burning
mountains Etna, Vefuvius, and Hecla, by whose eru-
pions it is thrown up in vast abundance; and being by its
lightnefs supported in the air, is carried into seas at some
diftancc by the winds, and thence to distant shores. The
great ufe of the pumice among the ancients, feems to
have been as a dentifrice, and at prefent it is retained in
the shops on the fame account.
Pump, in hydraulics. See Hydrostatics, p. 808. &c.
Air-Pump. See Pneumatics, p. 491.
Pun, or Punn, a conceit arifting from the use of two words
that agree in sound, but differ in the fene. Afcwelle-
describes two or three kinds of puns among the beaties
of good writing, and produces instances of them out of
some of the greatest authors in the Greek tongue. Ci-
cero has sprinkled feveral of his works with puns; and
in his book, where he lays down the rules of oratory,
quotes abundance of fayings, which he calls pieces of wit,
that upon examination prove perfect puns.
Punch, an instrument of iron or steel, used in feveral arts,
for the piercing or flamping holes in plates of metal, &c.
being to contrived as not only to perforate, but to cut
out and take away the piece.
Punchion, a little block or piece of steel, on one end
whereof is some figure, letter, or mark, engraven either
in
PURIFICATION, in matters of religion, a ceremony on the end not engraved.

PURIFEO is also a measure for liquids, containing an hogfhead and one third, or eighty-four gallons.

PUNCTUATION, in grammar, the art of pointing, or of dividing a discourse into periods, by points expressing the pauses to be made in the reading thereof.

PUNCTUM SALIENTS, in anatomy, the first rudiments of the heart in the formation of the fetus, where a throbbing motion is perceived.

PUNCTURE, in surgery, any wound made by a sharp-pointed instrument.

PURCHASE, in law, the buying or acquiring of lands, &c. with money, by deed or agreement, and not by descent or right of inheritance.

PURE, something free from any admixture of foreign or heterogeneous matters: thus we say pure fire, &c.

PURPLE, in heraldry, according to some, was excluded by the ancient heralds as only an imperfect colour. In the coats of noblemen it is called amethyft; and fixing it with alum.

PURLE, or Purlieu, signifies all that ground near a woods; either bathing; or only wading the face, hands and feet. The first is requested only in extraordinary cases, as after having lain with a woman, touched a dead &c. But left so necessary a preparation for their devotion should be omitted, either where water cannot be had, or when it may be prejudicial to a person's health, they are allowed in such cases to make use of fine sand or dust instead of it; and then they perform this duty by clapping their open hands on the sand, and passing them over the parts, in the same manner as if they were dipped in water.

There were also many legal purifications among the Hebrews. When a woman was brought to bed of a male-child, she was esteemed impure for forty days; and when of a female, for sixty; at the end of which time she carried a lamb to the door of the temple, to be offered for a burnt-offering, and a young pigeon or turtle for a sin-offering, and by this ceremony she was cleansed or purified.

PURIM, or the feast of lots, a solemn festival of the Jews, instituted in memory of the deliverance they received from Haman's wicked attempt to destroy them, by means of Mordecai and Esther.

PURITAN, a name formerly given in derision to the dissenters from the church of England, on account of their professing to follow the pure word of God, in opposition to all traditions and human constitutions.

PURPLE, a colour composed of a mixture of red and blue. A beautiful transparent purple for painting may be made by boiling four ounces of rasper balsam-wood in a pint of stale beer, and half an ounce of logwood, till the liquor is heightened to the colour you desire, which may be known by dipping a piece of paper in it. If you find it too red, add a quarter of an ounce more of logwood, which will render it still deeper; and by this method you may bring it to any degree of purple, by putting in either more or less logwood to the former composition, and fixing it with alum.

PURPURA, in natural history. See MUREX.

PURPURE, or Purple, in heraldry, according to some, is one of the five colours of armories, compounded of gules and azure, bordering on violet, and, according to others, of a great deal of red and a little black. But it was excluded by the ancient heralds as only an imperfect colour. In the coats of noblemen it is called amethyft; and in those of princes, mercury. It is represented in engraving, by diagonal lines drawn from the sinister chief to the dexter base points. See Plate CXLVII. fig. 3.

PURSER, an officer aboard a man of war, who receives her victuals from the victualler, feeds that it be well flowed, and
and keeps an account of what he every day delivered to the steward. He also keeps a list of the ship's company, and sets down exactly the day of each man's admission, in order to regulate the quantity of provisions to be delivered out, and that the paymaster or treasurer of the navy may suffice out the disbursements, and pay off the men, according to his book.

PURSLAIN, in botany. See Portulaca.

PUS, in medicine, a white or yellowish putrid matter, deemed offensive to the body of the sick, &c. as contradistinct from the preambles.

PURULENT, in medicine, something mixed with or partaking of pus or matter.

PUS, in medicine, a white or yellowish putrid matter, designed by nature for the healing and cementing of wounds or sores.

PUSTULE, a pimple, or small eruption on the skin full of pus; such are the pustules of the small-pox and fmall-pox. See Medicine.

PUTTORIUS in zoology. See Mustela.

PUTREFACTION. See Chemistry, p. 98.

PUTTY, is a kind of paste, compounded of whiting and linseed oil, beaten together to the consistence of thick dough.

It is used by glaziers for the fastening in the squares of glass in sash-windows, and by painters for filling up the crevices and holes in timber and wainscots, &c.

PYCNOSYLLE, in the ancient architecture, is a building where the columns stand very close to each other; only one diameter and a half of the column being allowed for the intercolumniations.

PYGARGUS, in ornithology. See Falco.

PYGMY, a person not exceeding a cubit in height.

This appellation is given by the ancients to a fabulous nation said to have inhabited Thrace; who brought forth their augury: sometimes they threw pitch on it; and, if it took fire immediately, they esteemed it a good augury.

PYRGUS, in architecture. See Anatomy, p. 238.

PYRAMID, in geometry, a solid standing on a triangular, square, or polygonal base, and terminating in a point at the top; or, according to Euclid, it is a solid figure consisting of several triangles, whose bases are all in the same plane, and have one common vertex.

PYRAMIDALIS, in anatomy. See Anatomy, p. 195.

PYRAMIDALIA CORPORA, in anatomy. See Anatomy, p. 205.

PYROMANCY, a kind of divination by means of fire. The ancients imagined they could foretell future events, by inspecting fire and flame; and to this end, they considered its direction, which way it turned; sometimes they added other matters to the fire, such as a vessel full of urine, having its neck bound about with wool, watching narrowly on which side it burnt, and thence taking their augury: sometimes they threw pitch on it; and, if it took fire immediately, they esteemed it a good augury.

PYROTECHNY, the art of fire, or science which teaches the management and application of fire in several operations. See Chemistry.

PYROTICS, in medicine, caustics, or remedies, either actually or potentially hot; and which accordingly will burn the flesh, and raise an ulcer. See Caustics.

PYRRHICUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short; as, Δυς.

PYRRHICUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short; as, Δυς.

PYRRHICUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short; as, Δυς.

PYRRHICUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short; as, Δυς.

PYRRHICUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short; as, Δυς.

PYRRHICUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short; as, Δυς.

PYRRHICUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short; as, Δυς.

PYRRHHONIANISTS, a sect of ancient philosophers, so called from Pyrrho, a native of Elis, in Peloponnesus. The opinions of these philosophers, who were also called sceptics, terminated in the incomprehensibility of all things, in which they found reason both for affirming and denying; accordingly they seemed, during their whole lives, to be in search of truth, without ever acknowledging that they had found it: hence the art of disputing upon all things, without ever going farther than suspending our judgment, is called pyrrhonism.

PYRRUS, in botany, a genus of the decandria monogynia class. The calyx consists of five segments, and the corolla of five petals; and the capsule has five cells. There are four species, three of them natives of Britain, viz. the roundifolia, or common winter-green; the minor, or lesser winter-green; and the secunda, or dented leaved winter-green.
to Livy, in the reign of Servius Tullius, in the year of the world 2472.

His maxims of morality were admirable; for he was for having the study of philosophy solely tend to elevate man to a resemblance of the Deity. He believed that God is a soul diffused through all nature, and that from him human souls are derived; that they are immortal; and that men need only take pains to purge themselves of their vices, in order to be united to the Deity. He made morality the principle of all things; and believed, that between God and man there are various orders of spiritual beings, who are the ministers of the Supreme Being. He condemned all images of the Deity, and would have him worshipped with as few ceremonies as possible. His disciples brought all their goods into a common stock, and in the pleasures of society, abstained from swearing, eating anything that had life, and believed in the doctrine of a metempsychosis. See Metempsychosis.

Pythagoras made his scholars undergo a severe noviciate of silence for at least two years; and it is said, that the delay where he discerned too great an itch for talking, he extended it to five. His disciples were therefore divided into two classes: of which the first were simple hearers; and the last such as were allowed to propose their difficulties, and learn the reasons of all that was taught there. The Pythagoreans, it is said, on their rising from bed, roused the mind with the sound of the lyre, in order to make them more fit for the actions of the day; and at night resumed the lyre, in order to prepare themselves for sleep, by calmaing all their tumultuous thoughts. The figurative manner in which he gave his instructions, was borrowed from the Hebrews, Egyptians, and other orientals. Some think he derived his philosophy from the books of Moses, and that he converted with Ezekiel and Daniel at Babylon; but this is mere conjecture.

Some authors say, that he left nothing in writing; but Laertius and others attribute several treatises to him. His golden verses, attributed by some to one of his disciples, are allowed to be an exact copy of the sentiments of that divine philosopher, from whose school proceeded the greatest philosophers and legislators.

Pythia, in antiquity, the priestess of Apollo at Delphi, by whom she delivered oracles; she was thus called from the god himself, who was denominated Apollo Pythis, from his slaying the serpent Python.

Q.

Quack, among physicians, the same with empiric. See Empiric.

Quadragesima, a denomination given to lent, from its consisting of forty days. See Lent.

Quadrangle, in geometry, the same with a quadrilateral figure, or one consisting of four sides and four angles.

Quadrans, the quarter or fourth part of any thing, particularly the as, or pound.

Quadrant, in geometry, the arch of a circle, containing 90°, or the fourth part of the entire periphery. It also denotes a mathematical instrument, of great use in astronomy and navigation, for taking the altitudes of the sun and stars. See Astronomy, p. 451.

Quadrat, a mathematical instrument, called also a geometrical square, and line of shadows: it is frequently an additional member on the face of the common quadrant, as also on those of Gunter's and Sutton's quadrant.

Quadrant, in astrology, the same with quartile. See Quartile.

Quadrat, in printing, a piece of metal cast like the letters, to fill up the void spaces between words, etc. There are quadrats of different sizes, as m-quadrat, n-quadrat, etc., which are, respectively, of the dimensions of these letters.

Quadratic Equation, in algebra. See Algebra, p. 90.

Quadratrix, in geometry, a mechanical line, by means of which we can find right lines equal to the circumference of circles, or other curves, and their several parts.

Quadratrix of Dinostrates, so called from its inventor Dinostrates, is a curve, whereby the quadrature of the circle is effected mechanically.

Quadrature, in geometry, denotes the squaring, or reducing a figure to a square. Thus, the finding of a square, which shall contain just as much surface or area as a circle, an ellipse, a triangle, etc. is the quadrature of a circle, ellipse, etc. See Geometry.

Quadrature, in astronomy, that aspect of the moon, when it is 90° distant from the sun. See Astronomy.

Quadratus, in anatomy, a name given to several muscles on account of their square figure. See Anatomy, Part II.

Quadrel, in building, a kind of artificial stone, so called from its being perfectly square.

The quadrates are made of chalky earth, etc., and dried in the shade for two years. These were formerly in great request among the Italian architects.

Quadriennium Utile, in Scots law. See Law, Tit. vii. 17.

Quadriga, in antiquity, a car or chariot drawn by four horses.

On the reverses of medals, we frequently see the emperor or victory in a quadriga, holding the reins of the horses; whence these coins are, among the curious, called nummi quadrigati, and victoriati.

Quadrilateral, in geometry, a figure whose perimeter consists of four right lines, making four angles; whence it is also called a quadrangular figure.

Quadrille, a little troop or company of cavaliers, pompously dressed, and mounted, for the performance of caroufals.
QUESTUS, in law, signifies whatever a person has by contract, in Scots law. See Law, Tit xxii. 14.

QUAIL. See Tetrao.

QUADRUPEDS in zoology. See Natural History.

Quadrille, is also a game at cards, to be learned only by practice.

QUADRUPEDS, in zoology. See Natural History.

QUASI CONTRACT, in Scots law. See Law, Tit xxii. 14.

QUESTUS, in law, signifies whatever a person has by purchase; as hereditas denotes that which one has by descent, or hereditary right.

QUAIL. See Tetrao.

QUAKERS, a religious society that began to be distinguished by this name in England, where it first took its rise, about the middle of the last century.

In treating of this people, we shall deviate from the generality of those who have mentioned them in their writings; by exhibiting the account which they give of themselves, without making ourselves answerable for their principles or their practices.

William Sewel, a Dutchman, published; in the year 1717, the history of this people. He was one of their preachers, a man of learning, and known to the public by his dictionary of the Dutch and English languages. He had access to all their records, corresponded with the most eminent, lived at the time when the facts he recorded were recent, and we have not heard that any part of his history has been controverted; and as we are informed that it has been published by the approbation of the quakers, we may therefore consider it as an authentic history of their rise, progress, and principal opinions.

George Fox, (for whose birth and parentage, see page 6th of Sewel's History, &c.) was the first of this people. He was of a grave, sedate turn from his infancy; always most true, and not unworthy the disquisitions of the a-
timents as a religious society; to have instituted one of the character, fortune, and understanding, and embodied collected from all professions, and most ranks, men of sanctity of his life, the simplicity of his doctrines, to have access to all their records, corresponded with the public by their apologists, who has largely commented on these topics in a work that has passed through no less than eight editions in English, and has been printed in most of the modern languages.

Their particularities of address, language, and behaviour; their declining the use of arms, even in their own offence; their refusing to pay tithes, or contribute to the support of ministers in any shape; likewise their refusing to swear or take an oath on any occasion whatever; have subjected them to much obloquy, and many grievous sufferings. On what principles, and by what arguments, they vindicate themselves from the objections raised against them by their adversaries, may be seen in this elaborate.
boration. Government has, however, in ma-
hended from a people who difclaim the ule of arms
end that nothing dangerous to fociety could be appre-
that their profeffions of confcientious fcruples were fincere,
ny inftances, extended to this people great indulgen-
both ofience and defenfive. The oeconomy of this so-
cies; convinced, no doubt, by their patient {offering,
had drawn together in many parts of England confiderable
}

gular meetings for difciplme. The following is, as
it expedient for their better government to ellablifli re-
nearly as we can colle<5i, the plan that is eltabltfhcd a-
complaints arifing among themfelves; to inquire into the
rality and conformity to their religious fentimentsg to al-
and to provide for their relief; to hear and determine
morgfl them.

Where there are any Quakers, they meet together e-
very month, to consider of the neceffities of their poor,
and to provide for their relief; to hear and determine
complaints arifing among themselves; to inquire into the
conversation of their repective members in regard to mo-
ality and conformity to their religious fentiments; to al-
low the paffing of marriages; and to enjoin a strict regard
the peace and good order of the fociety, the proper
ducation of their young people, and a general attention
to the principles and practices of their profeffions.

In every country where there are monthly meetings, a meet-
ing of the like kind is held, and for fimilar purposes, ev-
ey quarter. This meeting confists of deputies fent from
the several monthly meetings, who are charged with an-
ers in writing to queries propofed to them respecting
the good order of the fociety. At these meetings appeals
are received, in cafe of any difpujes; and differences fett-
lit, if poaffeible. Advices are given as occasions offer, and
affiftance aforded to any of the monthly meetings, in cafe
of a larger proportion of poor, or any fimilar expences.

As there are Quakers in moft parts of England, there are
few counties which have not thefe quarterly meetings. And from thefe are deputed 4, 6 or 8 of their members
once a-year to their annual assembly at London.

The annual meeting is commonly held in Whitsun-
weak, not from any fuperflitious reference, as they fay,
to the effufion of the Holy Ghost at the time of petcoft,
but merely as it is a feafon moft generally convenient
to the body. At this anniversary meeting, confifting of
deputies from every quarterly meeting, and a number of the
moft judicious of their perfusion in London, selected
for the purpoce of acting on all emergencies for the good
of the fociety, accounts are received of the state of the
fociety in every part of the world where it exists.

The deputies bring with them accounts signed by order of the
repective quarterly meetings, informing the yearly meet-
ing, if any diffufion appears; if there is anyneglecf in re-
gard to the religious education of their youth; if the poor
are well provided for; if they keep to their testimony a-
againp paying tythes, againp bearing arms; if they pay the
king his duties, customs, and excife, and forbear to deal
in goods fufpefted to be run. Appeals are here received,
and finally determined; propositions received, and con-
sidered; and rules formed on particular emergencies:
And, lafly, fuch advices are fent to the fubordinate
meetings as the particular or general flate of the fociety
requires.

Perhaps this is the only fociety in the world that have al-
lowed any fhare in the management of their affairs to the fe-
male fex; which they do upon the principle that male and fe-
amale are one in Chrift. Accordingly we find them in ev ery-
department of their inftitution. They have women-preach-
ers, for whom the celebrated Locke made an excellent apo-
logy. These have alo their meetings of discipline; in
which the like care is taken in regard to the female youth,
and the good order of their fex, as is done by the men
in respect to their own. And when we reflect what a nu-
ber of individuals of both fexes are kept in good order by
the police of this fociety, how few of them are brought into
courts of justice as delinquents, how peaceable their behavi-
our, and how exemplary their conduct, we cannot but think
their principles deferve a more accurate examination than
has hitherto been attempted, owing perhaps to the vulgarpre-
judices circulated againft them. We fhall clofe this article
with observing, that, according to the beft of our informa-
tion, neither their minifters, nor thoafe who have the prin ci-
care of the fociety, enjoy any pecuniary emolument or
advantages. A few clerks only receive salaries for keeping
their records; fo that perhaps there is not a religious
fociety now existing, where principle has greater influence
in promoting the ends of their inftitution.

It is remarkable, that all the fettlements of the Eu-
ropans in America, except the Quaker fettlement of Pen-
sylvania, were made by force of arms, with very little
regard to any prior title in the natives. The kings of
Spain, Portugal, France, and Britain, together with the
States of Holland, then the only maritime powers, gave
grants of fimilar parts of America as their people could lay
hold on, fludying only to avoid interference with their
European neighbours. But Mr Jen, being a Quaker,
did not think his powers from the hearty Charles II. a sufici-
tent title to the country fince called Pennsylvania: He there-
fore assemblfl the fachems or princes then in that coun-
try, and purchafed from them the extent of land that he
wanted. The government of this province is mofty in
the hands of the Quakers, who never have any quarrels
with the natives. When they Defire to extend their fett-
lements, they purchafe new lands of the fachems, never
taking any thing from them by force. How unlike is this
conduct to that of the Spaniards, who murdered millions
of the natives of Mexico, Terra Firma, Peru, Chili, &c.
The barbarities used to these poor Indians in conquering
their country, and forcing them to discover their gold,
are a reproach to human nature.

QUALITY, is defined by Mr Locke, to be the power
in a subjedt of producing any idea in the mind. See ME-
TAPHYSICS.

Chemical Qualities, those qualities principally intro-
uced by means of chemical experiments, as fufification, al-
malation, cupellation, volatilization, precipitation, &c.
See CHEMISTRY.

Quality is alfo used for a kind of title given to certain
persons, in regard of their territories, fignories, or other
pretentions.

QUAMSI, a province of China, bounded by the province
of Yunnan on the weft, by Quecheu on the north, by Quantum
on the eaf, and by Tongquin on the fouth.

QUAMSI, a province of China, bounded by the province
of Yunnan on the weft, by Quecheu on the north, by Quantum
on the eaf, and by Tongquin on the fouth.

QUAMSI, a province of China, bounded by the province
of Yunnan on the weft, by Quecheu on the north, by Quantum
on the eaf, and by Tongquin on the fouth.

QUAMSI, a province of China, bounded by the province
of Yunnan on the weft, by Quecheu on the north, by Quantum
on the eaf, and by Tongquin on the fouth.

QUAMSI, a province of China, bounded by the province
of Yunnan on the weft, by Quecheu on the north, by Quantum
on the eaf, and by Tongquin on the fouth.

QUAMSI, a province of China, bounded by the province
of Yunnan on the weft, by Quecheu on the north, by Quantum
on the eaf, and by Tongquin on the fouth.
QUANTITY, any thing capable of estimation, or manifestation; or which, being compared with another thing of the same kind, may be said to be greater or less than it, equal or unequal to it. See Arithmetic, Algebra, Geometry.

QuANTITY, in grammar, an affection of a syllable, whereby its measure, or the time wherein it is pronounced, is ascertained; or that which determines the syllable to be long or short.

QUARANTINE, is used for a term of forty days, which vessels, coming from places suspected of contagion, are obliged to wait in certain places appointed to air themselves, before they come into port. See Lazar-house.

QUARRY, a place under ground, out of which are got marble, freestone, slate, lime-stone, or other matters proper for buildings.

QUARRY OF QUARREL, among glaziers, a pane of glass, cut in a diamond form.

QUART, a measure containing the fourth part of some other measure.

QUARTAN, in medicine, a species of intermittent fever. See Medicine.

QUARTATION, a method of purifying gold, by melting three parts of silver with one of gold, and then throwing the mixture into aqua-fortis. See Chemistry, p. 129.

QUARTER, the fourth part of anything.

Quarter, in weights, is generally used for the fourth part of an hundred weight avoirdupois, or 28 lb. Used as the name of a dry measure, quarter is the fourth part of a ton in weight, or eight bushels.

Quarter, in heraldry, the fourth part of the moon's period.

Quarter, in heraldry, is applied to the parts or members of the first division of a coat that is quartered, or divided into four quarters. See Quartering.

Franc Quarter, in heraldry, is a quarter single or alone; which is to possess one fourth part of the field. This makes one of the honourable ordinarv's of a coat.

Quarter Masters, or Quartermasters, in a man of war, are officers whose business is to rummage, flow, and trim the ship in the hold; to overlook the steward in his delivery of victuals to the cook, and in pumping or drawing out beer, or the like. They are also to keep their watch duly, in conning the ship, or any other duty.

Quarter Master, an officer in the army, whose business is to look after the quarters of the soldiers; of which there are several kinds, viz. The quarter-master general, whose business is to provide good quarters for the whole army; quarter-master of horse, he who is to provide quarters for a troop of horse; quarter-master of foot, he who is to provide quarters for a regiment of foot.

Quartering, in the seal language, is disposing the ship's company at an engagement, in such a manner as that each may readily know where his station is, and what he is to do.

Quartering, in heraldry, is dividing a coat into four or more quarters or quarterings, by parting, coupling, &c. that is, by perpendicular and horizontal lines, &c.

Quatuor vir, in antiquity, formerly written III. VIR, a Roman magistrate who had three colleges joined with him in the Roman administration, and had the care of conducting and letting the colonies sent into the provinces.

There were also quatuor-viri appointed to inspect and take care of repairs, &c.

Quaver, in music, a measure of time equal to half a crotchet, or an eighth of a semibreve. See Music.

Quebec, the capital of Canada, in North America, situated on the west side of the river of St. Lawrence, 300 miles north-west of Boston in New England: W. long. 74° N. lat. 47° 35'.

Queen, a woman who holds a crown singly.

The title of queen is also given by way of courtesy to her that is married to a king, who is called by way of distinction queen-consort; the former being termed queen-regent. The widow of a king is also called queen, but with the addition of dowager.

Queen's County, a county of Ireland, bounded by King's county, on the north; by Kildare, on the east; by Kilkenny, on the south; and by the province of Munster, on the west.

Queen's Ferry, a town of Scotland, on the south side of the river Forth, ten miles west of Edinburgh.

Queenborough, a borough town on the isle of Sheppey, in Kent, twelve miles north-west of Canterbury. It tends two members to parliament.

Quercus, in botany, a genus of the monoecia polyandria class. The calyx of the male has five segments; it has no corolla; and the stamens are from five to ten. The calyx of the female is one entire, rough leaf; it has no corolla; the stamens are from two to five; and the seed is ovated. There are 14 species, only one of them, viz. the robur, or common oak, a native of Britain.

Quercy, the south-east division of the province of Guienne, in France, have Limousin on the north, and Languedoc on the south.

Queria, in botany, a genus of the triandria trigynia class. The calyx consists of five leaves; it has no corolla; and the capsule has one cell and one seed. There are two species, none of them natives of Britain.

Question, in logic, a proposition proposed by way of interrogation. See Logic.

Questor, in Roman antiquity, an officer who had the management of the public treasure.

The questrorship was the first office any person could bear in the commonwealth, and gave a right to sit in the senate.

At first there were only two; but afterwards two others were created, to take care of the payment of the armies abroad, of the selling plunder, booty, &c. for which purpose they generally accompanied the consuls in their expeditions: on which account they were called peregrini, as the first and principal two were called urbani.

The number of questors was afterwards greatly increased: They had the keeping of the decrees of the senate, and hence came the two offices of questor principis, or augusti, sometimes called candidatus principis, whose office resembled in most respects that of our secretaries of state; and the questor palatii, answering in a great measure to our lord chancellor.

Queue, in heraldry, signifies the tail of a beast; thus if a lion be borne with a forked tail, he is blazoned doublequeued.

Quick, or Quickest Hedge, among gardeners, denotes all live hedges, of whatever sort of plants they are composed, to distinguish them from dead hedges; but in a
QUINQUAGENARIUS, in Roman antiquity, an officer to the house of Austria: E. long. 18°, N. lat. 48°.

RAAB, a city of Lower Hungary, situated at the confluence of the rivers Danube and Raab, and subject

QUANTICUS, in botany. See Potentilla.

QUINQUAGYNIUM, in Roman antiquity, a magistrature in the colonies and municipal cities of that empire, who had much the same office as the ædile at Rome.
RACK, an engine of torture, furnished with pulleys and cords, &c. for extorting confession from criminals.

RACKED wines. See to draw them off from their lees, after their having stood long enough to clear and settle, from whence the liquor runs through a small wooden pipe. This liquor is more intoxicating than brandy distilled from wine.

To Rack wines, &c. to draw them off from their lees, after their having stood long enough to clear and settle. Hence physicians talk much of a radical moisture.

Hence rack-vintage is frequently used for the second voyage our wine-merchants used to make into France for racked-wines.

RACKOON, in zoology. See Viverra.

RACKS, in building, are pieces of timber, which stand upright, and most in use. It is made of the bottom bunch of the cocoa-tree: for which purpose they tie the bunch, situated under the head. There are nine species, one of which is the torpedo, or crap-fish, found in the Mediterranean and Persian Gulf. When touched, it defends itself by a tremulous motion, which benumbs any animal which attempts to injure it.

RAJANIA, in botany, a genus of the dicotyledonous plants, the remains of which are found in the ruins of those who ruled there before the Moguls. Some of the rajas are said to preferve their independence, especially in the mountainous parts; but most of them pay an annual tribute to the Mogul.

RAJA, the title of the Indian black princes, the remains of whose who ruled there before the Moguls. Some of the rajas are paid to preserve their independency, especially in the mountainous parts; but most of them pay an annual tribute to the Mogul.

RAJA, in ichthyology, a genus belonging to the order of amphibian nates. There are five species, one of which is the torpedo, or crap-fish, found in the Mediterranean and Persian Gulf. When touched, it defends itself by a tremulous motion, which benumbs any animal which attempts to injure it.

RAJANIA, in botany, a genus of the dicotyledonous plants, the remains of which are found in the ruins of those who ruled there before the Moguls. Some of the rajas are paid to preserve their independency, especially in the mountainous parts; but most of them pay an annual tribute to the Mogul.

Mr. Derham accounts for the precipitation hence, that the vehicule being full of air, when they meet with a colder air than that they contain, their air is contracted into a less space; and consequently the watery fluid rendered thicker, so as to become heavier than the air, &c.

Others allow the cold a part in the action, and bring in the winds as sharers with it: indeed, it is plain, that a wind, blowing against a cloud, will drive its vehicule upon one another, by which means several of them coalescing, will be enabled to deflect; and the effect will be still more considerable if two opposite winds blow towards the same place. Add to this, that clouds already formed, happening to be aggravated by fresh accretions of vapour continually ascending, may thence be enabled to descend.

According to Rohault, the great cause of rain is the heat of the air; which, after continuing for some time near the earth, is at length carried up on high by a wind, and there thawing the frozen vehicule, reduces them into drops; which, coalescing, descend.

Others, as Dr. Clarke, &c. ascribe this descent of the clouds rather to an alteration of the atmosphere than of the vehicule; and suppose it to arise from a diminution of the elastic force of the air. This elasticity, which depends chiefly or wholly on the terrene exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall.

Now the little vehicules, being once upon the descent, will pervert therein, notwithstanding the increase of resistancy they every moment meet with. For as they all tend toward the centre of the earth, the farther they fall, the more coalitions will they make; and the more coalitions, toward the centre of the earth, the farther they fall, the more matter will there be under the same surface; and the latter have a latent acidity with the sweetness that renders them much less agreeable.

The battering ram was of two sorts; the one rude and plain, the other compound. The former seems to have been no more than a great beam which the soldiers bore on their arms and shoulders, and with one end of it by main force affailed the wall. The compound ram is thus described by Josephus: it is a vall beam, like the mallet of a ship, strengthened at one end with a head of iron, something resembling that of a ram, whence it took its name.

This was hung by the middle with ropes to another beam, which lay across two posts; and hanging thus equally balanced, it was by a great number of men drawn backwards and pushed forwards, striking the wall with its iron-head.

Plutarch informs us, that Marc Anthony, in the Parthian war, made use of a ram fourscore feet long; and Vitruvius tells us, that they were sometimes an hundred and six, and sometimes an hundred and twenty feet in length; and to this perhaps the force and strength of the engine was in a great measure owing. The ram was managed at one time by a whole century of soldiers; and they being spent, were seconded by another century, so that it played continually without any interruption.

Ram's head, in a ship, is a great block belonging to the fore and main halliards. It has three sheers in it, into which the halliards are put, and in a hole at the end of it are reeved the ties.

Ramadán, a solemn season of fasting among the Mahometans. See Mahometanism.

Ramification, the production of boughs or branches, or of figures resembling branches.

Rammer, an instrument used for driving down stones or piles into the ground; or for beating the earth, in order to render it more solid for a foundation.

Ram of a gun, the gun-flick; a rod used in charging of a gun, to drive home the powder, as also the shot and the
the wad, which keeps the shot from rolling out. See Gunner.

RAMPANT, in heraldry, a term applied to a lion, leopard, or other beast that stands on his hind-legs, and rears up his forefront in the posture of climbing, slewing only half his face, as one eye, &c. It is different from fulant, in which the beast seems springing forward as if making a rally. See Plate CXLVII fig. 6.

RAMPART, in fortification, is an elevation of earth round a place capable of resisting the cannon of an enemy; and formed into bastions, curtains, &c. See Fortification.

RAMSEY, an island in the Irish channel, on the coast of Pembrokefhire: W. long 5° 20', N. lat. 51° 55'.

RAMUS, in general, denotes a branch of anything, as of a tree, an artery, vein, &c.

RANA, the frog, in zoology, a genus belonging to the class of amphibia reptilia. The body is naked, furnished with four feet, and without any tail. There are 17 species. Frogs undergo a very strange metamorphosis. When they first issue from the eggs, they appear in a roundish form, with a long tail, and are then denominated tadpoles. After continuing in this state for several weeks, the tail begins to mortify and fall off gradually, the feet at the same time springing as gradually out of the body, till they assume the complete form of frogs.

RANCHIERA, a port-town of Terra Firma, situated in W. long. 72°, N. lat. 10° 34'.

RANCID, denotes a fatty ferment that becomes rank or mulli, or has contracted an ill smell by being kept close.

RANGE, in gunnery, the path of a bullet, or the line it describes from the mouth of the piece to the point where it lodges. See Gunnery.

RANGIFER, the rein-deer. See Curvis.

RANK, the order or place allotted a person, suitable to his quality or merit.

RANKING OF CREDITORS, in Scots law. See Law, Tit. xix. 13.

RANSOM, a sum of money paid for the redemption of a slave, or for the liberty of a prisoner of war. In our law-books, ransom is also used for a sum paid for the pardon of some great offence, and to obtain the offender's liberty.

RANULA, a tumour under the tongue, which like a ligature hinders a child from speaking or sucking.

RANUNCULUS, in botany, a genus of the polyandria class. The calix consists of five leaves, and the corolla of five petals, with a melliferous pore in the corolla of five petals, with a melliferous pore in the claw of each; and the seeds are naked. There are 38 species; 11 of them natives of Britain.

RAPID, a city of the hither India, situated in the province of Bengal: E. long. 23°, N. lat. 6° 22'.

RAPAN, the rat-tails, or Arrests, in the manege, signify hard callous swellings upon the hinder legs under the hough, running along the sinew.

RAPHIDIA, in zoology, a genus of insects belonging to the order of neuroptera. The head is depressed and hony; it has two teeth, four pappi, and three hemmata; the wings are deflected; the feelers are cylindrical, and of the length of the thorax; and the tail of the female is furnished with a lax bended bristle. There are three species.

RAPIER, formerly signified a long old-fashioned broad sword, such as those worn by the common soldiers; but it now denotes a small sword, as contradistinguished from a back-sword.

RAPINE, in law, the taking away another's goods, &c. openly and by violence.

RAPPANNOCK, a large navigable river which rises in the mountains west of Virginia, and discharges itself into the bay of Chesapeake.

RAPTURE, an ecstasy, or transport of mind. See Ecstasy.

RARE, in physics, stands opposed to dense; and denotes a body that is very porous, whose parts are at a great distance from one another, and which contains little matter under a large bulk.

RAREFACTION, in physics, the act whereby a body is rendered rare; that is, brought to possess more room, or appear under a larger bulk without accession of any new matter.

RASEBURG, a port-town of Sweden, in the province of Finland, and territory of Nyland, situated on the gulf of Finland: E. long. 23°, N. lat. 60° 22'.

RASSTAT, the name of two towns of Germany: one in the circle of Bavaria and archbishopric of Salzburg, situated on the river Ens, thirty-five miles south of the city Ens; another in the circle of Swabia and marquisate of Baden, situated on the east side of the river Rhine, twenty-one miles south-west of Philipburg.

RAT, in zoology. See Mus.

RAT-TAILS, or ARRESTS, in the manege, signify hard callous swellings upon the hinder legs under the hough, running along the sinew.

RATAFIA, a fine spirituous liquor, prepared from the kernels, &c. of several kinds of fruits, particularly of cherries and apricots.

Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel wherein brandy has been long kept; then adding to them the kernels of cherries, with straw-berries, figs, cinnamon, white pepper, nutmeg, cloves; and to twenty pound of cherries, ten quarts of brandy. The vessel is left open ten or twelve days, and then stopped close for two months before it be tapped. Ratafia of apricots is prepared two ways, viz. either by boiling the apricots in white wine, adding to the liquor an equal quantity of brandy, with figs, cinnamon, mace, and the kernels of apricots; infusing the whole for eight or ten days, then straining the liquor, and putting it up for use: Or else by infusing the apricots cut in pieces in brandy, for a day or two, palling it through a straining bag, and then putting in the usual ingredients.
RATE, a standard or proportion, by which either the quantity or value of a thing is adjusted. 

RATE of a ship at warp, is its order, degree, or distinction, as to magnitude, burden, &c. 

RATEEN, in commerce, a thick woolen stuff, quilted, woven on a loom with four treddles, like ferges, and other stuffs, that have the whale or quilting. There are some rateens drefled and prepared like clothes; others left simply in the hair; and others where the hair or knop is friz'd. Rateens are chiefly manufactured in France, Holland, and Italy, and are mostly used in linings. The frize is a sort of coarse rateen, and the drugget is a rateen half linnen half woolen. 

RATIFICATION, an act approving off, and confirming something done by another in our name. 

RATIO, in arithmetic and geometry, is that relation of one from the quantity of another, without the intervention of a third. See Arithmetic, Algebra, and Geometry. 

RATIFICATION, the act of reasoning. See Reasoning. 

RATION, in the army, a portion of ammunition, bread, drink, and forage, distributed to each soldier in the army, for his daily subsistence. &c. The horse has rations of hay and oats, when they cannot go out to forage. The rations of bread are regulated by weight. The ordinary ration of a foot-folder is a pound and a half of bread per day. The officers have several rations according to their quality and the number of attendants that they are obliged to keep. When the ration is augmented on occasions of rejoicing, it is called a double ration. The ships crews have also their rations or allowances of biscuit, pulse, and water, proportioned according to their rank. 

RATIONAL, reasonable. See Reason. 

RATIONAL, is also applied to integral, fractional, and mixt numbers: thus we say rational fraction, rational integer, and rational mixt number. 

RATIONALISATION, a solution or account of the principles of some opinion, action, hypothesis, phenomenon, or the like. 

RAITPOR, a town of Bohemia, in the duchy of Sileia, situated on the river Oder, sixteen miles north-east of Tropau. 

RAITPOR, is also a city of bitter India, capital of the province of Malwa, situated E. long. 80°, N. lat. 25°. 

RATISBON, a city of Germany, in the circle of Bavaria, situated at the confluence of the rivers Danube and Regen, in E. long. 12° 5', N. lat. 49°. This is a free imperial city, and has the assembly or diet of the states of the empire meets. 

RATLINES or, as the seamen call them, Ratlines, those lines which make the ladder steps to go up the hatches and portholes, hence called the ratlines of the thords. 

RATTLE SNAKE, See Crotaulus. 

RATTLE SNAKE FOOT. See Polyomol. 

RAVA, a city of Great Poland, capital of the Palatinate of Rava, situated fifty miles south-east of Warsaw. 

RAVELIN, in fortification, was anciently a flat battery, placed in the middle of a curtin; but now a detached work composed only of two faces, which make a flat 

angle, without any flanks, and raised before the curtin on the counterescarp of the place. See Fortification. 

RAVEN, in ornithology. See Corvus. 

RAVENGLAS, a port-town of Cumberland, situated on the Irish Channel, thirty-eight miles south-west of Carlisle. 

RAVENNA, a city of Italy, in the pope's territories, capital of the province of Romagna, situated E. long. 13°, N. lat. 42° 30'. 

RAUVOLFIA, a genus of the pentandria monogynia class. The berry contains two seeds. There are two species; both natives of America. 

RAY, in optics, a beam of light, emitted from a radiant or luminous body. See Optics. 

RAYLEIGH, a market-town of Essex, ten miles south-east of Chelmsford. 

RAYONANT, or Cross Rayonant, in heraldry, one of the tinctures used in the escutcheon, as represented in Plate CXLVII. fig. 7. 

RAZOR, a well known instrument used by surgeons, barbers, &c. for shaving off the hair from various parts of the body. 

RAZOR-BILL, in ornithology. See Alca. 

REACTION, in physiology, the resistance made by all bodies to the action or impulse of others that endeavour to change its state whether of motion or rest. See Mechanics. 

READING, a borough town in Berkshire, situated forty miles west of London, near the confluence of the river Kent and Thames; it sends two members to parliament. 

REAL, is applied to a being that actually exists; in which something done by another in our name. 

REAL, or Credus, in stock, a diminutive of rius, thing, or knap is friz'd. Rateens are chiefly manufactured in France, Holland, and Italy, and are mostly used in linings. The frize is a sort of coarse rateen, and the drugget is a rateen half linnen half woolen. 

REALM, a country which gives its head, or governor, the denomination of a king. 

REALMONT, a town of France, in the province of Languedoc, situated thirty-two miles north-east of Tholouse. 

REAL, a term frequently used in composition, to denote something behind or backwards, in respect of another, in opposition to van: thus, in a military sense, it is used for the hind part of an army, in opposition to the front. 

REASON, a faculty or power of the mind, whereby it 

distin-
RECIPROCAL, in general, something that is mutual, or common to both.
RECIPIENT, the name with a receiver.

Reciprocal terms, among logicians, are those which have the same signification; and consequently are convertible, or may be used for each other.

RECEIVER, in heraldry, a diminution or abatement of the bearing of the coat of arms.
REBEL, a traitorous taking up of arms against the king by his own natural subjects, or those formerly subdued.
REBUS, in enigmatical representation of some name, or by using figures or pictures instead of words, or parts of words. Camden mentions an instance of this absurd kind of wit in a gallant, who expressed his love to a woman, named Rose Hill, by painting in the border of his gown a rose, a hill, an eye, a leaf, and a well; which, in the style of the rebus, reads, Rose Hill, I love well. This kind of wit was long practised by the great, who took the pains to find devices for their names. It was, however, ridiculed by Ben Jonson, in the humorous delineation of Abel Drummer's device, in the Alchemist; and by the Spectator, in the device of Jack Newberry, at which time the rebus, being raised to sign-posts, was grown out of fashion at court.
REBUTTER, in law, the defendant's answer to the plaintiff's surriferorder, in a cause depending in the court of chancery, &c.

RECAPITULATION, a summary, or a concise and remanent enumeration of the principal things inferred in the preceding discourse, whereby the force of the whole is collected into one view.
RECEIVER, in usury, a plain receipt for containing the thing on which an interest is computed; or the part of the interest computed.
RECOPTACULUM. See Anatomy, p. 282.
RECHABITES, a kind of religious order among the ancient Jews, instituted by Josiah the son of Rechab, comprehending only his own family and posterity. They are under the same three things: first, not to drink wine; secondly, not to build any houses, but to dwell in tents; and thirdly, not to own any corn, or plow-ivines. These rules the Rechabites observed with great fidelity.

RECIPE, in medicine, a prescription or remedy, to be taken by a patient; it is called a receipt, always beginning with the word receipt, i.e., recipe, which is generally denoted by the abbreviation R. Dr.
RECIPIENT, the name with a receiver.
RECPROCAL, in general, something that is mutual, or which is returned equally on both sides; or that affects both parties alike.

RECPROCAL TERMS, among logicians, are those which have the same signification; and consequently are convertible, or may be used for each other.

RECPROCAL FIGURES, in geometry, those which have the antecedents and consequents of the same ratio in both figures. See Geometry.
RECUITATIVO, in music, a kind of singing that differs but little from ordinary pronunciation, such as that in which the several parts of the liturgy are recited in cathedral; or that wherein the actors commonly deliver themselves on the theatre at the opera, when they are to express some sensoir passion, to relate some event, or reveal some design.

RECKONING, or a ship's reckoning. See Navigation.

RECLAMBUTER, in heraldry, a diminution or abatement, or redaction, in commerce, & term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer instead of taking time advances ready money.

REBATE, or rebatement, in commerce, a term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer instead of taking time advances ready money.

REBATEMENT, in law, the defendant's answer to the plaintiff's answer, i.e., to set forth against the accuser upon the same fact.
RECLAIM, in heraldry, a diminution or abatement.
RECRUITS, in military affairs, new-raised soldiers, designed to supply the place of those who have lost their lives in the service, or are disabled by age or wounds.

RECONNOITRE, in war, to view and examine the state and situation of things.
RECORD, an authentic testimony in writing, contained in rolls of parchment, and preferred in a court of record.
RECORDE, a person whom the mayor and other magistrates of a city or corporation associate to them, for their better direction in matters of justice, and proceedings in law; on which account this person is generally a counsellor, or other person well skilled in the law.

The recorder of London is chosen by the lord mayor and aldermen; and, as he is held to be the mouth of the city, he delivers the judgment of the courts therein, and records and certifies the city-culloms.

RECOUSE ON BILL, in Scots law. See Law, Tit. xx. 12.

RECLAMATION, in chemistry, some superfused matter separated from some other that is useful; in which sense it is the same with scoria, fuses, and excrèments. See Chemistry.

RECRIMINATION, in law, an accusation brought by the accused against the accuser upon the same fact.
RECRUITS, in military affairs, new-raised soldiers, designed to supply the place of those who have lost their lives in the service, or are disabled by age or wounds.

RECTIFICATION, in chemistry, is nothing but the repetition of a distillation or sublimation several times in order to render the substance pure, finer, and finer from aqueous or earthy parts.
RECTIFIER, in navigation, an instrument consisting of two parts, which are two circles one of which has its center in the other, and is fastened together in their centers, that they represent two compasses, one fixed, the other movable; each of them divided into the thirty-two points of the compass, and those hundred and sixty degrees, and numbered both ways, from the north and the south, ending at the east and west, in ninety degrees.

The first compass represents the horizon, in which the
the north and all the other points of the compass are fixed and immovable.

The moveable compass represents the mariners compass, in which the north and all other points are liable to variation.

In the centre of the moveable compass is fastened a silk thread, long enough to reach the outside of the fixed compass. But, if the instrument be made of wood, there is an index instead of the thread.

Its use is to find the variation of the compass, to rectify the course at sea; having the amplitude or azimuth given.

**Rectifier**, in the distillery, the person whose employment it is to take the coarse malt-spirit of the malt-filler, and redistil it to a finer and better liquor.

**Rectilinear**, in geometry, right-lined: thus figures whose perimeter consists of right lines, are said to be rectilinear.

**Rectitude**, in philosophy, refers either to the act of judging or of willing: and therefore whatever comes under the denomination of rectitude is either what is true, or what is good; these being the only objects about which the mind exercises its two faculties of judging and willing.

**Moral rectitude**, or uprightness, is the judging and purifying those things which the mind, upon due inquiry and attention, clearly perceives to be good; and avoiding those that are evil.

**Rector**, a term applied to several persons whose offices are very different: as, 1. The rector of a parish is a clergyman that has the charge and cure of a parish, and possesses all the tythes, &c. 2. The same name is also given to the chief elective officer in several foreign universities, particularly in that of Paris. 3. Rector is also used in several convents for the superior officer who governs the houfe: and the Jesuits give this name to the superiors of each of their houses as are either seminaries or colleges.

**Rectory**, a parish-church, parsonage, or spiritual living, with all its rights, tythes, and glebes.

**Rectum**, in anatomy, the third and last of the large intestines or guts. See Anatomy, p. 261.

**Rectus**, in anatomy, a name common to several pair of muscles, so called on account of the slantings of their fibres. See Anatomy, Part II.

**Recurrents**, in anatomy, a name given to several large branches of nerves sent out by the par vagum from the upper part of the thorax to the larynx.

**Recuvirostra**, in ornithology, a genus belonging to the order of grallse. The beak is sublated, bent back, sharp and flexible at the point; the feet are webbed, and furnished with three toes. But there is but one species, viz. the avocetta, a native of the southern parts of Europe. It migrates into Italy, and is seldom seen in England charged with double taxes, not merely as Romanists but as recusants.

In a moral sense, to redress grievances is to reform and remove them.

To redress a flag, among hunters, is to put him off his changes.

**Redruth**, a market-town of Cornwall, situated fifty miles south-west of Launceston.

**Redoubt**, in fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, or the end that one part may flank or defend another. It is called faw-work and indented-work.

**Redintegration**, in the civil law, the act of restoring a person to the enjoyment of a thing whereof he had been illegally dispossessed.

**Redoubt**, in fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, or the end that one part may flank or defend another. It is called faw-work and indented-work.

**Redressing**, the rectifying or setting any thing straight again.

**Red Sea** separates Asia from Africa.

**Reddell** separates Little Russia.

**Red Sea**, or Little Russia, a province of Poland, bounded by the province of Polefsia, on the north; by Volhynia and Podolia on the east; by the Carpathian mountains, which divide it from Transylvania and Hungary, on the south; and by the province of Little Poland, on the west; being two hundred miles long, and one hundred broad.

**Red Sea** separates Asia from Africa.

**Reddell** separates Little Russia.

**Red Sea**, or Little Russia, a province of Poland, bounded by the province of Polefsia, on the north; by Volhynia and Podolia on the east; by the Carpathian mountains, which divide it from Transylvania and Hungary, on the south; and by the province of Little Poland, on the west; being two hundred miles long, and one hundred broad.
RE-EXCHANGE, in commerce, a second payment of the price of exchange, or rather the price of a new exchange upon a bill of exchange that comes to be protested and to be refunded the bearer by the drawer or indorser.

RE-EXCHANGE, in commerce, a second payment of the price of exchange, or rather the price of a new exchange upon a bill of exchange that comes to be protested and to be refunded the bearer by the drawer or indorser.

REFER, in the language of jargon, the putting a rope through a block: hence pull a rope out of a block, is called unreeling.

RED, in the manufacories, the winding of thread, silk, cotton, or the like, into a skein, or upon a bottom, to prevent its entangling. It is also used for the charging or discharging of bobbins or quills, to use them in the manufacture of different fluffs, as thread, silk, cotton, &c. Reeling is performed different ways, and on different engines.

RE-EXCHANGE, in commerce, a second payment of the price of exchange, or rather the price of a new exchange upon a bill of exchange that comes to be protested and to be refunded the bearer by the drawer or indorser.

REFERENCE, in writing, &c. a mark relative to another similar one in the margin, or at the bottom of the page, where something omitted in the text is added, and which is to be inserted either in reading or copying.

REFINING, in general, is the art of purifying a thing; which is to be inserted either in reading or copying.

REFLEXION, the return or regressive motion of a moving body, occasioned by some obstacle which hindered it from pursuing its former direction.

REFLECTION is also used, figuratively, for an operation of the mind; whereby it turns its view backwards as it were upon itself, and makes itself and its own operation the object of its disquisition; and by contemplating the manner, order, and laws which it observes in perceiving ideas, comparing them together, reasoning, &c. it frames new ideas of the relations discovered therein. See Logic, and Metaphysics.

REFINING of gold. See Chemistry, p. 129.

REFINING of silver. See Chemistry, p. 130.

REFLECTION, the return or regressive motion of a moving body, occasioned by some obstacle which hindered it from pursuing its former direction. See Optics.

Reflection is also used, figuratively, for an operation of the mind; whereby it turns its view backwards as it were upon itself, and makes itself and its own operation the object of its disquisition; and by contemplating the manner, order, and laws which it observes in perceiving ideas, comparing them together, reasoning, &c. it frames new ideas of the relations discovered therein. See Logic, and Metaphysics.

REFLEXION of the fia, the ebbing of the water, or its returning from the shore. See Astronomy, p. 473.

REFORMATION, the act of reforming or correcting an error or abuse in religion, discipline, or the like. The Reformation, so called by way of eminence, is the separation of the Protestants from the church of Rome, in the beginning and towards the middle of the sixteenth century.

REFRACTION, in general, is the deviation of a moving body from its direct course, occasioned by the different density of the medium it moves in; or, it is a change of direction, occasioned by a body's falling obliquely out of one medium into another of a different density. See Optics.

REFRANGIBILITY of light, the disposition of rays to be refracted. See Optics.

REFRIGERATIVE, in medicine, a remedy which refreshes the inward parts, by cooling them, as cyphels, puffers, &c. See Chemistry, p. 62.

REFRIGERATORY, in chemistry a vessel filled with cold water, through which the worm passes in distillations; the use of which is, to condense the vapours as they pass through the worm.

REFUGE, a sanctuary or asylum.

REFUGEES, French Protesants, who, by the revocation of the edict of Nantes, have been constrained to fly from persecution, and take refuge in foreign countries.

REGAL or Royal, something belonging to a king.

REGALE, a magnificent entertainment or treat given to ambassadors, and other persons of distinction, to entertain or do them honour.

It is usual, in Italy, at the arrival of a traveller of eminence, to lend him a regale, that is, a present of sweetmeats, fruit, &c. by way of refreshment.

REGALE, in the French jurisprudence, is a royal prerogative, which consists in enjoying the revenues of bishops during the vacancy of their seats, of presenting to benefices, and of obliging the new bishop to take an oath of fidelity, and to register it in the chamber of accounts. The enjoyment of the fruits of the see is called the temporal regale; and that of presenting to the see, the spiritual regale.

REGALIA, in law, the rights and prerogatives of a king, which, according to civilians, are fixed: viz. 1. The power of judicature; 2. The power of life and death; 3. The power of peace and war; 4. A right to such goods as have no owner, as waifs, estrays, &c. 5. Assentments; and, 6. The coinage of money.

Regalia is also used for the apparatus of a coronation, as the crown, the sceptre with the cross, that with the dove, St. Edward's staff, the globe, and the orb with the crosses, four several swords, &c.

REGALIA, in Scots law. See Law, Tit. xiii. 3.

Lord of Regality, in Scots law. See Law, Tit. iv. 4.

REGARDANT, in heraldry, signifies looking behind; and is used for a lion, or other beast, with his head turned toward its tail.

REGARDER, an ancient officer of the king's forell, sworn to make the regard of the forell every year; that is, to take a view of its limits, to inquire into all offences and defaults committed by the foresters within the forest, and to observe whether all the other officers executed their respective duties.

REGEL, or Rigel, a fixed star of the first magnitude, in Orion's left foot.

REGENERATION, in theology, the act of being born again by a spiritual birth, or the change of heart and life experienced by a person who forsakes a course of vice, and sincerely embraces a life of virtue and purity.

REGENT, one who governs a kingdom during the minority or absence of the king.

In France, the queen mother has the regency of the kingdom during the minority of the king, under the title of queen-regent.

Regent also signifies a professor of arts and sciences in a college, who has a set of pupils under his care; but here regent is generally restrained to the lower classes, as regent of rhetoric, regent of logic, &c. those of philosophy are rather called professors.

REGICIDE.
REGICIDE, king-killer, a word chiefly used with us in speaking of the persons concerned in the trial, condemnation, and execution of king Charles I.

REGIFUGE, a feat celebrated in ancient Rome on the sixth of the kalends of March, in memory of the expulsion of their ancient kings, and particularly of Tarquin's flying out of Rome on that day.

REGIMEN, the regulation of diet, and, in a more general sense, of all the non-naturals, with a view to preserve or restore health. See Medicine.

REGIMENT, in grammar, that part of syntax, or construct which regulates the dependency of words, and the alterations which one occasions in another. See Grammar.

REGIMENT, in war, is a body of men, either horse or foot, commanded by a colonel.

Each regiment of foot is divided into companies; but the number of companies is not always alike; though our regiments generally consist of thirteen companies, one of which is always grenadiers.

Regiments of horse most commonly consist of six troops, but some have nine.

Regiments of dragoons, in time of war, are generally composed of eight troops; and in time of peace, of six.

REGION, in geography, a large extent of land, inhabited by many people of the same nation, and inclosed within certain limits or bounds.

REGISTER, a public book in which is entered and recorded memoirs, acts, and minutes, to be had recourse to occasionally, for knowing and proving matters of fact.

Register ships, in commerce, are vessels which obtain a permission either from the king of Spain, or the council of the Indies, to traffic in the ports of the Spanish West-Indies; which are thus called, from their being registered before they set sail from Cadiz, for Buenos Ayres.

Registers, in chemistry, are holes, or chinks with stoppers, contrived in the sides of furnaces, to regulate the fire; that is, to make the heat more intense, or, by opening them to let in the air, or keeping them close to exclude it.

REGISTRY, the office, books, and rolls, in which the proceedings in chancery, or any spiritual court, are registered.

REGRATOR, or Regrater, in law, formerly signified one who bought wholesale, or by the great, and sold again by retail; but the term is now used for one who buys any wares or victuals, and sells them again in the same market, or fair, or within fifteen miles round it. See Forstalling.

REGULAR, denotes any thing that is agreeable to the rules of art: thus, we say a regular building, verb, &c.

A regular figure, in geometry, is one whose sides, and consequently angles, are equal; and a regular figure with three or four sides, is commonly termed an equilateral triangle, or square; as all others with more sides are called regular polygons.

Regular, in a monastery, a person who has taken the vows; because he is bound to observe the rules of the order he has embraced.

REGULATION, a rule or order preferred by a superior, for the proper management of some affair.

REGULATOR of a watch, the small spring belonging to the balance; serving to adjust its motions, and make it go faster or slower. See Watch.

REGULUS, in ornithology. See Motacilla.

REGULUS, in chemistry, an imperfect metallic substance, that falls to the bottom of the crucible, in the melting of ores or impure metallic substances. See Chemistry, paffin.

REHABILITATION, in the civil and the canon law, the restoring a delinquent to his former condition.

REHEARSAL, in music and the drama, an essay or experiment of some composition, generally made in private, previous to its representation or performance in public, in order to render the actors and performers more perfect in their parts.

REIN-DEER, in zoology. See Cervus.

REINS, in anatomy. See Anatomy, p. 268.

REJOINDER, in law, is the defendant's answer to the plaintiff's replication or reply. Thus, in the court of chancery, the defendant puts in an answer to the plaintiff's bill, which is sometimes also called an exception; the plaintiff's answer to this is called a replication; and the defendant's answer to that a rejoinder.

REITERATION, the act of repeating a thing, or doing it a second time.

RELAPSE, a falling again into a danger, evil, or disease, from which a person has escaped.

RELATION, the mutual respect of two things, or what each is with regard to the other. See Metaphysics.

RELATION, in geometry. See Ratio.

RELATION is also used for analogy. See Analogy.

RELATIVE, something relating to, or respecting, another.

RELATIVE TERMS, in logic, are words which imply a relation: such are master and servant, husband and wife, &c.

RELAXATION, in medicine, &c, the act of loosening or slackening, or the looseness and slackness of the fibres, nerves, muscles, &c.

RELAY, a supply of horses placed on the road, and appointed to be ready for a traveller to change, in order to make the greater expedition.

RELEVANCY, in Scots law. See Law, Tit. xxxiii, 48.

RELIERS, in the Romish church, the remains of the bodies of saints or martyrs, and the instruments by which they were put to death, devoutly preserved, in honour to their memory; kissed, revered, and carried in procession.

RELICT, in law, the same with widow.

RELIEVO, or Relief, in sculpture, &c, is the projection or standing out of a figure; which arises prominent from the ground or plan on which it is formed; whether that figure be cut with the chisel, moulded, or cast.

There are three kinds or degrees of relief, viz. alto, baso, and demi reliefo. The alto-relievo, called also haut-relief, or high relief, is when the figure is formed after nature, and projects as much as the life. Baso-relievo, bas-relief, or low relief, is when the work is raised but a little from the ground, as in medals; and the frontispieces of buildings; and particularly in the histories, festoons, foliages, and other ornaments of friezes. Demi-relievo is when one half of the figure rises from the plan.
When, in a basse-relievo, there are parts that stand clear out, detached from the rest, the work is called a demi-basse.

RELIGION, OR THEOLOGY.

I. To know God, and to render him a reasonable service, are the two principal objects of religion. We know but little of the nature of bodies; we discover some of their properties, as motion, figure, colours, &c. but of their essence we are ignorant: we know still much less of the soul; but of the essence or nature of God, we know nothing: it is the prerogative of the Supreme Being alone to comprehend his own essence; all the efforts that we can make to attain that knowledge, are arrogant and ineffectual; it is foreign to the properties of the limited spirit: but our destiny is that of a man, and our desires are those of a God. In a word, man appears to be formed to adore, but not to comprehend, the Supreme Being.

II. We may say, however, with Virgil, Jovis omnia pleme; God manifests his existence, not only to the internal sensations of our minds, but in every object that surrounds us in the whole frame of nature; and if we cannot comprehend the Supreme Being by our senses, we may discover his attributes by our reason, almost as clearly as we distinguish the properties of matter, and many other objects: and this knowledge is sufficient for us. The end of every order of science is some temporal happiness: theology alone proposes an eternal felicity; its object therefore differs from all other sciences, as the age of threescore and ten differs from eternity. We cannot wonder therefore, that all the inhabitants of the earth, from the time of the creation, have made it their principal study, and have exerted all their abilities in the cultivation of it: we ought much rather to be astonished that they have been so slow to arrive at this knowledge is sufficient for us. The end of every order of science is some temporal happiness: theology alone proposes an eternal felicity; its object therefore differs from all other sciences, as the age of three-score and ten differs from eternity. We cannot wonder therefore, that all the inhabitants of the earth, from the time of the creation, have made it their principal study, and have exerted all their abilities in the cultivation of it: we ought much rather to be astonished that they have been so slow to arrive at this

III. From the first knowledge that we have of the world, that is to say, for about five thousand years past, men have blindly searched after the idea of the true God; and by the weakness of their discernment, they have fallen into a thousand errors. Paganism at first covered the whole earth, except that family alone which became the flock of the Jewish people: this paganism among different nations had different mixtures of idolatry. Moses first made known to the Hebrews the true God, and prescribed him the worship: his religion, however, was not adopted by any other people, not even by their neighbours. Jesus Christ appeared upon the earth, abolished a part of the Judaic law, reformed the religion of Moses, taught his divine doctrines, and offered himself as a sacrifice for the salvation of mankind. His gospel made a happy progress over all Europe, that is, over the then known part of the earth. Some time after, Mahomet arose in the east, and preached a religion that he had compounded of the Jewish and Christian, and of his own ideas. Lastly, came Luther and Calvin, who reformed the errors which, according to them, had been introduced into Christian under the reigns of the popes; and gave the idea of what is called the Protestant Religion. Confucius had taught the Chinese, and Zoroaster the Indians, religions drawn partly from philosophy, and partly from paganism; but the extent of these was very confined. All these religions, and their different sects, had their theology, their priests, their ceremonies, their triumphs, and even their martyrs.

IV. We shall not speak here of religions that are extinct, or that yet exist, but at a distance far from us: we shall treat only of the Christian theology, which teaches us to know God, by revelation and by the light of reason, so far as it is possible for the weakness of the human mind to comprehend that incomprehensible Being. The knowledge of the true God is indeed of little utility to man, unless he can suppose that there is some connection or relation between that Supreme Being and himself. Now it is from these connections or relations that are derived the necessity of the knowledge of the true God, and of the true manner in which he is to be worshipped: and this it is that forms the Christian theology; of which we shall now give the analysis.

V. To ascend by a chain of reasoning from things visible to things invisible, from palpable to impalpable, from terrestrial to celestial, from the creature even up to the Creator, is the business of theology: it is not surprising, therefore, that the union of many doctrines is necessary completely to form such a science. To understand, and properly to interpret the scriptures or revelation, demands not less sagacity than affinity. The gift of persuasion is also essential to the ministers of the gospel. And lastly, the civil government has committed to their care certain functions of society, which relate, or seem to relate, either to the doctrines or morality of the gospel. They assemble, for example, in bodies to form consistories; they judge in matrimonial cases; they carry consolation and hope to the souls of the sick; they prepare for death those criminals which justice sacrifices to public safety; they take upon themselves the charge of Ephor, with the inspection of some pious foundations; they distribute alms; they administer the sacraments, &c.

VI. To discharge fully so many duties, the theologian has need, 1. Of several preparatory studies; 2. Of some theoretic sciences; and, 3. Of many doctrines which have for their object his ministerial office. The first are,

1. The languages; and among these,
   (a) His native language, in which he is to preach and exercise his ministry, and with which he ought to be perfectly acquainted.
   (b) The Latin language, which is the language of the learned world in general.
   (c) The Greek language, in order to understand the New Testament.
   (d) The Hebrew language, of which the Talmudian and Rabbinical idioms are a part.
   (e) The Arabic language.
   (f) The Syriac language.
of the Dogmatic.

I. Under the general term of dogmatic, we comprehend that part which the different writers on theology have called sometimes theorems, sometimes the pulmonary, and sometimes dogmatic, &c. The term dogmatic appears to us the most general, and the most just, to express the subject that we intend, as it comprehends an entire system of all the dogmas or tenets that each religion professes; whether it teach these dogmas by the way of thesis, as articles of faith; by public lecture; by catechising; or in any other manner whatever.

II. Every positive religion must, naturally, have a system of certain points of doctrine to propound to its followers; otherwise, each one would form a particular system according to his own fancy; there would be as many different religions as there are individuals on the earth, and each society would consist of a confused mass of fantastic opinions; as the different modes of thinking, and the different degrees of discernment are varied and compounded by mankind to infinity; but truth, on the contrary, is uniform and invariable.

III. The Christian religion is as compound in its dogmas, as it is simple in its moral principle. It includes, 1. The dogmas founded on the lights of reason; 2. Those drawn from the Old Testament, and the law of Moses; 3. Those taken from the New Testament, and the doctrine of Jesus Christ; 4. Those that the fathers of the church have drawn from the Holy Scriptures; 5. Those that the church, under the New Testament, has prescribed to Christians, by ecumenical and other councils assembled in different ages; 6. The dogmas that the popes, in quality of heads of the church, have established by their bulls: and to these must be added, on the part of the protestants, 7. The dogmas which the reformers, especially Luther and Calvin, have taught; 8. The decisions of synods; and lastly, the tenets that are maintained by the different sects, as Socinians, Anabaptists, Quakers, &c. Each of these particular religions or sects pretend to support their dogmas both by reason and revelation: we do not here offer a work of controversy, and are very far from attempting to determine on which side truth and reason are to be found.

IV. Our zeal, however, for the Christian religion in general, which we regard as perfectly divine, and as the only religion adapted to promote the happiness of mankind in this world, and to secure it in the next, and the desire we have that it may endure to the end of time, compels us to make in this place one important reflection; which is, that simplicity is ever an essential attribute of perfection, as complexity is of imperfection. Now, it cannot be denied, without doing violence to truth, that among the different dogmas of which we have been speaking there are several that seem to be founded on speculations very abstruse, on subtleties very intricate, and on interpretations very ambiguous. God certainly never intended that all men should be theologians; he has not given them his divine word to be the cause of discord among men, nor that they should pass their whole lives
lives in a painful search after objects of belief; and articles
of faith; and that they should forego, in that pursuit, the
necessary offices of life, and their duties as citizens. The
dogmas, then, essentially necessary to the welfare of man-
kind, ought to consist of a small number, and to bear the
marks of simplicity and perspicuity; without which they must
be imperfect, and consequently the work of man. Our in-
tention, in making this remark, is, to extend our voice, if
it be possible, even to posterity, whom we would conjure
not to injure our religion, so holy and so admirable, by a
multiplicity of dogmas. It is necessary, however, that the
divine, who makes it his study and his profession, should be
thoroughly acquainted with the theory of this science, in
order that he may be able to instruct the sincere Christian,
and to explain the nature of each particular dogma, as well
as the solidity of its proofs; and to this it is that the study
of the dogmatic leads; of which we shall now continue the
analysis.

V. The dogmatic is then nothing but a succinct exposition
of all the dogmas of the Christian religion, in a natural
and philosophical order. By the word philosophic, we do not
here precisely mean the method of mathematicians, in the
manner the late Mr. Wolff has applied it to philosophy; e-
every subject is not capable of a demonstration so exact and
rigid; but a regular order is required in the arrangement of
the general system, and a connection to be preferred in the
several matters that form it: the definitions should be ju-
t; the divisions exact; the arguments solid; the proofs
clear; the citations conclusive; the examples striking; and,
in a word, every thing should be added that appertains to
so important a discipline.

It is very essential, moreover, in the dogmatic, at the
beginning of each thesis, to explain the several terms that
are peculiar to it, and that have been established in treating
of theology, to draw from each definition certain axioms, and
from thence to form propositions, and to illustrate them by
solid reasoning. Lastly, we should not neglect, in such a
system, to make use of the expressions used in the symbolic
books that have been received by the whole Christian church,
and which cannot be rejected or altered, without causing a
confusion in our ideas, and in the general system of the
Christian religion. But before we make the least advance
in the study of Christian theology, it is indispensably nec-
necessary to examine the proofs by which the truth, the authen-
ticity, and the divinity of the sacred and canonical books are
established; for this is the foundation of all the dogmas;
and the axis on which its whole doctrine turns.

VI. The systematic part of the Christian religion, among
the number of its dogmas or theses, has three principal,
from which all the rest are derived, and which form the
basis of its whole doctrine:

1. The existence of one God in three persons.
2. The necessity of a Mediator or Redeemer.
3. The real appearance of the Mediator or Messiah on
the earth.

Whoever writes, professes, or teaches the dogmatic,
should be, above all things, careful well to establish these
important truths; to convince them by the strongest and most
evident proofs, drawn partly from the lights of reason,
and partly from revelation; and be that all facility with which
all other theses flow from, and how easy it will be
to prove them by, these.

VII. The infinite variety that is found among mankind
in their manner of thinking, and in their method of treating
subjects; the frequent changes that have happened in the
exterior form of philosophy, and in the method of treating
it; the oppositions that have been raised at all times aga-

* Thos. of Du Pin and William Cave are most celebrated.
to prove the existences and the attributes of the Supreme Being; the necessity of the creation of the universe by Almighty God, in opposition to every other possible manner of its being produced: it furnishes, moreover, plausible conjectures concerning the intention of the Almighty in creating this world; it proves the necessity of a perpetual power to preserve it; it supposes, that, as God could not produce anything that was not perfect in its kind, he could not have created man as he now is; it vindicates the conduct of the Supreme Being, in appointing chastisements for transgressions, by shewing that moral evil was not introduced into the world by absolute necessity, but by the abuse of liberty, the most noble prerogative of the human soul; it determines the necessity of a Mediator; it furnishes arguments for the belief of the immortality of the soul, and of a future state that has a relation to the moral actions of this life; and lastly, it inspires a love of God as a Being of sovereign perfection, a gratitude towards him as our creator and preserver, and a submission to his will as our supreme ruler and director, motives of all others the most powerfully conducive to a virtuous conduct.

X. It is this use which theology makes of philosophy, that has given occasion to divide the theses of the dogmatic into pure and mixed; that is, into theses that are founded entirely upon revelation, and, such as arise from an union of reason with revelation. Of the first sort are, 1. The article of the Holy Scripture itself; which treats of its divine origin, its authority, and its efficacy. 2. The dogma of the Trinity. 3. That of the origin of evil, or of original sin. 4. The whole article of Jesus Christ. 5. The dogma of the efficacy and operations of the Holy Ghost. 6. That of the sacraments. 7. That of repentance. 8. That of the belief in Jesus Christ. 9. That of good and bad angels. 10. That of the end of the world, and the last judgment. 11. That of the church, &c. The mixed dogmas or theses are, 1. The doctrine of a Supreme Being, in general; his being, his attributes, and his works. 2. That of the creation. 3. That of providence, or the conservation of the world. 4. Of sin, as a transgression of the laws of God. 5. Of rewards and punishments after death, &c. He that attentively studies, thoroughly comprehends, and well digests all these theses, will have reason to rest content with his knowledge of the dogmatic.

Of the Exegesis and the Hermeneutic.

I. The term Exegete is derived from the Greek verb ἔργονται, which signifies to relate or explain; and that of Hermeneutic from ἔργονευειν, which means to search into, and, in a figurative sense, thoroughly to examine, and interpret. The learned, but especially the theologians, make use of these words, sometimes as synonymous, to express the same thing, and sometimes (as there are scarce any terms that are perfectly synonymous) to denote a small difference between two parts of learning of the same nature. By the word Exegesis they mean, that science which teaches clearly to investigate the true sense of the original text of the holy scriptures; and by the Hermeneutic, the art of interpreting and explaining the holy scriptures or others. This distinction is so subtle, that it becomes almost frivolous. They are, in fact, the same science; the one is only an explanation of the other, and for that reason we think we are authorized to treat of them together in this place.

II. In order to the true understanding of the sacred text of all the books contained in the Holy Bible, whether of the Old or New Testament, it is absolutely necessary that the theologian be thoroughly acquainted, not only with the languages in which these books were originally wrote, but likewise with the history and antiquities of those remote times in which their authors lived. With regard to researches into the history of the Jewish nation, their antiquities, their morals, and their customs, it will be found advantageous to pursue it as far as the nature of the subject will admit, without, however, engaging in critical subtleties, that lead to a labyrinth to which there is no end, and have spread more clouds over theology than even the scholastic controversies have formerly done.

III. He who would successfully interpret any work whatever, should first consider the spirit in which it is written; he should attentively reflect on the general design of that work, and the particular motives that induced the author to undertake it; his genius, his passions, his taste; the time, the place, and the people for whom it was written. These considerations are, above all, necessary, when we would undertake the explication of the Holy Scriptures. Independent of those reflections which the theologian will of himself naturally make on the subject, the excellent commentaries which we have on the Bible, in which the greatest men of every age have exercised their genius, may serve him as a guide in this course. The critical histories will likewise afford great aid, and throw admirable lights on this matter. Clear ideas, an acute discernment, and a solid judgment, will complete the work.

IV. With regard to the languages necessary for understanding the sacred text, the Hebrew language hold the first place. The student should have early recourse to the manner of accenting, and the Massorets of the Jews: to these he may add, with advantage, the reading of the Jewish interpreters or Rabbins. There are the grammars and dictionaries, Rabbinic and Talmudic, of Buxtorff, Cellarius, and others, which greatly facilitate his study. The Talmud is true is stuffed with a thousand fables and ridiculous stories; it contains, notwithstanding, some things useful and curious, which the learned theologian should not entirely pass over. For the well understanding of the explications and applications of the best Rabbins, he should likewise have recourse to their Cabalas, which they divide into real and liberal.

V. The Massorets is a kind of critic on the Hebrew text, that the ancient Jewish doctors invented, in order to prevent any alteration. They there count the verses, the words, and the letters of the text, and have marked all their diversities. The text of the sacred books was formerly wrote in close continuation, without any division of chapters, verses, or even words, after the manner of the ancients, as we still see in many manuscripts. As the sacred books have undergone an infinity of changes, which form various readings; and the true original has been either lost or altered; the Jews have had recourse to this rule, which they have judged infallible, and which they call the Massora, to fix the reading of the Hebrew text.

VI. The ancient Rabbins, or Doctors of the Jewish law, have

* The Exegesis is a kind of rational grammar. The Hermeneutic is the art of interpreting entire passages.
have wrote many superflitious traditions, which they observe 
as copiously as the law of Moses; and have also made ma-
y commentaries on the sacred text, among which there 
are some that are good and useful. "The language they use 
here is different from the common Hebrew, as is also the Rab-
binic character.

VII. The Talmud is a book in which the Jews have 
comprised everything that concerns the explanation of 
their law, and the duties that are enjoined them by scripture, 
by tradition, or by authority of their doctors; by their par-
ticular customs, their civil government, their doctrine, their 
ceremonies, their moral theology, the decisions of cafes of con-
fidence, &c. The Talmud is composed, in general, of 
two parts; which are called, the Midrash, and the Gemara. 
The Jews would not at first commit these things to writing; 
but after the destruction of Jerusalem, finding themselves 
dispersed in the world, they became obliged to do it. 
They had two celebrated schools, one at Babylon, and the other 
at Jerusalem; at these schools were made two different col-
clections of traditions, each of which is called the Talmud. 
The commentary, called Gemara, contains the decisions of 
the Jewish doctors, and their explanations of the text; it 
is filled with absurdities, reveries, and ignorance, and written 
in a vulgar style. On the contrary, the text, that is called 
Midrash, consists of solid reasoning, written in a pure style. 
The Rabbin Moses, son of Maimon, has made an abridg-
ment of it, which is of more value than even the Talmud it-
self.

VIII. The Cabballa or Kabala (a Hebrew word, which 
properly signifies tradition) contains the different interpreta-
tions of the laws of God by different Rabbins; their deci-
sions on the obligations that they impose, and the manner of 
performing them. There are some of them that are occult 
and mysterious, and consist in singular and mystic signifi-
cations which are given to a word, or even to each of the 
letters that compose it; and from these various combinations, 
they draw explications of the scripture very different from 
that which it seems naturally to import. This Cabballa is 
divided into three kinds: the first they call Gematria, and 
consists in taking the letters for the numbers of arithmet-
icalk, and explaining each word by the arithmetical value of the 
numbers that compose it; the second is called Notarikon, 
and consists in taking each letter for a word, or in compo-
sing a word of the first letters of several words; the third is 
called Tiekuma, and consists in changing a word, and the 
letters of which it is composed.

IX. The Chaldees seems to be indispensible, after 
the study of the Hebrew and Rabbinic; this is proper-
ly no more than a particular dialect of the Hebrew lan-
guage. The Jews give to their commentators, and to the 
Chaldee paraphrase on the Scripture, the title of Targum. 
As, during their long captivity in Babylon, they had forgot 
the Hebrew, and only retained the Chaldee language; it 
became necessary to explain the prophets in that language; 
and to this necessity is owing the first commencement of the 
Chaldee paraphrase. The Rabbins have since collected to-
gether these divers interpretations of their doctors, which 
form the paraphrase that is called Targum.

X. The other oriental languages, as the Arabic, the Sy-
riac, the Samaritan, and the Coptic, are also of great use 
to the learned theologian.

XI. All the books of the New Testament being wrote in 
Greek, the study of that language becomes necessary to the 
thoels. But it must not be imagined, that this Greek 
is that of Athens or Lacedemon; and that they who under-
stand the New Testament, will fully comprehend Homer, 
Aesop, or Thucydydes. It is very necessary to observe, 
here, that during the Babylonish captivity, the Jews, as 
we have just said, having forgot the Hebrew, and having 
adopted, in process of time, several idioms, the Greek lan-
guage was at last successively diffused over almost all the east; 
and, at the time of the coming of Jesus Christ upon the 
earth, that language was in use in Palestine, not only among 
men of letters, but in the polite world: every thing was 
written, every thing was treated of, in Greek. The Jews no 
longer underlood the Holy Scriptures in the Hebrew lan-
guage, but made use of the version that the Septuagint had 
made of the Old Testament in the Greek language. The ev-
gelists and the apostles, therefore, wrote their historic 
relations, as well as their epistles or letters, in the same 
language: but their style is not pure, being filled with 
hebrisms and barbarisms, and with theological terms and 
phrases. The four evangelists differ, moreover, among them-
elves, with regard to their style; and so do the apostles: 
St Matthew is not so elegant as St John; nor St Jude so 
elegant as St Paul, who was a man of letters, and an able 
writer. The editions of St Luke is the most elegant, and 
most correct, especially in his book of the acts of the apostles.

XII. The translations that have been made of the sacred 
books in the west, will also very frequently affit in clearing 
up many passages.

XIII. The Jewish antiquities are naturally connected 
with the study of the sacred history of the Old Testament. 
Josephus is the best author who has wrote on this subject: 
John Michael, Vossius, L. iust, Gaisfeld, &c., are the 
moderns to whom we are indebted for learned researches in 
these matters. Hermannus Wulfius, in his treatise de E-
gyptiacis, has thrown admirable lights on the Egyptian an-
tiquities. The antiquities of the Chaldeans, Babylonians, 
Perfians and Medes, has been excellently well explained 
by Baronius Briffon, in his book de regno & rege Per-
farum; and by Thomas Hyde, in his treatise de religione et facri 
Perfarum. The writings of Meursius, and the Compendium 
Antiquitatum Grecorum of John Potter, are very useful 
to give theologians an idea of what they will find necessary 
to know of the Grecian antiquities; and lastly, the abridge-
ment of Cantet will make them sufficiently acquainted with 
the Latin antiquities.

XIV. Spencer has given an excellent work on the cer-
emonies of the Jewish religion, de Legibus Hebreworum ri-
tuallibus, &c. We have likewise works that fully treat of 
their temples, their sacrifices, their priests and Levites, their 
priestly and purific, of their tithes, their vestments and fa-
cred habits, and of their manners and customs; but it would 
be too prolix to mention all these in this place.

XV. The modern commentaries on the Holy Scriptures 
may also serve to instruct the young theologian; but he 
should use them with caution and moderation. All that 
shines is not gold, as well in this instance as in others; and 
a man of learning should not often make use of other peo-
ples eyes.

XVI. The Bibles called Polyglots are also of great af-
fistance in interpreting the sacred text. They are printed 
in several languages. The first is that of cardinal Ximenes, 
printed in the year 1515, and called the Bible of Com-
plete; it contains the Hebrew text, the Chaldean para-
phrases.
phrase, the Greek version of the Septuagint, and the ancient Latin edition. The second is that which is called the Royal Bible, printed at Antwerp in 1572. The third, that of le Fay, printed at Paris in 1645. The fourth is the English polyglot, printed at London in 1657, of which Walton is the editor. There are still fuller more that have been printed since, but they are neither so complete nor so celebrated as the former.

XVII. The Bibles that are called Biblia Graeca, are also here of very great use. The sacred text is there everywhere accompanied with explanations and observations. There are of these in each of the three principal communions of the Christian Religion, and in most of the modern languages of Europe. Lastly, as the interpretation of the sacred text depends in a great measure on the lights and the proofs drawn by comparing together different passages of scripture, there are several Bibles where the editors have placed, on the side of each verse of the text, what they call the Concordance; that is, a citation of other parallel passages, which are found dispersed in the Old and New Testament. These Concordances are of daily and indispensible use to the divine, in composing his sermons, and in many parts of his ministry. See Bible.

XVIII. These parallels in are yet different from that which theologians call the real parallelism; by which they mean, the relation that the typical or parabolic sense of a passage has with the expressions literally imply, or seem to imply; the mystic sense with the real sense; the figured and the images that the sacred authors have employed, with the things or the objects that they intended to describe. The greatest theologians have taken infinite pains in determining these points, explaining them, and producing their proofs: in many places they have succeeded; and we cannot but admire their sagacity, their zeal, and their success: but he will more wise, and less vain, than to attempt to impose his decisions on mankind, at all times, as authentic and infallible. The human discernment is ever confined and imperfect; and God has not granted to any man, to any theologian, or assembly of divines, an exclusive power of interpreting his divine word: he has moreover denounced his anathema against all those who shall add, or take away, a single word thereof. But to explore the true sense of any passage, and to explain it to others, cannot certainly be deemed either adding or retrenching.

Of Sacred Criticism.

I. As the authors and professors, who treat of the different parts of theology, make frequent mention of the sacred criticism, we must not omit to shew in what manner it is connected with the Exegesis and the Hermeneutic, and in what respect it forms a separate study or science. Criticism, in general, is in fact no more than a superior part of grammar; a kind of rational grammar founded on reflection, and the rules of language; but which employs the aid of divers other sciences, as history, chronology, antiquities, &c. in order to search out and determine the true sense of an obscure or ambiguous passage. The sacred criticism is only distinguished by its object; it adopts the same rules, but it adds others which take their rise and principles from the peculiar language of the New Testament; and has regard to the Bible in general, an account of the nature, essences, and qualities of its divine Author. So far it has an intimate connection with the Exegesis.

II. But, if we would consider it as a separate study, we may say, that it is a science which is employed in examining the exterior circumstances of the Holy Scripture. For example: in what time each book was wrote; who was its author; the precision and fidelity of the text; the difference between the canonical books and the apocryphal; and many other matters of like nature. In order still the better to shew in what manner, and with how much precaution, the sacred criticism proceeds in its operations, we shall here recite some of those subjects that belong to its province.

III. It is commonly received, that it was Elisha who, after the return from the captivity of Babylon, collected and fixed the canon of the sacred books of the Old Testament. Thereat least is the opinion of the Jews, who all attribute to him that glorious work; and the assertion appears so much the more probable, as it was the same Elisha who reestablished their state, who brought the whole Jewish people into one body as a nation, and formed the Judaic republic, which was so intimately connected with their religion. The collecting of the canon of the books of the New Testament is attributed, with great appearance of probability, to St John; although historic and formal testimonies of it cannot be produced, unless it be what Eusebius relates of the four Evangelists. In process of time, each council has decided what books should thereafter be held by the Christian church as canonical; and we commonly find, at the end of the decrees of each council, a repertory or list of those books.

IV. The Old Testament was wrote in Hebrew, except a small number of passages where the dialect is Chaldaic. The form of the letters or characters, as we now have them, are also properly Chaldaic; whereas, before the Babylonian captivity, the Samaritan character was probably used. Buxtorff and Capell have had warm disputes upon the subject of the vowel-points; the former would retain those points, and the latter rejects them; each of them has had his adherents. As it is impossible to decide in this dispute but by historic proofs,
RELIGION, OR THEOLOGY.

That of Symmachus, who applied himself to write the Greek with purity and elegance. 3. That of Theodotion, who has very closely followed the text, notwithstanding the fine language he employs. Origens published these versions in six languages in his edition of the Old Testament, which he calls Hexapla. To all these versions may be added, 4. Those of Jericho and Nicopolis, which are much celebrated. We have not now any one of these versions entire. The fragments that remain of them have been collected and published by Drujus and F. Montfaucon. Lastly, The Syriac versions, of which one was made on the Hebrew text, and the other on the Greek.

IX. The sacred criticism is likewise employed in acquiring a knowledge of the principal and most celebrated manuscripts, as well of the sacred text itself, as of the translations; in learning to discern the hand-writing, and the essential characteristics which distinguished the real original from the counterfeits: and lastly, it is employed in knowing the best modern editions of the Holy Bible; as for example, the Polyglots, among which those of London, of the years 1653 and 1655, are the best. The introduction by Walton, which is at the beginning of these editions, is a model and a masterpiece of sacred criticism.

Of Moral Theology.

I. If it were allowable to compare the Saviour of the world to a weak mortal, we would say, that the conduct of Jesus Christ resembled that of Socrates, who has left us no part of his doctrine in writing, but whole whole instructions (as well as the particulars of his life) have been collected, digested, and published, by his disciples. The Evangelists are the only historians of the Messiah: it is to their labours that we owe the knowledge of his actions upon earth, and his divine doctrine. The four Evangelists, and the Acts of the Apoftles, wrote by St. Luke, contain therefore alone the history of the life of Jesus Christ, and the doctrine that he taught. His apstles and disciples began by paraphrasing his doctrine, as well as their evangelic sermons, as in the epistles they addressed to the faithful of several Christian Churches: they have given explications, and have added pastoral instructions, which are in effect admirable; but which, nevertheless, form not the original text of the discourse of our Saviour. The bishops of the apostolic century, the fathers of the church in all succeeding centuries, the other bishops and ecclesiastics, the councils, the synods, the doctors of theology, the popes, the confiliators, the reformers likewise, and an infinity of theologians, have drawn from the Gospel, and sometimes also from the letters of the apostles, and from other commentaries on the Gospel, various tenets; which, united, form at this day the general system of the Christian Religion. The theologians who devote themselves to the service of the altar, study this system in the dogmatic: the laity learn it by means of catechisms; and after they have made confession of their faith, solemnly adopt it, when they are received into the bosom of the church.

II. It is not the same with regard to the morality of Jesus Christ, which every one may read in the Gospel; and to know which, it is not necessary to become learned, nor to study a complicated system. If the dogmatics were not armed with a thousand arguments to establish the Divinity of Jesus Christ, yet would the morality of his Gospel sufficiently prove it; seeing that it is perfectly holy, entirely simple.
simple, strictly just, and most-completely adapted to promote the felicity of the human race in this world, and in that which is to come. The Saviour of the world has not enjoined any part of mankind to engage in disputes, or abstract refinements: the sole command that he has given them is, to believe in his Gospel; and that is comprised in one word only. Love: the grand and only principle on which the whole of his sacred doctrine is founded.

III. To produce the greatest effects possible, by the least efforts, is the highest perfection in nature, and at the same time the true characteristic of Divinity. God has given to all the beings that compose the universe, one simple principle alone, by which the whole, and every part, is connected and perpetually supported; and that is Love. The attraction of the celestial bodies, as well as of those of which our globe is formed, is a species of love; a mutual tendency toward each other. The uniform generation, by which all beings are perpetuated, is founded in love. This is the true minimum; the true system of the least action, which includes something so divine. It appears to be the will of God to establish, by the mouth of the Messiah, the same simple principle in morality, that is, the rule of human actions, by saying, Love: in a word, it was his will, that in the conduct of mankind, as in every other part of nature, there should be no other principle than that of Love.

IV. That in the different systems of ethics of the ancient Heathen Philosophers many maxims and precepts of admirable morality are to be found, cannot be denied; but, beside that these philosophers are almost continually contradicting each other in their maxims, no one of their systems is founded on the true principle. In searching after it, they have discovered some excellent truths; but it has been by chance, and they are at best imperfect. Jesus Christ has alone taught mankind perfect morals, by deducing them from this true principle. Every principle should be simple; the idea of a compound principle implies at once an imperfection. Every principle should be comprehensive, even universal in its effects. Every principle, whose effects are limited, is imperfect. God himself is uniform in his principle, and infinite in his effects. His doctrine, or his law, should be the same. Jesus Christ has made known to mankind this principle, simple and universal. He has therefore been, in this sense also, the true Saviour of the world. He has preached to mankind; and his only doctrine has been that of Love.

V. By the word Love, with regard to Bodies in general, in mean a tendency, a mutual inclination that urges them to join and to coalesce; and with regard to men in particular, a lively, affecting pleasure, that possesses the mind on contemplating the perfections of any object. This pleasure is always accompanied with a desire, either to posses that object, or to render it propitious. By adopting therefore this principle, and this last definition of Love, it follows, that all the duties of man consist,

1. In the love of God in preference to all other objects.
2. In the love of himself.
3. In the love of his own species.
4. In the love of every other creature to a certain degree.

The doctrines of Jesus Christ are, in these respects, the most explicit.

VI. From this principle flows our duty towards God, towards ourselves, our neighbour, and to those beings that are subject to our power. The first rule is, to communicate to all those, whom it is our duty to love, all the good, and to preserve them from all the evil in our power. The second, to do to no one what we would not have done to ourselves in similar circumstances. The third, which is the simple effect of love, is to endeavour to please the object that we ought to love. The fourth, to endeavour to render the pleasures that we communicate to others, as lively as possible, and those inevitable evils, which we are sometimes constrained to do to them, as supportable as we can; and of the reft. The whole evangelical doctrine of our Saviour is replete, from beginning to end, with admirable precepts for these purposes; and these precepts, with their applications, general and particular, we learn from that science which we call Moral Theology.

VII. This doctrine we distinguish from moral philosophy, or the simple doctrine of Ethics; because Jesus Christ has made known, in his divine morality, a far greater degree of perfection than is discoverable by the mere light of human reason. For the renouncing of self-interest, and private pleasures; the forgiveness of offences; the love of his enemies; the triumph over destructive passions; and many other like virtues, the Christian is alone indebted to the doctrine of Jesus Christ.

VIII. In order to shew, moreover, in a few words, of how easy, just, and natural an application all these precepts are susceptible, we shall here give a few instances. "It is our duty to love God." Now nothing is more natural than to feel a lively and penetrating pleasure in the contemplation of the united perfections of the Supreme Being; nothing more natural than a desire to please him, and to render him propitious to us: and as it is not possible for us, weak creatures, to do him either good or evil, all our power to please him consists in offering him an upright heart; a rational devotion; to be possessed with gratitude toward him, and to exert all possible efforts to accomplish the end of our creation. "It is our duty to love all mankind:" and yet we inflict pains and chastisements on some of them; we even put them to death; but we chastise them only to render them better, to prevent them from becoming pernicious to society in general: we retrench the number of the living, as we cut off a corrupted branch of a tree, in whose preservation we are interested: it is because we love mankind, that we endeavour to prevent the destruction of the good by the malignity of the wicked: but it must ever be an indissoluble necessity alone that can compel us to chastisement. "It is our duty, likewise, to feel a kind of love for other creatures, even for mere animals." Nevertheless we harass, we oppose, we destroy them. "If we harass them wantonly, to support a criminal luxury, or to satisfy a brutal pleasure; if we pursue a savage chase, or encourage combats between animals themselves, or other like horrible diversions, we act contrary both to the spirit and the letter of the Gospel. But if we destroy a part of these animals, to serve as an indissoluble nourishment to man, observing at the same time to put them to the least misery possible, and taking all necessary care for the preservation of the species, we act in conformity to the laws of nature and of morality; we employ to our own preservation, and to that of the rest of mankind, what appears destined to that purpose by the Creator.

IX. Moral theology likewise differs from philosophy, inasmuch as it requires that our virtues be absolutely disinterested: it enjoins us to fly the evil, and to pursue the good, merely as our duty towards God: it admits indeed the precept of the love of ourselves, and the love of our neighbour; but
RELIGION, or THEOLOGY.

but it regards this love only as a duty that results from our love towards God; and that from the principle, That God must love all his creatures as the work of his hands; and that we cannot therefore, from the very nature of love, please him, without entertaining sentiments of affection towards those to whom the Sovereign Lord of the Universe vouchsafes his benign regard. Now, as the Christian morality does not regard virtue, but as it is a duty towards God; and as it considers all our actions, that have any other motive, either as blameable, or at least imperfect, and as but little acceptable to the Supreme Being; it does not regard the advantages that result from them to society, but as useful consequences of the true Christian virtue; and from this principle it draws new arguments for the encouraging of mankind to the practice of it.

X. From what has been said, a second difference arises between Christianity and philosophy. The first adds to the second still new motives to the practice of virtue. That of redemption, and pardon, obtained by Jesus Christ, is not one of the least. Its argument is this: If God has so loved mankind, as to afford them the means by which the evil, caused by their own fault, may be abolished, it would be the greatest of all ingratitude and malice towards himself, if man should not endeavour to acknowledge this love, to merit it, and to embrace the means of pleasing God. A third motive, taken also from the merit of Jesus Christ, here offers itself as an auxiliary to the two former: According to the Christian doctrine, man has not by nature the power to practise all those virtues which are agreeable to God: but the same doctrine teaches, on the other hand, the conditions by which it is possible to please that most holy and perfect Being; and gives the Christian hope also, that he shall never labour in vain.

XI. Lastly, the Christian morality is of far greater efficacy in adversity, than philosophy: it carries with it a wonderful consolation in misfortune, and even in the hour of death; for the Christian may say, with the Apostle, that godliness (or the practice of evangelical morals) is in all things profitable, having the promise of the present life, and that which is to come.

Of Polemic THEOLOGY, or Controversy.

I. We cannot sufficiently lament, that the church of the God of peace should be a church militant; and that a doctrine so simple and clear as that of the Gospel should be the cause of discord, even among Christians themselves. Nevertheless, as the truth is so difficult to discover in all things, and especially in matters of religion; as it is so frequently covered with the clouds of interest and ambition; as the same object appears so different to different men; and as error, in the face of the world, constantly assumes the mask of truth; it is but just that the true religion be furnished with arms to combat error, and to pluck off that deceitful mask by which so many poor mortals are seduced.

II. The theologian, who has made the proper preparatory studies, who is thoroughly instructed in natural religion, in the dogmatic and the hermeneutic, and who joins to these found logic, is already well prepared for this spiritual combat: he is armed, but he is still to learn how to use these arms: he must also be made acquainted with the enemies he has to encounter, to know their force, and the arts they will use against him. It is plain enough, we suppose, that we here speak of spiritual arms; of those with which we are furnished by reason and the Holy Scripture: evil be to him that employs any other: force is an infallible proof of the want of argument. The propagation of a religion by the sword, after the manner of Mahomet; perfections, either secret or open; constraint, violence, every sort of religious war, is so atrocious, so contrary to the spirit of the Gospel, in a word, so detestable, that every true Christian must avert his sight from such infamous horrors.

III. Controversy is conducted, either from the pulpit or chair, by way of harangue, by conversation, or by writing. The first quality that is necessary to a disputant is reason, and the next moderation; in what manner the contest is conducted, these two qualities should constantly be manifest, during the whole course of altercation.

IV. There are some errors that attack the system of religion, and there are others that attack even its morality. In order properly to oppose an error, we must begin by finding out its real meaning; we must therefore study the different systems of other religions, and the principal heresies, if we would successfully refute them. We don't mean by this, that the theologian should know all the errors that spring up in the brain of each individual; we speak only of those that are preferred by whole sects.

V. They who attack our religion, found their opinions, either on the interpretation of the sacred text, or on philosophy, or history; and we should always oppose them with the same arms with which they pretend to defeat us. It is necessary to begin by dethroning ourselves of all prejudices, in order the better to shew others these prejudices by which they are deluded. We should not make use, but especially when we oppose weak minds, of opprobrious terms in the course of the debate, nor contend about words or expressions, nor attack incidental circumstances that may attend erroneous principles; but bend our whole force against the root of the tree, the principal error, to uncover it, to dig it up, to destroy it.

VI. Polemic theology is taught in universities by two methods, according to the views of the student. If he learn it merely in order hereafter to defend his pantheism against the most prevalent errors, he is only to examine the principal controversies according to the systematic order of theology; and may content himself with knowing their true meaning, together with the arguments of those that oppose them. But if it be his intention to teach this science to others, or to engage in controversy, either by conversation or writing; in short, if he aspire to renown in it, he should study the origin and history of each controversy, he should make himself a complete master of the arguments for and against it, the exceptions that it makes, its interests, its different revolutions and actual state, &c. These follow, in this study, either the order established in the dogmatic, or that which is used in symbolic books, that is, such as treat on articles of faith.

VII. In order the better to elucidate the method to be observed in this sort of study, we shall say, that to acquire a complete knowledge of theological disputes, the student should, 1. Make the examen of each religion, and even of each controversy. 2. He should thoroughly examine his system in the symbolic books, and likewise the sources of his religion. 3. He should precisely determine the principal and capital error of each religion, sect, or individual; that which is the source from whence all the other errors flow. 4. Search into the political causes of each error, and each.
each controversy, from history. 5. Examine the natural order according to which all the errors have taken their rise, the one from the other: and lastly, 6. Confront the respective arguments, the answers, and exceptions, that each party has made to defend its cause. To all this is to be added, 7. What they call Collegium disputatorium; an exercise, by which all that is learned in the closet and in the schools is called forth and animated, under the inspection of a professor; and the mind is accustomed to think, and the tongue to speak, with facility and efficacy.

VIII. The principal contests in which the theologian may be engaged, are, 1. Against those who admit of no revealed religion; as the atheists and deists. 2. Against those who admit of a revealed religion, but adopt not the true Revelation; as the Heathens, the Mahometans, &c. 3. Against those who believe only a part of the true Revelation; as the Jews. 4. Against those who add to the true Revelation matter foreign to it; as traditions, &c. 5. Against those who make a false interpretation of the sacred text, and draw from it erroneous systems; as the heretics and the schismatics, &c. And lastly, 6. Against those who make a wrong use of certain expressions of Revelation, and build, on whimsical notions, ridiculous systems; as the Fanatics, Quakers, &c.

IX. According to this division, the theologian will have to combat principally with,
1. The Atheists, with Spinoza at their head.
2. The Deists.
3. The Heathens and Idolaters.
4. The Mahometans.
5. The modern Jews.
6. The Arians and Manicheans, or rather those who in these days follow their ancient errors.
7. The Socinians.
8. The Catholics, opposed to the Protestants.
9. The Protestants, opposed to the Catholics.
10. The Molinists, opposed to the Jansenists.
11. The Jansenists, opposed to the Molinists.
12. The Reformed, opposed to the Lutherans.
13. The Lutherans, opposed to the Reformed.
14. The Arminians.
15. The Anabaptists.
17. The Quakers or Tremblers.
18. The Fanatics, at the head of whom is Jacob Bohm.
19. The pretended new Prophets.
20. The Indifferentists.
21. The Pietists.
22. The Moravian Brethren, or the Herenhuters, &c.

X. Now, as each of the religions, communions, or sects above mentioned, have not scrupled to publish to the world their dogmas and creeds, the theologian ought carefully to instruct himself in those symbolic books, in which each of them have comprised its system; to study and to make a good analysis of them; and to prepare such arguments as are the most just, the most weighty, and proper to confute them.

XI. Before we quit this subject, there is one remark to be made, or rather one caution that is very essential, which we would offer to the young theologian; which is, that the polemic is useful, and even necessary in the study of theology in general; but that it is a discipline which ought to be treated with great prudence and moderation. Disputation in general is a dangerous art; and religious disputation is a deceitful art, and of infinite peril. The student will do right well to remember, that there is no sect, no communion on earth, that is perfectly true in all its dogmas without exception; that there are some small errors in all religions; that infallibility never was, nor ever will be, the portion of humanity. He should likewise remember, that the masters who teach him, or the books that he reads, are constantly partial to the religion they profess; and that when he has supported a thesis, and confuted his adversaries in a collegial dispute (where his adversaries, as well as his preceptors, are of the same side of the question, and will not fail to adjudge him the victory,) he should be persuaded, that the victory would not have been so easily obtained had he contended with able adversaries of the opposite religion; he should remember, that we triumph without glory when we combat without danger; and let him not be vain of his laurels, nor imagine himself some wonderful scholar; seeing that it is very possible, that he may go off victorious from such a dispute, that he may receive vast applause from his professors and his colleagues, and at the same time have reason to doubt.

XII. On the other hand, the most able theologians, and the most consummate professors in this science, ought to be constantly on their guard against the abuse of polemic theology; which frequently serves to clear and confirm the truth of the dogmas of a communion, than to establish perpetual discord and hatred among Christians. Every theologian should also remember, that by the nature of the subject, it is not possible to produce demonstration in support of his theses and opinions; but that his arguments will be only valid, and preponderate in proportion to their degree of evidence; and lastly, that it is a ridiculous and insufferable vanity to imagine, that every man, who does not think precisely as we do, is guilty of palpable error.

Pastoral Theology.

I. Having described the theoretic sciences of theology, we now come to those which regard the practice. It would be to bury the talents that God has given him, and the studies that he has made, if the theologian did not employ them to the edification of his neighbour, and the prosperity of the Church. His office in society is attended with constant and anxious labours. He is charged with the cure of souls, with the instruction of youth, with preaching of the Gospel, the conduct of his flock, and the administration of the Sacraments, with visitations to the sick and the dying, with calming the terrors of weak minds, with administering comforts to afflicted souls, and many other functions equally difficult and important. The practical sciences that we shall here describe, will serve him as guides in this unbounded field.

II. Pastoral theology is usually divided into three parts; which are,
1. Homilitic Theology.
2. Catechetical Theology.
3. Casuistic Theology.
To which are added;
4. The Consistorial Prudence.
5. The premeditated Exercise of the different functions of the minisiry.
As the homily makes a part of eloquence, it is unnecessary to say any thing of it in this place, but treat the others in their order.

III. It is in vain that a son of the church possesses all the sciences that belong to his profession, that he is an agreeable and even a renowned preacher, if he do not give a life, an efficacious spirit, to his ministry, by a good example; for that is the first precept in pastoral theology. He is at the head of a flock, and ought to be their guide: but how absurd, if his words and his actions be at continual variance with each other! How scandalous, if he be not the first to practice these lessons of wisdom that he preaches! How indecent, if, while he edites by his discourses, he dilutes by his morals! What baseless, if it should even glory in his irregularities? It is left shameful for a father to relate that he has tamely suffered an affront, than for an ecclesiastic to praise these lessons of wisdom that he preaches! How incredible, if he should vainly hope to mend his morals, and a dogmatic and clerical manner of deciding the common affairs of life; a ridiculous inclination to discover inquiry in innocent actions; to confound pleasure with vice, and to be an enemy to joy, the greatest boon that God has bestowed on man; and a hundred other like foopies there are, with which the religious make a parade, that is shocking both to good sense and the evangelical morality, and which render their ministry, in the eyes of sensible people, more contemptible than respectable. These are rocks on which the young theologian is much too liable to run, and of which he cannot be sufficiently cautioned.

IV. But this exemplary conduct should be free from all affectation in the external behaviour. A singularity of dress, and an air of asperity; the head declined, the eyes turned up to heaven, the hands constantly clasped, a plaintive tone of voice, and a solemn gait; a scrupulosity in things indifferent, and a dogmatic and clerical manner of deciding in the common affairs of life; a ridiculous inclination to discover inquiry in innocent actions; to confound pleasure with vice, and to be an enemy to joy, the greatest boon that God has bestowed on man; and a hundred other like foopies there are, with which the religious make a parade, that is shocking both to good sense and the evangelical morality, and which render their ministry, in the eyes of sensible people, more contemptible than respectable. These are rocks on which the young theologian is much too liable to run, and of which he cannot be sufficiently cautioned.

V. After this candid caution, and brief introduction, we pass to the examen of the different parts, the union of which composes the system of the pastoral, the most important article perhaps, in all theology. The design of Revelation was, without doubt, to conduct man by faith to a virtual life. It is not the opinions or the learning of weak minds the Aril principles of religion, such as are contained in good catechisms, and that they be explained to them in particular lessons; which is the most usual and most natural method of enabling youth to give an account of their faith. The sermons that are given in the catholic churches on controversy, and in protestant churches on the catechism, serve to instruct those who are of riper years and have their judgment more formed. These sermons compose, at the same time, a sort of course of the dogmatic and the polemic theology.

III. Both in private catechising, and in sermons that are purposely intended to explain the catechism, the theologian should avoid, as much as possible, the use of technical terms; or (which is still better) he ought to begin by explaining those terms, of which he should give such clear and determinate definitions, that no person of a moderate capacity can possibly mistake them. In a word, he should endeavour more to prove than to persuade; and as eloquence sometimes persuades at the expense of truth, he should cautiously avoid that sort of delusive persuasion, and in its room substitute clear and solid argument.

Of Casuistic Theology.

I. Happily for man, and for society, all are not so obstinate, or so inoffensive, as to ask, what sort of animal conscience is, or never to know what is remote. Happily, the greatest part of mankind are sensible, that all their actions are not conformable to the laws of divine wisdom, nor to the rules of natural equity; are afflicted at their past conduct, and find a generous and earnest desire arise in their souls to avoid for the future those dangerous rocks. To calm the troubled mind; to appease the timorous conscience; to communicate the confolations of grace to the afflicted soul; to explain and decide in doubtful cases; to direct those that err, and to support their weakness; to convince such as persist in their errors; to pierce the hardened heart; to intimidate the wicked, and to rouze the indolent; to conduct the Christians, committed to the care of their pastor, in the way that leads to true felicity; are the important objects of casuistic theology, and for which it affords the proper instructions.

II. In a more confined sense, by casuistic theology is meant, the science that decides in doubtful cases of moral theology,
The need of their counsel and consolation: for where there is no sign of service to those of their fellow citizens who have afforded them the means and the opportunities of rendering theologian is supposed to have made, and the confidence abused that is made, in some Christian countries, of the dual and important, that he who devotes himself to the service of the altar, should early study all those sciences which will enable him worthy to perform this important part of his ministry.

IV. God forbid, however, that we should countenance the abuse that is made, in some Christian countries, of the duties that we have here explained. To reduce these matters into a political system; to make the direction of consciences a profession, a regular trade; to provide each house with a spiritual director, as with a butcher or baker, a steward or porter, who by that mean may infinuate himself into the confidence of families, and become the depository of all their secrets; may sometimes sow discord between husband and wife, or the nearest relations; who may avail himself of the confidence of his devotees, to direct them confultantly in matters of a worldly, and sometimes even of a criminal nature; to efface the legitimate and sacred authority of the father of a family, and, in its place, to substitute a foreign power; to undermine the confidence, the union and concord of families, in order to confirm and render necessary this secondary authority; to captivate the spirit, and oft-times the heart of a wife or daughter, and in general of weak minds; to enjoin them ridiculous mummeries that lead to fanaticism, and a thousand dangerous superstitions, or to religious exercises that divert them from their domestic duties; in a word, to assume an absolute authority over the consciences of mankind, is a pernicious invention, contrary to the evangelical moral, to the welfare of society, to the interest of the state, and to the sovereign authority; and well deserves an exemplary punishment.

V. But the care of souls, faithfully intended, and properly limited, differs totally from this despotic power. He, who is charged with it by a lawful vocation, should remember that there are four classes of men with whom he will be engaged: 1. With those of weak minds; of little knowledge, and little ability. 2. With those whose spirits are afflicted by some great reverses of fortune. 3. With those of nice and timorous consciences, who suffer by their scruples, whether they be vain or rational. 4. And lastly, the wicked, the hardened and incorrigible sinner. The grand art here consists in representing to each of these classes of men, the truth, in a manner so clear, so strong and full, that they can no longer retain any doubts, that conviction must take place, and conformation or conversion be the consequence.

VI. Truth is in its nature highly problematic: each one, however, is persuaded that he knows it, that he possesses it, and is guided by it; every man thinks himself in the right. We should therefore begin by discovering the truth in the subject before us, and in placing it upon a solid foundation. This business of demonstrating the truth to others, is attended in the mean time with infinite difficulty. Every mind is not capable of discovering it at the first glance; nor can all discern it from the same point of view. Sometimes men require conviction by abstract philosophical arguments, and sometimes by the express decisions of the Holy Scripture. Sometimes by authority, sometimes by gentle remonstrance, and sometimes by dreadful menaces. Sometimes they are to be reclaimed by properly exposing the necessary and fatal consequences that result from their conduct; and at others, by the alluring promises of the Gospel. Now vice is to be boldly confronted; and now the transgressor is to be conducted into the right path by artful turnings; now the sinner's crimes are to be painted in the strongest colours; and now a veil is to be lightly cast over them; and sometimes we should even indulge a favourite inclination, in order to induce them to abandon a more pernicious passion: and so of the rest.

VII. As it is impossible that the books which have been wrote on this subject, though of an immense quantity, can contain every case that daily occurs in the ministry of the Gospel; and as these cases are not always justly decided by these authors; and, if they were, the consulting of such enormous works would take up too much of a theologian's time, and divert him from his other studies; and as the cauflitic writers contain, moreover, a number of puerile subtleties and wretched chimera; it is highly proper that the minister of the altar, whom we suppose to have a masterly knowledge of the principles, the dogmas, and moral of the Christian religion, should endeavour to draw from the true source the means that he is to employ on each occurrence, and not have recourse to books for their decisions. For which purpose it is necessary, 1. That he accomplish himself to reason according to the rules of sound logic. 2. That he learn to know the human heart, under its different disguises; the characters of men, their arts, and ruling passions. 3. That he do not attempt to gain or convince by little pious frauds, or by lucky sophisms artfully represented. 4. That he do not inflict what are called penances, which are the height of absurdity. 5. That he do not enjoin mummeries, pilgrimages, austerities, and a thousand like matters, which can never carry with them a real conviction, and only serve to divert men from their labours and the duties of society. But, 6. That he constantly present, as we have before said, and cannot too often repeat, the truth, in all its native force and purity.

VIII. This truth, however, is no enemy to sacred eloquence; on the contrary, the latter serves to introduce the former into the mind of the auditor, and there to give it such strong impressions, as neither time, the dissipations of the world, nor the distractions of fortune, are able easily to efface. The whole ministerial function consists in teaching, preaching, administering the sacraments of the church, visiting the sick and the dying, comforting the afflicted, and affording the spiritual aids to all those who have need of them. Eloquence is of the greatest efficacy in all these functions; and, without affecting it, the minister of the gospel should never neglect it. There are some professors in universities who give their auditors a complete fylematic course on pastoral theology, which may be attended with many advantages.

Consistorial Prudence, or General Economy of the Church.

I. Among the practical sciences of theology, we must...
not pass over in silence that which is called the Consistorial or Ecclesiastic Prudence, whose object is the exterior order or arrangement of the Christian church, on principles founded on the Holy Scriptures; and which are proper, not only to maintain religion in its purity and splendor, but to defend it against all schisms, divisions and separations whatever. This economy is necessary in the councils, the synods, the consistories, and in the faculties of theology. We must not, however, confound this with the ecclesiastic jurisprudence, which is the science of interpreting and applying the laws, instituted by the sovereign, relative to the persons, goods, and affairs of the church; whereas the object of consistorial prudence is the arrangement of the church itself, and the ecclesiastic state, on Christian and rational maxims. The one is a sort of legislation in itself; and the other, on the contrary, an application of the civil laws.

II. The theological prudence includes therefore, first, the whole plan of church-government, and the arrangement of the ecclesiastic state; secondly, the ordinances relative to exterior ceremonies, and divine worship; and lastly, the discipline of the church, the errors, the schisms, the heresies, and divisions that arise among Christians. The source of this prudence is a thorough knowledge of the essence of the Christian religion, and the method of drawing from it just consequences.

III. This discipline is likewise employed in deciding, wherein consists the difference between the clergy and the laity; or if there be, in fact, any real difference between them: if the church form a distinct state in the general system of government; and to whom belongs the right of deciding circa facra; and what are the limits of the spiritual and temporal powers in this respect: wherein consists the hierarchy of the church, and what are its rights and privileges: to whom appertains the nomination of a prelate, or other ecclesiastic, according to the divine ordinance: to whom is committed the right of preaching in public, of administering the sacraments, and of exercising the communicative power of expelling, or again admitting, any particular Christian, or even a whole country, into the pale of the church: the bans and interdicts; the exercise of sacred or theological studies; the schools, the seminaries, the universities and academies, the clergies, the convents; and so of the rest: all subjects vigorously attacked and obstinately defended.

IV. The consistorial prudence examines likewise the liturgies, the ceremonies and religious customs, the brevies, the rituals, the canons, and other books of devotion adopted by the church; the formularies, the rite of discipline, &c. the credos, the confessions of faith, the catechisms, and many other like matters; and lastly, the doubts and objects of controversy, that occasion the holding of synods and councils; the question, if the Pope be above the councils, or the councils above the Pope; the practice of elenchastic theology, or the public elenchy; the separation and reunion of the church, which the Syncretists and Hellenists dispute; the divorces more or less allowable; matrimonial, and consistorial matters, &c. &c.

V. All these subjects, and an infinity of others, which arise from, or have an immediate connection with these, require to be thoroughly considered, reduced into a regular system, explained and fixed on solid principles, and confirmed by just and pertinent examples. From all this results what is called Ecclesiastic Prudence. This science has not yet been reduced into a system or formal discipline, and that principally because it has been constantly confounded with the ecclesiastic law: but that in reality differs as much from this, as political prudence differs from the common law.

Of Theologic Prudence in the Different Functions of the Ministry.

I. Independent of casuistical theology, and of the economy of the church in general, the theologian has, moreover, need of great sagacity in the particular exercise of his ministry; and many able divines have reduced this science into a system, and have given general precepts, and particular rules, for the conduct of the minister of the altar, in the different circumstances that may arise in this part of his duty. We shall decline the particular explanation of these different systems, as it would lead us into numberless minutiae. Conrad Porta has wrote a work on the subject, intitled Paffiole Lutheiri; Stoltzhus, Korthout, Philip Hahn, Hartman, and many other theologians, have wrote large volumes concerning it: but, above all, the treatise of Dr. John Mayer, which is called Museum Minifteri Eccle- siæ, is to be consulted on this matter. We more readily omit the names and titles of other works of this kind, as we have prescribed it to ourselves as a law, to avoid, as much as possible, these sorts of citations, seeing that the number of new books that are continually appearing frequently supercede their predecessors; and moreover, in this part of theology, each Christian communion has its particular authors, who treat it in conformity to the dogmas and principles which that communion adopts.

II. The humour of reducing every thing into system, has also taken place in this matter, which in fact appears to have no occasion for any peculiar discipline that could not be included under some other part of theology. But as this distinction is already made, it is our business to explain it, for the use of such as devote themselves to the altar. The prudential theology is, for them and their ministry, what political prudence is for a man of the world in the commerce of life. It is the art of attaining the end proposed: and as each condition in life has its particular pursuits, the divines have also naturally theirs, and the precepts of theological prudence serve to conduct them to it.

III. But as the dogmas, the ceremonies, the rites and objects that the ministers of the different Christian communions propose to themselves, are by no means the same, each communion, each sect, does not follow, in this respect, the same rules and precepts, nor even part of the same principles. All that we can therefore do amidst this diversity of opinions, and contrariety of maxims, is to point out, in a few words, the principal objects that one or other of them comprehend in this part of their pastoral theology.

IV. The Afcetic Theology, for instance, treats of the various particular exercises of piety; and the principles, that it propounds with this regard, serve as guides to the minister of the altar, in his recommendation of the practice of it, as well as in many parts of his ecclesiastical duty. Falls, pilgrimages, and many other matters of the same kind, belong to the province of ascetic theology, and which we will not absolutely reject, because we write for readers of all sorts of comunions. Truth, however, obliges us to remark, that the ascetic theology of every communion is the offspring of principles falsely attributed to the Gospel, and belongs
REMEMBRANCE, or THEOLOGY.

REM. REMEMBERANCE. See MEMORY.

REM. REMEMBRANCERS, antiently called clerks of the remembrance, certain officers in the exchequer, whereof three are distinguished by the names of the king's remembrancer, the lord treasurer's remembrancer, and the remembrancer of the first fruits. The king's remembrancer enters in his office all recognizances taken before the barons for any of the king's debts, for appearances or observery of orders; he also takes all bonds for the king's debts, &c. and makes out processes thereon. He likewise issues processes against the collectors of the customs, excise, and others, for their accounts; and informations upon penal statutes are entered and filed in his office, where all proceedings in matters upon English bills in the exchequer-chamber remain. His duty further is to make out the bills of composition upon penal laws, to take the statement of debts; and into his office are delivered all kinds of indentures and other evidences which concern the asiling any lands to the crown. He, every year in craltino animarum, reads in open court the statute for election of sheriffs; and likewise openly reads in court the oaths of all the officers, when they are admitted.

The lord treasurer's remembrancer is charged to make out processes against all sheriffs, escheaters, receivers, and bailiffs, for their accounts. He also makes out writs of fieri facias, and extent for debts due to the king, either in the pipe or with the auditors; and processes for all such revenue as is due to the king on account of his tenures. He takes the account of sheriffs; and also keeps a record, by which it appears whether the sheriffs or other accountants pay their proffers due at Easter and Michaelmas: and at the same time he makes a record, whereby the sheriffs or other accountants keep their prefixed days: there are likewise brought into his office all the accounts of customers, comptrollers, and accountants, in order to make entry thereof on record: also all cistrei and amercements are certified here, &c.

The remembrancer of the first-fruits takes all compositions and bonds for the payment of first-fruits and tithes; and makes out processes against such as do not pay the same.

REMINISCENCE, that power of the human mind, whereby it recolles its self, or calls again into its remembrance such ideas or notions as it had really forgot; in which it differs from memory, which is a treasuring up of things in the mind, and keeping them there, without forgetting them.

REMISSION, in physics, the abatement of the power or efficacy of any quality.

REM. in law, &c. denotes the pardon of a crime, or the giving up the punishment due thereto.
RENUCATION, Te adt of renouncing, abdicating, or
REVERSE', inverted, in heraldry, is when any
RENT, in law, a fum of money, or other consideration,
REPARTEE a ready smart reply, especially in matters of wit, humour, or raillery.
REPEALING, in law, the revoking or annulling of a statute, or the like.
REPEAT, in music, a character showing that what was last played or sung must be repeated or gone over again.
REPELLENTS, in medicine, remedies which drive back a morbid humour into the mass of blood from which it was unduly secreted.

RENUNCIATION is in Scots law. See ADJUDICATION.
REPRESENTATIVE, one who personates or supplies the place of another, and is invested with his right and authority. Thus the house of commons are the representatives of the people in parliament.

RENOWN, something resembling the figure or shape of kidneys.

REPLENISHMENT, the restituting of an act.

REPTILES, 

The most remarkable in the class of repellents are the white of an egg, the laps calaminaris, litharge of gum, red-lead, turvy, pampholix, house-leek, putty, and cow-web. REPELLENT, the restituting of an act.

REPELLENT, in rhetoric, a figure which gracefully and emphatically repeats either the same word, or the same fentences in different words.

REPLETION, in medicine, a plenitude or plethora. See PLETHORA.

REPRESENTATION, in the drama, the exhibition of a theatrical piece, together with the scenes, machines, &c. See COMPOSITION.

REPUTATION, the reiterating of an act.
REQUEST, in law, a supplication or petition preferred to a prince, or to a court of justice, begging relief in some controversial cases where the common law grants no immediate redress.

REPULSION, in physics, that property in bodies, whereby, if they are placed just beyond the sphere of each other's attraction, they mutually fly from each other. See Electricity, and Mechanics.

REQUEST, in law, a supplication or petition preferred to a prince, or to a court of justice, begging relief in some controversial cases where the common law grants no immediate redress.

Court of Requests, an ancient court of equity, instituted about the nineteenth year of Henry VII. See Court.

In the fortieth and forty-first years of queen Elizabeth, it was adjudged upon solemn argument, in the court of common pleas, that the court of requit was then no court of equity.

REQUIEM, in the Roman church, a mass sung for the rest of a person deceased. See Mass.

REQUISITION, in Scots law. See Law, Tit. xiv. 7.

Res Judicata, in Scots law. See Law, Tit. xxxii. 4.

RES Publica, in Scots law. See Law, Tit. viii. 2.

RESOLUTION, in chemistry, be. the reduction of a mixed body into its component parts, or bit principles, by a proper analysis. See Chemistry, p. 100.

RESONANCE, Resounding, in music, be. a sound propagated through a body of solid substance, and returned by the air, inclosed in the bodies of stringed musical instruments, as lutes, &c. or even in the bodies of wind instruments, as flutes, &c. See Music, and Pneumatics.

RESPiration, the act of respiring or breathing the air. See Anatomy, p. 281.

RESPITE, in law, &c. signifies a delay, forbearance, or prolongation of time, granted any one, for the payment of a debt or the like.

RESPONDENT, in the schools, one who maintains a thesis, in any art or science; who is thus called, from his being to answer all the objections proposed by the opponent.

RESPONSE, an answer or reply. A word chiefly used in speaking of the answers made by the people to the priets, in the litany, the psalms, &c.

RESSAULT, in architecture, is the effect of a body which either projects or sinks back; that is, stands more out or in than another, so as to be out of the line or level with it.

RESSERT, a French word, sometimes used by English authors, to signify the jurisdiction of a court, and particularly one from which there is no appeal.

RESIDENT, a public minister, who manages the affairs of a kingdom or state, at a foreign court.

They are a class of public ministers inferior to ambassadors or envoys; but, like them, are under the protection of the law of nations.

RESIDUE, the remainder or balance of an account, debt, or any thing else.

RESIN. See Chemistry, p. 94.

RESIGNATION, in Scots law. See Law, Tit. xiv. 7.

RESISTANCE, or Resisting force, in philosphy, denotes, in general, any power which acts in an opposite direction to another, so as to destroy or diminish its effect. See Mechanics, Hydrostatics, and Pneumatics.

RESIDENT, a public minister, who manages the affairs of a kingdom or state, at a foreign court.

They are a class of public ministers inferior to ambassadors or envoys; but, like them, are under the protection of the law of nations.

RESIDUE, the remainder or balance of an account, debt, or any thing else.

RESIDENT, a public minister, who manages the affairs of a kingdom or state, at a foreign court.

They are a class of public ministers inferior to ambassadors or envoys; but, like them, are under the protection of the law of nations.

RESIDUE, the remainder or balance of an account, debt, or any thing else.
RESUSCITATION, the fame with resurrection and revival.

RESTITUTION, in a moral and legal sense, is restoring and retrieving the strength and vigour both of the body and animal spirits. All under this class, says Quincy, are rather nutrimental than medicinal and are more administred to recover the waffles of the constitution, than to alter and rectify its disorders.

RESTORATIVE, in medicine, a remedy proper for restoring and retrieving the strength and vigour both of the body and animal spirits.

RESTORATION, the fame with restitution. See Restoration.

RESTRINGENT, in medicine, the fame with astringent. See Astringents.

RESTRICTIVE, in medicine, a term used by antiquaries, for such medals as were struck by the emperors, to retrieve the memory of their predecessors.

Hence, in several medals we find the letters rest. This practice was first begun by Claudius, by his striking on six several medals of Augustus. Nero did the fame; and Titus, after his father's example, struck restitutions of molt of his predecessors. Gallicius struck a general restitution of all the preceding emperors, on two medals, the one bearing an altar, the other an eagle, without the rest.

RESTAURATION, the adl of re-establishing or setting a thing into its former good state.

RESTITUTION of medals, or Restituted medals, is a term used by antiquaries, for such medals as were struck by the emperors, to retrieve the memory of their predecessors.

Hence, in several medals we find the letters rest. This practice was first begun by Claudius, by his striking on six several medals of Augustus. Nero did the same; and Titus, after his father's example, struck restitutions of most of his predecessors. Gallicius struck a general restitution of all the preceding emperors, on two medals, the one bearing an altar, the other an eagle, without the rest.

RESTATIVE, or Resty, in the manage, a flubborn, unruly, ill-broken horse, that hops, or runs back, instead of advancing forward.

RESTORATION, the fame with restitution. See Restoration.

RETINUE, the attendants or followers of a prince or person of quality, chiefly in a journey.

RETIRADe, in fortification, a kind of retreatment made in the body of a bastion, or other work, which is to be disputed, inch by inch, after the defences are dismantled. It usually consists of two faces, which making a re-entering angle, when a breach is made in a bastion, the enemy may also make a retirade or new fortification behind it.

RETLINGEN, an imperial city of Germany, in the circle.
of Swabia and duchy of Württemberg, situated in E. long. 9°, N. lat. 48° 18'.

RETOUR, in chemistry. See Chemistry, p. 112.

RETRACTS, among horsemen, pricks in a horse's feet, arising from the fault of the Farrier in driving nails that are weak, or in driving them ill-pointed, or otherwise amiss.

RETRACEMENT, literally signifies something cut off or taken from a thing; in which sense it is the same with subtractions, diminution, &c.

Retrenchment, in the art of war,—any kind of work to prevent or hinder the enemy. See Fortification.

RETRACINGENTS, in natural history, a class or division of animals, whose characteristic it is that they have, or make water, backwards, both male and female.

REVE, Reeve, or Greve, the bailiff of a franchise, or jurisdiction of the crown, thus called, especially in the west of England.

REVEILLE, a beat of drum about break of day, to give notice that it is time for the soldiers to arise, and that the sentries are to forbear challenging.

REVEL, a port-town of Livonia, situated at the southern extremity of the gulph of Finland: E. long. 24° 8', N. lat. 59°.

REVELATION, the act of revealing, or making a thing public that was before unknown: it is also used for the discoveries made by God to his prophets, and by them to the world; and more particularly for the books of the Old and New Testament. See Bible and Religion.

Revelation of St. John. See Apocalypse.

REVELS, entertainments of dancing, masquerades, acting comedies, farces, &c. anciently very frequent in the inns of court, and in noblemen's houses, but now much diminished. The officer who has the direction of the revels at court, is called the master of the revels.

REVENUE, the annual income a person receives from the rent of his lands, houses, interest of money in the stocks, &c.

Revenue, in hunting, a fleshly lump formed chiefly of a cluster of whitish worms on the head of deer, supposed to occasion their calling their horns by gnawing them at the roots.

Reverberation, in physics, the act of a body repelling or reflecting another after its impinging thereon.

Reverberation, in chemistry, denotes a kind of circulation of the flame by means of a reverberatory. See Chemistry, p. 112.

REVOLVATION, in politics, signifies a grand change or revolution in government. In which sense the revolution is used, by way of eminence, for the great turn of affairs in England, in the year 1688, when King James II. abdicated the throne, the prince and princess of Orange were declared king and queen of England, &c. In geometry, the revolution of any figure, is its motion quite round a fixed line, as an axis.

The revolution of a planet, or comet, round the sun, is nothing but its course from any point of its orbit till its return to the same. See Astronomy.

REVULSION, in medicine, turning a flux of humours from one part to another, by bleeding, cupping, friction, sinapisms, blisters, lacerations, bathings, astringents, fomenting or purging of the bowels, &c. See Medicine.

REYGATE, or Rygate, a borough of Surrey, twenty-two miles south-west of London. It sends two members to Parliament.

REZANSKOI, the capital of the province of Rezan, in Russia; east long. 41°, north lat. 55°.

RHAGADES, in medicine, denotes chaps or clefts in any part of the body; arising either from any aridity of the parts, or acrimony of the humours.

RHAMNUS, in botany, a genus of the pentandria monogynia class. The calyx is tubulose, the corolla of five petals, the fruit is a beiry.

RHAPSODY, in antiquity, a discourse in verse sung or performed on the theatres, and sometimes sung the Iliad, and in others the Odyssey, and in blue when they sung the Odyssey. They performed on the theatres, and sometimes strove for prizes in contests of poetry, singing, &c. But there seems to have been other rhapsodies of more antiquity than those people, who composed heroic poems or songs in praise of heroes and great men, and sung their own compositions from town to town for a livelihood, in which profession Homer himself is said to be.

Rhapsodi, rhapsodist, in antiquity, persons who made a busines of singing pieces of Homer's poems. Cuper informs us, that the rhapsodi were cloathed in red when they sung the Iliad, and in blue when they sung the Odyssey. They performed on the theatres, and sometimes strove for prizes in contests of poetry, singing, &c. But there seems to have been other rhapsodies of more antiquity than those people, who composed heroic poems or songs in praise of heroes and great men, and sung their own compositions from town to town for a livelihood, of which profession Homer himself is said to be.

Rhapsody, in antiquity, a discourse in verse sung or performed by a rhapsodist. Others will have rhapsody
to signify a collection of verses, especially those of Homer, which having been a long time dispersed in pieces and fragments, were at length by Pindar's order, digested into books called rhapsodies. Hence, among moderns, rhapsody is also used for an assemblage of passages, thoughts, and authorities, raked together from diverse authors, to compose some new piece.

RHE, or REE, a little island in the bay of Biscay, near the coast of Anzin in France: W. long. 1° 30', N. lat. 49° 14'.

RHEIMS, or REIMS, a city of France, capital of the province of Champagne, one of the most elegant cities in France, situated seventy-five miles north-east of Paris: E. long. 4°, N. lat. 49° 20'.

RHETERIANS, a sect of heretics in Egypt, so denominating from Rhetorius their leader. The distinguishing doctrine of this heresiarch, as represented by Philalethus, was, that he approved of all the heresies before him, and taught that they were all in the right.

RHETORIC, the art of speaking copiously on any subject, with all the advantage of beauty and force.

Lord Bacon defines rhetoric: 'very philosophically, to be the art of applying and addressing the dictates of reason to the fancy, and of recommending them there as to affect the will and desires. The end of rhetoric, the same author observes, is to fill the imagination with ideas and images which may allure nature without oppressing it. Vellius defines rhetoric: 'The faculty of discovering what every subject affords of use for persuasion. Hence, as every author must invent arguments to make his subject prevail; dispose those arguments, thus found out, in their proper places; and give them the embellishments of language proper to the subject; and, if this discourse be intended to be delivered in public, utter them with that decency and force which may strike the hearer; rhetoric becomes divided into four parts, invention, disposition, elocution, and pronunciation.'

Rhetoric and oratory differ from each other as the theory from the practice; the orator being he who describes the rules of eloquence, and the orator he who uses them to advantage. Ordinarily, however, the two are used indifferently for each other. See Composition.

RHEUM, a thin serous humour, occasionally oozing out of the glands about the mouth and throat.

RHEUM in botany. See Botany, p. 642.

RHEUMATISM, in medicine. See Medicine, p. 124.

RHEUMATISM, in medicine. See Medicine, p. 124.

RHEXIA, in botany, a genus of the dodecandria monogynia class. The calyx consists of four segments, and the corolla of four petals, inserted into the calyx; the antheres are declined; and the capsule has four cells. There are three species, none of them natives of Britain.

RHINANTHUS, in botany, a genus of the dactylium angiospermae class. The calyx is twilled, and has four segments; the capsule is oblong, compressed, and bilocular. There are six species, only one of which, viz. the crista-galli, yellow rattle, or cock scomb, is a native of Britain.

RHINOCEROS, in zoology, a genus of quadrupeds belonging to the order of.bizones, of which there is but one species, viz. the unicorn, a native of Africa and India. It has two fore-teeth in each jaw, situated at a great distance from each other, and blunt, and a solid conical horn upon the nose. This, of all quadrupeds, approaches nearest to the elephant in size, the body being nearly as bulky, but the legs much shorter. A full-grown rhinoceros is fourteen feet high; and the legs are so short with all this height, that the belly comes near the ground: the head is very large and oblong, of an irregular figure, broad at top, and depressed towards the snout; the ears resemble those of a hog; the eyes are very small, and situated at a small distance from the extremity of the snout: on the upper part of the snout, near the extremity, flanks the horn, growing to about two feet and a half in length, bent a little back, of a black colour, and valetly firm and hard: the skin is remarkably thick and hard, so that the creature could not turn its body in any direction but for the joints and folds in it: the tail is short, and furnished with some long and extremely thick black hairs. The rhinoceros feeds upon thorns and brushwood; like the sow, he wallows in the mire. He is gentle and inoffensive, except when he is injured. But, when irritated, he even overturns large trees in his fury.

RHINOCEROS BIRD. See Buceros.

RHIZOPHORA, in botany, a genus of the dodecandria monogynia class. Both calyx and corolla consist of four segments; and there is but one long seed, siliqua at the base. The species are seven, none of them natives of Britain.

RHODES, the capital of an island of that name. Situated in the Mediterranean sea, in E. long. 28°, and between 36° and 37° N. lat.

RHODODENDRUM, in botany, a genus of the decapetrae clasa. The calyx of the male consists of four segments, and the corolla of four petals; the calyx of the female has four segments; it has no corolla, but four nectaria, and four pistils; and it has four capsules, containing many seeds. There is but one species, viz. the rose, or rose-wort, a native of Britain.

RHODODENDRUM, in botany, a genus of the decapetrae class. The calyx of the male consists of four segments, and the corolla of four petals; the calyx of the female has four segments; it has no corolla, but four nectaria, and four pistils; and it has four capsules, containing many seeds. There is but one species, viz. the rose, or rose-wort, a native of Britain.
RIB (552) RIB

dria monogynia class. The calix has five segments; the corolla is somewhat funnel-shaped; the stamens are declined; and the capsule has five cells. There are six species, none of them natives of Britain.

RHOMBODES, in geometry, a quadrilateral figure whose opposite sides and angles are equal, but is neither equilateral nor equiangular.

RHOMBOSIDES in anatomy. See Anatomy, p. 193.

RHOMBOSIDIA, in natural history, the name of a genus of fards, given them from being of a rhomboidal form.

RHOMBUS, in geometry, an oblique-angled parallelogram, or a quadrilateral figure whose opposite sides are equal and parallel, but the angles unequal, two of the opposite ones being obtuse, and the other two acute.

RHOMBUS, in ichthyology. See Pleuronectes.

RHONE, one of the largest rivers in France; which rising in one of the Alps of Switzerland, passes through the lake of Geneva, visits that city, and then runs south-west to Lyons, where joining the river Soane, it continues its course due south, falling by Orange, Avignon, and Arles, and falls into the Mediterranean a little westward of Marseilles.

RUBARB. See Botany, p. 642.

RHUMB, RUM, or RUM, in navigation, a vertical circle of any given place, or the intersection of such a circle with the horizon; in which last sense, rhumb is the same with a point of the compass. See Navigation.

RHUMB LINE, is also used for the line which a ship describes when sailing in the same collateral point of the compass, or oblique to the meridians. See Navigation.

RHUS, in botany, a genus of the pentandria trigynia class. The calix has five segments; the corolla is somewhat funnel-shaped; the stamens are declined; and the capsule has five cells. There are six species, none of them natives of Britain.

RHYME. in music, the variety in the movement, as to the quickness or slowness, length or thorough, of the notes. Or it may be defined more generally, the proportion which the parts of the motion have to each other. See Music.

RIBBAN, or RIBBON, in heraldry, the eighth part of a bend, like that represented in Plate CXLVII. fig. 10.

RIBBAND, or RIBBON, a narrow sort of silk, chiefly used for head-ornaments, badges of chivalry, &c.

RIBES, in botany, a genus of the pentandria monogynia class. It has five stamens, and five petals, both inserted into the calix; the style is bifid, and the berry contains many seeds. There are eight species, three of them natives of Britain, viz. the rubrum, or currants; the alpinum, or black currants; and the nigrum, or black currants.

RIBS, in anatomy. See Anatomy, p. 173.

RICCIA, in botany, a genus of the cryptogamia algae class.

RICHARDIA, in botany, a genus of the hexandria monogynia class. The calyx has six segments, and the corolla one subcyllindrical petal; and the seeds are three. There is but one species, a native of Vera Cruz.

RICHELIEU, a town of France, in the province of Orleans, in territory of Poitiers, situated twenty-six miles north of Poitiers.

RICHMOND, a village in the county of Surry, ten miles west of London, formerly the residence of the kings of England.

RICHMOND is also a borough town of Yorkshire, thirty-three miles north-west of York. It sends two members to parliament.

RICHNUS, in botany, a genus of the monce da monadelphia class. The calyx of the male has five segments; it has no corolla, but the stamens are numerous. The calyx of the female has three segments; it has no corolla; the stamens are three, and bifid; and the capsule has three cells, and one seed. There are three species, none of them natives of Britain.

RICKETS, in medicine. See Medicine, p. 160.

RIDGE, in agriculture, a long piece of rising land, between two furrows. See Agriculture, p. 57.

RIDGING, or RIDGE, among farriers, &c. the male of any beast that has been but half gelt.

RIDICULE, in matters of literature, is that species of writing, which excites contempt with laughter.

RIDING, a division of Yorkshire; of which there are three, viz. the east, west, and north ridings.

In all induftries in that county, both the town and riding must be expressed.

RIEF, in Scots law. See Robbery.

RIGA, a port-town of Livonia, one of the best harbours and trading towns in the Baltic: E. long. 24°, N. lat. 57°.

RIGGING of a ship is all her cordage and ropes, belonging to her masts, yards, &c.

RIGHT, in geometry, signifies the same with a straight line.

RIGIDITY, in physics, denotes a brittle hardnes. It is opposed to delicacy, malleability, and softness.

RIVER, in medicine, a convulsive shuddering, from severe cold, an ague-fit, or other disorder.

RIMINI, a port town of Italy, in the territories of the pope, and province of Rome, situated on the gulf of Venice: E. long. 13° 30', and N. lat. 44° 8'.

RING, the skin of any fruit that may be cut off or pared. Rind is also used for the inner bark of trees, or that whitish soft substance which adheres immediately to the wood.

RING, an ornament of gold, silver, &c. made of a circular form, and generally worn on the finger.

RING-BONE, in farriery, a hard callous substance, growing in the pattern of a horse, above the coronet: it is thus called from its growing quite round like a ring. See Farriery.
ROB, in pharmacy, the juices of fruits purified and purified till it is of the consistency of honey. 

ROANOAK, an island in North America, near the coast of Albermarle-county, in North Carolina: W. long. 75°, N. lat. 35° 40'.

ROB OF ALDER-BERRIES is thus prepared: Take two quarts of the juice of ripe alder-berrries, and half a pound of refined sugar. Evaporate over a gentle fire, or in a water bath, till it is of a due consistence.

ROBINIA, in botany, a genus of the diadelphia decandra class. The vexillum is open, reflexed, and roundish; the vexillum has four teeth, the uppermost being emarginated. There are six species, none of them natives of Britain.

ROBOANTS, in pharmacy, medicines which strengthen the parts, and give new vigour to the constitution.

ROCHEFOCAUT, a town of Orleans, in France, fifteen miles east of Angoulême.

ROCHELLE, a city and port-town of Orleans, in France; and one of the flations of the French navy, having a commodious harbour, well secured by forts and batteries. 

ROCHEFORD, a market-town of Essex, thirty-three miles east of London, and fifteen south-east of Chelmsford.

ROCHFORD, a market-town of Essex, thirty-three miles east of London, and fifteen south-east of Chelmsford.

ROCHFORT, a port-town of Guinne, in France, twenty-three miles south of Rochelle: W. long. 1° 5', N. lat. 46° 7'.

ROBINIA, in botany, a genus of the diadelphia decandra class. The vexillum is open, reflexed, and roundish; the vexillum has four teeth, the uppermost being emarginated. There are six species, none of them natives of Britain.

ROCHEFOCAUT, a town of Orleans, in France, fifteen miles east of Angoulême.

ROCHELLE, a city and port-town of Orleans, in France; and one of the stations of the French navy, having a commodious harbour, well secured by forts and batteries. 

ROCHEFORD, a market-town of Essex, thirty-three miles east of London, and fifteen south-east of Chelmsford.

ROCHFORT, a port-town of Guinne, in France, twenty-three miles south of Rochelle: W. long. 1° 5', N. lat. 46° 7'.

ROBINIA, in botany, a genus of the diadelphia decandra class. The vexillum is open, reflexed, and roundish; the vexillum has four teeth, the uppermost being emarginated. There are six species, none of them natives of Britain.

ROCHEFOCAUT, a town of Orleans, in France, fifteen miles east of Angoulême.

ROCHELLE, a city and port-town of Orleans, in France; and one of the stations of the French navy, having a commodious harbour, well secured by forts and batteries. 

ROCHEFORD, a market-town of Essex, thirty-three miles east of London, and fifteen south-east of Chelmsford.

ROCHFORT, a port-town of Guinne, in France, twenty-three miles south of Rochelle: W. long. 1° 5', N. lat. 46° 7'.

ROBINIA, in botany, a genus of the diadelphia decandra class. The vexillum is open, reflexed, and roundish; the vexillum has four teeth, the uppermost being emarginated. There are six species, none of them natives of Britain.

ROCHEFOCAUT, a town of Orleans, in France, fifteen miles east of Angoulême.

ROCHELLE, a city and port-town of Orleans, in France; and one of the stations of the French navy, having a commodious harbour, well secured by forts and batteries. 

ROCHEFORD, a market-town of Essex, thirty-three miles east of London, and fifteen south-east of Chelmsford.

ROCHFORT, a port-town of Guinne, in France, twenty-three miles south of Rochelle: W. long. 1° 5', N. lat. 46° 7'.
ROHAN, a town of France, in the province of Bntany.

Rogation week, the week immediately preceding Whit-week.

ROELLA, in botany, a genus of the pentandria monogy-

nia class. The corolla is funnel-shaped; the stigma is bifid; and the capsule is cylindrical, and has two cells. The species are two, none of them natives of Britain.

ROER, the name of two rivers in Germany, one of which rises on the confines of Heife, and falls into the Rhine; a little below Duyburg; the other rises in the duchy of Juliers, and falls into the Meafe at Roermond.

ROGA, in antiquity, a present which the emperors made to the senators, magistrates and even to the people; and the popes or patriarchs to their clergy.

These rogues were distributed by the emperors on the first day of the year, on their birth day, or on the natalis dies of the cities; and by the popes and patriarchs, in passion-week.

Roga is also used for the common pay of the soldiers.

ROGATION, in the Roman jurisprudence, a demand made by the consuls or tribunes of the Roman people, when a law was proposed to be passed. Rogatio is also used for the decree itself made in consequence of the peoples giving their assent to this demand, to distinguish it from a senatorial-consultum, or decree of the senate.

ROGATION WEEK, the week immediately preceding Whit-sunday, so called from the three days therein, on Monday, Tuesday, and Wednesday, which are also called rogations, or rogation days, from the extraordinary prayers and supplications at this time offered to God by devout Christians to appease his anger and depreciate his judgments.

ROGUE, in law, an idle sturdy beggar; who by ancient statutes is for the first offence called a rogue of the first degree, and punished by whipping, and boring through the gristle of the right ear with a hot iron; and for the second offence, is termed a rogue of the second degree, and, if above eighteen-years of age, ordered to be executed as a felon.

ROHAN, a town of France, in the province of Brittany, situated twenty miles north of Vannes.

ROLL, in manufacturies, something wound and folded up in a cylindrical form.

Roll, in law, signifies a schedule or parchment which may be rolled up by the hand into the form of a pipe.

Mafter-roll, that in which are entered the soldiers of every troop, company, regiment, &c.

Rolls-office, is an office in Chancery-lane, London, appointed for the custody of the rolls and records in chancery.

Rols of parliament, are the manuscript registers, or rolls of the proceedings of our ancient parliaments, which, before the invention of printing, were all engrossed on parchment, and proclaimed openly in every county. In these rolls are also contained a great many decisions of difficult points of law, which were frequently in former times referred to the decision of that high court.

Roll, or roller, is also a piece of wood, iron, brass, &c. of a cylindrical form, used in the construction of several machines, and in several works and manufacturies.

ROMAN, in general, something belonging to the city of Rome. See Rome.

King of the Romans, in modern history, is a prince elected to be successor to the reigning emperor of Germany.

ROMANCE, in matters of literature, a fabulous relation of certain adventures designed for the entertainment and instruction of the readers.

The true nature and genuine characteristics of this species of writing are excellently explained by the ingenious author of the Rambler; who observes, that the works of fiction, with which the present generation seems more particularly delighted, are such as exhibit life in its true flate, diversified only by the accidents that daily happen in the world, and influenced by those passions and qualities which are really to be found in conversing with mankind.

ROMANIA, a province of the pope's territories in Italy, including the Bolognese and Ferrarese. See Bologna and Ferrara.

ROMANIA, is also the modern name of ancient Thrace, which now makes a province of Turkey in Europe; lying wellward of the Propontis, between the Euxine Sea and the Archipelago.

ROME, the capital of the pope's territories and of Italy, and anciently the mistress of the Roman Empire; E. lon. 13°, N. lat. 41° 45'.

Rome is still a large and fine city, though not to be compared to ancient Rome; the streets are spacious, and magnificently built; it has five bridges over the Tiber, twenty gates, three hundred churches, and a vast number of palaces, convents, triumphal arches, pillars, obelisks, statues, theatres, &C.

ROMNEY, a borough town of Kent, and one of the five ports, situated twelve miles south-west of Dover. It lends two members to parliament.

ROMPEE, or Rompu, in heraldry, is applied to ordina-

ries that are represented as broken, and to chevrons, bends, or the like, whose upper points are cut off. See Plate CXLVII, fig. 11.

RONDELETIA, in botany, a genus of the pentandria monogy-

nia class. The corolla is funnel-shaped, and the capsule has two cells containing many round coronated seeds. There are two species, none of them natives of Britain.

ROOD, a quantity of land equal to forty square perches, or the fourth part of an acre.

ROOF, in architecture, the uppermost part of a building. See Architecture, p. 361.

ROOK, in ornithology. See Corvus.

ROOM, a chamber, parlour, or other apartment, in a house. See Architecture, p. 359.

ROOT, among botanists, denotes that part of a plant which imbibles the nutritious juices of the earth, and transmits them to the other parts. See Agriculture, p. 42.

Root, in algebra and arithmetick. See Algebra, p. 84, &c. and Arithmetic, p. 420.

ROPE, hemp, hair, &c. spun out into a thick yarn, and then several strings of this yarn twisted together by means of a wheel. When made very small, it is called a cord; and when very thick, a cable.

Rope yarn, among sailors, is the yarn of any rope untwist-

ed, but commonly made up of junk; its use is to make fennet, mats, &c.

ROSA, in botany, a genus of the icofandria polygamia class.

The petals are five; the calyx has five fleshy segments; and the seeds are numerous, rough, and inserted into the interior side of the calyx. There are 14 species, five of them natives of Britain, viz. the glannteria, or sweet briar; the spimalfluma, or burnet rofe; the arvensis, or white-flowered dogs-rose; the vullofa, or apple-rose; and the canina, or red-flowered dogs-rose, or hip-tree.

ROSA-
with it, only by removing them into broom-fields. Scurvy-grafs, mugwort, parsley, and thyme, are also good for the prevention of it.

ROTA, the name of an ecclesiastical court at Rome, composed of twelve prelates, whereof one must be a German, another a Frenchman, and two Spaniards; the others are Italians, three of whom must be Romans, and the other five a Bolognese, a Ferraran, a Milanese, a Venetian, and a Tuscan.

This is one of the most august tribunals in Rome, which takes cognizance of all suits in the territory of the church, by appeal; as also of all matters beneficary and patrimonial.

ROTATION, in geometry, a term chiefly applied to the circumvolution of any surface round a fixed and immovable line, which is called the axis of its rotation: and by such rotations it is, that solids are conceived to be generated.

ROTHERAM, a market-town of York, twenty-two miles west of York.

ROTHSAY, a parliament-town of Scotland, on the island of Bute; W. long. 5°, and N. lat. 55° 50'.

ROTONDO, or Rotondo, in architecture, an appellation given to any building that is round both within and without side, whether it be a church, a saloon, or the like. The most celebrated rotondo of the ancients, is the pantheon at Rome.

ROTENNESS. See Putrefaction.

ROTTERDAM, a city of the province of Holland, situated on the north bank of the Meuse, thirty miles south of Amsterdam, and thirteen miles south-east of the Hague; E. long. 4° 20', and N. lat. 52°.

ROTONDA, in anatomy, See Anatomy, p. 185.

ROUNDHOUSE, a kind of prison, for the nightly watch in London to secure disorderly persons, till they can be carried before a magistrate.

ROUSILLON, formerly a province of Spain, now united to France, is bounded by Languedoc on the north, by the Mediterranean sea on the east, by Catalonia on the south, and by the Pyrenean mountains on the west, being about fifty-five miles long, and thirty-six broad.
ROUTE, a public road, highway, or course, especially that which military forces take. This word is also used for the defeat and flight of an army.

Rout, in law, is applied to an assembly of persons, going forcibly to commit some unlawful act, whether they execute it or not.

ROWEL, among farriers, a kind of issue, made by drawing a flain of silk, thread, hair, or the like, through the nape of the neck, or other part of a horse; answering to what in surgery is called a feron. See Farriery.

ROYALTON, a market-town, situated in the counties of

ROYENA, in botany, a genus of the decandria digynia class.

ROYAL, something belonging to a king; thus we say, royal family, royal affent, royal exchange, &c.

ROYAL-oak, a fair spreading tree at Boscobel, in the parish of Donnington in Staffordshire, the boughs whereof were once covered with ivy; in the thick of which king Charles II. fat in the day time with colonel Careless, and in the night lodged in Boscobel house: so that they are mistaken who speak of it as an old hollow oak, it being then a very flourishing tree, surrounded with more. The poor remains thereof are now fenced in with a handsome wall, with this inscription over the gate in gold-letters: Felicitatum arboris quam in vos, while potentissimi regis Caroli II. Deus op. max. per quem reges regnant, hic crescre votuit. See.

ROYAL-fociety. See Society.

ROYALTIES, the rights of the king, otherwise called the king's prerogative, and the regalia. See Prerogative, and Regalia.

ROYENA, in botany, a genus of the decandria digynia class. The calix is urceolate; the corolla consists of one bell-shaped petal; and the berry contains one seed. There are three species, all natives of the Cape of Good Hope.

ROYSTON, a market-town, situated in the counties of Hertford and Cambridge, thirty-eight miles north of London.

RUBELLIO, in ichthyology. See Cyprinus.

RUBETA, in zoology. See Rana.

RUBIA, in botany, a genus of the tetrandria monogynia class. The corolla consists of one bell-shaped petal; and the berry contains one seed. There are two species, none of them natives of Britain.

RUBIGALIA, in antiquity, a feast celebrated by the Romans, in honour of the god Rubigus, or the goddess Rubiga, to engage these deities to preserve the corn from Mildew, being a species of blight. See Blight.

RUBIGALIA, in antiquity, a feast celebrated by the Romans, in honour of the god Rubigus, or the goddess Rubiga, to engage these deities to preserve the corn from Mildew, being a species of blight. See Blight.

RUBIC, in the canon-law, signifies a title or article in certain ancient law-books; thus called because written, as the titles of the chapters in our ancient Bibles are, in red letters.

RUBUS, in botany, a genus of the icofandria polygynia class. The calix consists of five segments, and the corolla of five petals; and the berry has many seeds. There are 13 species, five of them natives of Britain, viz., the idee-, or raspberry-bush, the caesius, or small bramble; the fruticosus, or common bramble; the saxatilis, or stone-bramble; and the chamaemorus, or cloud-berries.

RUBIA, in botany, a genus of the tetrandria monogynia class. The receptacle is conical and furnished with many more. The poor remains thereof are now fenced in with a handsome wall, with this inscription over the gate in gold-letters: Felicitatum arboris quam in vos, while potentissimi regis Caroli II. Deus op. max. per quem reges regnant, hic crescre votuit. See.

RUBIC, in the canon-law, signifies a title or article in certain ancient law-books; thus called because written, as the titles of the chapters in our ancient Bibles are, in red letters.

RUBUS, in botany, a genus of the icofandria polygynia class. The calix consists of five segments, and the corolla of five petals; and the berry has many seeds. There are 13 species, five of them natives of Britain, viz., the idee-, or raspberry-bush, the caesius, or small bramble; the fruticosus, or common bramble; the saxatilis, or stone-bramble; and the chamaemorus, or cloud-berries.

RUBY, in natural history, a species of gems, being a beautiful gem of a red colour with an admixture of purple.

This, its most perfect and bell-coloured stone, is a gem of prodigious beauty and extreme value; it is often found perfectly pure and free from blemishes or faults, but much more frequently debased greatly in its value by them, especially in the larger specimens. It is of very great hardness, equal to that of the sapphire, and second only to the diamond. It is various in size, but left subject to variations in its shape than most of the other gems. It is usually found very small, its most common size being equal to that of the head of the largest sort of pins; but it is found of four, eight, or ten carats, and sometimes, though very rare, up to twenty, thirty, or forty. It is never found of an angular or crystalliform shape, but always a pebble-like figure, often roundish, sometimes oblong and much larger at one end than at the other, and in some form resembling a pear, and is usually flattened on one side. It commonly is naturally fo bright and pure on the surface, as to need no polishing; and when its figure will admit of being set without cutting, it is often worn in its rough state, and with no other than its native polish.

We have the true ruby only from the East Indies; and the principal mines of it are in the kingdom of Pegu and the island of Ceylon.

Ruby, in heraldry, denotes the red colour wherewith the arms of noblemen are blazoned; being the same which, in the arms of those not noble, is called, gules. See Gules.

RUCTATION, a ventosity arising from indigestion, and discharging itself at the mouth with a very disagreeable noise.

RUDBECKIA, in botany, a genus of the syngenia polygynia fruiticana class. The receptacle is conical and palaeaceous: the pappus has four teeth on its edge; and the berry discharges itself at the mouth with a very disagreeable noise.
RUGEN, an island of the Baltic sea, on the coast of Germany, being part of the duchy of Swedish Pomerania, separated from the continent by a narrow channel: this island is thirty miles long, and near as many broad.

RUGER, a term particularly used for magnificent buildings fallen into decay by length of time, and whereof there only remains a confused heap of materials.

RULE, in matters of literature, a maxim, canon, or precept, to be observed in any art or science.

Rule of three. See Arithmetick, p. 331.

RUM, a species of brandy or vinous spirit, distilled from sugar-canes.

Rum, according to Dr. Shaw, differs from simple sugar-spirit, in that it contains more of the natural flavour or essentiel oil of the sugar-cane; a great deal of raw juice and parts of the cane itself being often fermented in the liquor or solution of which the rum is prepared. The unctuous or oily flavour of rum is often supposed to proceed from the large quantity of fat used in boiling the sugar; which fat, indeed, if coarse, will usually give a flinking flavour to the spirit, in our distillations of the sugar liquor, or wash, from our refining sugar-houses; but this is nothing of kin to the flavour of the rum, which is really the effect of the natural flavour of the cane.

The method of making rum is this: When a sufficient stock of the materials is got together, they add water to them, and ferment them in the common method, though the fermentation is always carried on very slowly at first; because at the beginning of the season for making rum in the islands, they wait yeast, or some other ferment to make it work; but by degrees, after this, they procure a sufficient quantity of the ferment, which rises up as a head to the liquor in the operation; and thus they are able afterwards to ferment and make their rum with a great deal of expedition, and in large quantities.

When the wash is fully fermented, or to a due degree of acidity, the distillation is carried on in the common way, and the spirit is made up proof: though sometimes it is reduced to a much greater strength, nearly approaching to that of alcohol or spirit of wine, and it is then called double-distilled rum. It might be easy to rectify the spirit, and bring it so much greater purity than we usually find it to be of: for it brings over in the distillation a very large quantity of the oil; and this is often so disagreeable, that the rum must be suffered to lie by a long time to mellow before it can be used; whereas, if well rectified, it would grow mellow much sooner, and would have a much less potent flavour.

The best state to keep rum in, both for exportation and other uses, is double distillation of alcohol, or rectified spirit. In this manner it would be transported in one half the bulk it usually is, and might be let down to the common proof-strength with water when necessary; for the common use of making punch, it would likewise serve much better in the state of alcohol; as the taste would be cleaner; and the strength might always be regulated to a much greater exactness than in the ordinary way.

The only use to which it would not so well serve in this state, would be the common practice of adulteration among our distillers; for when they want to mix a large portion of cheaper spirit with the rum, their business is to have it of the proof-strength, and as full of the flavouring oil as they can, that it may drown the flavour of the spirits they mix with it, and extend its own. If the business of rectifying rum was more nicely managed, it seems a very practicable scheme to throw out so much of the oil, as to have it in the fine light state of a clear spirit, but lightly impregnated with it; in this case it would very nearly resemble arrack, as is proved by the mixing a very small quantity of it with a tasteless spirit, in which case the whole bears a very near resemblance to arrack in flavour.

Rum is usually very much adulterated in England: some are so bare-faced as to do it with malt-spirit; but when it is done with molasses spirit, the tasts of both are so nearly allied, that it is not easily discovered. The best method of judging of it is, by letting fire to a little of it; and when it has burnt away all the inflammable part, examining the phlegm both by the taste and smell.

RUMELIA, in geography, the name of ancient Greece, now a part of Turkey in Europe.

RUMEN, the paunch, or third stomach of such animals as chew the cud, whence called ruminant animals.

The rumen is by far the largest of all the stomachs, and in it the whole mists of crude aliments, both solid and liquid, lies and macerates, to be thence transmitted to the mouth to be again chewed, comminuted, and fitted for farther digestion in the other ventricles.

RUMEX, in botany, a genus of the hexandria trigynia class. The calix has three leaves, and the corolla three connivent petals; and there is but one triangular seed.

The species are 27, of which ten are natives of Britain.

RUMFORD, a market-town of Essex, ten miles east of London.

RUNGS, in a ship, the same with the floor or ground timbers, being the timbers which constitute her floor, and are bolted to the keel, whose ends are rung-heads.

Rung-heads, in a ship, are made a little bending, to direct the sweep or mold of the futtocks and navel timbers; for here the lines, which make the compass and bearing of a ship, do begin.

RUNIC, a term applied to the language and letters of the ancient Goths, Danes, and other northern nations.

RUNNER, in the sea-language, a rope belonging to the garnet, and to the two bolt-tackles. It is received in a single block, joined to the end of a pennant, and has at one end a hook to hitch into any thing, and at the other end a double block, into which is received the fall of the tackle, or the garnet, by which means it purchases more than the tackle would without it.

RUNNET, or Rennet, the acid juice found in the stomachs of calves that have fed on nothing but milk, and are killed before the digestion is perfect. It curdles milk.

RUPERT’S drops, a sort of glass-drops with long and slender tails, which burn to pieces on the breaking off the ends in any part, said to have been invented by prince Rupert, and therefore called after his name. This surprising phenomenon is supposed to rise from hence, that while the glass is in fusion, or in a melted state, the particles of it are in a state of repulsion; but being dropped into cold water, it coagulates the particles in the external parts of their superficies, that they are easily reduced.
RUPTURE, in surgery. See Surgery.

RUPICAPRA, in zoology. See Capra.

RUSCUS, butcher's broom, in botany, a plant of the dicotyledonous class. The calyx of the male consists of six leaves; it has no corolla; the nectarium is central, oval, and perforated at the top; the calyx, corolla, and nectarium of the female are the same with those of the male; it has one style; and the berry has three cells, and two seeds. There are five species, only one of them, viz. the aculeatus, knee-holly, or butcher's broom, a native of Britain.

RUSTIC, in architecture, implies a manner of building in imitation of nature, rather than according to the rules of art. See Architecture.

RUTICILLA, in ornithology. See Muscicapa.

RUTICILLIUS, in ichthyology. See Cyprinus.

RUTLAND, the least county in England, bounded by Lincolnshire on the north-east, by Northamptonshire on the north-west, and by Leicestershire on the west and north-west.

SAB, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABA, one of the Caribbee islands, subject to the Dutch: W. long. 63°, N. lat. 18°.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABALANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.

SABAEANS, in church-history, a sect of idolaters, much ancienester than the Jewish law.
SABBELLIANS, an sect of the 2nd century, that embraced the opinions of Sabellius, a philos-

phier of Egypt, who openly taught that there is but one person in the Godhead.

SABBATH, or the day of rest, a solemn festival of the Jews, on the seventh day of the week, or Saturday, beginning from sun-fan on Friday, to sun-fet on Saturday.

The observation of the Sabbath began with the world: for God having employed six days in its creation, appointed the seventh as a day of rest to be observed by man, in commemoration of that great event. On this day the Jews were commanded to abstain from all labour, and to give rest to their cattle. They were not allowed to go out of the city farther than two thousand cubits; or a mile; a custom which was founded on the diligence of the ark from the tents of the Israelites, in the wilderness, after their leaving Egypt; for being permitted to go, even on the sabbath day, to the tabernacle to pray, they from thence inferred, that the taking a journey of no greater length, than on a different account, could not be a breach of the sabbatical rest.

As the seventh day was a day of rest to the people, so was the seventh year to the land; it being unlawful in this year to plow or sow, and whatever the earth produced belonged to the poor: this was called the sabbatical year. The Jews, therefore, were obliged, during the six years, and more especially the last, to lay up a sufficient store for the sabbatical year.

The modern, as well as the ancient, Jews, are very superstitious in the observance of the sabbath; they carry neither arms, nor gold nor silver about them, and are permitted neither to touch thefe, nor a candle, nor any thing belonging to the fire; on which account they light up lamps on Friday, which burn till the end of the sabbath.

SABBELLIANS, a sect of Chriftians of the 2nd century, that embraced the opinions of Sabellius, a philos-

philosopher of Egypt, who openly taught that there is but one person in the Godhead.

The Sabellians maintained, that the Word and the Holy Spirit are only virtues, emanations, or functions of the Deity: and held, that he who is in heaven is the Father of all things, descended into the virgin, became a child, and was born of her as a son; and that having accomplished the mystery of our salvation, he diffused himself on the apostles in tongues of fire, and was then denominated the Holy Ghost. This they explained by resembling God to the sun, the illuminative virtue or quality of which was the Word, and its warming virtue

Vol. III. N° 92, 2.

the Holy Spirit. The Word, they taught, was darted, like a divine ray, to accomplish the work of redemption; and that, being ascended to heaven, the influences of the Father were communicated after a like manner to the apostles.

SABINA, in botany. See Juniperus.

SABINA, a province of Italy, in the pope's territories, bounded by Umbria on the north, by Naples on the south, and by St. Peter's Patrimony on the west.

SABLE, in heraldry, denotes the colour black, in coats of arms belonging to gentleman; but in those of noblemen it is called diamond; and in those of sovereign princes, Saturn. See Colour.

It is expressed in engraving by perpendicular and horizontal hatches crossing one another, as represented in Plate CXLVII. fig. 12.

SABLUSTAN, a province of Persia, which comprehending Gaur and Candalor, is bounded by Chorassan on the north, by India on the east, and by Sigishin on the south.

RABRE, a kind of sword or scimitar, with a very broad and heavy blade, thickest at the back, and a little falcated or crooked towards the point; it is the ordinary weapon worn by the Turks, who are said to be very expert in the use of it.

SABBURRE, grits, in natural history, a genus of fossils, found in minute masses, forming together a kind of powder, the several particles of which are of no determinate shape, nor have any tendency to the figure of crystall; but seem rudely broken fragments of larger masses; not to be dissolved or diluted by water, but retaining their figure in it, and not cohering by means of it into a mafs; considerably opaque, and in many species fermenting with acids; often fouled with heterogeneous matters, and not infrequently taken in the coarser ftony and mineral or metallic particles.

Grits are of various colours, as 1. The flinty or sparry grits, of a bright or greyish white colour. 2. The red flinty grits. 3. The green ftony grits, composed of homogenous sparry particles. 4. The yellow grits, of which there is only one species. 5. The black and blackish grits, composed of ftony or taly particles.

SACCACIDE, in the mange, is a sort more or less violent, given by the horfeman to the horfe, in pulling or twitching the reins of the bridle all on a sudden, and with one pull, and that when a horfe lies heavy upon the hand, or obstinately arms himself.

SACCAL, a city and port-town of Japan, situated on the bay of Mecao, three hundred miles south-west of Jeddo: E. long. 125°, and N. lat. 36.

SADRCHARUM, in botany, a genus of the triandria digynia clafs. It has no calyx, but long down in place of it; and the corolla has two valves. There are two species, both natives of India. See Sugar.

SACCARUM SATURNI, sugar of lead, is thus ordered to be made in the London Dispensatory; boil cerul with distilled vinegar, until the vinegar becomes sufficiently sweet; then filter the vinegar through paper, and after due evaporation let it to crystallize.

SACCULUS, in anatomy, a diminutive of fasciculus, signifies a little bag, and is applied to many parts of the body. See Anatomy.

7. B.
SACRED, something holy, or that is solemnly offered and consecrated to God, with benedictions, unctions, &c.

SACRAMENT, signifies, in general, a sign of a thing sacred and holy; and is defined to be an outward and visible sign of a spiritual grace. Thus there are two objects in a sacrament, the one the object of the senses, and the other the object of faith. Protevangelists admit only of two sacraments, baptism and the eucharist or Lord's supper; but the Roman Catholics own seven, viz. baptism, confirmation, the eucharist, penance, extreme unction, ordination, and marriage.

The Romanists, however, by way of eminence, call the eucharist the holy sacrament. Thus to expel the holy sacrament, is to lay the consecrated host on the altar to be adored. The procession of the holy sacrament, is that in which this host is carried about the church, or about a town.

SACRAMENTARY, an ancient Roman church-book, which contains all the prayers and ceremonies practiced at the celebration of the sacraments.

It was written by Pope Gelasius, and afterwards revised, corrected, and abridged by St. Gregory.

SACRED, something holy, or that is solemnly offered and consecrated to God, with benedictions, unctions, &c.

SACRIFICE, a solemn act of religious worship, which consists in dedicating or offering up something animate or inanimate on an altar, by the hands of the priest, either as an expression of their gratitude to the Deity for some signal mercy; or to acknowledge their dependence on him, or to conciliate his favor. The origin of sacrifices is by some ascribed to the Egyptians; but Popery ascribes it to the Egyptians, who first offered the first-fruits of their grounds to the gods, burning them upon an altar of turf: thus in the most ancient sacrifices there were neither living creatures, nor any thing corporeal, and no myrrh or frankincense. At length they began to burn perfumes; and afterwards men leaving their ancient diet of herbs and roots, and beginning to use living creatures for food, they began also to change their sacrifices. The scriptures, however, furnish us with a different account: for Noah, it is said, sacrificed animals at his coming out of the ark; and even Abel himself sacrificed the fatted and fattened of his flock; but Grotius thinks it more probable that he contented himself with making a mere oblation of his lambs, &c. without slaying them.

The Jews had two sorts of sacrifices, taking the word in its largest signification: The first were offerings of tythes, first-fruits, cakes, wine, oil, honey, and the like; and the last, offerings of slaughtered animals. When an Israelite offered a loaf or a cake, the priest broke it in two parts; and offering aside that half which he reserved for himself, broke the other into crumbs, poured oil, wine, incense, and salt upon it, and spread the whole upon the fire of the altar. If these offerings were accompanied with the sacrifice of an animal, they were thrown upon the victim to be consumed along with it. If the offerings were of the ears of new corn, they were parched at the fire, rubbed in the hand, and then offered to the priest in a vessel, over which he poured oil, incense, wine and salt, and then burnt it upon the altar, having first taken as much of it as of right belonged to himself.

The principal sacrifices among the Hebrews consisted of bullocks, sheep, and goats; but doves and turtle doves were accepted from those who were not able to bring the other; these, beasts were to be perfect, and without blemish. The rites of sacrificing were various, all of which are very minutely described in the books of Moses.

The manner of sacrificing among the Greeks and Romans was as follows. In the choice of the victim, they took care that it was without blemish or imperfection; its tail was not to be too small at the end; the tongue not black, nor the ears cleft; and that the bull was one that had never been yoked. The victim being pitched upon, they girt his forehead and horns, especially if a bull, heifer, or cow. The head they also adorned with a garland of flowers, a woollen infula or holy fillet, whence hung two rows of chaplets with twisted ribbands; and on the middle of the body a kind of flue, pretty large, hung down on each side: the lesser victims were only adorned with garlands and bundles of flowers, together with white tufts or wreaths.

The victims thus prepared were brought before the altar; the lesser being driven to the place, and the greater led by a halter; when if they made any struggle, or refused to go, the priest was taken for an ill omen, and the sacrifice frequently was let aside. The victim thus brought was carefully examined, to see that there was no defect in it: then the priest, clad in his ephod, and accompanied with the sacrificers and other attendants, and being washed and purified according to the ceremonies preferred, turned to the right-hand and went round the altar, sprinkling it with meal and holy-water, and also besprinkling those who were present. Then the crier proclaimed with a loud voice, Who is here? To which the people replied, Many and good. The priest then having enjoined the people to join with him by saying, Let us pray, confessed his own unworthiness, acknowledging that he had been guilty of divers sins; for which he begged pardon of the gods, hoping that they would be pleased to grant his requests, accept the oblations offered them, and send them all health and happiness; and to this general form added petitions for such particular favours as were then desired. Prayers being ended, the priest took a cup of wine; and having tasted it himself, caused his attendants to do the like; and then poured forth the remainder between the horns of the victim. Then the priest or the crier, or sometimes the most honourable person in the company, killed the beast, by
by knocking it down, or cutting its throat. If the sacrifice was in honour of the celestial gods, the throat was turned up towards heaven; but if the sacrifice to the heroes or infernal gods, the victim was killed with its throat towards the ground. If by accident the beast escaped the stroke, leaped up after it, or expired with pain and difficulty, it was thought to be unacceptable to the gods. The beast being killed, the priest inspected its entrails, and made predictions from them. They then poured wine, together with frankincense, into the fire, to increase the flame, and then laid the sacrifice on the altar; which in the primitive times was burnt whole to the gods, and thence called an holocaust; but in after-times, only part of the victim was consumed in the fire, and the remainder referred for the sacrificers; the thighs, and sometimes the entrails, being burnt to their honour, the company feated upon the reit. While the sacrifice was burning, the priest, and the person who gave the sacrifice, jointly prayed, laying their hands upon the altar. Sometimes they played upon musical instruments in the time of the sacrifice, and on some occasions they danced round the altar, singing sacred hymns in honour of the gods.

Sacrifice, is also a name of an island in the gulf of Mexico, forty-five miles east of La Vera Cruz; it is subject to the Spaniards.

Sacrilege, the crime of profaning sacred things, or those devoted to the service of God. See Sexton.

Sacrister, a church-officer, otherwise called sexton. See Sexton.

Sacristy, in church history, an apartment in a church, where the sacred utensils were kept; being the same with our vestry. See Vestry.

Sacro Lumbarlis, in anatomy. See Anatomy, p. 203.

Sacrum or S, in Anatomy, p. 170.

Saderasapatan, a port-town of the coast of Commandel forty miles south of Fort St George. Here the Dutch have a factory.

Saddle, is a seat upon a horse's back, contrived for the convenience of the rider.

A hunting saddle is composed of two bows, two bands, fore-boots, panels, and saddle-irons; and the great saddle has, besides these parts, corks, hind-boots, and a trough-quern.

The pomell is common to both.

Sadducees, in Jewish antiquity, a famous sect among the ancient Jews, so called from their founder Sadoc. Antigonus of Socho, president of the sanhedrim at Jerusalem, and teacher of the law in the divinity school of that city. Having often, in his lectures, afferted to his scholars, that they ought not to serve God in a servile manner, with respect to reward, but only out of filial love and fear; two of his scholars, Sadoc and Baitthus, inferred from thence, that there were no rewards or punishments after this life; and, therefore, separating from the school of their master, they taught that there was no resurrection, nor future state. Many embracing this opinion, gave rise to the sect of the Sadducees, who were a kind of Epicureans; but differing from them in this, that though they denied a future state, yet they allowed the world was created by the power of God, and governed by his providence; whereas the followers of Epicurus denied both.

The Sadducees denied all manner of predetermination whatever; and not only rejected all unwritten traditions, but also all the books of the Old Testament, excepting the Pentateuch.

Safeguard, a protection formerly granted to a stranger, who feared violence from some of the king's subjects, for seeking his right by course of law.

Saffron, in botany, &c. See Colchicum.

Meadow Saffron, in botany. See Colchicum.

Sagamen, in pharmacy, &c. A gum resin, brought to us in two forms: the inner and purer is in loose granules, or single drops; the coarser kind is in masses composed of these drops of various sizes, cemented together by a matter of the same kind. In either case, it is of a firm and compact consistence, considerably heavy, and of a reddish colour on the outside, brownish within, and spotted in many places with small yellowish or whitish specks. Its smell is strong and disagreeable: its taste acrid and unpleasing.

It is brought to us from Persia and the East-Indies.

Sagamen is a very great attenuant, aperient, and diffusent: it is good in all disorders of the breast that owe their origin to a tough phlegm.

Sage, in botany. See Salvia.

Sagene, a Russian long measure, five hundred of which make a verst: the sagene is equal to seven English feet.

Sagina, in botany, a genus of the tetrandria tetragynia class. The calyx consists of four leaves, and the corolla of four petals; the capsule has four cells, and four valves, containing many seeds. There are three species, two of them natives of Britain, viz. the procumbens, or pearl wort; and the erecta, or the least ditch wort.

Sagittaria, in botany. See Astronomical, p. 487.

Sagittalis suture, in anatomy. See Anatomy, p. 152.

Sagittaria, in botany, a genus of the monocata polyandra class. The calyx of the male consists of three segments, and the corolla of three petals; and the flamina are about 24. The calyx and corolla of the female are the same with those of the male; it has no pistillum; and the seeds are many, and naked. The species are four, only one of them, viz. the fagittifolia, or arrowhead, a native of Britain.

Sagittarius, in astronomy. See Astronomy, p. 487.

Sago, a simple brought from the East-Indies, of considerable use in diet as a restorative.

Sago is a sort of bread produced in the following manner, from a tree called landan, growing in the Moluccas. When a tree is flied, they cleave it in two in the middle, and dig out the pith, which is eatable, when it comes fresh out of the tree. They pound it in a mortar, till it is reduced into a kind of powder somewhat like meal. Then they put a piece made of the bark of the same tree, placing it over a cilkern made of its leaves, and pour water on it, which separates the pure part of the powder from the woody fibres wherewith the pith abounds. The flour thus filtrated they call fago, which they make into pate, and bake it in earthen furnaces.

Sagreed, in ichthyology. See Squalus.

Sail, in navigation, an assemblage of several breadths of sail.
SAILING properly denotes the art of navigating and working a ship, or of causing her to observe such motions and directions as are aligned by the navigator; in which sense, failing differs from navigation, and must be learned by practice on shipboard. See Navigation.

SAINT, in the Roman church, a holy person deceased, and since his decease canonized by the pope, after several informations and ceremonies. See Canonization.

SAINT FOIN, in botany. See Hedysarum, and Agriculture. p. 65.

SALEP, in the materia medica, the root of a species of orchis. See Orchis.

Salep should be chosen clean, firm and hard; it is very little liable either to decay or sophistication. The salep differs very little from the common orchis in virtue. Its appearance is owing to the manner of preparing it, and consequently this may be done from the roots of orchis of our own growth. To prepare the salep imitate in preparation of salep, Mr. Geoffroy chose the largest, fairest, and plumpest roots he could find; these he nicely skinned; then throwing them into cold water, he suffered them to macerate there for some time: after this he lightly boiled them, and then taking them out of the water and draining them, he had them strung upon threads to be dried in a warm dry air; when the roots were thoroughly dried, they were very transparent, and resembled pieces of tragacanth, and continued dry and hard. The roots thus prepared may be reduced to powder, which will dissolve in boiling water; and a scruple of it will make a balsam full of jelly, in the manner of the Turkish salep. This jelly is an admirable medicine in all cases in which a balsam is required: it is an excellent medicine in fevers, whooping cough, and other cases of consumption.

SALEM, a port-town of New England, a little north of Boston.

SALE P, in the materia medica, the root of a species of orchis. See Orchis.

SALISBURY, the capital city of Wiltshire, situated eighty miles west of London, and thirty-five miles south-east of Bristol. It sends two members to parliament.

SALIVA, spittle, a thin pellucid humour, separated from the arterial blood, by the glands about the mouth and fauces, and conveyed, by proper salivary ducts, into the mouth, for several uses. See Anatomy, p. 307.

SALIVAL, an epithet applied to the glands and ducts which supply and secrete the saliva. See Anatomy, p. 307.

SALIVATION, in medicine, a promoting of the flux of saliva, by means of medicines, mostly by mercury. The chief use of salivation is in diseases belonging to the glands and the membranes adipose, and principally in the cure of the venereal disease, though it is sometimes also used in epidemic diseases, cutaneous diseases, &c. whose crises tend that way. See Medicine.

SALIX, in botany, a genus of the dioecia diandria class. There are thirty species.

Salep should be chosen clean, firm and hard; it is very little liable either to decay or sophistication. The salep differs very little from the common orchis in virtue. Its appearance is owing to the manner of preparing it, and consequently this may be done from the roots of orchis of our own growth. To prepare the salep imitate in preparation of salep, Mr. Geoffroy chose the largest, fairest, and plumpest roots he could find; these he nicely skinned; then throwing them into cold water, he suffered them to macerate there for some time: after this he lightly boiled them, and then taking them out of the water and draining them, he had them strung upon threads to be dried in a warm dry air; when the roots were thoroughly dried, they were very transparent, and resembled pieces of tragacanth, and continued dry and hard. The roots thus prepared may be reduced to powder, which will dissolve in boiling water; and a scruple of it will make a balsam full of jelly, in the manner of the Turkish salep. This jelly is an admirable medicine in all cases in which a balsam is required: it is an excellent medicine in fevers, whooping cough, and other cases of consumption.

SALOON,
SAMARICAND, a city of Uzbek Tartary, formerly its capital: E. long. 66°, N. lat. 40°.

SAMARIA, an ancient city of Palestine, in Asiatic Turkey, forty-five miles north of Jerusalem.

SAMPSEANS, in church history, an ancient sect, who were properly neither Jews, Chriftians, nor Gentiles, though they took their names from the Hebrew word fe-mer, fun; as though they worshipped that planet. They acknowledged only one God; washed themselves often; and in almost every thing attached themselves to the religion of the Jews.

Books of SAMUEL, two canonical books of the Old Testament, so called as being usually ascribed to the prophet Samuel. The books of Samuel, and the books of Kings, are a continued history of the reigns of the Kings of Israel and Judah; for which reason the books of Samuel are like-
wife styled the first and second books of Kings. Since the first twenty-four chapters contain all that relates to the history of Samuel, and the latter part of the first book, and all the second, include the relation of events that happened after the death of that prophet, it has been supposed that Samuel was author only of the first twenty-four chapters, and that the prophets Gad and Nathan finished the work. The first book of Samuel comprehends the transactions under the government of Eli, and Samuel; and under Saul, the first king; and also the acts of David, whilst he lived under Saul, and is supposed to include the space of a hundred and one years. The second book contains the history of about forty years, and is wholly spent in relating the transactions of king David's reign.

SAMYDA, in botany, a genus of the decandria monogyne class. The calix consists of five coloured leaves; it has no corolla; and the berry has three valves, and one cell. There are five species, none of them natives of Britain.

SANCTIFICATION, the act of sanctifying, or rendering a thing holy.

The reformed divines define sanctification to be an act of God's grace, by which a person's desires and affections are alienated from the world, and by which he is made to die to sin, and to live to righteousness; or, in other words; to feel an abhorrence of all vice, and a love of virtue and religion.

SANCTION, the authority given to a judicial act, by which it becomes legal and authentic.

SANCTUARY, among the Jews, also called Sanctum sanctorum or Holy of holies, was the holiest and most retired part of the temple of Jerusalem, in which the ark of the covenant was preserved, and into which none but the high priest was allowed to enter, and that only once a year, to intercede for the people. Some distinguished the sanctuary from the sanctum sanctorum, and maintain that the whole temple was called the sanctuary.

To try and examine any thing by the weight of the sanctuary, is to examine it by a just and equal scale: because, among the Jews, it was the custom of the priests to keep stone weights, to serve as standards for regulating all weights by, though these were not at all different from the royal, or profane weights.

Sanctuary, in the Roman church, is also used for that part of the church in which the altar is placed, encompassed with a rail or balustrade.

SANCTUARY, in our ancient customs, is the same with asylum. See Asylum.

SAND, in natural history, a genus of fossils, the characters of which are, that they are found in minute concretions; forming together a kind of powder, the genuine particles of which are all of a tendency to one determinate shape, and appear regular, though more or less compleat concretions; not to be dissolved or disunited by water, or formed into a coherent mass by means of it, but retaining their figure in it; transparent, vitrifiable by extreme heat, and not dissoluble in, nor effervescing with, acids. Sands are subject to be variously blended both with homogene and heterogene substances, as that of talcs, &c. and hence, as well as from their various colours, are subdivided into a number of species.

SAND-BAGS, in the art of war, are bags filled with earth or sand, holding each about a cubic foot; their use is to raise parapets in haste, or to repair what is beaten down.

SANDECK, a town of little Poland, thirty-five miles south of Cracow.

SANDEEL, ammodites, in ichthyology. See Ammodites.

SANDAL, in antiquity, a rich kind of slipper worn on the feet by the Greek and Roman ladies, made of gold, silk, or other precious stuff. It consists of a sole, with an hollow at one extreme to embrace the ankle, but leaving the upper part of the foot bare.

Sandal, is also used for a shoe or slipper worn by the pope, and other Roman prelates, when they officiate. It is also the name of a sort of slipper worn by several congregations of reformed monks. This last consists of no more than a mere leather sole, fastened with latches or buckles, all the rest of the foot being left bare. The capuchins wear sandals; the recollects, clogs: the former are of leather, and the latter of wood.

SANDARACH, in natural history, a very beautiful native fossil, though too often confounded with the common fictitious red arsenic, and with the red matter formed by melting the common yellow orpiment.

It is a pure substance, of a very even and regular structure, is throughout of that colour which our dyers term an orange-scarlet, and is considerably transparent even in the thickest pieces. But though, with respect to colour, it has the advantage of cinnamon while in the mafs, it is vastly inferior to it when both are reduced to powders. It, is moderately hard, and remarkably heavy, and, when exposed to a moderate heat, melts and flows like oil: if set on fire, it burns very briskly.

It is found in Saxony and Bohemia, in the copper and silver mines; and is sold to the painters, who find it a very fine and valuable red: but its virtues or qualities in medicine, are no more ascertained at this time, than those of the yellow orpiment.

Gum-Sandarach, is a dry and hard resin, usually met with in loose granules, of the bigness of a pea, a horse-bean, or larger; of a pale whitish yellow, transparent, and of a rufinous smell, brittle, very inflammable, of an acid and aromatic taste, and diffusing a very pleasant smell when burning. It is produced from a species of the juniper.

It flows only from these trees in hot countries; but the natives promote its discharge by making incisions in the bark.

Sandarach is good in diarrhoeas, and in haemorrhages.

The varnish makers make a kind of varnish of it by dissolving it in oil of turpentine or linseed; or in spirit of wine.

Sandiver, a whitish salt, continually cast up from the metal, as it is called, whereof glass is made; and, swimming on its surface, is skimmed of.

Sandiver is also plentifully thrown out in the eruptions of volcanos; some is of a fine white, and others tinged bluish or yellowish.

Sandiver is a detergent, and good for foulnesses of the skin. It is also used by gilders of iron.

Sandix, a kind of mineral, or red-lead, made of ceruse, but much inferior to the true minium.

Sandwich, one of the five ports, in Kent, ten miles east of Canterbury: it sends two members to parliament, and gives the title of Earl to the noble family of Montague.
SANGUINATION, in the animal economy, the conversion of chyle into true blood. See CHYLE.

SANGUNARIA, blood-wort, in botany, a genus of the polyandria monogyna class. The corolla consists of eight petals, and the calyx of two leaves; the pod is oval, with one cell. There is but one species, a native of America.

SANGUNE, in general, something abounding with, or resembling blood. See Blood.

SANGUIS, See Blood.

SANGUISORBA, in botany, a genus of the tetrandria monogyna class. The corolla consists of one petal; the stigma lies upon the tube; the stigmas are simple; and the fruit is a berry. There is but one species, a native of India. The wood is reckoned to be attenuant and cordial.

SANGUIFICATION, in the animal economy, the conversion of chyle into true blood. See CHYLE.

SANHEDRIM, among the Jews, the great council of the nation, consisting of seventy senators, taken partly from among the priests and levites, and partly out of the inferior judges, who formed what was called the lesser sanhedrim. They had the right of judging in capital cases, and sentence of death might not be pronounced in any other place; for which reason the Jews were forced to quit this hall, when the power of life and death was taken out of their hands, forty years before the destruction of the temple, and three years before the death of Christ.

SANEDRIM, among the Jews, the great council of the nation, consisting of seventy senators, taken partly from among the priests and levites, and partly out of the inferior judges, who formed what was called the lesser sanhedrim. The room they met in was a rotunda, half of the room they met in was a rotunda, half of the temple, and three years before the death of Christ.

The authority of this council was very extensive: for they decided such causes as were brought before them by way of appeal from the inferior courts; and the king, the high-priests, and prophets, were under the jurisdiction of this tribunal. They had the right of judging in capital cases, and sentence of death might not be pronounced in any other place; for which reason the Jews were forced to quit this hall, when the power of life and death was taken out of their hands, forty years before the destruction of the temple, and three years before the death of Christ.

There were several inferior sanhedrims in Palestine, each of which consisted of twenty-three persons; all these depended on the great sanhedrim of Jerusalem.

SANTALUS, in botany, a genus of the decandriamonoamyla class. The umbellae are thick; the fruit is rough; and the stigma is semitectate. There are eight species, none of them natives of Britain.

SANTOLINA, a genus of the syngenesia polygamy equalis class. The receptacle is paleaceous; the pappus is very short; and the calyx is hemispherical and imbricated. The species are four, none of them natives of Britain.

SAP, a juice furnished by the earth, and changed into the sap of plants. See Anatomy, p. 243.

SAPIENZA, an island and cape in the Mediterranean Sea, on the south-west point of the Morea, E. long. 21° 14', N. lat. 26° 45'.

SAPPHIC, in poetry, a kind of verse much used by the Greeks and Latins, denominated from the inventreis Sappho. The Sapphic verse consists of five feet, whereof the first, fourth, and fifth are trochees, the second a sponde, and the third a dactyl.

SAPINDUS, in botany, a genus of the ocdandria digynia class. The calyx consists of four leaves; and the corolla of four petals; and there are three round, connate, ventricose capsules. The species are three, none of them natives of Britain.

SAPPHIRE, a pellucid gem, which, in its finest state, is of a deep blue; in the finest specimens it is of the deepest azure, and in others varies into paleness in shades of all degrees, between that and a pure crystal brightness; without the least tinge of colour, but with a lustre much superior to the crystal. They are distinguished into four sorts, viz. the blue sapphire, the white sapphire, the water sapphire, and the milk sapphire. The gem known to us by this name is extremely different from the sapphire of the ancients, which was only a semi-opaque stone, of a deep blue, veined with white, and spotted with small gold-coloured spangles, in the form of stars, and was only a more beautiful kind of the lapis lazuli: but our sapphire they have described under the name of beryllus aeroides, or the sky-blue beryl.
kingdom of Pegu in the East Indies, where some are found perfectly colourless, and others of all the shades of blue; these are all found in the pebble-form. We have very fine faphires also, partly pebble, partly crystal-shaped, from Bifnagar, Conoor, Calicut, and the island of Ceylon; these also are of all the shades of blue. And in Ceylon there are sometimes found a sort of baffard gems, of a mixed nature between the fapphire and ruby. The ocidentals are from Silefia, Bohemia, and many other parts of Europe; but though these are often very beautiful stones, they are greatly inferior, both in lulishe and hardness, to the oriental.

SAPPHIRINE WATER, in the materia medica, also called blue eye-water, is thus prepared: Pour a pint of lime-water, made strong and fresh, into a copper-veffel, add to it a dram of crude saI ammoniac, and throw in some filings or small pieces of copper, and let it stand till it has acquired a beautiful colour.

This is used as an eye-water; also to do to tere old ulcers; and sometimes it is mixed with other things in injections in gonorrhoeas.

SARABANDES, a sort of monks among the ancient Christians, who did not reftort to the wildernefs as others did, but lived publicly in cities. Two or three of them usually dwelt together, but they had no rule or government; they however observed very strict rules; wore loose sleeves, wide focking, coarse clothes, frequently sighed, and always bitterly inveighed against the clergy.

SARABAND, a musical composition in triple time, the motion of which are slow and serious.

SARACENS, the inhabitants of Arabia; so called from Sarab, which signifies a desert, as the greatest part of Arabia is; and this being the country of Mahomet, his disciples were called Saracens.

SARAGOSA, the capital of the province of Aragon in Spain: W. long 1° 15'; and N. lat. 41° 32'.

SARCASM, in rhetoric, a keen bitter expression which has the true point of satire, by which the orator scoffs and insults his enemy: such was that of the Jews to our Saviour. "He favored others, himself he cannot save." J. W. "

SARCOCELE, in surgery, a spurious rupture, or hernia, wherein the nettle is considerably tumid or indurated, like a festiitis, or much enlarged by a feathery excrecence, which is frequently attended with acute pains and sometimes ulceration, so as to degenerate at last into a cancerous disformation. See SURGERY.

SARCOCOLLA, in pharmacy, a gum-refin, which approaches greatly to the nature of the simple gums. It is brought to us from Peria and Arabia, in small granules moderately heavy, and of a whitish-brownish, or reddish colour, very friable, of a faintish disagreeable smell, and of an acrid and nauseous taste. Hoffman absolutely condemns the internal use of it. However, it is recommended in ophthalmias, and defcriptions of a sharp matter upon the eyes; and is generally ordered to be dissolved in milk for this purpose.

SARCOLOGY is that part of anatomy which treats of the soft parts, viz. the moles, interlines, arteries, veins, nerves, and fat. See ANATOMY.

SARCOMA, in surgery, denotes any feathery excrecence.

SARCOPHAGOUS medicines, in surgery, &c. are those which at away bad flesh, and otherwise called caustics. See CAUSTICS.

SARCOMA, in surgery, medicines which generate flesh in wounds.

SARDINIA, an island of the Mediterranean, situated between 3° and 10° E. long. and between 39° and 41° N. lat. It is about one hundred and forty miles long, and sixty broad; and gives the title of king to the duke of Savoy, under whose dominion it is.

SARDIS, the ancient capital of Lydia, in Asia, now in ruins.

SARDONYX, in natural history, a genus of semi-pellucid gems, of the onyx structure, zoned or tabulated, and composed of the matter of the onyx variegated with that of the red or yellow carnelian. See CARNELIAN and ONYX.

SARGUS, in ichthyology. See SPARUS.

SARK, a little island between Guernsey and Jersey, subject to Great Britain.

SAROTHRA, in botany, a genus of the pentandria tri-gynia class. The calix consists of five segments, and the corolla of five petals; the capsule is coloured, and has three cells and one valve. There is but one species, a native of Virginia.

SARSAPARRILLA, in botany. See SMILAX.

SATORIUS, in anatomy. See ANATOMY, p. 207.

SARUM, or Old Sarum, a dorough-town of Wiltshire, situated a little north of Salisbury. It lends two members to parliament.

SASSAFRAS, in botany. See LAURUS.

SATURDAY, the seventh or last day of the week so called from the idol Satir, worshipped on this day by the ancient Saxons, and thought to be the same as he Saturn of the Latins.

SATIN, a glossy kind of silk stuff, the warp of which is very fine, and stands out so as to cover the coarser woof.

SATINET, a slight thin kind of fattin, commonly striped, and chiefly used by the ladies for summer night-gowns.

SATURANTS, in pharmacy. See ABSORBENTS.

SATURATION, in chemistry, is the impregnating an acid with an alkali, or vice versâ, till either will receive no more, and the mixture will become neutral.

SATURDAY, the seventh or last day of the week, so called from the idol Satir, worshipped on this day by the ancient Saxons, and thought to be the same as the Saturn of the Latins.

SATUREIA in botany, a genus of the didynamia gymnoperma class. The lacinæ of the corolla are nearly equal; and the flamina are approximate. The species are nine, none of them natives of Britain.

SATUREIA is botany, a genus of the didynamia gymnoperma class. The lacinæ of the corolla are nearly equal; and the flamina are approximate. The species are nine, none of them natives of Britain.

The leaves of summer favory are very pungent, warm, and aromatic; and afford, in distillation with water, a subtile effential oil. Both are esteemed good in crudities of the stomach, asthma, and menstrual obstructions.

SATURN, in astronomy. See ASTRONOMY, p. 442.
SAUNDER S. See SANTALUM.
SAX, VOLAXIA, a subdivision of Finland, in Ruflia, situated between Cajania, Boxholm, Farala, and Bothnia.
SAVOUR, in botany. See SAVOR.
SAVOUR. See Taste.
SAVOY, a duchy, situated between France and Italy, on the well side of the Alps; bounded by the lake and territory of Geneva, on the north; by Switzerland and Piedmont, on the east; by another part of Piedmont and Dauphine, on the south; and by Franche Comte and Dauphine, on the west.
SAVAGESIA, in botany, a genus of the protandria monogynia class. The calix consists of five leaves and the corolla of five limbed petals; the stamen has five leaves, lying alternately between the petals; and the capsule has one cell. There is but one species, a native of Jamaica.
SAW, an instrument which serves to cut into pieces several fold matters, as wood, flone, ivory &c.
The belt saws are of tempered steel ground bright and smooth; those of iron are only hammer hardened; hence the rift, besides their being stiffer, is likewise found smoother than the last. They are known to be well hammered by the thin bending of the blade; and to be well and evenly ground, by their bending equally in a bow.
SAW-FISH. See SQUALUS.
SAXIFRAGA, in botany, a genus of the decandria digynia class. The calyx consists of five segments, and the corolla of five petals; the capsule has a double beak and one cell. The species are 38 nine of them natives of Britain.
The tuberous roots at the foot of the granulata or white-flowered saxifrage are kept in the shops, under the name of saxifrage seeds; they are diuretic and attenuant; and therefore good in nephritic cataracts and obstructions of the monads and vesica.
SAXONY, the name of two circles of the German empire, distinguished by the epithets Upper and Lower. The circle of Upper Saxony comprehends the duchy of Saxony, the marquises of Mecklenburg, and Brandenburg, and the duchies of Pomerania, Sax Mecklenburg, Sax Merseburg, and Sax Naumburg. The circle of Lower Saxony comprehends the duchies of Mecklenburg, Holstein, Lauenburg, Luneburg, Zell, Bremen, Brunfwic, Hanover, and Magdeburg; the principalities of Verden and Halberstadt, and the bishopric of Hildesheim.
SAY, or SAYS, in commerce, a kind of serge or woollen stuff, much used abroad for linings, and by the religious for shirts; with us it is used for aprons by several forts of artificers, being usually dyed green.
SCABIOSA, in botany, a plant of the tetrandria monogyonia class. The common calyx consists of many leaves, and the proper one is double; the receptacle is paleaceous. The species are 25; three of them natives of Britain, viz. the sucuola, or devil's bit; the arvensis, or common field scabious; and the columbaria, or leffer field scabious.
SCAFFOLD, among builders, an assemblage of planks and boards, fastened by tassels and pieces of wood fixed in the wall; whereon masons, brick layers, &c. stand to work in building high walls, &c. and plasterers in plastering ceilings, &c. [Scaffold]
SCAF, in poetry, the measuring of a verse by feet, in order to see whether or no the quantities be duly observed. The term is chiefly used in regard to the Greek and Latin verses. Thus an hexameter verse is scanned, by resolving it into six feet; a pentameter, by resolving it into five feet, &c.

SCAPE-GOAT, in Jewish antiquity, the goat which was set at liberty on the great day of expiation.

Spencer is of opinion, that the scape-goat was called Azazel, because it was sent to Azazel, i.e. the devil; the reasons of which ceremony, he takes to be these: 1. That the goat, loaded with the sins of the people, and sent to Azazel, might denote the miserable condition of the sinners. 2. The goat was thus loaded to the demons, to show that they were impure, and to deter the people from worshipping them. 3. That the goat sent to Azazel sufficiently expiating the sins of the Israelites, they might The more willingly abate from the expiatory sacrifices of the heathens.

SCARABÆUS, or BEE, in zoology, a genus of insects, of the coleoptera-order: the antennae of the beetles are of a clavated figure, but little vermilion produces a good scarlet; but if a flower in a print is to be painted of a scarlet colour, the lights as well as the shades should be covered with minium, and the shaded parts finished with carmine, which will produce an admirable scarlet.

SCARIFICATION, in surgery, the operation of making several incisions in the skin by means of lancets, or other instruments, particularly the cupping instrument. See Surgery.

SCARLET, a beautiful bright red colour.

In painting in water-colours, minium mixed with a little vermilion produces a good scarlet; but if a flower in a print is to be painted of a scarlet-colour, the lights as well as the shades should be covered with minium, and the shaded parts finished with carmine, which will produce an admirable scarlet.

SCARP, in fortification, is the interior talus, or slope of the ditch next the place, at the foot of the rampart.

SCARP, in heraldry, the scarf which military commanders wear for ornament.
SCEPTICISM, the doctrines and opinions of the sceptics, whose distinguishing tenet was, that all things are uncertain and incomprehensible, and that the mind is never to assent to any thing, but to remain in perpetual doubt and suspense. This doctrine was also called pyrrhonism, from the name of its author, See Pyrrhonians.

SCHAFFHOUSE, the capital of the canton of Schaffhouse, one of the most northern cantons of Switzerland: E. long. 8° 40', N. lat. 47° 42'.

SCHALHOLT, the capital of Iceland, subject to Denmark: W. long. 19°, N. lat. 64° 30'.

SCHAMACHIA, a city of Persia, in the province of Chirvan, situated on the west side of the Caspian sea, in E. long. 50°, N. lat. 41°.

SCHELD, a river which rises in the confines of Picardy, and runs north-east by Cambrai, Valenciennes, Tourney, Oudenarde, &c. and receiving the Lys at Ghent, runs east by Dendermond, and then north to Antwerp; below which city it divides into two branches; one called the Water-Scheld, which separates Flanders from Zealand, and discharges itself into the sea near Flushing; and the other called the Oster-Scheld, which runs by Bergen-op-Zoom, and afterwards between the islands Beveland and Schouwen, and a little below falls into the sea.

SCELLING, an island of Holland, at the entrance of the Zuyder sea, between Flie Island and Amseland: E. long. 5° 20', N. lat. 53° 34'.

SCHEMNITZ, capital of the mine towns in Upper Hungary, sixty miles north-east of Preiburg.

SCHENECTIDA, a fortress of New-York, in America, situated on Hudson's River, in the province of Albany, a hundred miles north of New York city.

SCHELTLAND, about forty islands, which constitute part of the country of Orkney, and the Orkades, in Scotland, valuable on account of the herring-fishery on their shores: situated between 1° east and 2° west longitude, and between 61° and 62° of north latitude.

SCHIRAS, or Sheras, a city of Persia, in the province of Fars, 180 miles south of Isphahan; reckoned the second city in that kingdom.

SCHISM, a separation, or breaking off from communion with any church; on account of some disagreement in matters of faith or discipline.

SCHOENUS, in botany, a genus of the triandria monogynia class. The glumes are paleaceous, and have but one valve; it has no corolla, and but one round seed. The species are 13, five of them natives of Britain.

SCHOLASTIC, something belonging to the schools, See School.

SCHOLIAST, a grammarian, who writes scholia, that is, notes, glosses, &c. upon ancient authors, who have written in the learned languages. See the next article.

SCHOLIUM, a note, annotation, or remark, occasionally made on some passage, proposition, or the like. This term is much used in geometry, and other parts of mathematics, where, after demonstrating a proposition, it is customary to point out how it might be done some other way, or to give some advice, or precaution, in order to prevent mistakes, or add some particular use, or application thereof.

SCHOOL, a public place, wherein the languages, or arts and sciences are taught. Thus we say, grammar-school, writing-school, &c.

SCHWALBACH, a town of Germany, in the circle of the Upper Rhine, and in the territory of the Wetterau, and county of Nassau, eight miles north of Mentz.

SCHWALBEA, in botany, a genus of the didynamia angiospermia class. The calix consists of four segments,
SCI, (570) SCO

SCIRPUS, in botany, a genus of the triandria monogynia class. The calix is imbricated and pappuse; and it has no corolla, and but one beardless seed. The species are 27, ten of which are natives of Britain.

SCIRRUS, in surgery and medicine, a hard tumour of any part of the body, void of pain, arising from the inflammation and induration of the fluids contained in a gland; though it may appear in any other part, especially in the fat, being one of the ways wherein an inflammation terminates. See Medicine and Surgery.

SCIURUS, the Squirrel, a genus of quadrupeds belonging to the order of Gliridae. It was two feet in each jaw, the superior ones shaped like wedges, and the inferior ones compressed. There are eleven species.

- The vulgaris, or common squirrel, which is a native of most southern parts of Europe, has a pencil of hairs on the top of the ears, four toes on the fore-feet, and live on the hind ones: In the summer, it is of a reddish colour, with a white belly; in the winter, it is of a blueish ash-colour. The squirrel is a very active animal; it feeds upon nuts, berries, &c. which it carries to its mouth by the fore-feet: It lays up its superfluous food in holes; and makes a round nest of moss.

SCLAREA, in botany. See Salvia.

SCLAVONIA, a province subject to the house of Austria, and bounded on the north-east by the rivers Drave and Danube, which separate it from Hungary; being about two hundred miles long, and fifty broad.

It takes its name from the Slav, an ancient people of European Scythia; who, from whom is the Slavonic language, which is said to be the most extensive language in the world, except the Arabic; as being the common mother of the Rusian, Hungarian, Polish, Bulgarian, Carinthian, Bohemian, &c. languages.

SCLERANTHUS, in botany, a genus of the decandria monogynia class. The corolla consists of six open, deciduous petals; and the filaments resemble threads. There are eight species, two of them natives of Britain, viz. the bifolia, or vernal star-hyacinth; and the autumnalis, or lesser autumnal star-hyacinth.

The middle part of the root of the scilla maritima, a native of Spain, is only used in medicine: the apothecaries cut the root perpendicularly in two; and separating the heart and the outer parts, they expose the others to dry. This root is extremely acid, attenuant, and diffolvent: it is apt to prove emetic in whatever form it is given; but this may be prevented, by adding a few grains of cinnamon to it: it then becomes a powerful medicine in all obstructions of the visera; it promotes urine and the menses, and cuts the tough phlegm which almost chokes in asthmatic and many other disorders of the breast.

SCLEROPSIA, in botany, a genus of the lygnesia polygamy equalis class. The receptacle is pellucid; the calix is imbricated and pappose; and it has no pappus. There are two species, both natives of Italy.

SCLEROTICAS, medicines proper to harden and constrict any part of the body, void of pain, arising from the inflammation and induration of the fluids contained in a gland; though it may appear in any other part, especially in the fat, being one of the ways wherein an inflammation terminates. See Medicine and Surgery.

SCLEROTICA, in anatomy. See Anatomy, p. 289.

SCLEROTICS, medicines proper to harden and constrict the flesh of the parts to which they are applied: as pursuing, house-leek, fleawort, garden night-hade, &c.

SCLEROPAX, in ornithology, a genus belonging to the order of grallae. The beak is cylindrical, obtuse, and longer than the head; the nostrils are linear; the face is covered; and the feet have four toes. There are 18 species.

SCLEROPENDRA, in zoology, a genus of insects belonging to the order of aptera. The feet are very numerous, being as many on each side as there are joints in the body; the antennae are fuscacese; there are two jointed pappi; and the body is depressed. There are eleven species.

SCLYMYUS, in botany, a genus of the lygnesia polygamy equalis class. The receptacle is pellucid; the calix is imbricated and pappose; and it has no pappus. There are two species, both natives of Italy.

SCOMBER, in ichthyology a genus belonging to the order of thoracii. The head is smooth and compressed; and there are seven rays in the gill-membrane. The species are ten.

SOME,
SCORZONERA, in botany, a genus of the fyngegenia polygamia class. The calix consists of four segments; the corolla is rotated, with four segments; and the capsule has one cell, and two valves, containing many seeds. There are two species, none of them natives of Britain.

SCOPARIA, in botany, a genus of the tetrandria monogynia class. The receptacle is naked; the calix consists of four segments; the corolla is fomewhat globular; and the capsule分离s from the water in boiling; this substance they call scratch; and these pans, being placed at the corners of the salt-pan, where the heat is least violent, catch it as it fubfides there.

SCOPARIA, in botany, a genus of the diadelphia de-
SCULPTURE, an art by which, in taking away, or adding to matter, all sorts of figures are formed by the hand, either in the stone, wood, wax, or metal. In its full extent, it signifies both the art of working in cretnx, properly called carving; and of working in relief, which is more strictly called sculpture.

The first works in sculpture were with clay, not only in making statues, but in forming models; and to this day a sculptor never undertakes anything considerable, without forming a model, either in clay or wax. In making figures of these materials, they begin and finish their work with their hands, using only three or four pieces of wood, which are roundish at one end, and at the other flat, with a sort of claws and teeth, which are to smooth and scratch the work. For waxy models, they use every pound of wax add half a pound colophony to them, and melt it together with oil of olives; more or less of the latter being used as they would have the matter harder or softer: some also add turpentine, and melt it together with oil of olives; but it must be such, however, as is firm and close: for smaller works and ornaments, the softer wood is used; but it must be fuch, however, as is firm and close: for a large work, though it be only a single figure, it is better to make use of several pieces of wood, or bits of board, glued together, than of one whole piece, which is more liable to crack; for a thick piece of wood may not be dried to the heart, however it may appear on the outside.

In sculpture in marble and other stone, the first thing to be done is to saw out a block of marble, of the bigness of the model, and this being done, the superficialities are to be taken off by a clового tool, called a dog's tooth, it having two points, but one not so sharp as the other. After this he makes use of his graining, which is a flat cutting tool, with three teeth; he then takes off, with a smooth chisel, the graining left on the marble, and uses it with dexterity and delicacy, to give finish and tenderness to his figure; till at length, taking rasps of different degrees of fineness, the work is gradually rendered fit for polishing. To polish the work, the sculptor uses pumice stone and flint; then he goes over it with tripod; and when he would give it more luster, rubs it with leather and straw ashes. There are several other tools used by sculptors, adapted to the different parts of the work, and the nature of the stone they make use of. As the models of clay shrink as they grow dry, whenever sculptors undertake a considerable piece of work, they only use the model for making a mould of plaster or flucco, in which is formed a figure of the same matter, which serves them thenceforth for a model, and by which they adjust all their measurements and proportions. To proceed the more regularly, on the head of the model they place an immovable circle divided into degrees, with a moveable rule or index, fixed in the centre of the circle, and divided also into equal parts; from the end of the rule hangs a line with a plummet, which serves to take all the points, to be transferred thence to the block of marble, from whose top hangs another plummet, like that of the model. But there are some excellent sculptors, who disapprove of this method; urging, that the smallest motion of the model changes their measures, for which reason they chuse rather to take all their measures with the compasses.

SCUM, properly denotes the impurities which a liquor, by boiling, casts up to the surface.

The term sea is also used for what is more properly called the scoria of metals.

SCURVY, in medicine. See Medicines, p. 106.

SCURRENCE, in botany. See Cochlearia.

SCUTELLARIA, in botany, a genus of the didynamia gymnoferma class. The calix is entire on the edge, is that after the flowering, and operculated. The species are 13, two of them natives of Britain, viz. the galeri- culata, or hooded-willow-herb; and the minor, or lesser hooded-willow-herb.

SCUTIFORME OS, in anatomy, the same with rotula.

SCUTIFORMIS CARTILAGO, in anatomy, the same with the thymus cartilage. See Anatomy, p 185.

SCUTITILES, in a ship, square holes cut in the deck, big enough to let in the body of a man, serving to let people down into any room below upon occasion, or from one deck to another.

SCYTHIA. The northern parts of Europe and Asia were anciently so called, which afterwards obtained the name of Tartary.

SEA, is frequently used for that vast tract of water encompassing the whole earth; but is more properly a part or division of these waters, and is better defined a lesser assemblage of water, which lieth before and wasteth the coasts of some particular countries from whence it is generally denominated, as the Irish sea, the Mediterranean sea, the Arabian sea &c.

What proportion the superficialities of the sea bear to that of the land is not precisely known, though it is said to be somewhat more than two thirds. As the waters of the earth must necessarily rise to the surface thereof, as being specifically lighter than the earth, it was necessary there should be large cavities therein for receptacles to contain them; otherwise they would have overflowed all the superficialities of the earth, and left them rendered it utterly uninhabitable for terrestrial animals. For the centre of the earth being the common centre of gravity, and the nature of fluids being such that they equally yield to equal powers, and the power of attraction being everywhere equal at equal distances from the centre, it follows, that the superficial parts of the water will every where conform themselves to an equidistant situation from the centre, and consequently will form the surface of a sphere so far as they extend. Hence, that the sea seems higher than the earth or land, results from the fallacy of vision, whereby all objects, and the parts of land as well as sea, the farther they are off from us, the higher they appear; the reason of all which is plain from optics: for it is well known, that the denser any medium is through which we behold objects, the greater is the refraction, or the more their images appear above the horizontal level, also the greater quantity of the medium the rays pass through, the
the more will they be bent from their first direction: on both these accounts the appearances of things remote, and on the sea, will be somewhat above the horizon, and the more fo as they are the more remote.

With regard to the depth or profundity of the sea, Varan us affirms, that it is in some places innumerable, and in other places very various, being in certain places 20, 40, 60, 80, 100, and 120 English miles, in other places deeper, and much hills in bays than in oceans. In general, the depths of the sea bear a great analogy to the height of mountains on the land, so far as is hitherto discovered.

There are two principal reasons why the sea doth not increase by means of rivers, &c. falling every where into it. The first is, because waters return from the sea by subterranean cavities and aqueducts, through various parts of the earth. Secondly, because the quantity of vapours rais'd from the sea, and falling on the land, only cause a circulation, but no increas of water. It hath been found by calculation, that in a summer's day there may be rais'd in vapours, from the Mediterranean sea, 26320000000 tons of water; and yet this sea receiveth not, from all its nine great rivers, above 1527000000 tons per day, which is but a third part of what is exhal'd in vapours.

With regard to the saltness of the sea-water, it is very rationallly judged to arise from great multitudes both of mines and mountains of salt, dispersed here and there in the depths of the sea. Dr Halley supposes that it is probable the greatest part of the sea salt, and of all salt lakes, as the Caipian sea, the Dead sea, the lake of Mexico, and the Titicaca in Peru, is deriv'd from the water of the rivers which they receive; and since this sort of lakes has no exit or discharge, but by the exhalation of vapours; and also since these vapours are entirely fresh, or devoid of such particles; it is certain the saltness of the sea and such lakes must, from time to time increas, and therefore the saltness at this time is greater than at any time heretofore. He further adds, that if, by experiments made in different ages, we could find the different quantity of salt which the same quantity of water (taken up in the same place, and in all other the same circumstances) would afford, it would be easy from thence, by rules of proportion, to find the age of the world very nearly, or the time wherein it has been acq'ting its present saltness.

With regard to the use of this salt property of sea-water, it is observed, that the saltness of the sea prevents its waters pure and sweet, which otherwise would corrupt and stink like a filthy lake, and consequently that none of myriads of creature that now live there could then have a being. From thence also the sea-water becomes much heavier, and therefore ships of greater size and quantity may be used thereon. Salt water also doth not freeze so soon as fresh water, whence the seas are more free for navigation. We have lately published a dissertation, by Dr Russel, concerning the medical ufed of sea-water in diseases of the glands, &c. wherein the author promises some observations upon the nature of sea-water, confider'd as impregnated with particles of all the bodies it passes over, such as submarine plants, fish salts, minerals, &c. and saturat'd with their several effluvia, to enrich it, and keep it from putrefaction; hence this fluid is suppos'd to contract a soapiness, and the whole collection, being pervaded by the fulphureous freams passing through it, to constitute what we call sea-water, the confecut'd diffin-

guiding characteristics of which are saltiness, bitterness, nitritility, and unquickness: whence the author concludes, that it may be justly expected to contribute signal to the improvement of phyic. The cases in which our author informs us we are to expect advantage from sea-water, are,

1. In all recent obstructions of the glands of the intestines and mefacenter. 2. All recent obstructions of the pulmonary glands, and those of the vifeera, which frequently produce consumptions. 3. All recent glandular swellings of the neck, or other parts. 4. Recent tumours of the joints, if they are not suppurated, or become scirrhou's, or cancerous, and have not curios bones for their caufe. 5. Recent defeciations upon the glands of the eye-lids. 6. All defeciations of the skin, from an erysipelas, to a lepra. 7. Defcences of the glands of the nose, with their usual companion a thicknes of the lip. 8. Obstructions of the kidneys, where there is no inflammation, and the fiane not large. 9. In recent obstructions of the liver this method will be proper, where it prevents constrictions of the belly, and affilds other mediciines directed in icteric cafes. The fame remedy is laid to be of signal service in the bromchocie; and is likewise recommended for the prevention of thole bilious colics that do frequently affiict our mariners.

To make sea-water fresh is a thing lalong and much wanted, for the advantage of navigation and commerce; a method for doing which has been long ago invented by Mr Hauton, and the secret published in the Philof. Tranfaft. It is performed by precipitating the water with oil of tartar, and then distilling it. But Mr Appleby's process, which was referred by the lords of the admiralty to the college of phyficians, and communicat'd to the royal society, with some experiments therewith, on Feb. 8, 1753, appears to be more successful, and is performed thus: into twenty gallons of sea-water put fix ounces of a fixed alkali prepare with quick lime as strong as lapis infernalis, and fix ounces of bones calcined to a whitenes, and finely pow'ded; with a low fire, draw off, in a common still, fifteen gallons. Mr Appleby conceives that the alkali here employ'd is the bell adapted to prevent the luminous matter in sea-water from rising by heat in distillation.

In the year 1755, a method of procuring any quantity, of fresh water at sea was publish'd by Dr Butler; together with a method also of preferring fresh-water entirely pure, sweet, and wholesome, during the longeft voyage, and in the warmeft climates. The method more expressly recommended by the doctor for making sea-water fresh is to put a measured wine-quart of the strongest soap leys to fifteen gallons of sea-water; which being distill'd, he affires us will generally yield twelve gallons of fresh water. The above quantity of soap leys, we are told, will bear a repetition of the fame quantity of water four or five times.

This method of Dr Butler was tried, by order of the lords of the admiralty, at the fame time with Mr Appleby's: but the latter, being found to be performed with a less quantity of fuel, was prefered.

In order to keep fresh-water sweet, Dr Butler directs to take of fine, clear, white pearl-ashes, a quarter of a pound avoidupoise, and put into one hundred gallons of fresh water; observing this proportion to a greater or less quantity.
quantity, and flop up your cask as usual, till you have oc-
casion to broach it.

For the ebbing and flowing of the sea, see Astronomy, p. 472.

Seamen, such as are referred to serve the king, or other
persons, at sea, who may not depart without license, &c. Seamen fighting, quarrelling, or making any
perturbation, may be punished by the commissioners of the
navy with fine and imprisonment. Registered seamen are ex-
cempted from serving in any parish office, &c. and
are allowed bounty-money besides their pay. By the law
of merchants, the sea-men of a vessel are accountable to
the master or commander, and the master to the owners,
and the owners to the merchants, for damage sustained
either by negligence or otherwise. Where a seaman is
hired for a voyage, and he deserts it before it is ended,
he shall lose his wages; and in case a ship be lost by a
tempest, or in a storm, the seamen lose their wages,
as well as the owners their freight.

Seaford, a port-town of Sussex, situated on the En-
glish channel, seven miles south of Lewes. It sends two
members to parliament.

Seal, a puncheon, or piece of metal, or other matter,
usually either round or oval, wherein are engraved the
arms, device, &c. of some prince, state, community,
magistrate or private person, often with a legend or sub-
scription, the impression whereof in wax serves to make
acts, instruments, &c. authentic.

Seal is also used for the wax or lead, and the impression
thereon, affixed to the thing sealed.

Seal, in Scots law. See Law, Tit. xii. ey.

Sealer, an officer in chancery appointed by the lord
chancellor or keeper of the great seal to seal the writs
and instrument there made in his presence.

Sealing, in architecture, the fixing a piece of wood or
iron in a wall with plaster, mortar, cement, lead, and
other solid binding. For flapples, hinges and joints, pla-
ster is very proper.

Sealing-wax. See Wax.

Seam or Seme of corn, is a measure of eight bushels.

Seam of glass, the quantity of 120 pound, or 24 tones, each
five pounds weight. The seam of wood is an horse-load.

Sear cloth, or cere-cloth, in surgery, a form of
external remedy somewhat harder than an unguent, yet
fotyer than an emplater, though it is frequently used both
for the one and the other. The fear-cloth is always sup-
poused to have wax in its composition, which distinguishes
and even denominates it. In effect, when a liniment or
unguent has wax enough in it, it does not differ from a
fear-cloth.

Seasin, in a ship, the name of a rope by which the boat
rides by the ship's side when in harbour, &c.

Seasons, in cosmography, certain portions or quarters
of the year, distinguished by the signs which the earth
then enters, or by the meridian altitudes of the sun, con-
sequent on which are different temperatures of the air,
different works in tillage, &c. The year is divided into
four feasons; spring, summer, autumn, and winter. See
Astronomy, p. 546.

St. Sebastian, a port-town of Spain, in the province of
Bicay, and territory of Guipuscoa: situated in W. long.
t° 50', N. lat. 43° 35'.

Secale, Rye, in botany, a genus of the triandria digy-
nia class. The involucrum consists of two leaves, and
contains two flowers. There are four species, only one
of them, viz. the villosum, or wood rye-grass, a native
of Britain. For the cerealia, or common rye cultivated
in our fields, see Agriculture, p. 61.

Secant, in geometry, is a line that cuts another, or di-
vides it into two parts.

Seceder, a sect of Presbyterians, who differed from
the established church of Scotland in the year 1733.
The following circumstance gave rise to this sect. Meff. Erskine,
Wilfon, Moncrieff, and Fisher, ministers of the church
of Scotland, obstinately refused, for several years, to
obey the decisions of the General Assembly with regard to
the settlement of ministers agreeably to the law of patron-
age: For this open contempt of authority, the Assem-
ibly, after many and repeated admonitions, were at last
obliged to eject them from their respective charges. These
four clergymen, when they saw matters carried this
length, immediately complained of persecution; professed
uncommon sanctity and austerity of manners; and cried
out that the church was over-run with various errors,
such as, a compliance with the law of patronage: the
tenderness of the assembly to Professors Simson and Camp-
bell, who were accused of Arian and Arminian heresies;
and a multitude of practical deviations from the cove-
nanted reformation of Scotland: They even inveighed
against the conduct of the government for their ready ad-
mittance of malignant and wicked men into places of truf-
the army and state; for the useless and unlimited restora-
tion of Charles II. to the throne; for the restoration
of prelacy in England, which had been solemnly abjured;
for restoring the superflitious Christmas vespers; for
the repeal of the penal laws against witches, &c. &c. These
things, joined to the popular talents of some of the a-
bove ministers, alarmed the minds of many well-meaning
people, and in a few years procured a numerous train of
followers. Elated with this unexpected success, they
soon split into two parties. The chief point of contest
among the leaders of this sect was concerning the lawful-
ness of what is called the burgess-oath; and hence the
one party have ever since been called Burghers, and the
other Antiburghers. This division naturally weakened
their caufe, and diminished their number, which still
seems to be upon the decline.

Secomiae, in natural history, the name of a genus of
fofis, of the class of the septaria, the characters of
which are; that they are bodies of a dusky hue, divided
by lepta, or partitions of a parry matter, into fewer
or less regular portions, of a moderately firm tex-
ture, not giving fire with steel, but fermenting with acid
menitra, and easily calcining.

The septaria of this genus are, of all others, the most
common, and are what have been known by the little ex-
preffive, or mistaken names of the waxen vein, or Indus
helmontii. We have many species of these bodies com-
mon among us. Of the whitest or browniest kinds we
have thirteen; of the yellowish five; and of the ferrugi-
ous ones, four.

Second, in music, one of the musical intervals; being

Second, in geometry, chronology, &c. the sixieth part
of a prime or minute, whether of a degree, or of an hour.

Second, in music, one of the musical intervals; being

SECONDARY, in general, something that acts as second, or in subordination to another.

SECRETARY, an officer who by his master's orders writes letters, dispatches, and other instruments, which he renders authentic by his signet. Of these there are several kinds: as, 1. Secretaries of state, who are officers that have under their management and direction the most important affairs of the kingdom, and are obliged constantly to attend on the king; they receive and dispatch whatever comes to their hands, either from the crown, the church, the army, private grants, pardons, dispensations, &c. as likewise petitions to the sovereign; which when read, are returned to them; all which they dispatch according to the king's direction. They have authority to commit persons for treason, and other offences against the state, as conservators of the peace at common law, or as justices of the peace throughout the kingdom. They are members of the privy-council, which is seldom or never held without one of them being present: and as to the business corresponding in all parts of this kingdom, it is managed by either of the secretaries without any distinction: but with respect to foreign affairs the business is divided into two provinces, or departments, the southern and the northern, comprehending all the kingdoms and states that have any intercourse with Great Britain; each secretary receiving all letters and addresses from, and making all dispatches to, the several princes and states comprehended in his province. Ireland and the plantations are under the direction of the elder secretary, who has the southern province, which also comprehends France, Italy, Switzerland, Spain, Portugal, and Turkey: the northern province includes the Low Countries, Germany, Denmark, Sweden, Poland, and Muscovy. Each of the secretaries has an apartment in all the royal houses, both for their own accommodation and their officers; they have also a table at the king's charge, or else board-wages. The two secretaries of state have each two under secretaries, and one chief clerk, with an uncertain number of other clerks and translators, all wholly depending on them. To the secretaries of state belong the custody of that seal properly called the signet, and the direction of two other offices, one called the paper-office, and the other the signet-office. 2. Secretary of an embassy, a person attending an ambassador for writing dispatches relating to the negotiation. There is a great difference between the secretary of an embassy, and the ambassador's secretary; the last being a domestic or menial of the ambassador, and the first a servant or minister of the prince. 3. The secretary of war, an officer of the war-office, who has two chief clerks under him, the last of which is the secretary's messenger. There are also secretaries in most of the other offices.

SECTION, in general, denotes a part of a divided thing.

SECRETION, the separation of some fluid from the blood by means of the glands. In the bodies of animals we observe a great number of juices of different natures viz. the blood, lymph, saliva, stomach liquor, intestinal juices, pancreatic juice, bile, urine, &c. and the blood is the general source of all. See Blood, Lymph, Saliva, &c.

SECTOR, in geometry, is a part of a circle comprehended between two radii and the arch; or it is a mixed triangle, formed by two radii and the arch of a circle. Sector is also a mathematical instrument, of great use in finding the proportion between quantities of the same kind, as between lines and lines, surfaces and surfaces, &c. for which reason the French call it the compass of proportion.

The great advantage of the sector above common scale, &c. is, that it is adapted to all radii, and all scales. For, by the line of chords, sines, tangents, &c. on the sector, we have lines of chords, sines, tangents, &c. adapted to any radius between the length and breadth of the sector, when opened.

The sector is founded on the fourth proposition of the sixth book of Euclid, where it is demonstrated, that similar triangles have their homologous sides proportional.

SECULAR, something that is temporal; in which sense the word stands opposed to ecclesiastical: thus we say, secular power, secular jurisdiction, &c.

SECULAR GAMES, ludi seculares, in antiquity, solemn games held among the Romans once in an age. These games lasted three days and as many nights, during which time sacrifices were performed, theatrical shows exhibited, with combats, sports, &c. in the circus. The occasion of these games, according to Valerius Maximus, was to stopt the progress of a plague. The first who had them celebrated at Rome was Valerius Publicola, the first conful created after the expulsion of the kings. The ceremonies to be observed therein were found prescribed in one of the books of the Sibyls. At the time of the celebration of the secular games, heralds were sent throughout all the empire, to intimate that every one might come and see those solemnities which he never yet had seen, nor was ever to see again. Authors are not agreed as to the number of years wherein these games returned, partly because the quantity of the age or seculum among the ancients is not known, and partly on other accounts; some will have it that they were held every hundred years, and that the seculum or age was our century.

SECULARIZATION, the act of converting a regular perfon, place, or benefice, into a secular one.

SECUNDINES, in anatomy, the several coats or membranes wherein the fetus is wrapped up in the mother's womb, as the chorion and amnios, with the placenta, &c. See Midwifery.

SECURIDACA, in botany, a genus of the diadelphia class. The calyx consists of three leaves; the corolla is papilionaceous, with a vexillum; and the pod is oval, and contains one seed. There are two species, both natives of America.

SECUTORES, in antiquity, a kind of gladiators among the Romans, who fought against the retiarii. The secutores were armed with a sword and a buckler, to keep off the net or morsa of their antagonists, and they wore a cape on their head.
SEDAN, a town of Champagne, in France, situated on the river Maas; in E. long. 4° 45', N. lat. 49° 46'.

SEDAN, a city of Upper Hungary, situated on the river Tisza, in E. long. 21° 45', N. lat. 46° 21'.

SEGEDIN, a city of Transylvania, situated E. lon. 24°, N. lat. 47° 25'.

SEGUR, a town of Portugal, in the province of Beira, ten miles north-west of Alcantara. This is also the name of a town in Spain, in the province of Cadiz, and territory of La Mancha, situated among the mountains of Segura; W. long. 2° 50', N. lat. 38° 25'.

SEGURA, a river of Spain, which rising in the north of Cadiz, runs through the province of Segura, and territory of La Mancha, and terminates in the city of Segovia, the largest of the Philippine Islands, situated in E. long. 119°, N. lat. 18° 30'. This is also a name of a city of Spain, in the province of Old Castile, situated W. long. 4° 35', N. lat. 41°.

SEGUES, in the Italian music, is often found before aria, allegro, andante, &c. to show that these portions or parts are to be sung immediately after the last note of that part over which it is written; but if these words a place, or ad libitum, are joined therewith, it signifies that these portions may be sung or not, at pleasure.

SELENDERS, in the manege, are chops, or hairy sores, which are caused by the horse being over-strained in a case of cancer, or from being thrown down from a carriage, or in the act of jumping. These sores are to be taken care of, and if neglected, they will become very offensive. In some cases, they are caused by the horse being thrown down by a fall from a carriage, or in the act of jumping. These sores are to be taken care of, and if neglected, they will become very offensive.

SELENIUM, moonstone, in natural history, a class of plants. The calyx has five segments. The corolla is capillary and there is but one seed. The species are eight, none of them natives of Britain. See Generation, and Agriculture, p. 40.

SELEGAR, a genus of the didynamia angiospermia class of plants. The calyx has five segments; the tube of the corolla is capillary, and there is but one seed. The species are eight, none of them natives of Britain.

SEelic, in botany, a genus of the decandria pentagynia class. The calyx contains five segments, and the corolla of five petals; it has five nectariferous scales at the base of the germen, and five capsules. There are 19 species, nine of them natives of Britain, all orpines and house-leeks.

SEED, in physiology, a substance prepared by nature for the reproduction and conservation of the species both in animals and plants. See Generation, and Agriculture.

SEEDS, in botany, a genus of the didynamia angiospermia class of plants. The calyx has five segments; the tube of the corolla is capillary, and there is but one seed. The species are eight, none of them natives of Britain.

SEEDY, in the brandy trade, a term used by the dealers, to denote a fault that is found in several parcels of French brandy, which renders them unsaleable. The French suppose that these brands are caused by the name by which the brandy is made was pressed. See Seed.

SEEING, the act of perceiving objects by the organ of sight; or it is the sense we have of external objects by means of the eye. See Optics.

SEEING, in the manege. A horse is said to feel when he begins to have white eye browns, that is, when there grows on that part about the breadth of a farthing of white hairs, mixed with those of his natural colour, which is a mark of old age. It is said, that a horse never feels till he is fourteen years old, and always does before he is sixteen years.

SEELED, in the same sense nearly with feeling: when a slip lies down constantly, or steadily on one side, the crane may be seen; and they call it feeling when the rumbles violently and suddenly, by reason of the sea being rough; and they call it feeling when a horse for taking her, as they call it, that is, the weaves leaving her for a time in a bowling sea.
YEAR OF THIS ERA FALLS IN THE YEAR 314 BEFORE CHRIST, BEING TWELVE YEARS AFTER ALEXANDER'S DEATH.

SELLINGENSKOY, A TOWN OF ASIATIC MOSCOVY, IN THE

SELKIRK, A BOROUGH TOWN OF SCOTLAND, IN THE COUNTY OF TWEEDALE, SITUATED 32 MILES SOUTH OF EDINBURGH.

SELENUS, IN BOTANY, A GENUS OF THE PENTANDRIA DIGYNIA CLAS.

SELLATURCICA. SEE ANATOMY, P. 149.

SELZTER WATER, THE NAME OF A MINERAL WATER OF GERMANY, WHICH ARSES NEAR NIDER SEITZ, AND IS NOW USED IN ENGLAND AND MANY OTHER COUNTRIES. WE CALL IT SELTZ, OR SALTZER WATER; AND THE PHYSICIANS PREFER IT IN MANY CASES, AS SWEETISH, EMESIS, AND DIARRHÓE, IN CONTUMPTIONS; IN THE LAST CASE, MIXING IT WITH MILK.

SEMI, A WORD BORROWED FROM THE LATIN, SIGNIFYING HALF.

SEMENDRIA, A TOWN OF EUROPEAN TURKEY, IN THE PROVINCE OF SERVI.

SEMI-CIRCLE, IN GEOMETRY, HALF A CIRCLE, OR THAT FIGURE COMPREHENDED BETWEEN THE DIAMETER OF A CIRCLE AND HALF THE CIRCUMFERENCE.

SEMIELOCCULUS, IN BOTANY, A TERM USED TO EXPRESS THE FLOWERS OF THE SYNGENETIA CLAS.

SEMINARIA, A KIND OF COLLEGE, OR SCHOOL, WHERE YOUTH ARE INSTRUCTED IN THE SCIENCES AND ARTS.

SEMINARY, A KIND OF COLLEGE, OR SCHOOL, WHERE YOUTH ARE INSTRUCTED IN THE SCIENCES AND ARTS.

SEMINARY, A KIND OF COLLEGE, OR SCHOOL, WHERE YOUTH ARE INSTRUCTED IN THE SCIENCES AND ARTS.

SEMITIC, A WORD BORROWED FROM THE LATIN, SIGNIFYING HALF.

SEMIFLORICULUS, IN BOTANY, A TERM USED TO EXPRESS THE FLOWERS OF THE SYNGENETIA CLAS.

SEMIFLORICULUS, IN BOTANY, A TERM USED TO EXPRESS THE FLOWERS OF THE SYNGENETIA CLAS.

SEMIFLORICULUS, IN BOTANY, A TERM USED TO EXPRESS THE FLOWERS OF THE SYNGENETIA CLAS.

SEMPERVIVUM, IN BOTANY, A GENUS OF THE DODECANDRIA CLAS.

SEMINAL, SOMETHING BELONGING TO THE SEMEN OR SEED.

SEMINARY, A KIND OF COLLEGE, OR SCHOOL, WHERE YOUTH ARE INSTRUCTED IN THE SCIENCES AND ARTS.

which falls into the Atlantic ocean, in 16° N. lat., whence the gum-fenega is imported.

SENECAL, a term anciently used for steward or major-domo.

SENS, a town of Champagne, in France, situated on the river Yonne, sixty miles south-east of Paris.

SENSATION, in philosophy, the act of perceiving external objects, by means of the senses.

SENSE, a faculty of the soul, whereby it perceives external objects, by means of the impressions they make on certain organs of the body. These organs of sensation are commonly reckoned five, viz. the eye, whereby we see objects; the ear, which enables us to hear sounds; the nose, by which we receive the ideas of different smells; the palate, by which we judge of tastes; and the cutis, or skin, which enables us to feel the different forms, hardnes, or softnes of bodies. See Anatomy, p. 289, 293, 295, 303; Optics, p. 391; and Pneumatics.

SENSITIVE plant, in botany. See Mimosa.

SENTENCE, in Scots law. See Law, Tit. xxxii, &c.

SENTENCES, a period or set of words, composed of a fparry matter greatly debased by earth, fermenting with acids, and in great part dissolved by them, and calcining in a moderate fire.

SENTENCE, in grammar, a period or set of words, composed of a fparry matter greatly debased by earth, fermenting with acids, and in great part dissolved by them, and calcining in a moderate fire.

SEPULCHRE, a tomb, or place destined for the interment of the dead. This term is chiefly used in speaking of the burying places of the ancients, those of the moderns being usually called tombs. Sepulchres were held sacred and inviolable, and the care taken of them has always been held a religious duty, grounded on the fear of God, and the belief of the soul's immortality. Those who have searched or violated them have been thought odious by all nations, and were always severely punished.

SEPULCHRES, in anatomy, an inclosure, or partition, a term applied to several parts of the body which serve to separate one part from another.

SEPULCHRE, a tomb, or place destined for the interment of the dead. This term is chiefly used in speaking of the burying places of the ancients, those of the moderns being usually called tombs. Sepulchres were held sacred and inviolable, and the care taken of them has always been held a religious duty, grounded on the fear of God, and the belief of the soul's immortality. Those who have searched or violated them have been thought odious by all nations, and were always severely punished.

SEPULCHRE, a tomb, or place destined for the interment of the dead. This term is chiefly used in speaking of the burying places of the ancients, those of the moderns being usually called tombs. Sepulchres were held sacred and inviolable, and the care taken of them has always been held a religious duty, grounded on the fear of God, and the belief of the soul's immortality. Those who have searched or violated them have been thought odious by all nations, and were always severely punished.
into Flanders, by the counts thereof; many also came into England. This order was however suppressed by pope Innocent VIII who gave its revenues and effects to that of our Lady of Bethlehem; which also becoming extinct, they were belittled on the knights of St John of Jerusalem. But the suppression did not take effect in Poland, where they still subsist, as also in several provinces of Germany. These follow the rule of St. Auguf- tine.

**Knights of the holy Sepulchre**, a military order, established in Palestine about the year 1114.

The knights of this order in Flanders chose Philip II, king of Spain, for their master in 1558, and afterwards his son; but the grand master of the order of Malta prevailed on the last to reign; and when afterwards the duke of Nevers assumed the fame quality in France, the fame grand master, by his interest and credit, procured a like renunciation of him, and a confirmation of the union of this order to that of Malta.

**SEQUELS**, in Scots law. See Law, Tit. xvi. 12.

**SEQUESTRATION**, in Scots law. See Law, Tit. xix. 10 and xx. 12.

**SEQUIN**, a gold-coin, struck at Venice, and in several parts of the grand seignior's dominions.

**SERAGLIO**, a Peruvian word, which signifies the palace of a prince or lord; in which the houfes of the ambassadors of England, France, &c. are, at Constantinople, called their seraglios. But the term seraglio is used by way of eminence, for the palace of the grand seignior at Constantinople, where he keeps his court, in which his concubines are lodged, and where the youth are trained up for the principal posts of the empire. It is in form of a triangle, about two miles round, at the end of the promontory Chrysoferos, now called the Seraglio-point; the buildings extend to the top of the hill, and from thence there are gardens that reach to the sea. The outward appearance is not very beautiful, the architecture being irregular, consisting of separate edifices, in the manner of pavilions and domes. The old seraglio is the palace where the grand seignior's old mistresses are kept.

The ladies of the harem, which is the part allotted to the women, is a collection of young beautiful girls, who, on their admission, are committed to the charge of some old lady, and taught music, dancing, and other accomplishments. These frequently play and dance before the grand seignior, while others entertain him with their conversation. Belonged to the ladies, there are a great many black eunuchs, and female slaves, in the seraglio, whose business it is to guard and wait upon them.

**SERAPH, or SERAPHIM**, a spirit of the highest rank in the hierarchy of angels; who are thus called from their being supposed to be most inflamed with divine love, by their nearer and more immediate attendance at the throne of God, and to communicate their fervour to the remotest and inferior orders.

**SERAPHIC**, burning or inflamed with love or zeal, like a seraphim: thus St. Bonaventure is called the seraphic doctor, from his abundant zeal and fervour.

**SERAPIAS**, in botany, a genus of the gynandria diandria class. The nectarium is oval and gibbous, with an oval lip. There are five species, two of them natives of Britain, viz. the latifolia, or broad-leaved bastard hellebore; and the linifolia, or white-flowered bastard hellebore.

**SERENAIDE**, a kind of concert given in the night, by a lover to his mistress, under her window. These sometimes only consist of instrumental music, but at other times voices are added: the music and long composed for these occasions are also called serenades.

**SERENE**, a title of honour given to several princes, and to the principal magistrates of republics. The king of England, the republic and the doge of Venice, and the children of the king of Spain, are called Most Serene: and when the pope, or the sacred college, write to the emperor, to kings, or the doge, they give them no other title: in like manner the emperor gives no other title to any king, except to the king of France.

**SERGE**, a woolen stuff manufactured in a loom, of which there are various kinds, denominated either from their different qualities, or from the places where they are wrought; the most considerable of which is the London serge, which is highly valued abroad, and of which a manufacture has been for some years carried on in France.

**SERGEANT, or SERJEANT at law**, or of the cafes, is the highest degree taken at the common law, as that of doctor is of the civil law; and as these are supposed to be most learned and experienced in the practice of the courts, there is one court appointed for them to plead in by themselves, which is the common-pleas, where the common law of England is most strictly observed; but they are not restrained from pleading in any other court, where the judges, who cannot have that honour till they have taken the degree of serjeant at law, call them brothers.

**SERJEANT at arms**, or mace, an officer appointed to attend the person of the king; to arrest traitors, and such persons of quality as offend; and to attend the lord high steward when sitting in judgment on a traitor.

The number of these officers is by statute limited to that of thirty.

**SERGEANT, in war**, is an inferior officer in a company of foot, or troop of dragoons, armed with a halbard, and appointed to see discipline observed, to teach the soldiers the exercise of their arms, and to order, stricten, and form ranks, files, &c.

**SERICUM**, See Silk.

**SERIES, in general**, denotes a continued succession of things in the same order, and having the same relation or connexion with each other: in this sense we say, a series of emperors, kings, bishops, &c.

**SERIES, in mathematicks**, is a number of terms, whether of numbers or quantities, increasing or decreasing in a given proportion. See Algebra, p. 88.

**SERIPHIUM**, in botany, a genus of the gynandria monogastrina class. The calyx is imbricated; the corolla consists of separate edifices, in the manner of pavilions and domes. There are gardens that reach to the sea. The outward appearance is not very beautiful, the architecture being irregular, consisting of separate edifices, in the manner of pavilions and domes. The old seraglio is the palace where the grand seignior's old mistresses are kept.

The ladies of the harem, which is the part allotted to the women, is a collection of young beautiful girls, who, on their admission, are committed to the charge of some old lady, and taught music, dancing, and other accomplishments. These frequently play and dance before the grand seignior, while others entertain him with their conversation. Belonged to the ladies, there are a great many black eunuchs, and female slaves, in the seraglio, whose business it is to guard and wait upon them.

**SERAPH, or SERAPHIM**, a spirit of the highest rank in the hierarchy of angels; who are thus called from their being supposed to be most inflamed with divine love, by their nearer and more immediate attendance at the throne of God, and to communicate their fervour to the remotest and inferior orders.

**SERAPHIC**, burning or inflamed with love or zeal, like a seraphim: thus St. Bonaventure is called the seraphic doctor, from his abundant zeal and fervour.

**SERAPIAS**, in botany, a genus of the gynandria diandria class. The nectarium is oval and gibbous, with an oval lip. There are five species, two of them natives of Britain, viz. the latifolia, or broad-leaved bastard hellebore; and the linifolia, or white-flowered bastard hellebore.

**Vol. III No 93.**

**SERENAIDE**, a kind of concert given in the night, by a lover to his mistress, under her window. These sometimes only consist of instrumental music, but at other times voices are added: the music and long composed for these occasions are also called serenades.

**SERENE**, a title of honour given to several princes, and to the principal magistrates of republics. The king of England, the republic and the doge of Venice, and the children of the king of Spain, are called Most Serene: and when the pope, or the sacred college, write to the emperor, to kings, or the doge, they give them no other title: in like manner the emperor gives no other title to any king, except to the king of France.

**SERGE**, a woolen stuff manufactured in a loom, of which there are various kinds, denominated either from their different qualities, or from the places where they are wrought; the most considerable of which is the London serge, which is highly valued abroad, and of which a manufacture has been for some years carried on in France.

**SERGEANT, or SERJEANT at law**, or of the cases, is the highest degree taken at the common law, as that of doctor is of the civil law; and as these are supposed to be most learned and experienced in the practice of the courts, there is one court appointed for them to plead in by themselves, which is the common-pleas, where the common law of England is most strictly observed; but they are not restrained from pleading in any other court, where the judges, who cannot have that honour till they have taken the degree of serjeant at law, call them brothers.

**SERJEANT at arms**, or mace, an officer appointed to attend the person of the king; to arrest traitors, and such persons of quality as offend; and to attend the lord high steward when sitting in judgment on a traitor.

The number of these officers is by statute limited to that of thirty.

**SERGEANT, in war**, is an inferior officer in a company of foot, or troop of dragoons, armed with a halbard, and appointed to see discipline observed, to teach the soldiers the exercise of their arms, and to order, stricten, and form ranks, files, &c.

**SERICUM**, See Silk.

**SERIES, in general**, denotes a continued succession of things in the same order, and having the same relation or connexion with each other: in this sense we say, a series of emperors, kings, bishops, &c.

**SERIES, in mathematicks**, is a number of terms, whether of numbers or quantities, increasing or decreasing in a given proportion. See Algebra, p. 88.

**SERIPHIUM**, in botany, a genus of the gynandria monogastrina class. The calyx is imbricated; the corolla consists of separate edifices, in the manner of pavilions and domes. There are gardens that reach to the sea. The outward appearance is not very beautiful, the architecture being irregular, consisting of separate edifices, in the manner of pavilions and domes. The old seraglio is the palace where the grand seignior's old mistresses are kept.

The ladies of the harem, which is the part allotted to the women, is a collection of young beautiful girls, who, on their admission, are committed to the charge of some old lady, and taught music, dancing, and other accomplishments. These frequently play and dance before the grand seignior, while others entertain him with their conversation. Belonged to the ladies, there are a great many black eunuchs, and female slaves, in the seraglio, whose business it is to guard and wait upon them.

**SERAPH, or SERAPHIM**, a spirit of the highest rank in the hierarchy of angels; who are thus called from their being supposed to be most inflamed with divine love, by their nearer and more immediate attendance at the throne of God, and to communicate their fervour to the remotest and inferior orders.

**SERAPHIC**, burning or inflamed with love or zeal, like a seraphim: thus St. Bonaventure is called the seraphic doctor, from his abundant zeal and fervour.

**SERAPIAS**, in botany, a genus of the gynandria diandria class. The nectarium is oval and gibbous, with an oval lip. There are five species, two of them natives of Britain, viz. the latifolia, or broad-leaved bastard hellebore; and the linifolia, or white-flowered bastard hellebore.
The Virginian snake-root obtained its name, as being accounted a specific against venomous bites: but whatever truth there may be in that, it is undoubtedly an excellent diuretic, diaphoretic, and alepharmac medicine, and consequently good in inflammatory and malignant fevers; it is also a powerful antiscptic, and its dose is from four to ten or fifteen grains in powder.

SERPENTARIUS, in astronomy. See Astronomy, p. 487.

SERPENTINE, in general, denotes any thing that resembles a serpent: hence, the worm or pipe of a stick, twisted in a spiral manner, is termed a terpentine worm.

SERRATED, in general, something indented, or notched, in the manner of a saw; a term much used in the description of the leaves of plants.

SERRATULA, in botany, a genus of the genenia polygama class. The calix is somewhat cylindrical, imbriated, and blunt. There are 16 species of them natives of Britain, viz. the tinctoria, or saw-wort; the alpina, or mountain saw-wort; and the arvensis, or corn saw-wort.

SERRATUS, in anatomy, a name given to several muscles, from their resemblance to a saw. See Anatomy, Part II.

SERVANT, a term or relation signifying a person who owes and pays a limited obedience for a certain time, to another in quality of master. See Law, Tit. vii. 34.

SERVIETISTS, a name given to the modern antitrinitarians, from their being supposed to be the followers of Michael Servetus, who, in the year 1599, was burnt at Geneva, together with his books.

SERVIA, a province of European Turkey, bounded by the Save and the Danube, on the north; by Bulgaria, on the east; by Albania and Macedon, on the south; and by Bofnia and Dalmatia, on the west.

SERVICE OF EIRS, in Scots law. See Law, Tit. xxvii. 22, &c.

SERVITES, a religious order in the church of Rome, founded about the year 1233, by seven Florentine merchants, who, with the approbation of the bishop of Florence, renounced the world, and lived together in a religious community on mount Senar, two leagues from that city.

SERVITOR, in the university of Oxford, a student who attends on another for his maintenance and learning.

SERVITUDNE, in Scots law. See Law, Tit. xvi. 1, &c.

SERUM, a thin, transparent, faintish liquor, which makes a considerable part in the mass of blood. See Blood.

SESAMOIDA, in anatomy. See Anatomy, p. 488.

SESAMUM, in botany, a genus of the didynamia angiosperma class. The calyx consists of five segments; the corolla is campanulated, with five segments; the stigma is lanceolated; and the capsule has four cells. There are two species, both natives of India.

The seeds of this plant, upon expression, yield a larger quantity of oil than almost any other known vegetable; among the Indians, they are used for food.

SESELI, in botany, a genus of the pentandria digynia class. The umbel is globular; the involucrum consists of many leaves; and the fruit is oval and frted. There are 13 species, only one of them, viz. the carufolia, or meadow-faxifrage, a native of Britain.
SHADER, in ichthyology. See Clupea.

SEYNE, a river of France, which rising in Montgomeriyshire, runs east till it enters Shropshire; and having passed by Shrewbury turns south, and discharges itself into the Bristol channel.

SEVILLE, a city of Spain, capital of the province of Andalusia, situated on the river Guadalquivir: in W. long. 6°, N. lat. 37° 15'.

SEWERS, in the household, an officer who comes in before the meat of a king or noblemen, to place and range it on the table.

SEWERS is also a passage or gutter made to carry water into the sea or a river, whereby to preserve the land, &c. from inundations and other annoyances.

SEX, something in the body which distinguishes male from female.

SEXAGENARY, something relating to the number sixty; thus sexagenary or sexagefimal arithmetick, is a method of computation proceeding by sixties. See Arithmetick, p. 418.

SEXAGESIMA, the second Sunday before Lent, or the third Sunday after Shrove-Sunday, to be called as being about the sixtieth day before Easter.

SEXAGESIMALS. See Arithmetick, p. 418.

SEXTANS, a sixteenth part of certain things. The Romans having divided their as into twelve ounces, or ases of liquor, or two cyathii.

SEXTILE, the position or aspect of two planets when at sixtieth degrees distance, or at the distance of two signs from one another.

SEXTON, a church-officer, whose business is to take care of the vessels, vestments, &c. belonging to the church, and to attend the minifter, church wardens, &c. at church.

SEXUATE, in music, denotes a mixed sort of triple which is beaten in double time. See Music.

SEXUALISTÆ, among botanical writers, those who have established the classes of plants upon the differences of the sexes and parts of fructification in plants, according to the modern method, as Linnaeus, &c. See Botany, p. 643.

SHAD, in ichthyology. See Clupea.

SHADOW, in optics, a privation or diminution of light, by the interposition of some opaque body; or it is a plane where the light is either altogether obstructed, or greatly weakened, by the interposition of some opaque body between it and the luminary.

SHADOW, in painting, an imitation of a real shadow, effected by gradually heightening and darkening the colours of such figures as by their dispositions cannot receive any direct rays from the luminary that is supposed to enlighten the piece.

SHAFT of a column, in building, is the body thereof between the base and capital: so called from its straightness.

SHAFT, in mining, is the pit or hollow entrance into the mine.

SHAFFTBURY, a borough of Dorsetshire, twenty-five miles north-east of Dorchester; from whence the noble family of Cooper took the title of earl. It sends two members to parliament.

SHAG, in ornithology. See PELICANUS.

SHAGREEN, or CHAGREEN, in commerce, a kind of grained-leather, prepared, as is supposed, of the skin of a species of Squalus, or hound-fish, called the shagree, or shagrain; and much used in covering cases, books, &c.

SHAKLES, in a ship, are the rings with which the ports are shut fast, by lashing the port-bar to them. There also shakles put upon bilbow-bolts, for confining the men who have deserved corporal punishment.

SHAMBLES, among miners, a sort of niches, or landing places, left at such distances in the adits of mines, that the hoestring-men may conveniently throw up the ore from shamble to shamble, till it comes to the top of the mine.

SHAMMY, or CHAMOIS-LEATHER, a kind of leather, dressed either in oil, or tanned; and much esteemed for its softness, pliancy, and being capable of bearing soap without hurt.

The true shammy is prepared of the skin of the chamois-goat. See CAPRA.

SHANK, in the menage, that part of a horse's fore leg which lies between the knee and the fetlock.

SHANKER, or CHANCRE, in medicine. See Medicine, p. 152.

SHANNON, the largest river in Ireland, which rising in the county of Leitrim, runs southwards, dividing the provinces of Leinster and Connaught; and then turning southerly, runs through the province of Munster; and passing by the city of Limeric, afterwards falls into the western or Atlantic ocean.

SHARE of a plough, that part which cuts the ground, the extremity forwards being covered with a sharp-pointed iron, called the point of the share; and the end of the wood behind, the tail of the share. See Agriculture, p. 54.

SHASTER, or Shastram, a sacred book, containing the religion of the Banians: it consists of three parts; the first of which contains their moral law; the second, the ceremonial; and the third delivers the peculiar observances for each tribe of Indians.

SHEAT, in a ship, are ropes bent to the clews of the

SHEETS, in a ship, are ropes bent to the clews of the

SHEATHING, in the seaman's language, is the casing that part of a plough, that part which cuts the ground, the extremity forwards being covered with a sharp-pointed iron, called the point of the share; and the end of the wood behind, the tail of the share. See Agriculture, p. 54.

SHEATH OF A PLUGH, a part falling through the beam, and 'fastened to the share. See Agriculture, p. 54.

SHEATING, in the seaman's language, is the casing that part of a ship which is to be under water, with fir board of an inch thick; first laying hair and tar, mixed together, under the boards, and then nailing them on, in order to prevent worms from eating the ship's bottom.

SHEATS, in a ship, are ropes bent to the clews of the

SHIELDS, a port-town of the bishopric of Durham, first-
SHIELRDIA, in botany, a genus of plants belonging
SHIELD, in heraldry, the escutcheon or field on which the
Sheriff in Scots law. See Law, Tit. iv. 1.
SHEW-BREAD, among the Hebrews, the name given
to those loaves of bread which the priests placed every
Shetland, or Zetland, where they are produced.
As to the formation of a shell, it is now generally al-
lowed to be formed by a viscous fluid composed of glue,
and several sandy particles of an exquisite fineness, which
are transmitted through an infinite number of little chan-
nels to the pores where it transpires, condenses, and
hardens. When the animal increases in bulk, and the
body of animals, and not from the shell, as some have
imagined.
SHELLS, those found buried at great depths in earth,
and often imbedded in the hardest stones. These felle
shells, as well as those found lying on the sea-shore,
make an excellent manure, especially for cold clayey
lands; upon which it does not produce nearly so great
an effect for the two first years, as it does in the succe-
eding ones; the reason of which is, that it is not then
sufficiently mixed, but in succeeding time it breaks itself
into a number of very small particles, and these all be-
come intimately blended with the molecules of earth,
and produce their effect more properly.
SHELTER, a small but strong kind of horse, so called from
Shetland, or Zetland, where they are produced.
SHEPPY, an island at the mouth of the river Medway,
making part of the county of Kent.
SHERARDIA, in botany, a genus of plants belonging
to the tetrandra monogynia class. The corolla consists
of one funnel-shaped petal; and there are two seeds hav-
ing three teeth. The species are three, only one of
them, viz. the arvensis, or little field-madder, a native
or Britain.
SHERBORN, a market-town, twelve miles south-west of
York.
SHERBRO, a fort at the mouth of the river Sherbro, in
Guinea, formerly in the possession of the English.
SHERENESS, a fort on the north-west part of the isle of
Sheppey, situated at the mouth of the river Medway, to
defend its entrance.
SHERIFF, an officer in each county of England, nomi-
nated by the king, invested with a judicial and ministerial
power, and who takes place of every nobleman in the
county during the time of his office.
SHERIFF in Scots law. See Law, Tit. iv. 1.
SHEW-BREAD, among the Hebrews, the name given
to those loaves of bread which the priests placed every
SHEEP, in zoology. See Ovis.
SHEERING, in the sea-language. When a ship is not flea-
ered hastily, they say the sheers, or go sheering; or
when at anchor they go in and out, by means of the
current of the tide, they also say the sheers.
SHEFFIELD, a market-town of Yorkshire, 38 miles
south-west of York.
SHEFFORD, a market-town of Bedfordshire, seven miles
south-west of Bedford.
SHEFFNEL, a market-town of Shropshire, fourteen miles
east of Shrewbury.
SHEIK, an officer in the mosques of Egypt, whose busi-
ness is the same with that of the imans of Constantinople.
SHEIK-BELLET, in the Turkish affairs, a magistrate, an-
twering to the mayor of a city with us.
SHELDs, a port-town of the bishopric of Durham, situ-
ated at the mouth of the river Tyne, eight miles east of
Newcastle.
SHEKEL, in Jewish antiquity, an ancient coin, worth 2 s.
and 3d. sterling.
SHILL, among miners, the same with what they other-
wise call fall ground, or fall country; being that part of
the internal structure of the earth, which they find lying
even; and in an orderly manner, and evidently having
retained its primitive form and situation.
SHELL, in natural history, a hard, and as it were ftony
covering, with which certain animals are defended, and
thence called shell-fish.
As to the formation of a shell, it is now generally al-
lowed to be formed by a viscous fluid composed of glue,
and several sandy particles of an exquisite fineness, which
are transmitted through an infinite number of little chan-
nels to the pores where it transpires, condenses, and
hardens. When the animal increases in bulk, and the
body of animals, and not from the shell, as some have
imagined.

Preventer
Thus we have pointed out the external parts, masts, yards, and pendants in Plate CXLIX. In Plate CXLIX. is represented the sections of a first-rate ship of war, shewing the inside thereof: where A is the head; containing, 1, The stem. 2, The knee of the head, or cut water. 3, The lower and upper keel. 4, The after deck. 5, The figure. 6, The gratings. 7, The brackets. 8, The false stem. 9, The breast-hooks. 10, The haufd hole. 11, The bulk head, forward. 12, The cat-head. 13, The catbook. 14, Necessaries, seats. 15, The manger within board. 16, The bowsprit. 17, The forecastle. 18, The partners of the forecastle. 19, The gun wells. 20, The belfry. 21, The funnel for the smoke. 22, The gangway going off the forecastle. 23, The forecastle guns.

In the forecastle, 24, The door of the bulk head, forward. 25, The officers cabins. 26, The stait-cake. 27, The fore top sail sheet bits. 28, The beams. 29, The car lines.

D, The middle gun-deck forward. 30, The fore-jeer bits. 31, The oven and furnace of copper. 32, The captain's cook-room. 33, The ladder, or way up into the forecastle.

E, The lower gun-deck forward. 34, The knots fore and aft. 35, The sprikettins, or the first streak next to each deck; the next under the beams being called clamps. 36, The beams of the middle gun-deck, fore and aft. 37, The car-lines of the middle gun-deck, fore and aft. 38, The fore bits. 39, The after, or main bits. 40, The hatchway to the gunner's and boat-swan's fore-rooms. 41, The jeer capstan.

I, The orlop a midships. 63, The cable tire. 64, The main hatchway.

K, The lower gun-deck a midships. 65, The ladder leading up to the middle gun-deck. 66, The lower tire or ports.

L, The middle gun-deck a midships. 67, The middle tire ports. 68, The entering port. 69, The main jeer bits. 70, Twisted pillars or slantons. 71, The capstan. 72, The gratings. 73, The ladder leading to the upper deck.

N, Abaft the main mast. 84, The gang-way off the quarter-deck. 85, The bulkhead of the coach. 86, The stair-case down to the middle gun-deck. 87, The beams.
of the upper deck. 88. The gratings about the main-
mast. 89. The coach, or council-chamber. 90. The
stair-case up to the quarter-deck.
O, The quarter-deck. 91. The beams. 92. The car-
lines. 93. The partners of the mizen mast. 94. The
gangway up to the poop. 95. The bulk-head of the cuddy.
P, The poop. 96. The trumpeter's cabin. 97. The
taffarel.
Q, The captain-lieutenant's cabin.
R, The cuddy, usually divided for the master and se-
cretary's officers.
S, The state-room, out of which is made the bed-chamber,
and other conveniences for the commander in chief.
98, The entrance into the gallery. 99, The bulk-head of the
great cabin. 100. The stern-lights and after galleries.
T, The ward-room, allotted for the lieutenants and
land-officers. 101, The lower gallery. 102. The steer-
age and bulk head of the ward-room. 103, The whip-
staff, commanding the tiller. 104, The after-stair-case
down to the lower gun-deck.
V, Several officers cabins abaft the main-mast, where
the soldiers generally keep guard.
W, The gun-room. 105. The tiller commanding the rudder. 106.
The rudder. 107. The stern-post. 108. The
tiller-tranfom. 109. The several tranfoms, viz.
1, 2, 3, 4, 5. 110. The gun-room ports, or stern chafe.
111, The bread-room scuttle, out of the gun-room. 112.
The main capton. 112. The main capton. 113. The
pall of the capton. 114. The partner. 115, The bulk-
head of the bread room.
X, The bread-room. Y, The steward's room, where all
provisions are weighed and served out. Z, The cock-pit,
where are subdivisions for the purfer, the surgeon, and
his mates.
A A, The platform, or orlop, where provision is made
for the wounded in time of service. 116. The hold abaft
the main-mast. 117. The step of the mizen mast. 118.
The keelson, or false keelson. 119. The dead-wood, or ri-
fing.

Different kinds of Ships. All ships at first were of the same
form, whatever uses they were designed for; but the
various ends of navigation, some of which were bet-
ter answered by one form, some by another, soon gave
place to the many varieties of ships. 1. The bilander, (Plate CXLIX, fig. 2.) which has
rigging and sails not unlike a hoy, only broader and
flatter; bilanders are seldom above twenty-four tons, and
can lie nearer the wind than a vessel with cross-sails can
do. 2. Bomb-veeffels, (ibid. fig. 3.) have sometimes
three masts, and square sails, as represented; but they
are also frequently ketch-fashion, with one mast and a
design. 3. Brigantines (ibid. fig. 4.) are vessels made ufe of for laying down or
felling the masts fixed on its deck, for fetting ships mads. 7. Ketches (ibid fig. 8.) are fitted with two mads; and their main-
mast and top-sail stand square as those of ships do, but
their fore-sail and jibbs as those of hoy's do. 8. Lighters
(ibid. fig. 9.) are veffels made ufe of for laying down or
shifting the masts, for bringing ahore or carrying on
board ships cables, anchors, &c. 9. Pinks (ibid. fig. 10.)
fail with three masts, ship-fashion; but are round sterned, with a small projection above the rudder. 10. Punts (ibid. fig. 11.) are built square, and used about the docks for fetching clay and other ferrices as the master shipwright wants them for. 11. Shallop (ibid. fig. 12.) is a small light vessel, with only a small main and fore mast, and lug sails, to haul up and let down on occasion. 12. Sloops (ibid. fig. 13.) have only one mast, with shoulder of motion, square, lug, and smack sails. 13. Smacks (ibid. fig. 14.) are transporting vessels, with one mast, and an half sprit-sail. 14. Yachts (ibid. fig. 15.) have only one mast, with an half sprit or smack sail, and sometimes ketch-fashion.

The most celebrated ships of antiquity are those of Ptolemy Philopater. One was 280 cubits long, 38 broad, and 48 high, each cubit being 1 English foot 5½ inches, and carried 400 rowers, 400 sailors and 3000 soldiers. Another which the same prince made to sail on the Nile, we are told, was half a stadium long. Yet these were nothing in comparison with Hiero’s ship, built under the direction of Archimedes; on the structure whereof Mohsen wrote a whole volume. There was wood enough employed in it to make 50 galleys: it had all the variety of apartments of a palace; such as banqueting-rooms, galleries, gardens, inlaid ponds, stables, mills, baths, and a temple to Venus. It was encompassed with an iron rampart, eight towers, with walls and bulwarks, furnished with machines of war; particularly one, which threw a stone of 300 pounds, or a dart 12 cubits long, the space of half a mile, with many other particulars related by Athenagoras.

Construction of Ships. Naval architecture may be divided into three principal parts: 1. To give the ship such a figure and proportion as may suit the service she is designed for. 2. To find the true form of all the pieces of timber that shall be necessary to compose such a solid. 3. To make proper accommodations for guns, ammunition, provisions, and apartments for all the officers, and likewise room for the cargo.

As to the first part, the length of the keel, greatest breadth, depth in the hold, height between decks and in the wale, and sometimes the height and breadth of the wing-transom, in ships for the merchants service, are agreed on by contract; and from these dimensions the builder forms a draught suitable to the trade the ship is designed for. The first thing that is generally done, is to lay down the keel, the stem, and stern-post, upon the centre-plane, or plane supposed to pass through the middle line of the keel, stem, and stern-post, cutting the ship in two halves lengthwise. They next determine the proper height of the midship timber, where a perpendicular is erected, and is generally about two thirds of the keel, before the stern-post; on this line the given depth of the hold is let off, from the upper side of the keel; to obtain which point, the thickness of all the timber and plank must be added to the height agreed on. This being fixed, will enable us to determine the upper-height of the extreme or greatest breadth of the ship; which, sometimes, is that very point; and from the same place the lower height of the breadth must be determined. The two main heights of the breadth-lines, which nearly unite above and below, are next determined. The height of the breadth-line of the top timber is next formed; being limited in the midship by contract, but above and below only by the judgment and fancy of the artist. If a square stern is designed, the breadth at the wing-transom is limited, being generally about two thirds of the greatest breadth. The artist next fixes the breadth of the top-timber, and then describes the two half-breadth lines. After these are formed the places where the several timbers are fixed; and for forming the midship-frame, radii are affumed at pleasure, till the sweeps are made to please the fancy and judgment of the artist. When this midship-frame is formed, a pattern or mould is made to fit exactly to the curve, and the dead-rising, or water-line; and by this and a hollow mould, all the timbers are formed, as far as the rising line, which is parallel to the lower height of the breadth-line.

We come next to consider the upper-works, or all that is above water, called the dead-work; and here the ship must be narrower, by which means the will strain less by working the guns, and the main-fall will be easier trimmed, as the shrouds spread less than they would otherwise do. But though these advantages are gained by narrowing a ship above water, yet great care must be taken not to narrow her too much, lest there should not be sufficient room upon the upper deck for the guns to recoil. The security of the masts should likewise be considered, which require sufficient breadth to spread the shrouds: though this may be ascertained by enlarging the breadth of the channels.

Principal qualities belonging to Ships. A ship of war should carry her lower tier of guns four or five feet above water; a ship for the merchants service should flow the cargo well; and both of them should be made to go well, carry a good sail, steer well, and lie-to easily in the sea.

1. To make a ship carry a good sail, Mr Du Hamel recommends a flat floor-timber, and somewhat long, or the lower futtock pretty round; also a straight upper futtock, and the top timber to throw the breadth out aloof; and at any rate, to carry her main-deck as high as the lower-deck; for if the rigging be well adapted to such a body, and the upper-works heightened as much as possible so as all to concur to lower the centre of gravity, there will be no room to doubt of her carrying a good sail. 2. To make a ship steer well, and answer the least motion of the helm, the fashion-pieces should be well formed, the tuck carried pretty high, and the midship-frame carried pretty forward; also there should be a considerable greater draught of water abaft than afore, a great rake forward, and none abaft, and a snug quarter-deck and fore-castle: all these will make a ship steer well. 3. To make a ship carry her guns well out of the water, is effected by a long floor-timber, and not of great rising, a very full midship-frame, and low tuck, with light upper-works. 4. To make a ship go smoothly through the water, without pitching hard, her keel should be long, her floor long and not rising high afore or aft; the area or space contained in the fore-body should also be duly proportioned to that of the after-body, according to the respective weights they are to carry. 5. To make a ship keep a good wind, she should have a good length by the keel, not too broad, but pretty deep in the hold; which will make her floor-timber.
timber short, and rising great. As such a ship will meet with great resistance in the water going over the broad side, and but little when going a-head, it will not fall much to the leeward. Now some ship-builders imagine, that it is impollible to make a ship carry her guns well, carry a good sail, and be a prime sailor at the same time; because it requires a very full bottom to gain the two first qualities; and a sharp-bottomed ship will answer the latter; but when it is considered, that a full ship will carry a great deal more sail than a sharp one, a good artist may so form the body as to have all these three good qualities united, and likewise steer well; for which purpose, Mr Du Hamel recommends somewhat more in length than has been commonly practiced.

SHIPTON, a market-town, twenty-four miles south-east of Worcester.

SHIRE, in geography, signifies the same as county; being originally derived from a Saxon word which signifies to divide.

SHIVERS, in the sea language, names given to the little rollers or round wheels of pulleys.

SHORT-HAND WRITING.

AS STENOGRAPHY, or the Art of Short-hand writing, when well understood, and rendered familiar by practice, is attended with many valuable consequences, we shall, without attempting to enumerate the infinite variety of systems that have been published, furnish our readers with that system which appears to be the most easy, beautiful, and expeditious, and at the same time calculated for general use.

PART I.

THE Alphabet being the foundation upon which the perfection of the art depends, great care must be taken to establish it in the best manner. All the simple sounds must be represented by the shortest marks possible. We must, therefore, not only reject the complex marks established by custom in our common alphabet, but also those letters themselves whose sounds may always be signified by others; and simple marks must be provided for such simple sounds as are by custom represented by two letters a-piece: for which reason, it is necessary to examine the alphabet, and to fix the number of characters, before we proceed to investigate the marks which are to represent them. First, then, let us consider what number of consonants may be requisite. We shall afterwards treat of the vowels, which are to be represented by points or dots.

The consonants, according to our usual reckoning, are, b, c, d, f, g, h, j, k, l, m, n, o, p, q, r, s, t, v, w, x, y, z. But custom differs from nature in inferring the letters c, g, w, x, y, and in omitting sh, zh, th, dh, ch: for c having always either the sound of k or s, q that of koo, w of oo, x of ks, and y of i; in an alphabet according to nature none of these could have found a place: and sh, zh, th, dh, ch, representing single consonantal sounds as much as ph does, whose power is that of f, ought all to have been denoted by single characters, as most of them are in the alphabets of other languages.

The natural alphabet, therefore, might have been taken for our short-hand one, rejecting the superfluous letters e, q, w, x, y, and inferting in their stead sh, zh, th, dh, ch: but having some marks that were not conveniently applicable to any other purpose, and it being a compendium to represent two letters by a single character, as in the q and x, and some ease to the reader to retain at the beginning of words the w and y, to which he has been long accustomed; we shall, totally rejecting the c, appropriate distinct marks to denote q, x, w, y, when they are initial letters; not scrupling however, in other situations, if it prove more convenient, to denote them by k, ks, wo and h, respectively.

Zh never had any particular mark to signify it by; and custom has, for a long period of time, ceased to make any distinction in writing between the th and dh: and as the adherence to nature in making nice distinctions, where custom has not, would be so far, in this case, from serving any valuable purpose of short-hand, that it would rather, on the contrary, render the learning to write and read it more difficult, we have, in pursuance of our plan, complied with custom in dropping the zh, and marking the sounds both of th and dh by the same character.

S and z bear the same relation to each other, that the wh and ab do; and the sound of z in our customary way of writing is very frequently expressed by s, except in cases when it occurs at the beginning of words, which happen but very seldom. These considerations induce us to secure the great convenience which arises from signifying both s and.
and z by one mark. And, for a like reason, we shall make one mark representative both of f and v. The idea of the place will easily discover, to a man tolerably acquainted with English, which of the two it must there represent; and the reader will be taught, when the characters are appropriated to the consonants, that, in most cases, entirely to remove any little ambiguity that possibly might arise from it. Our alphabet will then consist of the following consonants, viz. b, d, ʃ, v, g, b, j, k, l, m, n, p, q, r, s, t, w, x, y, ch, sh, th.

The number of our consonants being thus settled, and the reasons for fixing upon that number being given; the next business must be, to invent as many simple marks, easy to be made and distinguished from each other, as are necessarily required to represent them. They must be simple, if brevity be consulted; and they must be easily distinguishable from each other, to avoid the confusion arising from mistaking one letter for another.

Nature affords us four straight lines, sufficiently distinguishable from each other, by their horizontal, perpendicular, and inclined position, to execute our design by; (see Plate C.L. No. 1.) but it affords only these four. In this scarcity of straight lines, recourse must be had to curved ones for a further supply. The four straight lines being in the following manner, that is to say, the horizontal upwards and downwards, the perpendicular and inclined ones to the right and left, will each of them furnish two more very good short-hand marks; ibid. No. 2.

The number of marks thus increased still falls short of supplying our wants. The best expedient to remedy this defect, is the addition of a little twirl to the beginning of as many of the foregoing marks as there will be occasion for. It is easily and quickly made, when the marks are formed separately; and the twirled marks are joined to preceding ones in as little time as the plain ones. No. 3, 4.

A sufficient number of proper marks being thus obtained, it remains that each of them be appropriated to the particular consonant which it is to represent. Easy as this may seem, it is, however, a point of the greatest nicety; and demands, not only the most careful consideration, but also the most laborious application to continual trials and alterations. A short-hand alphabet may have all its characters simple, easy, and distinguishable, when separately formed; and yet not be a perfect one. To merit that title, it is further requisite, that they be so contrived and adjusted, that all the consonants occurring in any word may be easily, beautifully, and interlineally joined together, betwixt two given parallel lines, without taking off the pen. Experience has taught quick writers even of long-hand, that the joining all the letters of a word together contributes much to dispatch, though they are obliged to make little additional strokes for that purpose.

Let us then consider, to what particular consonant each of our marks is to be appropriated; and begin with the four straight lines.

The first of these lines, viz. the horizontal, as it goes straight forwards, can never exceed the limits of the given parallels, whatever part it begins from; and therefore, in a short-hand formed for lineal beauty, it must be appropriated to that consonant, which, of all others: occurs the oft, and challenges, of right, the most commodious character for beauty and dispatch. Now the consonant that occurs the most frequently in our language (and perhaps in most others) is the r; which has a property, peculiar to itself, of mixing with other consonants before or after it, without the intervention of a vowel. The plural number of most of our substantives, and the third person singular of our verbs, are formed by it; which must occasion the most frequent repetition of it; so that, being undoubtedly the commonest of all our consonants, it must of necessity be denoted by the horizontal straight line.

The second straight line, or perpendicular, is also a very easy mark, and, separately made, even preferable to the other; but as, in union with others, it may endanger our defribing below the line, it must therefore be allotted to a common consonant, and one also that will the least occasion us to run that hazard. Now the s has, in fact, these and other properties that entitle it to this perpendicular straight line.

The third straight line, by its peculiar inclination, is adapted to a very easy and convenient joining with other characters; because our customary method of inclining the letters, in common writing, teaches us to form it with equal readiness upwards or downwards, as the keeping the previous or following marks within the prescribed parallels shall require. The consonant, therefore, that claims this character, is the t, which makes so many of our double consonants (as we call them) and admits any other single one to follow it immediately. The straight line then which slopes downwards to the left, is r.

The last line of the four straight ones, by its direction or slope to the right, is awkward to make (and therefore never is made) upwards, like the foregoing, to which it unites the most readily. Its properties, upon trial, fix it with the occurrence of the consonants f or v.

The twirl being formed to the left hand in these four marks, (No. 5.) disqualifies them from an easy junction with any preceding consonant. They must then, for that reason, be allotted to such consonants as occur the seldomst in the middle or at the end of words, or to such as may be otherwise signified when they do occur in such situations. Now the h, or j, are rarely to be met with in the middle of words, unless immediately preceded by some preposition, as inhamb, reject, etc. In which case, the reader will be taught hereafter how to write them; and when x and y are not at the beginning of words, they may be expressed by ks, and the dot for the vowel ſ respectively.

The properties of these four letters agreeing well with those of the four marks, luckily point out a use for four easy characters, which could not however have been conveniently allotted to any other consonants; and the following appropriation of them, upon trial, is found to be the most commodious, viz. the first for h, the second for j, the third for x, and the fourth for y.

K is a very common consonant; and the frequency of its occurrence will be much increased by its being made so often representative of the rejected c, and ks of x: a character, therefore, which is not only easy to be made, but which will also join readily with all the rest, without running either above or below the line, must be appropriated to it. The horizontal straight line, with the additional twirl, will, for these reasons, be the most commodious. But as the distinguishing the k and q, at the beginning of words especially, will, in some degree, facilitate the reading; the horizontal straight line with the twirl above is made for k, with the twirl below for q, when they are initial letters.
In all other cafes, there are two marks are used promiscuously for & or g, whenever a more easy, beautiful junction may by that means be obtained; the one joining evidently much better with the characters which are written upwards, the other with those downwards.

But to give a detail of all the reasons for the appropriation of each particular mark to each consonant, would prove tedious. Most of them cannot escape the observation of an attentive practiser as he goes along. It will, therefore, be sufficient to assure the reader, that no pains was prove tedious. Most of them cannot escape the observation of each particular mark to each consonant, would

better with the characters which are written upwards, the other with those downwards.

Two marks are allotted to b; (see Table of the Alphabet, Plate CL.) The first of these marks is the bell when separate, or not well with the / or r. For familiar reasons, some other of the consonants have more than one mark allotted to them.

One or other of the two marks appointed for w is always to be used when it is an initial letter; in other situations we scruple not to express it by a dot in the o or ou place, writing pour for power; especially if it joins not well with the preceding consonant, or no great ambiguity arises thereby.

The marks being thus adjusted to the particular consonants which they are to represent, let us see how any peculiar arrangement, or subjoined, or intermediate vowel may be affixed to any of these consonants, as occasion shall require.

In separate letters there is no difficulty, there being five distinguishable places for any given vowel or point, either preceding or following the consonant: reckoning, therefore, the vowels a, e, i, o, u, according to the established numbers and sequence, a is to be placed at the beginning of the consonant, e at the end of the first quarter, i at the end of the second quarter, that is, the middle, o at the end of the third quarter, and u at the end of the consonant itself.

In the perpendicular and inclined letters, the vowels which precede are placed upon the left hand; those which follow, upon the right; because we write from left to right; and, for example, at, et, it, ot, ut; sa, te, ti, to, tu. No. 6.

In the horizontal letters, the vowels which precede are placed above; those which follow, below; because we write from top to bottom; as, at, et, it, os, ut; sa, te, ti, to, tu. No. 7.

In the semicircular letters, the vowels a, e, o, u, are placed upon the left hand, the i above when they precede, and the contrary when they follow, agreeably to the two foregoing remarks; as, am, em, im, om, um; ma, me, mi, mo, mu. No. 8.

A vowel between two consonants may be referred to either, and therefore seems to have two places; but in letters which form an angle when joined, this is the case of i only; for a and e can only be placed immediately after the first consonant, o and u only before the last; left a and e, if placed before the last, should, in the narrow part of the angle, be confounded with u and o after the first; as, rat, ret, rit, rot, rut. No. 9.

This twofold place of i may be of use in distinguishing, when thought necessary, the short i from the long one, by making it short when placed immediately after the first consonant, long when before the second; as quit, quits.

The great difficulty of learning the true pronunciation of our language, occasioned chiefly by our perplexed, various, and confused way of spelling, has been always matter of much complaint with all foreigners who have attempted to learn it. But this absurd irregularity is by far the most remarkable, in the customary management, or rather mismanagement of the vowels. It is hardly possible to give a rule for them, against which the exceptions will not be almost as numerous as the agreeing inftances. How frequently do we put two, nay sometimes three vowels, to express the sound of one only? What, for example, has the e and a to do in the word beauty? The short-hand writer, however, is not embarrassed with any of these difficulties. He, totally disregarding the common way of spelling, is to insert only such letters as are pronounced; and must consequently write the word beauty thus: buty. But the insertion of more vowels than are necessary to the sound is not the only instance of irregularity to be met with;—there being more than five vowel sounds in our language; and custom, having allotted only five letters to signify them all by, often makes one vowel express two or three different ones. nay, even diphthongs or combinations of vowels. We therefore, taking the advantage which custom in this case affords us, shall extend the power of our dots or points to the same degree: The fairness and propriety of doing this will more fully appear upon a particular examination of all the vowels in their order.

And firft, in common writing, the letter a has three powers, viz. that of a, of ai or ay, and of au or aw; as in the words father, false, fall, or amen, able, altar; which are pronounced all one as if they had been written father, false, fal, or amen, able, altar: so that we are fairly authorized to extend the power of our vowel or point to the same degree in all other inftances.

The vowel e sometimes expresses singly the sound that two of them are often made for, as, he, me, we; where its sound is the same as that of two e's, as in see, tree, agree, &c. We are therefore free to use one e in this case, whenever it suits our purpose, as well as for ea, ey, ei, eo; for of what use is the latter of these vowels in pea, press, beijer, people, but to puzzle children and foreigners?

The same irregularity and confusion is observable in the customary management of the other vowels, i, o, and u; they each of them singly expressing different sounds, which altogether are denoted at other times by several different combinations of them. The vowel i, for instance, when it is short, is founded in English as ee, agreeable to the pronunciation of it in most foreign languages; when long, it has always the sound of a diphthong, or combination of the two vowel-sounds, (which we might express by the open a or au, and the short i or ee;) which found or diphthong is also sometimes expressed by ei, as fill, file, fail, fin, join.

In like manner, the vowel o has several different founds; as in the words pol, pole, do: the founds of the o in pole, is sometimes expressed by ow, as to poor; sometimes by ou, asoward; sometimes by oo, as solid; its found in do, by oo, ough, as too, two, through.

And lastly, the found of u (which is always really a diph-
thong, expreflible by the combination of the two vowel sounds ee and oo) is denoted in a great variety of ways in our common spelling, viz. by u, oe, eu, iu, iu, ugh, eu, you; as in the words tune, due, few, adieu, view, ugh, beauty, you. We are therefore certainly at liberty to represent all these by a point, in the place of the vowel u; and thus not only all the single vowels, but all the combinations of them, are expreflible by the shorteft and eafilfst of all marks, viz. a dot in the place of the vowel of nearest sound.

We will now proceed to examine what further use we can make of these marks for the purpofes of short-hand. And as numeral figures exhibit to us a kind of short-hand with which every one is acquainted, an allusion to them will perhaps explain what we have to say hereupon.

Obferve, then, the figures by which the words or numbers, one, five, four, fix, are expreffed in the Roman characters, which are likewise fome of thofe which we make ufe of: I, V, IV, VI. Here we fee the figure I is confidered in three different situations, as flanding by itfelf, clofe before, and clofe after another figure: and has accordingly three different powers, of numeration, infubraction, and addition. When it flands by itfelf, its name and power is one; when it is clofe to, or belongs to another figure, it lofes its name, yet retains fomething relative to its power, by leffening or increafing that other figure by one; and has accordingly three different situations, as flanding by itfelf, flanding before another figure, and clofe after another figure: and has accordingly three different powers, viz. as flanding by itfelf, as flanding before another figure, and as flanding after another figure.

All the reft of the confonants are to be confidered in the fame threefold light, viz. as flanding by itfelf, as flanding by themselves, as flanded before other marks; and muft, accordingly, have a power of denoting fome common word, preposition, or termination, in which that confonant is found.

This is the general rule; but in practice there are few prepositions and terminations neceffary or ufeful beftides thofe feft down in the alphabetical table. This rule is very convenient in fome cafes; as where the confonants of which the word is compos'd join not well together, or cannot be kept within the parallels; for inftance, in behold, inhabit, deposit, N° 13. and affords a great contrivance in others, as underwritten, diflfuion, direction, N° 14. But here it is to be obferved, that, in placing the termination, regard-
is to be had to the vowel's place with respect to the line, and not to its place after the last consonant, (except that happens to be one or other of the three horizontal characters s, k, or q), as in the above word direction: the s is drawn from the o's place in the line, but it is in the o's place with respect to the last consonant r, which appears evidently to have begun at the bottom of the line. But when s, k, or q, immediately precede the termination, regard is then to be had to the vowel's place after the letter: as assumption affection. (N° 15. first and second examples.) The plural number of the termination is denoted by adding a little s; as  : ... definations, (ibid. third and fourth examples)

Before the learner begins to write by the preceding alphabet, it may not be improper to premise a few observations upon the form and respective proportions of the letters, and the ways of joining the curved ones with the most cafe and elegance.

First, All the perpendicular and inclined letters (that is, all the letters except s, k, q, m, n, cb, and g,) are made to touch two parallel lines, the distance of which is measured by the perpendicular straight line t, as in N° 16.; but, however, these letters are sometimes, for greater convenience, made of half-size, and two of them included between the parallels, as in the seventh and eighth examples, N° 16.

The letters m, n, cb, and g, are semicircles; the diameter of which is the t, and their radius or height is rather more than one third part of the t.

The letters formed from the three straight lines t, r, and f, are segments of larger circles, whose chords are the letters t, r, and f, respectively.

It must be observed, however, that it is not necessary, nor indeed scarce possible, that these proportions should be exactly kept, especially in quick writing; but they are given here, because the nearer they are kept to, the more beautiful the writing appears.

Secondly, When m and n are joined together, they are not each of them to be made complete; but a part is to be cut off from each of them; and in the same manner the inclined letters, when joined with m or n, are not made complete, but, running into one another, lose each a part, as N° 17. So the rest of the curve line letters, when joined together, are made to run into one another smoothly; avoiding, by this means, that slopping of the pen which the making of any angle necessarily occasions; so as for instance mp is not written, as in the first example N° 18.; but as in the second, part of the curved line being in common both to the m and p.

Thirdly, The twirl is always made at the beginning, never at the end of any letter; whenever, therefore, the six last characters (N° 18.) occur, they must be supposed to have been begun from the bottom of the line.—The general rule is, That all perpendicular and inclined letters are to be begun from the top, and drawn downwards; but in all instances, in which the inclined letters (N° 19.) will join better with the preceding or following marks if drawn upwards, they must be drawn in that direction, as in these words, N° 20.

Fourthly, The initial or final vowels (the e mute excepted) are generally expressed, and the middle ones omitted, except in cases where there are many words confounding the name consonants which might be liable to be taken for one another. But all words which have one consonant only (except those in the table of the alphabet, which are expressed by the letter alone) must always have the proper vowel point expressed, as by, to, &c. because these little words are, as it were, the keys of the sentences in which they are found.

Fifthly, Few monosyllables beginning with a vowel are immediately followed with either h or w; for which reason, these characters, having a point before them, are always expressed, with the proper vowel between them; as hat, hit, hot, but, and and and, met, met, met, met, N° 21.

Sixthly, As the horizontal letters s, k, and the curved ones m, n, cb, and g, may be written at the top, or bottom, or any part of the line, the vowel following them may be expressed by their situation betwixt the parallels; as fan, fan, man, man N° 22.

Seventhly, The first mark for the th in the table, not joining well with the mark for r, which, however, is very frequently combined with it; and the other, th, being, by reason of our customary method of leaning the letters the contrary way in common writing, not to readily made; t may be put for th, when the adjoining letter is of half size only, as thr, rhs, rhs, rhs, N° 23. In other cases, a letter of half size signifies that the adjoining one is to be resolved into two letters rr, rr, in the first example N° 24; for here the r being twice as long in proportion to the t as it ought to have been had only one r been designed, shows, that in this case the r of double length denotes rr: but, in the second example, the last character does not signify r, for it cannot be resolved into //; but it may into //; for if you divide the last character into two halves, the lower is our mark for r; in like manner, the third example is ft.—When there is no other consonant to be joined to the inclined letters f or r, the lengthening of them by a greater inclination than usual denotes that they are to be resolved into two letters rr, rr, or 0, 0, or 0; as in the three first examples, N° 25. error, fine, fpeoff; but when two t's form a word, as for example the word taught, or, as we should spell it, tuat. this expedient cannot be used, without going either above or below the line, which is not to be done upon any account whatsoever. In this case a little break must be made in the t, to show that there are two t's, N° 25. This must be confessed to be not altogether regular, and conformable to our rules of joining the letters; and, had many instances occurred, their frequency would have furnished a just objection against our alphabet; but on the contrary, the repetition of the t forming fewer words than that of the other consonants, was one reason of appropriating the perpendicular line to the t. The word taught being the only one that often occurs in practice.

Eightly, In some few instances, where a letter joins not well with the preceding one, as the g with any drawn downwards, the cb with any upwards, and the j with neither; we scruple not to borrow the opposite one, or some other of nearly the same found, in its stead; writing instead of voyage, voyach, for voyage; church, for church; macheffy, for majefty; N° 26. And when n happens to be at the bottom of the line, and is followed by d; for the sake of easy joining, we write p instead of the d, as in the first example N° 27. fmp for finp; and few words in our language ending in np, this can cause little ambiguity.

Ninthly, Cm and ch occurring very frequently, for the sake of dispatch we shorten the marks for k and q, when followed by m or n, as in the third and fifth examples, N° 27.
N° 27. These cannot be mistaken for oh and g, the twirl being on the contrary side.

Tenthly, The first mark, N° 28. placed close after a word, denotes that there is one syllable still wanting to complete the word, and ing being a very common final syllable, it is often so denoted as, being, writing, N° 28.

Eleventhly, A point standing by itself has a power, as well as the consonant marks, of representing a common word. At the top of the line, it signifies the particle a; as, a man: in the middle l, or eye; as, I will, his eye: in the o's place p; as, I Lord; at the bottom you; as, you will. N° 29.

Twelfthly, The common way of writing numbers being very compendious we generally use it when numbers occur. The comma, as it does not resemble any of our short-hand marks, may always be used; but when a full stop word at the top of the line, it signifies the particle a; as, being on the contrary side.

In writing words (as before observed) we join all the consonants, that are wanted, together; to which, if they suffice to distinguish a word, it is needless to add any of its vowels. As for instance, to write the word *sirs* we join the four consonants of which it is composed into one continued mark or figure comprised within the due limits, as in N° 30. first example: for if, without regarding the limits, we should make it as in example second, the letters would be the same indeed; but the direction in this, and all similar cases, is evidently more incommodious. When therefore, there are different ways of joining the same letters together, we must accustom ourselves to the best, or most lineal. The sameness of the entire figure, as well as that of its composing letters, is worth the writer’s while to maintain; and also facilitates mutual reading between the several practisers of the same method. There is a kind of mechanism in the case, by which the attention, being left fatigued with any deviations of unusual appearance, easily apprehends the meaning of that which is more conformable to a standard.

Though the letters *sir* are abundantly descriptive of the word *sirs*; yet if any one pleases, he may add the point for the vowel i, (as in the example, N° 20.) to suggest the word to him at first, until he can read it readily without that assistance.

In single words, the chief difficulty is, to unlearn the unnatural and perplexed method of speaking to which we have been long habituated. In this word *practice*, for example, the consonant c is pronounced as k in the first syllable, and as f in the second, and the vowel e has no pronunciation at all. But, being used to these difficulties, it is now become one to know the word by its true and genuine spelling according to our short-hand alphabet, viz. *praktis*.

It may highly perplex a careless writer of new characters, to decipher the true sense thereof; though it should be easy enough to know it, by a little application and practice. But what child would not sooner learn to read this same sentence, if, after being taught the use of his alphabet, he should have it thus written?—*It may help a careless writer of new characters, to decipher the true sense thereof; though it should be easy enough to know it, by a little application and practice.*

Instead, therefore, of scrupling to return from such customary rules as children are first initiated in, to a more jutl and alphabetical way of writing short-hand, men may easily be taught, when ripened into some acquaintance with their mother-tongue, to reverse the liberties perpetually taken in long-hand; that is, instead of employing more letters than is precisely necessary to express the sound of words, they may make use of fewer, not only displacing such as are needless to the sound, but such also as may be omitted, and yet leave the sense of the words easily discoverable. If they can tell what is wanting, it is all one as if it was there; the less expression there is, so much the better for the purposes of brevity, which justifies the greatest omissions, provided what is left be intelligible.

And though the omission of the vowels in the middle of words may, for a while at the first, make it difficult for a learner to read even his own writing without hesitation; yet that difficulty will certainly vanish, in proportion as the short hand marks become familiar to him, as it arises, not so much from that omission, as from the strange and un-English appearances which the characters make to his eye, and which, for that reason, do not suggest to him the consonants, for which they stand, so immediately, but that the attention of the mind is necessarily taken up in recollecting them one by one; whereas, did they appear so familiar and well known to him as all to be apprehended in one view, he would soon discover the word, though all the middle vowels were left out. If any one doubts this, he may soon convince himself, by writing in the common long-hand exactly the same letters which he had written before in the short-hand characters; and if he can read it with ease when so transcribed, he may be certain that a little custom will make the reading of short-hand every whit as easy to him.

And now, the way being sufficiently cleared before him, the learner, after he has, by repeated trials, acquired a facility of forming, with tolerable exactness, all the letters of the alphabet separately, and of remembering what particular consonant each of them represents, may proceed to join two or three of the marks together; writing at first only short words, and frequently trying different ways of joining the marks, in order to discover the best, and most elegant. Several of them being formed almost as easily upwards as downwards, he will find it convenient sometimes to begin from the top, sometimes from the bottom of the line, according to the nature of the mark which follows; and when two marks, which admit of being written downwards only, come together, the line must be divided between them, making each of them half the usual depth, as in examples first and second, N° 31. and, in some very rare instances, he will be forced to make them three deep, as *flupid* (example third,) except he chooses to make use of the expedient of borrowing the b, a letter not very different in sound, writing *flubid* for *flupid*, as in the fourth example.

That the learner may proceed with the greater ease and certainty, we have given specimens of writing according to the above rules. (Plates CLI, CLI,) for his imitation. He ought to make himself fully master of the first specimen, by reading and copying it over and over with great care, until it becomes quite natural and familiar to him, before he proceeds to the second; and he ought in the same manner to make himself thoroughly acquainted with the second, before he proceeds to the third. Thus moving with flow, but sure steps, he will in a very few days find, that every difficulty has disappeared, and that nothing remains but to practice till the habit is acquired. If he has the curiosity to compare the number of strokes and dots in his first specimen...
PART II.

An alphabet, formed upon the most just and natural plan, by which, with the help of a few general rules, all the words of the language to which it is particularly adapted, may be easily, nearly, and speedily written, will not be sufficient to satisfy the expectations of an inquisitive reader; who must be felicitous, that however complete the alphabet may be, yet many compendious applications of it may be obtained by a proper inquiry into the nature of our language, and the abbreviations which it admits of. He will not be satisfied with being taught only how to express all the letters of a word by the shortest and easiest strokes, but will also require further instruction how to describe intelligibly words and sentences by as few of those strokes as possible. To investigate, from a few things given, many which are omitted, will be found no unpleasant nor unprofitable exercise of the learner’s sagacity; and if the few be properly given, the sense of the passage, and a due attention to the omission of these more certain, and also less difficult, than the unexperienced can easily imagine.—Without some such rules of abbreviation, one end of short-hand, that of following a speaker, would scarcely be attainable.

Before the invention of the art of printing, the tediousness of writing all the words at full length put the copyers of books upon forming many ways of abbreviating them, as appears in all manuscripts. In those of the New Testament, we find many principal words expressed by their initial and final letters only, with a dash over them. In Latin manuscripts, those terminations, by which the relations of words to one another are in that language usually expressed, were generally omitted; nor was there any need of writing them at length; for the principal word being given, the sense of the passage, and a due attention to the omission of these more certain, and also less difficult, than the unexperienced can easily imagine.—Without some such rules of abbreviation, the other end of short-hand, that of expressing the thoughts of a speaker, would scarcely be attainable.

But it will be proper, before we proceed further in this art of abbreviation, to advert the learner, who is apt to be too eager to pull forward, not to embarrass himself with it, till, by a competent practice of writing according to the rules laid down in the first part, he is become so well acquainted with the characters, as to be able to write and read them with as much ease as his own common hand. The best way to learn any art is to proceed by degrees, not venturing upon a second step before the first is perfectly mastered. And it is evident, that this method of proceeding is, on this occasion, particularly necessary: for though, in many sentences, the sense, and the particular construction of the words, may plainly enough point out such of them, as are described with unusual brevity; yet how shall an unpractised learner, unable to embrace in one view the words denoted by the preceding and following marks, determine what the intermediate contracted ones must needs be? But if he will have patience to abstain from this second part, until he can write readily, and read without hesitation whatever is written, according to the rules of the first, he may rest assured that he will meet with little more difficulty in reading words contracted than he did in those written more at length, provided that the rules of abbreviation be duly attended to. But, if the reader expects that we are to give him every particular manner of abbreviation which can possibly be invented, he will be disappointed. The principal and most useful rules are given; and it is left to the sagacity of the practitioner, by observing the nature of these, and proceeding upon the same principles, to make such further advances as his occasions may require. It would be vain to pretend to have exhausted a subject which is as extensive as the language itself in which we write; and consequently may be carried further and further by every one, in proportion to his skill in the language, and his knowledge of the subject treated upon.

The learner has been already taught how to write all the consonants of any word by one continued mark, those words only excepted which may be more briefly described by the help of prepositions and terminations. He may now advance a step further, and join together such short words as are either represented by the letters of the alphabet alone; or such as, by their frequent occurrence, are become so familiar, as to be readily known, though denoted by their first consonants only. This will be found a greater saving of time than can easily be imagined; and must therefore, when dispatch is required, be done in all instances in which they may be joined neatly and without ambiguity.

Rule I. The different times and modes of the verbs are generally expressed, in the English language, by the help of other verbs, for that reason called auxiliary; as, will, shall, have, bad, can, could, may, must, be, &c. These must, upon that account, occur very frequently; and, being signified by their first consonant, they may be joined to one another; as, can be, will have or has been, to be, ought to be, must be, &c. Plate CLIII N° 1. and, when the negative particle not intervenes, it may be denoted by its first consonant, and be joined with them; as, cannot be, N° 2. will not be, have not been, not to be, ought not to be, N° 3. When these joinings are, by a little practice, become easy to the learner, he may proceed further, and join the preceding pronouns to these auxiliary verbs; as, he must be, he cannot be, N° 4. This can occasion no ambiguity: for though he was taught in his alphabet, that these two marks (N° 5.) denoted, the former have and the latter bad; yet, when placed immediately before must and can, their signification shows that they cannot, in that case, signify have and bad, those auxiliaries never admitting of such an arrangement. And further, as we and he are often dropped in common speech and writing, as 'tis for he will, we've for we have; and, for the sake of joining, he omitted in short-hand; as, he will, he will not be, they have been. N° 6.

Rule II. The learner was taught in the first part, that in...

The Lord's prayer: "Our Father which art in heaven, Hallowed be thy name. Thy kingdom come. Thy will be done in earth as it is in heaven. Give us this day our daily bread. Forgive us our trespasses as we forgive them that trespass against us. And lead us not into temptation, but deliver us from evil. Amen."
in writing all the confonants of which any word was composed, the beginnings of the marks which follow must always be joined to the ends of those which precede them: Whenever, therefore, they are joined in any other manner, it is to denote, that each particular mark signifies a whole word, and not a single letter: as for example, the particular way of joining the letters in the first example, \( \text{No } 7 \), is a sufficient indication that they were not intended to represent a word consisting of those two confonants, but two words; and the \( n \) in the middle of the line standing for \( in \), and the \( t \) for \( th \), in the \( th \) may be written as in that example. So again, the second example, \( \text{No } 7 \), denotes two words; and the \( s \) being drawn from the place of \( s \), shows the latter of them to be \( s \); and through the straight perpendicular line usually represents the article \( the \), yet, in that situation, it cannot possibly do so; for that article can never come immediately before a verb, but the pronouns very frequently do. It is may therefore be very commodiously written as in that second example; and it is not to be, as it is, since it is, may be written as in \( \text{No } 8 \), and by dropping \( s \), as before, we may write it\( 's \), for it was, it was not \( s \); it\( ' \)ere to be, for \( it \) were to be; it seems to be; as in \( \text{No } 9 \). For the \( s \) being drawn from the place of \( s \), shows that it must be either it \( s \)---to be, or it \( s \)---to be; and it seems to be is so very common a phrase, that it will not give much trouble to the reader, though written in this concise manner.

Rule III. Points being the shortest of all marks, it would argue a great want of economy, as well as invention, not to make all the use of them that can be made consistently with the regularity of our system. The power of representing prepositions and terminations, which was allotted to the confonant marks, could not be given to the points: for, in that situation, they stand for the vowels; and all the distinguishable places, both before and after the confonant marks, are already taken up by the five vowels: but a point placed directly over or under the beginning or end of any of those marks, has as yet had no signification annexed to it. As for instance, in the second example, \( \text{No } 10 \), the point being so placed, that if the \( t \) was produced, it would pass through it, is very distinguishable from all the vowels. All derivative substantives may therefore be very conveniently represented by making the point stand for the substantive derived from the word at the end of which it is placed; so the two examples, \( \text{No } 10 \), signify forget, forgetfulness.---But as there are derivative adjectives and adverbs as well as substantives, it will be a great compendium to represent them also by points, distinguishable, by their situation, both from the substantive and the vowel points; which may be done by placing them in a line, which, if produced, would pass through the substantive point; and would also be perpendicular to the last confonant mark; and by making one placed before the substantive-point to signify the adjective, one after to signify the adverb: As, forgetful, forgetfulness, \( \text{No } 11 \); reasonable, reasonably, \( \text{No } 12 \); sufficient, sufficiency, sufficiently, \( \text{No } 13 \).

Rule IV. Although the above described mode of abbreviation is very extensive, there being in our language a great number of long words derived from short ones; yet it is far from being the only use which may be made of these adjective, substantive, and adverb points. In all discourses whatever, there must be some principal words, which, either by their more particular relation to the subject, or frequent occurrence, will be easily discoverable, however concisely written. If such words begin with a confonant, the first letter, if not the first vowel and confonant, with the adjective, substantive, or adverb point annexed, will suggest them immediately; and therefore will be, though a brief, yet a sufficient description of them. As for instance, if the following passage be transcribed out of a discourse upon the folly of worldly-mindedness, in common long-hand, after this manner, Our blessed Lord, always, \( \text{No } 16 \); altogether, occasion, accordingly, \( \text{No } 17 \); notwithstanding, opinion, perhaps, religion,
I'm preparing which is omitted.

Substantives, and the preposition connecting them may be confonants only, they may be joined together, placing a dot so, in English, if the two related substantives be such as may be readily known, even when represented by their first consonants only, they may be joined together, placing a dot at the point of their junction, to show that they are both substantives; and the preposition connecting them may be omitted, for it may as certainly and as readily be supplied by the reader as the cafes in Latin before mentioned. This consideration will therefore dictate the following rule, viz. That a dot placed at the point of concurrence of two consonant marks, as in No 20. denotes two substantives, of which those marks are the first consonants; and also that the latter is governed of, or connected to, the former, by some preposition which is omitted.

As for example, in this sentence, The sun or substance of all the commandments is contained in the two following, viz. the love of God, and the love of our neighbour; the words love of God may be wrote as in the last example, for as the particular situation of the dot denotes that both L and G are substantives, the article the before the full points will discover that it must be the love of God.

Or again, The love of money is the root of all evil; or, Seek ye first the kingdom of God, and his righteousness; these words love of money, and these other words kingdom of God, may be wrote as in No 21.

The articles a or the, in this and in many of the following ways of abbreviation, may, for the sake of joining, be omitted, as in the following sentence, Since the light of the gospel has shone upon the world, &c. the light of the gospel may be written as in No 20.

And further, though an adjective should precede either of the substantives, yet they may all three be represented by their first consonants joined together, with the dot always placed at the end of the first substantive. No difficulty can ever arise in distinguishing the adjective from the substantives. For, in the following sentence, The great goodness of God is manifest in all his dealings with his creatures; if these words, great goodness of God, be written as in No 22. the dot placed at the end of the second mark shows that it must be the first substantive, the third must therefore denote the latter substantive, and the first consequently the adjective. In like manner, in the following sentence, His Majesty the King of Great Britain, the words King of Great Britain may be wrote as in the first example, No 23. for the dot being placed at the end of the first mark, it is evident that the first must be a substantive; and a little attention to the usual arrangement of words in the English language will discover that the second must be an adjective, as adjectives generally precede the substantives to which they are related; there is therefore as much given as if it had been written in long-hand thus, His Majesty, the K— of G— B—; which, in a discourse concerning him, would be sufficient to discover that the contracted words must be King of Great Britain.

If each of the substantives have an adjective joined to them, there can be no difficulty, for the first and third must be adjectives, except in some rare instances in which the common order is sometimes changed, and the last adjective is put after its substantive, as in this, the good news of God Almighty: in such cases, either the last adjective must be separated from the rest of the mark; or, if joined, it must have the adjective dot annexed; and the good news of God Almighty may be written as in the second example, No 23.

This relation of substantives, which is expressed in Latin by the genitive case, in English by the preposition of, is by far the most common: but the rule is more extensive, and serves to express two substantives connected by any proposition whatsoever, as for, in, with, after, &c. provided that the context, or any particular words of the sentence, easily indicate not only the two substantives which are denoted by their first consonants, but also the proposition which ought to be inferred. As, for example, in this sentence, Happy is it for us, if, convinced by experience of the vanity of putting our trust in man, we place all our confidence in God, the three last words may be expressed as in the first example, No 24. For the context plainly points out the two substantives; and the verb place marks evidently, that the omitted preposition cannot be of, but must be in.

In this sentence, Our holy religion absolutely forbids all instances of revenge, our Saviour expressly commanding his disciples to return good for evil.—good for evil may be written as in the second example; for the verb return shows plainly that it cannot be good of evil, but must be good for evil. It may, perhaps, be objected here, that v is not the first letter of the word evil, but it must be observed, that the words of the rule are, That the dot denotes two substantives, of which those marks are the first consonants, not the first letters; and a word may sometimes be fo pointed out by others which accompany it, as to be easily discoverable, though the initial vowel be omitted.

It may not be improper to add another example or two for the better understanding of this rule; as thus, In this present state there is no such thing to be met with as pure annuitied pleasure or pain, good or evil; here below all things are mixed, pleasure with pain, good with evil. The latter part of the sentence, pleasure with pain, good with evil, may be wrote as in the two full marks No 25. for the word mixed requiring the preposition with after it, shows, that it cannot be p—o f — and g— of — v—, but must be p— with p— and g— with v—.

Or, He is now become quite blind. he cannot even distinguish light from darkness. The last three words may be wrote as in the third mark, No 25.

Or again, If we consider, that without health we cannot enjoy any of those pleasures which riches can procure; what man that estimates things according to their reality, rather than their appearance, would not prefer health to riches; or, would not choose health before riches. The three several expressions will be easily distinguished, though wrote all in the same manner, No 26.

Rule VI. The substantive point, placed before a single consonant
SHORT-HAND WRITING.

consonant mark, denotes, that the substantive represented by it is to be repeated, with some intervening preposition, as after, to, by; as for example, day after day, time to time, N° 27.

Rule VII. The substantive, adjective, or adverb point, placed before two or more consonant marks joined together, denotes two or more substantives, adjectives, or adverbs respectively, of which those marks are the first consonants, and also that they are connected by a conjunction.

As for example, Our blest Lord and Saviour Jesus Christ, by his death and passion, made a sufficient satisfaction and atonement for the sins of the whole world;—Lord and Saviour, death and passion, satisfaction and atonement, being wrote as in N° 28.

Or further, The precepts both of natural and revealed religion forbid us to do our neighbours any injury; example first, N° 29. Here the point shows, that both s and r are adjectives; and the word religion, to which they are connected, will immediately suggest the words natural and revealed.

Or, to add one other instance, What doth the Lord thy God require of thee, but to live soberly, righteously, and godly, in this present world? which surely would give very little trouble to fill up with the words soberly, righteously, and godly.

Thus any feries of substantives, adjectives, or adverbs, may be expressed by their first consonants joined together with the proper point prefixed. But we must not indulge ourselves in doing this at all adventures. It is only to be done in such instances, wherein the commonness of the phrase, or the nature of the subject, points out the words signified by those letters; or when the words, so briefly described, are such, that no other can be inferred in their stead consistently with the sense of the passage.

When great dispatch is required, as in the case of following a speaker, all omissions are allowable, which can afterwards be supplied by a careful attention to the idiom of the language, and to the connection of the contracted words with those which precede or follow them. And it may not be improper to observe, that greater or less liberties of contracting may be taken, in proportion as the speaker is more or less accurate in his language. For it is certain, that any contradictions, where the style is clear and regular, may be more easily deciphered, than where it is confused and embarrassed. It may happen, indeed, sometimes, that the words signified by such contractions will not occur at first sight; but a little thought will discover them; and the reader will find, that an attention of this fort will very agreeably and ingeniously lead him into a more perfect knowledge of the idiom of his own language.

Rule VIII. Many long words may be, and frequently are, expressed in common writing by their first syllable only, with a mark to show what is wanting, as multi— for multitude, cor— for correspondence. So in shorthand, long words, especially those in which the marks for the consonants will not join neatly, may be denoted by their first syllable, with as many points annexed as there are syllables wanting; as, multitude, correspondence, N° 30.

And when great dispatch is required, the points may be omitted, especially if the words do not begin with prepositions; as, satisfaction, difficulty, negligence, N° 31.

Rule IX. The power given to the consonant marks of representing prepositions and terminations, will enable us to write great numbers of long words after a very expeditious manner; for words beginning with prepositions may be denoted by their respective prepositions, together with the next consonant and vowel; and oftentimes with the next consonant only, adding to it the substantive, adjective, or adverb point, when necessary. As for instance, the first example, N° 32 expresses a word beginning with the two syllables de-li; and though there are many words which begin with those syllables, as deliberate, deliver, delicious, &c. yet if such a sentence as the following were to be written thus, He was not hasty in his resolution, but took time to deliberate;—about it, the word deliberate would immediately occur to every one.

The trouble of inferring the vowel may, in many instances, be saved, by beginning the consonant from that point after the preposition in which that vowel should be placed; as in example second, N° 32. the m beginning from the a's place after the t shows, that the next vowel after m is a, and the mark therefore is equivalent to transm—, which is a sufficient description of the word transmuted.

A few examples more will sufficiently explain this rule: as, recommend, recommendation, recommendatory, N° 33. resignation, resolution, consanguinity, N° 34. conveniently, superficially, N° 35.

The participles may be abbreviated after the same manner, by adding, instead of the points, the termination ing or ed to the latter consonant mark; as confidering, considered, N° 36.

Words beginning with double or treble propositions may be written after the same manner; as, misinformation, representation, misrepresentation, N° 37. incomprehensibility, example first, N° 38. The prepositions must always be joined together; and, if two consonants begin the next syllable, the writing of them both will help to disclose the remainder of the word; as misunderstanding, example second, N° 38.

It must appear plainly to every one, upon the least consideration, that the words in the foregoing instances are abbreviated. There can therefore be no danger of mistaking, for example, the mark N° 39. for some short word, such as daily, duly, &c. For, by our rule, the dis joined always signifies the preposition de: nor can it be a word consisting of the preposition de and the syllable li or ly only; for, if such a word had occurred, it would have been sooner written by joining the marks together, as N° 40. This way of writing therefore shows, that the word begins with the preposition de; that the next syllable is li; and that there are some other syllable, or syllables, wanting to complete it. Nor can the consonants in those examples in which the vowels were omitted, be mistaken for terminations; as in this example, N° 41. the k cannot be supposed to represent the termination ical; since it would be absurd to think of describing any word by its preposition and termination only: for as the

7 L

fame
Right mention of nothing of the new form of abbreviation.

For example, in the following sentences, this belongs to me; He made some good observations upon it; I want to dispose of my house; He agreed with me in opinion; —the words belongs, observations, disposed, agreed, may be written as in No. 46. And in these sentences, there was not the least difference between us; We must take particular care to guard against such passions as we find ourselves must liable to; As for his personal estate, he divided it amongst all his children in equal shares; —the words difference, guard, liable, and divided, may be wrote as in No. 47.

And it may be further observed, that as few English words end with the syllable to, the proposition to may for that reason be joined to the preceding word, which was directed to be signified by its first conjonant only. For the unusualness of the ending will be a sufficient hint, that the mark represents not one, but two words; and, therefore, this belongs to me, may be written as in example first, No. 48, and liable to, satisfactory to, and subject to, may be wrote as in the second, third, and fourth examples, the — in this last infance being made at the bottom of the line, to shew that the vowel following it is u. But if any one finds it difficult to write that upwards, he may, whenever it is necessary, distinguish the two last instances from one another, by inserting the u, and write subject to as in No. 49.

Other prepositions, which are denoted in the table of the alphabet by a single conjonant, may, in like manner, be joined to the preceding word; as in the example, He made some good observations upon it,—observations upon may be written as in No. 50. Nor will there be any great danger of the reader's being puzzled by mistaking such like marks for single words; for it will not often happen that the two conjonants of which they are composed will form any word, scarcely ever that they will form such a word as will suit the place and agree with the context. A little custom will therefore soon suggest to the learner, that the two marks must denote two words; the latter of which, being represented in his short-hand alphabet by the last conjonant mark, must for that reason immediately occur to him.

Rule XII. Prepositions generally require after them either a noun, or a pronoun. The pronouns being few in number, and in all languages used as substantives for nouns, must occur very frequently, and by that means soon become familiar to the reader; the pronoun, for that reason, may be joined to the preposition, without danger of creating any difficulty to the reader.

As for example, in these sentences, He gave it to me, He left it to my, to us, to our, to your, the words to me, to my, to us, to our, to your, may be wrote as in No. 51. The b, th, or wh, may, for the sake of joining, be dropped in the pronouns; which begin with those letters, as his, this, whom, &c. and we may write to his as in example first, No. 52, and to this as in example second; distinguishing, if it ever should be thought necessary, his from this, by the different situation of the point; to her and to their, as in example third; for a distinction between them cannot be made, as was done in the instance before, by the different placing of the point; but the sense of the passage will easily show which it must be. To whom, to those, or to whose, to which, to each, may be wrote as in the first four examples, No. 53. It was not in my power; in my, as in the
the fifth example. *It was thrown under my feet, He came and dwelt amongst us, You may depend upon me;* the words under my, amongst us, upon me, as in No. 54.

This rule is not to be restrained to those prepositions only which are denoted in the table of the alphabet by a single confonant, as among, under, upon, &c. but may be extended to others, which muft, in that cafe be represented by their confonant, and be joined to the pronoun; as, he did it with my content, writing with my as in No. 55. This will occasion no ambiguity, since we cannot in this place dignify the word-will; for fuch a fentence as, be did it will my content, would be neither fenfe nor grammar. Its ftitution in the fentence, and connection with the pronominal adjective my, plainly mark that it muft be some preposition which begins with w.

And though feveral prepositions fhoûd begin with the fame confonant, yet they muft be written in this manner, provided that the preceding or following words be fuch as will serve to diftinguish them, and fhew which of them muft needs there be meant; as in the following examples: He came privately and took it away without my knowledge; To flrop to fo mean an action was much beneath his dignity; It is beyond my reach. Without my may be written as with my, No. 55. and the words beneath his, beyond my, as in No. 56. Above may be diftinguifhed from beyound, by prefixing the initial vowel. Thus, in the following fentence, it is above my comprehension, above my may be wrote as in example firft, No. 57, and between them, before my, behind my, in thefe fentences, They divided it equally between them, He had the impudence to do it before my face. He did it fifty behind my back, may be wrote as in the three laft examples, No. 57.

But it is to be noted here, that when the prepositions themselves are abbreviated, as in thofe infances above, they cannot help to explain other words, as they did in thofe mentioned in the beginning of the 11th Rule, in which they were direcd to be written plainly; for it would be very puzzling indeed, if that word, which was to affift in explaining others, wanted explanation itfelf.

Rule XIII. After the learner has, by a little practice, made the laft method of abbreviation familiar to himself, he may venture to combine it with the foregoing, and join the preceding word, the preposition, and pronoun all together: and as he had learned before to write belongs to, as in example firft, No. 58. and as the laft rule taught him to write to me as in example focond, he may now join them all together, and write belongs to me, extends to us, agreed with me, depend upon me, as in No. 59. observations upon this, as in example firft, No. 60. and rebellion againft his, differences amongst his, as in the two following fentences, He was a notorious traitor and caught in actual rebellion againft his Majesty, He was an ill natured man, and always endeavouring to few dissensions amongst his neighbours, may be wrote as in No. 60.

When a pronoun, or a preposition and pronoun, follow the verb, and are thernselves followed by a preposition and pronominal adjective, they may all be joined together; as, I congratulated him upon his, &c. I consoled with him upon his, No. 61.

The words some, any, none, which, each, both, &c. followed by a preposition and pronoun, may, agreeably to this rule, be denoted by their firft confonants, and be joined to the preposition and pronoun; as, some of them, any of us, none of them, No. 62. both of them, which of them, each of them, No. 63. The firft dot is inferted to diftinguish the words from one another which begin with the fame confonant; as, none, any, &c. The latter dot muft never be omitted, as it is the appointed way of writing the pronouns when joined to prepositions; as, of them, No. 64.

Rule XIV. After the learner has for fome time accuftomed himfelf to the foregoing rule, he may advance a step further, and join the adverbs preceding the verbs, and the fubfiantives following the pronominal adjectives, to the verbs and adjectives refpectively, denoting both the adverbs and fubfiantives by their firft confonants, or at moft by their firft confonants and vowels; as for example, in this fentence, you may safely deped upon my word may (land as in No. 65. *

Difficult as this may seem to a beginner, yet habit, and a little refleétion upon the nature of our language, will quickly render it easy to him. His own experience will soon convince him, that contradictions, when judiciously made, may be more certainly and easily read than the unexperienced are apt to imagine. It may, perhaps, for a while at the firft, be a good method to take the contradictions to pieces, writing in long-hand exactly what is given in short-hand. The foregoing coercion fo tranfcribed would ftand thus, you may fay—d—upon my w. Here the preposition upon will foon fuggeft, that the preceding word, beginning with the confonant d, muft be deped; and the word denoted by its initial letters fa, coming between the auxiliary may, and the verb depend, is by its fition, according to the usual arrangement of words in our language, plainly enough marked to be an adverb; fo that it is nearly the fame as if it had been written thus, You may fa—by depend upon my w. *A rule too plain a descripition to prove a flumbling-block to any attentive reader.

Rule XV. Many common phrafes, formed by a fubfiantive preceded by the prepositions with, without, in, &c. and followed by to, of, &c. may be very conveniently conected; as, with regard, refeft, or reference to, No. 66. example firft. He safely broke his promise, without any regard to his honour; without any regard to his, as in example fecond; in relation to, as in the third example; in order to, in confefion, comparifon, or confideration of, in obedience to your, No. 67; by reafon of his, by virtue of his, No. 68. (in this laft inftance, the proportionally little 6 shows, that the mark following it is to be divided into two letters;) upon account of, in the power of, No. 69.

Rule XVI. Common adverbal phrafes are, in like manner, often denoted by their initial confonants joined together; as, for the fnture, at the fame time, at prefent, in this manner, No. 70. in like manner, in a great meafe, in the fame manner, No. 71.; to fo much that, fo much the more, in the mean time, No. 72.; in general, in particular, No. 73.

And when the proportion of equality is exprfied by fo—as, or as—as, with some one word intervening, they may be all joined together; as, fo much as, as much as,
as well as, as long as, as good, or as great as, &c. No 74.

Rule XVII. The contractions which may be made when it is or it was are followed by an adjective, and to or that, are so numerous, that we must content ourselves with giving a few of the most usual; as, it is impossible to, it was unnecessary to, it is contrary to, No 75; it is according to, it is observable that, it is evident that, it is not to be supposed that, &c. No 76.

The above methods of abbreviation are such as are of most common use and practice: and though they are not many in number, yet they are very extensive in their application; for a sentence can scarce occur in which one or other of them will not find a place. But yet we are far from pretending to have exhausted the subjedt. An accurate and diligent attention to the nature and idiom of our language may suggest others as useful and extensive as these. Proper care being taken to lay a right foundation, the legible ways of contracting will increase, in proportion to the writer's want of them. The more he writes, the more con- cievably he may venture to write, and yet be able to read his contractions with ease; provided that he builds them upon some known particularity of our language: for which rea- son we have been more solicitous to elucidate the grounds of our rules, than curious in the choice, or copious in the number of examples. But that the learner may have all the af- filiance necessary, we have furnished him with specimens, (Plates CLIII. CLIV. CLV) where he will find his rules exemplified; and as the last specimen is taken from a book not in every person's possession, we have given the passage in a note #.

But it may not be amiss, before we conclude, to make a remark or two upon abbreviations in general.—First, that in all the various ways that can be taken of contracting, (that is of describing words by some shorter method than that of writing all the consonants of which they consist,) care must be taken, when the contraction consists of two or more words joined together, that no one word of it be rep- resented by more than one character; and secondly, that the whole mark, by some means or other, if possible, be shown to be a contraction, as it has been generally done in the foregoing pages, either by the insertion of points in the middle of the marks, as No 77. (Plate CLIII.) for some of them; (which, when dispatch is required, is never practised to denote vowels in the middle of words;) or by the unusual ending of the mark, as No 78, for liable to, appears that; for few words (since the termination eth, so frequent in Scripture-language, is now almost grown obsolete) end in ; or by the unusual joining of the marks, as, in, the, it, is, &c. No 7. Otherwise the reader might be puzzled in hunting for some one word consoling of the letters which are written: whereas, as he knows it to be a contraction, he is not bewildered in his researches, but is at first directed the right road, and has nothing to do but to search after some word for every character, which will suit the description, and agree with the context.

And when contractions are judiciously made, the learner, provided he will observe the caution already given, (and which cannot be too often repeated), of beginning with the easel, and of not proceeding to a second, until the fist is become familiar, will certainly find the difficulty of deciphering them lessen every day.

But, supposing that there was more difficulty in the read- ing none by a secretary. It is true, there are divers for mandation Dom. Regis, by warrant from the Lords of the council. I have perused Dr. Rutillyn's Annals of King James the 11th, fol. 201, and Ruttten's, Vol. i. 458, and can find none by a warrant from a secretary. I have read Caleb, Selmers', and Littrens arguments upon that subjedt, but see nothing of a secretary's commitment. And it seems very strange, if such a power were lodged in this Rate-officer, that there should be no precedents for it in those times, when extrajudicial and general warrants were so frequent, that they became a grievance to the people, and such a one as laid the foundation for the petition of right.

I shall not controvert the power of the council at present, because it doth not appear to me a power quite unaccountable: but it first be- gan to be practised in Sir Lionel Jenkyn's time; and yet, even in 1678, when the high court of justice could not stop it, that council did not correct it. It is no- toriously known, that the chief justice Serggs was frequently and often sent for to Whitehall, to examine, and commit, and grant warrants. And hence since the council's practices, the secretaries of the council have thrown that burden off from themselves upon their secretaries under them, who have been sworn justices of the peace; and Mr. Sprigge, who accordingly executed the office of a justice of peace at Whitehall, and that frequently. It had been a question, Whether a chancellor, or keeper of the great seal, can commit; and the better opinion hath been, that he cannot. And it seems to be agreed by Gascoign's and other cases in Mirr's Reports, 851, and Adolphus, that his committment is illegal, unless for a cause within his jurisdiction as a court of equity; and the matter must be left to me. I must agree, that any man may apprehend another for felony or treason; but there is a vast difference between apprehending a traitor or felon upon suspicion or knowledge, and a formal com- mitment to prison with a charge of treason. And I am sure Mr. Attorney General will not insist upon this reason; for then the consequence will be, that any man may apprehend another for felony or treason, and lay it before the council; and I suppose that doctrine will scarce be al- lowed; though I think that any man may, as well as he. The reason of an appre- hending a traitor or felon upon suspicion or knowledge, and a formal com- mitment to prison with a charge of treason. And I am sure Mr. Attorney General will not insist upon that reason; for then the consequence will be, that any man may apprehend another for felony or treason. And I suppose that doctrine will scarce be allowed; though I think that any man may.-

And the precedents mentioned there upon each side, which are multitudes; there is no mark, as, in, the, it, is, &c. No 7. (Plate CLIII.) for foms of them; the whole mark, by some means or other, if possible, be shown to be a contraction, as it has been generally done in the foregoing pages, either by the insertion of points in the middle of the marks, as, in, the, it, is, &c. No 7. Otherwise the reader might be puzzled in hunting for some one word consoling of the letters which are written: whereas, as he knows it to be a contraction, he is not bewildered in his researches, but is at first directed the right road, and has nothing to do but to search after some word for every character, which will suit the description, and agree with the context.

And when contractions are judiciously made, the learner, provided he will observe the caution already given, (and which cannot be too often repeated), of beginning with the easel, and of not proceeding to a second, until the fist is become familiar, will certainly find the difficulty of deciphering them lessen every day.

But, supposing that there was more difficulty in the read- ing none by a secretary. It is true, there are divers for mandation Dom. Regis, by warrant from the Lords of the council. I have perused Dr. Rutillyn's Annals of King James the 11th, fol. 201, and Ruttten's, Vol. i. 458, and can find none by a warrant from a secretary. - lynxruum
ing of them; yet, provided that they may be certainly made out by due attention to the subject treated upon, and the idiom of the language, it will be sufficient: for the learner must be advertized, that these contractions are not design-
ed to be taught as the common standard method of writing short-hand upon all occasions.—That method which was taught in the first part, and which will be as easily read, upon a little practice, as common long-hand, will be found sufficiently short for all common purposes; and it should therefore be kept to when very great dispatch is not re-
quired.

Inventors of short-hand have generally introduced into their systems a multitude of arbitrary marks, to signify par-

The injudicious application of these arbitrary marks is not the only objection against them. They are not only burdensome to the memory, and tedious and difficult to be learned, but are forgot even by the writer himself, unless he sits down to decipher immediately whilst every thing is fresh in his memory.

These objections lie not against the above methods of abbreviation. They burden the memory with new and arbitrary marks, and with but few rules for the extension of the powers of the alphabetical characters; and the rules are so general, and applicable to such a multitude of cases perpetually occurring, that they give the system the advantage, even in point of expedition, over arbitrary marks, and at the same time leave the writing legible, whatever length of time intervenes, not only to the writer himself, but also to every fellow-practitioner of the same method.

S I A

SHOT, a denomination given to all sorts of balls for fire-
arms; those for cannon being of iron, and those for guns, pilots, &c. of lead.

SHOVELER, in ornithology. See ANAS.

SHOULDER bone, in anatomy. See ANATOMY, p. 175.

SHOULDER-BlADE. See ANATOMY, p. 176.

SHOWER, in meteorology, a cloud resolved into rain.

SHREW MOUSE. See Mus.

SHOVEL-HORN, in ornithology. See Anas.

SIBERIA, or Asiatic Russia, the most northern country of Asia, situated between Tibet on the east, and Labor on the west.

SIBIALDIA, in botany, a genus of the pentandria pentagynia class. The calix consists of ten segments, and the corolla of five petals inserted into the calyx; the stamens are placed on the side of the germen; and there are five seeds. The species are two, only one of them, viz. the pro-
cumbens, or bafballad cincquefoil, a native of Britain.

SICILY, the largest of all the Italian islands, anciently called Trinacria, from its triangular figure, it is situated between 12° and 16° E. long. and between 35° and 39° N. lat. being about one hundred and seventy miles long, and one hundred broad.

SHRINE, in ecclesiastical history, a case or box, to hold the relics of some saint.

SHROPSHIRE, a county of England, bounded by Chefsire on the north, by Staffordshire on the east, by Here-
fordshire on the south, and by Montgomeryshire on the west.

SHROVE-TUESDAY, is the Tuesday after Quinquagesima Sunday, or the day immediately preceding the first of Lent; being so called from the Saxon word Shrove, which signifies to confess, as having been employed by the people in time of popery, in confessing their sins, in order to receive the sacrament, and thereby qualify themselves for a more religious observance of Lent.

SHROWS, in a ship, are the great ropes which come down both sides of the masts, and are fastened below to the chains on the ship's side, and aloft to the top of the mast; being parcell'd and served in order to prevent the masts' falling them. The top-mast shrouds are fastened to the puttock-plates, by dead eyes and laniards, as the others are.

SHRUB, among naturalists, denotes a dwarf-tree, or a woody plant less than a tree; such are holly, box, priv-
et, &c.

SHUTTLE, in the manufactures, an instrument much used by weavers, in the middle of which is an eye, or cavity, wherein is inclosed the spool with the woof.

SI, in music, a seventh note or sound, added by Le Maire to the fix ancient notes invented by Guido Aretine, viz. ut, re, mi, fa, sol, la, si.

SIAM, the capital of a kingdom of the same name, in the Vol. III No. 94.
SIG (600) SIL

It is separated from Calabria, in Italy, by the straits of Messina, which, in the narrowest part, is not seven miles over.

SIDEROS, in botany, a genus of the monadelphia polyandria class. The calix and corolla of the male have each five segments; and these are three filaments; the calyx and corolla of the female are the same with those of the male; the style is trifid; and the drupe contains one seed. There are two species, none of them natives of Britain.

SIDA, in botany, a genus of the monadelphus polyandria class. The calyx is simple and angular; the style is divided into many parts; and there are many capsules, each containing one seed. There are 15 species, none of them natives of Britain.

SIDEREAL year. See Astronomy, p. 458.

SIDERIA, in natural history, the name of a genus of crs. It is used to express those altered in their figure by particles of iron. These are of a rhomboidal form, and composed only of fixed planes. Of this genus there are four known species: 1. A colorielves, Pellucid, and thin one, found in considerable quantities among the iron ores of the forest of Dean in Gloucestershire, and in other like places. 2. A dull, thick, and brown one, not uncommon in the same places with the former. And, 3. A black and very glossy kind, a fossil of very great beauty, found in the same place with the others, as also in Leicestershire and Suffolk.

SIDERITIS, in botany, a genus of the didynamia gymno sperma class. The flamina are within the tube of the corolla; and there is a short stigma over-lapping another one. The species are eleven, none of them natives of Britain.

SIDEROXYLUM, in botany, a genus of the pentandria class. The corolla consists of ten segments alternated crooked inwards; the stigma is simple; and the berry contains five seeds. There are three species, none of them natives of Britain.

SIDEMOUTH, a port-town of Devonshire, situated on a bay of the English channel, ten miles south-east of Exeter.

SIDON, or SAYD, a port-town of Palestine, in Arafic Turkey, seventy miles north of Jerusalem. It is still a place of some consideration, being the residence of a Turkish bakhsh.

SIDRA, an island of the Archipelago, situated at the entrance of the gulf of the Adriatic.

SIEGE, in the art of war, the encampment of an army before a fortified place, with a design to take it.

SIENNA, a city of Italy, in the duchy of Tuscany, situated thirty-six miles south of Florence.

SILK, is properly an animal fluid, hardened by the air, and in colour a brownish yellow. It breaks easily between the fingers, and does not stain the hands; is naturally of a smooth surface, and is readily diffusible in water, and melts freely into a butter-like substance in the mouth. It leaves no grittiness between the teeth, and does not ferment with acid menftra. It is found in the perpendicuilar fissures of rocks near the gold-mines at Strigonium in Hungary, and is supposed to be impregnated with the sulphur of that metal. It is a good astringent, and better than most of the barks in use.

SILENIUS, in botany, a genus of the decandria trigynia class. The corolla consists of five ungualciliated petals; and the capsule has three cells. There are 34 species, 6 of them natives of Britain.

SILESIA, a duchy belonging to the king of Prussia, two hundred miles long, and seventy broad: it is bounded by Brandenburgh on the north, by Poland on the east, by Hungary on the south, and by Moravia and Bohemia on the west.

SILESIAN earth, in the materia medica, a fine astringent balsam. It is very heavy, of a firm compact texture, and in colour of a brownish yellow. It breaks easily between the fingers, and does not stain the hand; is naturally of a smooth surface, and is readily diffusible in water, and melts freely into a butter-like substance in the mouth. It leaves no grittiness between the teeth, and does not ferment with acid menftra. It is found in the perpendicuilar fissures of rocks near the gold-mines at Strigonium in Hungary, and is supposed to be impregnated with the sulphur of that metal. It is a good astringent, and better than most of the barks in use.

SILICA, a term used by botanists to denote a pod.

SILICA. See Botany, p. 617.

and for one thread will be shorter than the other, wrought together: otherwise we may with justice suspect that it is refuse silk, and cannot be equally drawn out and spun; for one thread will be shorter than the other, which is labour and loss.

...disposed, that the creatures can discharge their contents at pleasure at the mouth; and, according to the nature of the juices that are supplied with, furnish different sorts of silk from them; all the fluid contents of these vessels hardening in the air into that sort of thread that we find the web or balls of this creature consist of.

As soon as the silk-worm is arrived at the size and strength necessary for beginning his work, he makes his web; for it is thus they call that flight tissue which is the beginning and ground of this admirable work. This is his first day's employment. On the second he forms his folliculus or ball, and covers himself almost over with silk. The third day he is quite hid; and the following days employs himself in thickening and strengthening his ball; always working from one single end, which he never breaks by his own fault; and which is so fine, and so long, that those who have examined it attentively think they speak within compass, when they affirm, that each ball contains silk enough to reach the length of six English miles.

In ten days time the ball is in its perfection, and is now to be taken down from the branches of the mulberry tree, where the worms have hung it. But this point requires a deal of attention; for there are some worms more lazy than others; and it is very dangerous waiting till they make themselves a passage, which usually happens about the fifteenth day of the month.

The first, finest, and strongest balls are kept for the grain, the rest are carefully wound; or if it is desired to keep them all, or if there be more than can be well wound at once, they lay them for some time in an oven moderately hot, or else expose them for several days successively to the greatest heats of the sun, in order to kill the insect, which, without this precaution, would not fail to open itself a way to go and use those new wings abroad it has acquired within.

Ordinarily, they only wind the more perfect balls; those that are double, or too weak, or too coarse, are laid aside, not as altogether useless, but that, being improper for winding, they are referred to be drawn out into skeins. The balls are of different colours; the most common are yellow, orange colour, iberella, and flesh colour; there are some also of a sea-green, others of a sulphur colour, and others white; but there is no necessity for separating the colours and shades to wind them apart, as all the colours are to be before the future scouring and preparing of the silk.

In the philosophical transactions, n° 252, we find the following observations concerning the goodness of silk, which is best distinguished by its lightness. The organice silk is the best made in the country of Piedmont of any; and two threads are equal in fineness, that is, in finarooms, thickness, and length, for the thread of the first twist. For the second, it matters not whether the single thread be strong before the two are joined, unless to see whether the first twist prove well.

It is necessary that the silk be clean; and it is to be observed, that the straw-coloured is generally the lightest, and the white the heaviest of all. The skeins should be even, and all of an equality, which shews that they were wrought together: otherwise we may with justice suspect that it is refuse silk, and cannot be equally drawn out and spun; for one thread will be shorter than the other, which is labour and loss.

Methods of preparing Silks. The several preparations which silks undergo to fit them to be used in the manufacture of silksen, are reeling, spinning, milling, bleaching, and dying. To wind silks from off the balls, two machines are necessary; the one a furnace, with its copper; the other a reel, or frame, to draw the silk. The winder, then, seated near the furnace, throws into the copper of water over the furnace (first heated and boiled to a certain degree, which custom alone can teach) a handful or two of balls, which have been first well purged of all their loose furry substance. She then flits the whole very briskly about with birchen rods, bound and cut like broches; and when the heat and agitation have detached the ends of the silks of the pods, which are apt to catch on the rods, she draws them forth; and joining ten or twelve, or even fourteen of them together, she forms them into threads, according to the bigness required to the works they are designed for; eight ends sufficing for ribbands; and velvets, &c. requiring no less than fourteen. The ends, thus joined into two or three threads, are first passed into the holes of three iron rods, in the fore-part of the reel, then upon the bobbins or pulleys and at last are drawn out to the reel itself, and then fastened each to an end of an arm or branch of the reel. Thus disposed, the winder, giving motion to the reel,
reel, by turning the handle, guides the threads; substitutes new ones, when any of them break, or any of the balls are wound out; strengthens them, where necessary, by adding others; and takes away the balls wound out, or that, having been pierced, are full of water.

In this manner, two persons will spin and reel three pounds of silk in a day; which is done with greater dispatch than is made by the spinning-wheel or distaff. Indeed, all silks cannot be spun and reeled after this manner; either by reason the balls have been perforated by the silk worms themselves; or because they are double, or too weak to bear the water; or because they are coarse, &c. Of all these together, they make a particular kind of silk, called fletta; which being carded, or even spun on the distaff, or the wheel, in the condition it comes from the ball, makes a tolerable silk.

As to the balls, after opening them with scissors, and taking out the insects (which are of some use for the feeding of poultry,) they are steeped three or four days in troughs, the water whereof is changed every day to prevent their thinking. When they are well softened by this scouring, and cleared of that gummy matter the worm had ingluing, and after washing them cut in the river, and drying them lined the inside withal, and which renders it impermeable to the water, and even to air itself, they boil them half an hour in a lye of ashes, very clear and well strained; and after washing them out in the river, and drying them in the sun, they card and spin them on the wheel, &c. and thus make another kind of fletta, somewhat inferior to the former.

As to the spinning and reeling of raw silks off the balls, such as they are brought from Italy and the Levant, the first is chiefly performed on the spinning-wheel; and the latter, either on hand reels, or on reels mounted on machines, which serve to reel several skeins at the same time. See Reel.

As to the milling, they use a mill composed of several pieces, which may mill two or three hundred bobbins at once, and make them into as many skeins.

For the dying of silk, see Dying.

SILPHIUM, in botany, a genus of the compositae. The receptacle is paleaceous; it has no pappus; the calyx consists of three valves; and the radius of the corolla is dimidiated. There are five species, none of them natives of Britain.

SILVER. See Chemistry, p. 79, 130.

SILVERING, the covering of any thing with silver. It is usual to silver metals, wood, paper, &c. which is performed either with fire, oil, or vails. Metal-gilders silver by the fire; painter-gilders all the other ways.

To silver copper or brass: 1. Cleanse the metal with aquafortis, by washing it lightly, and immediately throwing it into fair water; or by heating it red hot, and scouring it with salt and tartar, and fair water, with a small wire-brush. 2. Diffolve some silver in aquafortis, in a broad-bottomed glass vessel, or of glazed earth, then evaporate away the aquafortis over a chaffing-dish of coals. 3. Put five or six times its quantity of water, or as much as will be necessary to dissolve it perfectly, on the remaining dry calx; evaporate this water with the like heat: then put more fresh water, and evaporate again, and, if need be, the third time, making the fire towards the latter end so strong, as to leave the calx perfectly dry, which, if your silver is good, will be of a pure white. 4. Take of this calx, common-salt, crystal of tartar, of each a like quantity or bulk; and mixing well, the whole composition, put the metal into fair water, and take of the said powder with your wet fingers, and rub it well on, till you find every little cavity of the metal sufficiently silvered over. 5. If you would have it richly done, you must rub on more of the powder; and in the last place wash the silvered metal in fair water, and rub it hard with a dry cloth.

SILVERING of Glasses. See Foliating of Looking-glasses.

SIMIA, the Monkey, in zoology, a genus of quadrupeds belonging to the order of primates. They have four fore-teeth in each jaw, placed near each other; the dog-teeth are solitary, and remote; and the grinders are obtuse. There are 23 species: Of these, three, viz. the satyrus, sylvanus, and inuus, have no tail. Other three of them, viz. the nemestrina, apidea, and sphinx, have short tails. The other 27 have long tails. The specific distinctions are taken from the colour, and other circumstances.—The monkey-kind are remarkable for activity, a low species of cunning, and a facility of imitating the actions of men and other animals. The sagacity and docility of the simia are so well known that it is needless to spend time in giving instances of either.

SIMILE. or SIMILITUDE, in rhetoric, a comparison of two things, which though different in other respects, yet agree in one. The difference between a simile and comparison, is said to consist in this, that the simile properly belongs to whatever we call the quality of the thing, and the comparison to the quantity.

SIMONICAL, is applied to any person guilty of simony. See Simony.

SIMONIANS, in church-history, a sect of ancient heretics, so called from their founder Simon Magus the magician. The heretics of Simon Magus were principally his pretending to be the great power of God, and thinking that the gifts of the Holy Ghost were venal, and to be purchased with money. He is said to have invented the Eons, which were so many persons of whom the Godhead was composed. His concubine Helen, he called the first intelligence, and mother of all things; and sometimes he called her Minerva, and himself Jupiter. Simon Magus gained a great many prolesytes, who paid himself and his concubine divine worship; these were the earliest heretics, and those that St John, St Peter, and St Paul, in their epistles, so often warn the Christians against.

SIMONY, in ecclesiastical law, the crime of buying or selling spiritual gifts or preferments. In the ancient Christian church, this crime was always thought to be committed when men either offered or received money for ordinations. The apostolical canons lay a double punishment both of deposition and excommunication on such of the clergy as were found guilty of it. This was the first fort of simony, and that which was most properly so called; and to this the ancient reduced the exacting of any reward for administering the eucharist or baptism, or for any spiritual offices. A second fort of simony consisted in buying the spiritual preferments of the church: this was punished with deposition in any bishop, who promoted any church-officer for the sake of lucre; and the persons so promoted were to be degraded from their office. By the laws of Julianus, every elector was to deposit
pose upon oath, that he did not chuse the person elected for any gift or promise, or friendship, or any other cause, but only because he knew him to be a man of the true catholic faith, of unblameable life, and good learning. This last form of simony was, when men, by ambitious arts and undue practices, got themselves invested in an office or preferment to which they had no regular call, or when they intruded themselves into other mens places which were legally filled before. The caufiis for the church of Rome maintain, that all compacts or bargains in which benefices are concerned, are simoniacal, when it is done without the pope’s concurrence; but that, once obtained, gives a function to the thing; which they found upon this universal proposition, that the pope cannot commit simony in beneficiary matters, since he hath a power so absolute over all the ecclesiastical goods and benefices, that he can unite, divide, and bestow them in whatever manner he pleaseth.

Against the corruption of simony, there have been many canons made in our own church, which punish the offender with deprivation, disability, &c. and by a statute of the 31 Eliz. it is enacted, that if any person, for any sum of money, reward, gift, profit, or benefit, or by reason of any promise, agreement, grant, bond, covenant, or other assurance, shall present, or collate any person to any benefice with cure, dignity, or living ecclesiastical, every such presentation, or collation, and every admission or induction thereupon, shall be utterly void, and the crown shall present for that sum; and the person that shall give or take any sum of money, &c. shall forfeit double the value of one year’s profit of any such benefice; and the person so corruptly taking any such benefit, shall from henceforth be disabled to have and enjoy the same.

SIMPLE, something not mixed or compounded; in which fene, it stands opposed to compound. SIMPLÉ, in pharmacy, a general name given to all herbs or plants, as having each its particular virtue, whereby it becomes a simple remedy. SIN, a breach or transgression of some divine law, or command.

SINGULAR number, in grammar. See Grammar.

SINGULAR, something on, or towards the left-hand; sinister is also used among us for unlucky, though in the sacred rites of divination the Romans frequently used it in an opposite sense. SINNER, in heraldry. The sinister side of an escutcheon is the left-hand side; the sinister chief, the left angle of the chief; the sinister base, the left-hand part of the base.

SINGULARITY, a series of bends and turns in arches, or other parts of a building. SINGING, the action of making divers inflections of the voice, agreeable to the ear, and correspondent to the notes of a song, or piece of melody.

SINGING, the action of making divers inflections of the voice, agreeable to the ear, and correspondent to the notes of a song, or piece of melody.

SINE, or right Sine of an arc, is a right line drawn from one end of that arch, perpendicular to the radius drawn to the other end of the arch; being always equal to half the chord of twice the arch. See Trigonometry, and Geometry.

SINUS, in anatomy, denotes a cavity of certain bones, and of a very audere adstringent taste, and ferments very slowly in the mouth, and is perfectly fine and smooth to the touch, does not crumble easily between the fingers, and stains the hands. It melts easily between the fingers, and stains the hands. It melts readily, and is of a pure texture, but not very hard, and of an even, but dully surface. It adheres firmly to the tongue, is perfectly fine and smooth to the touch, does not crumble easily between the fingers, and stains the hands. It melts very slowly in the mouth, and is perfectly pure and fine, and of a very buller astringent taste, and ferments very violently with aqua-fortis. It was dug in Cappadocia, and carried for sale to the city Sinope, whence it had its name. It is now found in plenty in the New-Jerseys in America, and is called by the people there blood-stone. Its fine texture and body, with its high florid colour, must make it very valuable to painters, and its powerful astringency equally fo in medicine.

SINOPLE, in heraldry, denotes vert, or the green colour in armories.

SINOPLE, in heraldry, denotes vert, or the green colour in armories.

SINOPICA TERRA, in natural history, the name of a red earth of the ochre-kind, called also rubrica sinopica, and by some authors sinopis. It is a very close, compact, and weighty earth, of a fine glowing purple colour. It is of a pure texture, but not very hard, and of an even, but dully surface. It adheres firmly to the tongue, is perfectly fine and smooth to the touch, does not crumble easily between the fingers, and stains the hands. It melts very slowly in the mouth, and is perfectly pure and fine, and of a very buller astringent taste, and ferments very violently with aqua-fortis. It was dug in Cappadocia, and carried for sale to the city Sinope, whence it had its name. It is now found in plenty in the New-Jerseys in America, and is called by the people there blood-stone. Its fine texture and body, with its high florid colour, must make it very valuable to painters, and its powerful astringency equally so in medicine.

SINOSITY, a series of bends and turns in arches, or other irregular figures, sometimes jutting out, and sometimes falling in.

SINUS, in anatomy, denotes a cavity of certain bones, and other parts, the entrance whereof is narrow, and the bottom wider and more spacious.

SINUS,
SINUS, in surgery, a little cavity, or sacculus, frequently formed by a wound or ulcer, wherein pus is collected.
SION, a town of Switzerland, in the county of Valais, situated on the river Rhone, twenty-three miles south-east of the lake of Geneva, being a sovereign state.
SIPHON, a bended pipe, one end of which being put into a vessel of liquor, and the other hanging out of the said vessel over another, the liquor will run out from the first into the last, after the air has been sucked out of the external or lower end of the siphon, and that as long as the liquor in the upper vessel is above the upper orifice of the siphon.
SIPHONANTHUS, a genus of the tetrandria monogynia class. The corolla consists of one funnel-shaped petal, with eight segments; and there are two berries containing many seeds. There is but one species, a native of India.
SIRONAGER, a city of bither India, capital of the province of Siba, situated on the river Ganges: E. long. 80°, N. lat. 31° 30′.
SIRE, a title of honor in France, now given to the king only, as a mark of sovereignty.
SIREN, in antiquity, a kind of fabulous animal, otherwise called a mermaid.
The sirens are represented by Ovid, &c. as sea-monsters, with women's faces and fishes' tail; and by others decked with plumage of various colours. The three sirens are supposed to be the three daughters of the river Achelous; and are called Parthenope, Ligea, and Leucotha. Homer makes mention of only two sirens, and some others reckon five. Virgil places them on rocks with women's faces and fishes' tail; and by others furnished with plumage of various colours. The sirens are represented by scaly monsters, with a long fish's tail, which sailors were wrecked on their rocks without regret, and even expired in raptures.
SIREN, in antiquity, a kind of fabulous animal, otherwise called a mermaid.
SISHER, in zoology, a genus belonging to the order of amphiibia mcanes. See Astronomy, p. 487.
SISON, in botany, a genus of the pentandria digynia class. The fruit is oval and striated; and the involucrum consists of many leaves; and the petals are heart-shaped. There are 8 species, three of them natives of Britain, viz. the latifolium, or great water-parnise; the nodiflorum, or creeping water-parnise; and the ericulm, or upright water-parnise.
SIXTH, in music, one of the simple original concords, or harmonical intervals. See Music.
SIZE, the name of an instrument used for finding the bigness of fine round pearls. It consists of thin pieces or leaves, about two inches long and half an inch broad, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second, for pearls from eight grains, or two carats, to five carats, &c. and those of the third, for pearls from six carats and a half to eight carats and a half.
SIZE is also a sort of paint, varnish, or glue, used by painters, &c.
The shreds and parings of leather, parchment, or vellum, being boiled in water and strained, make size. This substance is used in many trades.
SIT, in alchemy, a bright star in the constellation Cancer. See Astronomy, p. 487.
SITTA, in ornithology, a genus belonging to the order of Passerine mcanes. This star is also a sort of paint, varnish, or glue, used by painters, &c.
SITOPHYLAX, in Grecian antiquity, an Athenian magistrate, who had the superintendence of the corn, and was to take care that nobody bought more than was necessary for the provision of his family.
SIUM, in botany, a genus of the pentandria digynia class. The fruit is somewhat oval, and striated; the involucrum consists of many leaves; and the petals are heart-shaped. There are 8 species, three of them natives of Britain, viz. the latifolium, or great water-parnise; the nodiflorum, or creeping water-parnise; and the ericulm, or upright water-parnise.
SIXTH, in music, one of the simple original concords, or harmonical intervals. See Music.
SIZE, the name of an instrument used for finding the bigness of fine round pearls. It consists of thin pieces or leaves, about two inches long and half an inch broad, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second, for pearls from eight grains, or two carats, to five carats, &c. and those of the third, for pearls from six carats and a half to eight carats and a half.
SIT is also a sort of paint, varnish, or glue, used by painters, &c.
The shreds and parings of leather, parchment, or vellum, being boiled in water and strained, make size. This substance is used in many trades.
The manner of using size is to melt some of it over a gentle fire; and scraping as much whitin into it as may only colour it, let them be well incorporated together; after which you may whiten frames, &c. with it. After it dries, melt the size again, and put more whitin, and whiten the frames, &c. seven or eight times, letting it dry between each time: but before it is quite dry, between each walking, you must smooth and wet it over with a clean brush-pencil in fair water.
To make gold-size, take gum animi and alphasium, of each one ounce; cinchonamine, of one ounce; litharge of gold, and amber, of each half an ounce; reduce all into a very fine powder, and add to them four ounces of linseed-oil, and eight ounces of drying-oil; digest them over a gentle fire that does not flame, so that the mixture may only simmer, but not boil; for fear it should run over and let the house afire, keep it Constantly stirring with a stick till all the ingredients are dissolved and incorporated, and do not leave off stirring till it becomes thick andropy; and being boiled enough, let it stand till it is almost cold, and then strain it through a coarse linen-cloth and keep it for use.
To prepare it for working, put what quantity you may have occasion to use in a horse-muscle shell, adding so much oil of turpentine as will dissolve it; and making it as thin as the bottom of your feed-lac varnish, hold it over a candle, and then strain it through a linen rag into another shell; add to these so much vermilion as will make
SLAB, an outsid flirt plank or board fawed off from the SKIRPTON, a town in the west riding of Yorkshire, situated thirty five miles west of York.

SKIRMISH, in war, a disorderly kind of combat, or en- counter, in presence of two armies, between small parties, or persons, who advance from the body for that purpose, and introduce to a general and regular fight.

SKIFF, the lead of two ship-boats, serving chiefly to go ashore in, when the ship is in harbour.

SKIN, in commerce, is particularly used for the membrane stripped off the animal to be prepared by the tanner, Skinner, currier, parchment-maker, &c. and converted into leather, &c. See TANNING, &c.

Skins and the hair of beasts manufactured become parchment and vellum; leather, of which are made shoes and boots, saddles, harnesses, and furniture for horses, gloves and garments, coaches and chairs, household stuff, covers of books, drinking vessels, &c. and furrs for clothing, hats, caps, &c.

SKINNER, one who works in skins. See SKIN.

SKIPTON, a town in the west riding of Yorkshire, situated thirty five miles west of York.

SKY, the blue expanse of air and atmosphere. The azure colour of the sky Sir Isaac Newton attributes to vapours beginning to condense there, and which have got confluence enough to reflect the most refractive rays.

SLAB, an outside fappy plank or board fawed off from the sides of a timber-tree: the word is also used for a flat piece of marble.

SLATE, a flone of a compact texture and laminated structure, splitting into fine plates.

Dr Hill distinguishes four species of flate ftagenium: 1. The whitish ftagenium, being a sort, friable, flaty flone, of a tolerably fine and close texture, considerably heavy, perfectly dull and dullfite of brightnefs, variegated with a pale brown, or brownifh yellow: this species is very common in many counties in England, lying near the surface of the ground; it is generally very full of perpendicular as well as horizontal cavities, many of which are filled up with a spar a little purer and more crystalline than the rest, and is commonly used for covering houses. 2. The red ftagenium is a very fine and elegant flate, of a smooth surface, firm and compact texture, considerably heavy, and of a very beautiful pale purple, glittering all over with small glossy spangles: it is com- posed of a multitude of very thin plates or flakes, laid closely and evenly over one another, and cohering pretty firmly: this is very common in the northern parts of England, and is much valued as a strong and beautiful covering for houses. 3. The common blue ftagenium is very well known, as an useful and valuable flone, of a fine smooth texture and glossy surface, moderately heavy, and of a pale greyifh blue: composed of a multitude of even plates, laid close upon one another, and easily splitting at the commiffures of them: this is also very common in the north parts of England, and is used in most places for the covering of houses. There are other species of this flate, viz. The brownifh blue friable ftagenium, usually called coal flate; the greyifh black friable ftagenium, commonly called fliver; and the greyifh blue sparkling flage-nium. 4. The friable, aluminous, black ftagenium, being the Irish flate of the flips: this is composed of a multitude of thin flakes, laid very evenly and regularly over one another, and splits very readily at the commiffures of them. It is common in many parts of Ireland, and is found in some places in England, always lying near the surface in very thick strata. In medicine, it is used in haemorrhages of all kinds with success, and is taken often as a good medicine in fevers.

There is a sort of flate-flones called, by Dr Hill, ammonchifta. Of this kind there are only two species: 1. That composed only of sparay and crystalline particles; or the grey, friable, dull ammonchiftum; being a coarse, harsh, and rough flone, of a very loose texture, considerably heavy; and composed of a large, coarse, obtuse-angled grit, surrouned, and in part held together, by a loose earthy spar. This flone is very common in moist countries, and is frequently used to cover houses, instead of tiles: it bears the weather but badly, and is apt to crumble after frosts. 2. That composed of taly, sparay, and crystalline particles. This comprehends five species, viz. the brownifh white glittering ammonchiftum; the greenifh grey shining ammonchiftum; the yellowifh grey glittering ammonchiftum; the hard purple and white laminated ammonchiftum; and the bluish glittering flate flone. These sorts of flate-flone are very common in the northern countries, and are used in covering houses, paving, building, &c.

SLAVE, a perfon in the absolute power of a master, either by war or conquest. We find no mention of slaves before the deluge; but immediately after, viz. in the curfe of Canaan: whence it is easily inferred, that servitude increased soon after that time; for in Abraham's time we find it generally established.

Among the Romans, when a slave was set at liberty, he changed his name into a surname, and took the name or prenomen of his master; to which he added the cognomen he had been called by when a slave. Great part of the Roman wealth consisted in slaves: they had the power of life and death over them, which no other nation had; but this severity was afterwards moderated by the laws of the emperors. The slaves were esteemed the proper goods of their masters, and all they got belonged to them; but if the master was too cruel in his correction, he was obliged to sell his slave at a moderate price.

Slavery is absolutely abolished in Britain and France, as to personal servitude. Slaves make a considerable article.
SLING, an instrument serving for casting stones with great power.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, &c.

SLEEP, is defined to be that state wherein the body appearing perfectly at rest, external objects move the organs of sense as usual, without exciting the usual sensations.

Sleep is broken off unnaturally, when any of the organs of sensation is so briskly acted on, that the action is propagated to the brain.

Sleeping being one of the non-naturals, it is not possible for thoes to preserve their health, who do not go to sleep in a regular manner: for sleep repairs the spirits, which are dissipated by watching; and consequently it restores the strength of those who are weak, indifposed, or labour much. It likewise promotes perspiration, contributes greatly to digestion, and more to nutrition. The night is the most proper for sleep; for the vigour of the mind and body are better restored in the night than in the day; thus nocturnal labour and lucubrations impair the health.

SLEEPER, or the great sleeper, in zoology. See Bradypus.

SLIGO, a county of Ireland, in the province of Connaught, bounded by the ocean on the north, by Lettrim on the east, by Roscommon on the south, and by Mayo on the west.

SLING, an instrument serving for casting stones with great violence. The inhabitants of the Balearic islands were famous in antiquity for the dexterous management of the fling: it is said they bore three kinds of flings, some longer, others shorter, which they used according as their enemies were either nearer or more remote. It is added, that the first served them for a head-band, the second for a girdle, and that a third they constantly carried with them in the hand.

SLIPPING, among gardeners, the tearing off a sprig from a branch, or a branch from an arm of the tree. These sorts of slips take root more readily than cuttings.

SLOANEIA, in botany, a genus of the polyandria monogyria class. The corolla consists of five petals, and the calyx of five deciduous leaves; the stigma is perforated; and the berry contains many seeds.

SLOATH, in zoology. See Bradypus.

SLOE. See Prunus.

SMALLAGE, in botany. See Apium.

SMALLLAND, a province in Sweden, in the territory of Smaland, in the Swedish dominions, according to the duchy of Lithuania and kingdom of Poland: situated in E. long 27°, and N. lat. 53°.

SMALLING, among gardeners, the tearing off a sprig from a branch, or a branch from an arm of the tree. These sorts of slips take root more readily than cuttings.

SMALAND, a province in Sweden, in the territory of Småland, a port-town of Dutch Flanders, situated opposite to the island of Cadant: E. long 3° 15', N. lat. 51° 18'.

SMALT, a preparation of arsenic. See Chemistry, p. 145.

SMALLISH, a port-town of Dutch Flanders, situated opposite to the island of Cadant: E. long 3° 15', N. lat. 51° 18'.

SMALLS, a preparation of arsenic. See Chemistry, p. 145.

SMARRAGDUS, in natural history. See Emerald.

SMARIDUS, a natural history. See Emerald.

SMASH, with regard to the organ, is an impression made on the nose, by little particles continually exhalimg from odorous bodies: with regard to the object, it is the figure and disposition of odorous effluvia, which striking on the organ, excite the sense of smelling: and with regard to the soul, it is the perception of the impression of the object on the organ, or the affection in the soul resulting therefrom.

The principal organs of smelling are the nostrils, and the olfactory nerves; the minute ramifications of which latter are described throughout the whole concave of the former. See Anatomy, p. 293.

SMELTING, in ichthyology, a species of Salmo. See Salmo.

SMELTING, in metallurgy, the fusion or melting of the ores of metals, in order to separate the metallic part from the earth: it is also used to purify metals, by the action of heat.
SMOKE, a dense elastic vapour, arising from burning bodies.

SMITHERY, a manual art, by which an irregular lump of iron is wrought into any intended shape, by means of fire, hammering, filing, &c.

SMOKE, a dense elastic vapour, arising from burning bodies. As this vapour is extremely disagreeable to the inhabitants of Britain, we have been sufficiently demonstrated, that, like other fluids, it has a constant tendency to preserve an equilibrium in all its parts; so that, if at any time the weight of it at one place is diminished, the heavier air rushes from all sides towards that point, till the equilibrium be again restored. We there like wise saw, that heat was one of the most powerful means of disturbing this general equilibrium of the air, by expanding it to a great degree, and making the same quantity occupy a much greater space than before, and consequently become lighter. Hence it necessarily follows, that wherever a fire is kindled, the air immediately contiguous to it will be heated, and of consequence rarified and made light; which must ascend into the higher regions of the atmosphere, till it becomes of the same gravity with the air contiguous to it, while the denser cold air below rushes toward the point from which it departed, is there heated and rarified in its turn, and ascends in the same manner, carrying the smoke or vapour arising from the burning body along with it. In this manner that constant motion of air towards every fire is produced, and from this cause proceeds the constant tendency of smoke to ascend upwards from the surface of the earth.

But as the body of our atmosphere is often agitated with wind, &c. and as it is an elastic fluid, it endeavour to spread itself every way; from which causes the warm air would quickly be diffused among the cold air before it could arise to any considerable height; so that the smoke would always remain low, and be tied about near the surface of the earth; all of which inconveniences are avoided by confining this heated air in a tube, which prevents it from mixing with the external air, till it arrives at the height to which we desire it should ascend.

To render this still more clear, see Plate CLVI. where AB (fig. 1.) represents the tube of a chimney, having a fire at the bottom at A. It is obvious, that, in this situation, the air which was heated by the fire at A, will ascend directly upwards, without mixing with the external air, till it arrives at B, beyond which it will be at liberty to diffuse in the atmosphere; and the more weighty air which profits in to supply its place can have no access to it but at the opening between A and E, where it also is heated by the fire, and in its turn ascends to the top of the chimney, thereby occasioning a conflant stream of air to ascend up the chimney, which carries the smoke along with it. This is the manner in which fuliginous vapours are made to ascend in chimneys; and by attending to it, we may draw the following corollaries with regard to the construction of this useful part of our habitations.

If, the higher the chimney, that is, the greater the distance between the fire-place and the top of the chimney, the greater will be the difference between the weight of the column of heated air in the tube, and another column of the atmosphere of the same diameter without the chimney, and consequently the air will enter with the greater force at the opening AE, and carry up the smoke more readily along with it: for as the warm air within the tube continues rarified to a high degree till it issues from the top of the chimney, and is, in every part of its length, lighter than the same bulk of external air marked by the dotted line CD, it follows, that the longer these two columns of unequal gravity are, the greater must be the difference of their weight. Hence it is, that high chimneys (elevated paribus) have a greater fiction of air, and are less liable to vent ill, than low ones. A smoky chimney may therefore sometimes be cured by raising it higher. It is likewise obvious, that if any opening is made into the chimney, as at F, the air will enter with less force at E, and carry up the smoke with less velocity, and by that means be in danger of producing smoke in the room; for this opening, as it admits the fresh air into the tube, has nearly the same effect as shortening the tube so much would have.

2d, As the smoke is forced up the chimney merely by the rarefaction
rarefaction of the air in consequence of heat, it is evident,
that the more the air is heated, with the greater force (ce-
teris paribus) will it ascend, because the difference between
the weight of the external and internal air will be great-
er; and as the air will be the more heated the nearer it is made
to pass by the fire in its entry into the chimney, it is evi-
dent, that the smaller the opening at AE is, or, in other words,
the lower the mantle of the chimney is, the air will be for-
ced to pass the nearer the fire, and therefore be more rarefied,
and ascend with the greater velocity; so that lowering the
mantle of the chimney will often cure smoke.

But it is frequently inconvenient to have the mantle of
the chimney too low. However, the same effect may often
be produced by another contrivance. For as the fire-place is
usually made wider than the length of the grate, a great
deal of cool air paffes at the two fides of the grate without
being much heated. This greatly diminishes the lucction of
the chimney: but it may easily be prevented by building up the
vacancies at each fide of the grate, so as to allow no air to
enter from below, except what comes immediately through,
or before the fire. For this purpose, grates confiding of a
sheet of milled iron within the mantle as in fig. 2. This ftruc-
ture allows a quantity of cool air to enter at the two corners of the
mantle, and fteal up the tube without coming near the fire.
The molft cally and eftual method of remedying this defect, is
to place a sheet of milled iron within the mantle on each
fide, as low down as poffible, making them flant a little up
wards towards the middle of the chimney; as in fig. 2. The
mantle being represented by the dotted line. By this con-
trivance, the air, which enters at the fide of the mantle,
before it can ascend into the chimney, is forced to pafs very
near the fire, and of course is much rarefied. The good ef-
efts of this would be still more strongly felt, if one of thefe
plates were placed a little lower than the other, and made fo
long, that the ends should cross each other, as at AB, fig. 2,
by which means every particle of air that went up the chim-
ney behaved to pafs immediately above the fire. It is al-
mot unnecessary to obferve, that these plates ought to be fo
contrived as to be taken out at pleasure to allow the chimney
to be cleaned.

A chimney may not only be defective by having the man-
tle too high, or by being too wide from fide to fide, but afo
by being too deep between the fore fide and the back, as is
often the cafe in very old houses. In this cafe, the diftance
between the fire and the mantle is fo great, that much air
paffes up without being sufficiently rarefied, as is represented
at fig. 3. This may be fometimes cured by bringing
the grate a little forward, which, by making the fire aft more
powerfully upon the mantle, rarefies the air more in its
paffage. But this can seldom produce the defired efpect,
and it often does harm: for when the grate is brought for-
ward, there is a great vacancy left between it and the back
of the chimney, fo that the air paffes under the grate, and
ascends behind it very little rarefied; so that, if the feet of
grate are not very low, there will be as much loft in this
way as will be gained in the other; and as there is not enough
of heated air in the chimneys of this kind to make the va-
pour ascend with rapidity, they are often choked with
thick fuliginous vapours hanging in them, almost in equili-
bro with the ref of the atmosphere, fo that the leaff puff
of wind beats them down the chimney, and pushes the
smoke into the room; whereas, when it is far back, it is dri-
ven down upon the hearth, and rises upwards again when
the gulf is over, and a great deal of it is catched within the
mantle as it rifies, which in the other cafe would have been
difpered through the room. When this is the cafe, the
most eftual method of cure is, to bring the grate forward
till the forepart of it is immediately under the inner edge of
the mantle; then build up the vacancy at the back of it, the
whole width of the fire-place from fide to fide, raiing it per-
pendicular till it is as high as the back of the grate, and
then bending it forward towards the mantle, as is repre-
sented at fig. 4. When it is as high as the workman can
reach, let it be suddenly turned backward again, floping a
little upward, as in the figure; then fit a fheet of milled
iron to the inside of the mantle, making it flant a little up-
ward toward the back part, at a small distance above the
new erected mafonry, and extend it within a few inches of
the back wall, as at A, fig. 4. By this conftruction all the
air that enters into the chimney is made to pafs immediately
above the fire, between it and the heated iron, upon which
the flame acts with the greater force, as the back of the
fire-place is bent a little forward above the grate, and
the heat is likewise reflected into the room with the
greater force: at the fame time, if the smoke is at any time
beat down the chimney by a fudden gulf of wind, it will be
catched by the fheet of iron, and prevented from coming into
the room. If the fire-place be very wide between the
the one fide and the other, the new mafonry may be carried
quite up to the fheet of iron on each of the tides.

3d. As every fire requires a conflant fucceffion of fresh
air, the tube for conveying this rarefied air to the higher
regions of the atmosphere must be of a fufficient fize to
contain the whole of it, and allow it a ready paffage; other-
wise a part of it will be forced to fekke fome other paffage;
by which means, the apartment in which the fire is placed
will be conflantly filled with fmoke. Every chimney there-
fore ought to have a degree of widenefs fufficient to carry
off the whole of the fmoke arifing from the fire usually
burnt in it, otherwife the apartment will be almoft continually
filled with fmoke. This is a fault more common at pre-
rent than any of thofe already mentioned, efpecially in large
towns, where the number of chimneys in one wall is often fo
great that it is difficult to get a fufficient fpace for each. The
moft obvous cure, where the situation admits of it, is to widen
the chimney, by opening a hole a little above the grate thro'
the back-wall of the chimney, flanting a little upward, and
building on the outside of the wall a small chimney open from
that hole to the top of the building, as in fig. 5, where AB
represents the new tube going through the wall at the opening
at A, which will receive the fuperfluous fmoke, and carry it
off. This additional chimney muft always be carried as high
as the other. But as there are many situations in which
this method of cure would be impracticable, we muft try er-
every method for accelerating the afeent of the fmoke; (for
the more quickly it afeends, the more narrow may the tube
be,) and with that view, the chimney may be heightened at
top, and contracled at bottom, in any or all the various
ways we have mentioned. But if none of thofe methods
prove eftual, let the chimney be built quite clofe at the
under part, leaving only as much room as is fufficient to
contain the grate, having a cover of metal fitted to that o-
pening, which can be taken off or put on at pleasure; by
which the whole air that enters into the chimney is made to
pafs through the fire like a furnace, and carries the fmoke
up it with great velocity. These are well known in large
towns by the name /make-chimneys/: but as they occasion a
prodigious waft of fuel without warming the room, and,
unless attended with very great care, are in danger of fet-
ting the building on fire, they ought to be as much avoided
as possible. But if neither this, nor any of the other meth-
ods prove effectual, the wall muft either be taken down
and rebuilt in a proper manner, or the chimney abandoned
as incurable. As this is a defect more difficult to be reme-
died than any other, we would strongly recommend it to every
builder to build his chimneys of a sufficient width through-
died than any other, we would strongly recommend it to every
builder to build his chimneys of a sufficient width through-
died than any other, we would strongly recommend it to every
builder to build his chimneys of a sufficient width through-
died than any other, we would strongly recommend it to every

4th. As the air which ascends through the chimney con-
tinues nearly of an equal degree of heat to the top, the
tube should be of an equal degree of width at the top as at
the bottom, as well as through the whole of its length.
It ought not therefore to be made tapering gradually from
the fire-place to the top, but to be suddenly contracted a-
bove the grate, as in fig. 6. from which it ought to be con-
tinued of an equal wideness throughout its whole length:
but if it is narrower at any one place than another, it ought
to be at the under part, immediately above the fire, for a
very short space; because, as this is within reach of the hand,
the foot can be cleaned from it as often as is necessary. So
that if the other parts of the chimney are full and
clogged with soot, they will not be narrower than this place
is at that time.

5th. It seldom happens that a chimney can be carried
quite straight upwards; and it is an advantage that it is so,
as they ought always to be bent a little. For if a chimney
be straight, and of a proper width to transmit the whole of
the smoke and no more, it will not be sufficient for that
purpose, when there is a heavy fall of rain, or snow, or
hail, with little wind; for the great drops will fall perpen-
dicularly from the top to the bottom of the chimney, and
as they occupy a considerable space, the smoke will not
have room to ascend, but must be forced down with the
flower, and dispersed in the apartment: whereas, if the chim-
ney is bent, the rain falls upon some of the sides, and slides
gently down without disturbing the ascent of the fmoke.
The fame inconvenience will be felt in a straight chimney,
where it is so placed as to be exposed to winds which
sometimes enter the top and blow down with a sudden puff:
for, if it be straight, the air meets with no interruption till
it descends into the chamber, and there disperses the fmoke;
but if it be crooked, the defcent of the wind will be ob-
structed its force broken, and the bad effects of it in a
great measure prevented. Upon the whole, bent chimneys
are always preferable to straight ones. However, a perpen-
dicularly chimney may be easily cured, by some of the con-
trivances after mentioned.

There are the most general defects arising from the struc-
ture of the chimney itself, which are all reducible to the
following cauies: 1. Too little height; 2. Too great
widenss of the bottom of the chimney; 3. Too little
width; 4. Unequal widenss between the top and bottom;
and, 5. Straightness of the tube. We have pointed out
the bell methods of curing each of these defects; and to fi-
and the air in it become as light as the external air at the through the outer wall of the houle, and communicates with pradiled, doors and windows might with fafety be made may occafion fmoke when the wind is in certain diredions.

the prefent mode of conftruding chambers, is kept alive by current of air will occafion a fort of fudion at the opening small hole made in the wall at the hack of the chimney, As the Imoke is impelled up the chimney by the prefiure its Tull widnefs when neceffary, or clofe it to any degree at so that the air within would be Toon u'artned, and continue turned about.

The wire might be fixed to a small brafs-handle moving freely upward and downward like a conftant fupply of air would be adminirered to the fire with- out the smallest inconvenience or trouble. If this were pracitifed, doors and windows might with safety be made much clofer than at prefent, and our apartments rendered equally warm and comfortable with a much smaller quan- tity of fuel than we ufe at prefent. For as the fire, in the prefent mode of conftruding chambers, is kept alive by a conftant fuccceffion of cold air from the doors, windows, and other crannies of the room rushing towards the chimney in all directions, the air of the room, which, if not cooled by this means, would be quickly heated to a great degree, is constantly kept cold in spite of the strong heat of a blazing fire; which, at the fame time that it scorches the parts of our body which are most expofed to it, does not warm the parts which are turned from it; and we experience at the fame time a burning heat and piercing cold, which is often productive of the moft difagreeable effects. But if the fire were supplied with air in the manner abovementioned, there would be lefs air drawn in through the crannies of the room, so that the air within would be soon warmed, and continue long fo even with a small degree of heat. However improper this might be for people in perfect health, it might sure- ly be of great ufe for thofe who are in a weakly habit of body; efpecially if care were taken to carry off the foul air, by having a small tube leading from the upper part of the room to the top of the houfe, through which the air which had been rendered noxious by the smoke of candles or per- spiration would be conveyed away, and a fuccedion of fresh air admitted from the tube near the fire-place to supply that want. That the reader may more readily comprehend what is here meant, we have repreffented in fig. 6, a view of two small tubes for this purpofe suppofed to be laid open by tak- ing away the boxing or inner coating of the wall which ought to cover them. Thes are of wood, and muft not be above one inch in diameter. One end, g g, goes quite through the outer wall of the houfe, and communicates with the open air, having a small grate upon it to prevent vermin from entering. The other end, b b, paffes behind the two flabs at the side of the fire-place, and open in the inside of the fire-place at i i, at which place they have each of them a small bit of brafs fitted to them, being clofed with two fild- doors exactly like thofe that are ufed to cover the end of telescopes, by means of which more or lefs air may be admitted at pleasure.

20, A second caufe of smoke, is the wrong poition of doors and windows, with refpect to the fire-places.

As the smoke is impelled up the chimney by the prefiure of the air, if that air is driven away from the fire-place by any caufe more powerful than the fudion occafioned by the fire, the smoke muft also be drawn away with it, and follow the fame direftions with that current of air; so that whatever tends to draw a current of air from the under part of the chimney, will also tend to produce smoke in the houfe; from whence it is easy to conceive how doors or windows may occasion smoke when the wind is in certain direftions.

Thus, fuppofe a chamber, A, B, C, D, fig. 9. having a door or window at E, another at F, and a fire-place at G; when the wind is in the direftion D A or C B, the general current of air will occafion a fort of fudion at the opening E, fo that the air will be drawn from the chimney G to- wards E; and if the current be ftrong, and the opening at E large, it will become more powerful than the fudion of the chimney, and produce smoke in the apartment. If the window at F should be opened in this cafe, it would not mend the matter; for any wind which fhould enter at F, would be carried freight out at the opening E, and the cur- rent of air would be drawn from the chimney as Strong as ever. If the window at E were fhut, and that at F left open, and the wind ftil! continued in the fame direftion as before, the current of air running pulf the window would have a tendency to draw the air of the room along with it, and

* If any one fhou'd think, that the wire d would be a difagreeable object in the middle of a chimney-piece, it might easily be hid by a picture of any kind. The wire might be fixed to a small brafs-handle moving freely upward and downward like that for a bell; only this should have a long fit in the middle of it, with notches on each fide, to receive a pin placed in the middle of the fit, by means of which the wire might be lengthened or shortened at pleasure. The whole of this apparatus is re- preffented at fig. 16, where (a) represents the wire fitten to the brafs-plate; (b) a piece of brafs, railed a little, to ferve as a handle. The fit in the middle is repreffented by the dark line, having notches very convenient distances. The pin d is fixed into the wall, but left at liberty to turn about with cafe; and its head stands up a little, fo as to be easily turned with the finger and thumb. The body of this nail is made fo thin in one direftion, that when it is turned half round, it eafily paffes through the fit in the plate; but in the other direftion its diameter is greater, fo that when the plate is brought to as to have one of the notches oppofite to the nail, and it is then turned half round, it catches the plate fo that it cannot be moved till the nail is again turned about.
and occasion smoke, but not so powerfully as if the window at E were open; but if the wind were in the direction D B, it would be very bad: but if it blew in the direction C A, the cafe would be very much altered; for then a quantity of air being forced in at the opening F, and finding no ready passage, it would be pent up in the chamber, and force itself up the chimney with violence. We omit mentioning what would be the effect if the wind were in other directions, as it is imagined there will be sufficiently obvious to every attentive observer...It is only necessary here to observe, that as doors or windows are seldom so exactly made, but they produce some effect, as they always admit some air even when shut, and often occasion smoke when the wind blows from a particular quarter; and as workmen and others generally apprehend, when houses are troubled with smoke in this manner, that it is occasioned by some external cause, and apply their attention to cure it by altering the top of the chimney, which never can produce the smallest service in this case; we would recommend a more particular attention to be paid to the situation of doors and windows than is generally bestowed, especially in such situations where they are exposed to any violent current of air in a particular direction, as in narrow lanes, or defiles of any sort, where the wind, when in particular directions, is hurried along with a prodigious rapidity. And, that the effects of different positions may be still more obvious, we shall produce several other examples.

Suppose a chamber, fig. 9, having a door at A, and two windows B C, with a fire-place D. If the wind came in the direction DA, and if the door tranmitted as much or more air than was admitted at both the windows, a current of air would run from all parts of the chamber towards A, and therefore would have a tendency to occasion smoke; but if as much or more air came in at the windows than could get out at the door, there could be no such current; but, on the contrary, it would be forced up the chimney, and carry the smoke along with it: wherefore in this situation, a room might sometimes be cured of smoke, by making the door as close as possible; nothing could be more hurtful in this case than boring a hole in the door. But if the house was in such a situation as to be more frequently exposed to a wind which came in the direction of AD, it would run little risk of being troubled with smoke.

Suppose a room, fig. 10, having a door at A, and two windows B and C, with a fire-place D. If the wind came in the direction CB or BC, and both the windows were open, it is evident that the smoke would be drawn from the chimney by the strong current of air passing through the room; or if the window upon which the wind came were closed, and the opposite one open, nearly the same effect would be produced: but if the window upon which the wind blew were open, and the opposite one and the door shut, the room would be immediately cleared of smoke entirely. In this situation, it is evident, that if the windows were badly made, so as to admit much air, it would tend to occasion smoke, especially if the door were in the same situation; it is therefore of consequence to attend to this circumstance in a situation similar to this.

Having premised so much with regard to single rooms, we shall now proceed to consider a more compound structure. Thus, let fig. 11, represent a building consisting of two chambers, K L, joined by a passage. The chamber K having a door B communicating with the passage, a window
wrong position of the house with regard to external objects, which, by interrupting the course of the air, makes it assume various directions, and wheel about in eddies, so as to prevent it from ascending with ease from the chimney top, or beat it down into the room with violence. This is more seldom the case of smoky houses than either of the two before mentioned; although it seems to be almost the only one attended to by the persons who pretend to cure smoky houses at present, as most of their remedies are adapted to remove the disorders arising from this cause alone. We shall briefly point out the several cases in which this can occur; that every one may be enabled to judge for himself when these cases are proper or not.

The air (as has been said) is a fluid, and wind a current of that fluid; which, when driven along the surface of the earth, flows with a smooth and equal stream, unless when opposed by some object which interrupts its course; but when it meets with any object which directly opposes its course, it is in some measure pushed back again, and made to spread on every side, till it meets with some open side, towards which it flows with great impetuosity. It is likewise a fluid of considerable gravity, and therefore preys upon the earth with great force; so that, when a current of it flows along the surface of our globe, it has a tendency to move forward and press downward at the same time: from whence it happens, that when a current of air is forced over the top of any high object, the side of which descends perpendicularly downward, the velocity of the current at first overcomes the gravity, and it flies a short way over in that direction; but the power of gravity acting upon the under surface, draws it downward, and in a short time overcomes the impetus that it had to rush forward, and occasions a sort of eddy nearly similar to what we see among water behind a flame which interrupts the violence of its currents.

To illustrate this more plainly, let AB, fig. 12, represent a part of a high building, near to which is a smaller one CD; and let the dotted line EF represent a current of air flowing with considerable force in the direction FE. It is plain that it will flow straight forward over the top of the smaller building; but when it meets with the large object, it will be interrupted in its course, and spread itself on every side, as represented by the dotted lines GG &c. at last it will flow towards that place through which it can escape with the greatest ease. If the opposing object be large, and has no opening through which it can issue near the ground, then it will ascend to the top of it, and flow off in that direction, carrying the smoke which ascends from the small chimney C along with it; but if there is any opening below, either a street or lane, or any other passage that will admit the wind to pass, then will the natural gravity of the air draw the general current downward to flow off through the lower passage; in which case, the smoke which ought to ascend through the chimney C, meeting with a current of air opposing its passage, will not be at liberty to issue forth, but be forced back again into the room from whence it proceeds, unless some contrivance is fallen upon to prevent it.

Again, let A, fig. 13, represent a small building at the side of a great rock B, and the wind coming in the direction CD; when the current of air comes to the point D, being hurried forward with great velocity, it goes a little forward, but soon descends downward, and gradually is reflected more and more inward, as represented by the dotted lines EE, &c. so that, descending downwards upon the top of the chimney A, the smoke is beat back again into the apartments. Thus it is that low houses, when contiguous to high objects, are in danger of being disturb'd with smoke. If the contiguous object be not very high, the disorder may be cured by heightening the chimney of the low house; but if it is very high, it will be necessary to cover the top of the chimney in such a manner as to prevent the wind from entering it, at the same time that a passage is left at some of the sides through which the smoke may issue with freedom. Many are the contrivances which have been invented for this purpose, which are to be met with everywhere; and as there is no difficulty in accomplishing the desired end by an infinite variety of methods, every one who needs such a thing may please his own fancy in the choice. We have thought it unnecessary to add any more but one kind of these, fig. 14, which will answer the end effectually.

It is evident that houses situated near high hills, or thick woods, will be in some measure exposed to the same inconvenience; but it is likewise plain, that if a house be situated upon the slope of a hill, as at F, fig. 13, it will not be in any danger of smoke when the wind blows towards that side of the hill upon which it is situated; for the current of air coming over the house-top in the direction G H, is immediately changed by the slope of the hill to the direction H C, which powerfully draws the smoke upward from the top of the chimney. But it is also evident, that a house in this situation will be liable to smoke when the wind blows from the hill; for the current of air coming downward in the direction C H, will beat downward on the chimney F, and prevent the smoke from ascending with freedom. But the effect will be much heightened, if the doors and windows are chiefly in the lowermost side of the house.

There are some of the most general circumstances which prevent the free ascent of smoke, arising from external objects: but there are many other lesser causes which may at times occasion smoke, all of which it would be tedious here to enumerate; such as, blasts of air, reflected from the sides of mountains, and coming down valleys with great impetuosity, occasioning, in particular situations, eddies or whirlwinds of different forms. In short, whatever in any measure disturbs the free motion of the air, is in danger of producing sudden gulfs, which may occasion smoke. Therefore, whoever builds in a situation which is not altogether free, may lay his account with having some sudden gulfs of smoke, unless he forms the top of his chimney so as to obviate it. And there are some situations so much exposed to sudden gulfs of wind, sometimes whirling round, sometimes beat suddenly downward, or as suddenly carried up again, that it is difficult to guard against every danger. In these situations we would recommend something of the form of what is represented at fig. 15, which would be proof against every wind whatever.

Having thus traced the causes of smoky houses, and reduced them to distinct classes for the sake of distinction, it is necessary before we quit this subject, to observe, that in many cafes, two or more of these may be combined to augment the malady, and therefore it is necessary to have all these circumstances in view in every particular case. It now only remains that we point out the several phenomena which may lead us to distinguish from which of these general causes the disorder complained of may proceed. And,
If it is owing to a fault in the construction of the chimney itself, it will smoke almost continually, especially in calm weather.

If it does not smoke in calm weather, or only when the wind comes from a particular quarter, and can then be cured by opening some door or window, the fault may be looked for in the distribution of the doors or windows of the house. The only case in which there is difficulty in distinguishing whether it is owing to the fault of the chimney or the house, is when it proceeds from too much closeness of the apartment. But this may be easily known by trying it in a calm: for if it proceeds from this cause, there will be no smoke in a perfect calm, if the doors are left open; whereas, if the defect proceeds from a fault in the chimney itself, it will still continue to smoke when calm, even when the doors are open.

When the smoke is occasioned by external causes, there can be generally seen; but it may be likewise known by this, that it proceeds in sudden puffs with great violence at times, even when the doors and windows are not altered. By attending to these few rules with care, there will be little danger of mistaking the cause from whence this disorder proceeds.

We shall conclude these observations with a few remarks on some particular cases which can hardly be reduced to any of the foregoing heads. And,

1st. It sometimes happens, that the smoke is prevented from ascending with freedom, by having a small part of the top of the chimney broken down, so that some parts of it remain higher than others, which in some measure reduces it to the stature of a chimney at the side of a higher one. To prevent this, it is always proper to have the top of the chimney finished with stones neatly cut, and firmly built. It is not to be doubted but that those things, which are placed upon particular chimneys with a view to cure them of smoke, do often, from the same cause, hurt the neighbouring chimneys built in the same wall.

2d. A chamber is sometimes filled with smoke, when a fire is kindled in a neighbouring chimney, and none in it, although there is no appearance of smoke when it has a fire burning in its own grate. This may sometimes proceed from a small hole breaking through the thin partition that divides the two chimneys from one another, and as smoke is a weighty body, which is only buoyed up by the warm air which passes through the fire, when it penetrates into the cold chimney it naturally subside, and comes down to the chamber with which the chimney communicates, when there is no fire to carry it off. But this disease is generally produced by the smoke entering at the top of the chimney, and descending downwards: if this last is the case, it may be cured, on many occasions, by letting a pretty high flue at the top of the chimney, as a division between each two: but the foreif method, in all cases, is to have a smokeboard exactly fitted into the chimney above the grate, which on all occasions effectually prevents it.

3d. It frequently happens, that a chimney does not carry off the smoke well at first when the fire is kindled, although there is not the smallest tendency to it at other times. This proceeds from the narrowness of the chimney; for when the fire is kindled, the whole tube is filled with cold air, as weighty as that in the apartment; and being expanded by the fire at the bottom, it endeavours to ascend upward, but being pent in by the narrowness of the tube, and pressed by the column of cold air above it, it is some time before it can wholly overcome that reflstance, and some of it is forced into the chamber, till by degrees the whole chimney is heated, and then it vents quite well. If the smoke produced by this means is not very troublesome, it may be borne with; but if it be extremely disagreeable, it may be cured by having a large sheet of milled iron, large enough to reach between the two sides of the fire-place, and as deep as to reach from the mantle to the grate, or lower, which might be any contrivance be hung up before the fire at that time to act in some measure as a smoke-chimney. This would quickly make thefire burn, and carry off the smoke entirely. After that is effected, it might then be removed, till another occasion.

SMOLENSKO, the capital of a province of the same name in Muscovy, situated on the confines of Poland: in E. long. 32°, and N. lat. 56°.

SMUGGLERS, in law, those persons who conceal or run prohibited goods, or goods that have not paid his Majesty's customs.

SMUT, in husbandry, a disease in corn, instead of being filled with flour, are full of a sticking black powder.

There are two remedies for this smut, recommended by writers on husbandry; viz. steeping the feed in salt brine, and changing the feed.

As to the steeping of feed, when wheat is intended for drilling, it must be soaked in a brine of pure salt, dissolved in water. Since urine is found to be highly prejudicial. The most expeditious way of brining wheat for drilling, is to lay it in a heap, and wash it with a strong brine sprinkled on it, stirring it up with a shovel, that it may be all equally brined, or wetted with it; after this, stir it up, still stirring more on the same manner till the whole is dusted with the lime: it will then be soon dry enough to be drilled without farther trouble. It must be quick-lime, in its full strength, that is used on this occasion.

The bread made of smutty corn, is very pernicious, acting as a narcotic, and occasioning—not only sleepiness, but vertigo, and even convulsions.

SMYRNA, a city and port-town of Asia Minor, situated on a bay of the Archipelago, in the province of Ionia, in Lat. 30° N. and long. 27° E. Leper Asia, 100 miles north of Rhodes, and 200 miles nearly south of Constantinople: E. long. 27° N. lat. 37° 30'.

SMYRNIUM, in botany, a genus of the pentandria digy.

SNEEZING, a convulsive motion of the muscles of the nose and throat, in consequence of the irritation of the upper membrane of the nose; whereby the air is expelled from the nose with much vehemence and noise.

Sneezing is caused by the irritation of the upper membrane...
Society, in general, denotes a number of persons united in the air, or by medicines called inhalatories.

Snetham, a market-town of Norfolk, twenty-eight miles north-west of Norwich.

Snipe, in ornithology. See Tantalus.

Snow, a meteor produced in this manner: When the vapours become considerably condensed, yet not so far as to be liquified, or dissolved into water; then, by a special degree of coldness in the upper region of the air, the particles of the condensed vapour are changed into ice; several of which adhering together, form little fleeces of a white sub stance, somewhat heavier than the air; and therefore descend in a slow and gentle manner through it; being subject, by reason of its lightness, to be driven about by the various motions of the air and wind; and is what, when arrived to the surface of the earth, we call snow.

Snowfritifies the ground; for instance, by guarding the corn or other vegetables from the intense cold of the air, especially the cold piercing winds.

Snowdon-hill, the highest mountain in Wales, situated in Caernarvonshire.

Snow-drop, in botany. See Galanthus.

Snuff, a powder chiefly made of tobacco, the use of which is too well known to need any description here.

Soalfish, in ichthyology. See Pleuronectes.

Soap, a kind of paste, sometimes hard and dry, and sometimes soft and liquid, much used in washing, whitening linens, and by dyers, fullers, &c. See Chemistry, p. 93, 149, 154.

The purer hard soap is the only sort intended for internal use. This, triturated with oily or resinous matters, renders them soluble in water; and hence becomes an ingredient in pills composed of reiks, promoting their dissolusion in the stomach, and union with the animal fluids. Boerhaave always prescribed soap in resinous pills, unless where an alka lemon or purgative fibre of the juices forbid its use. From the same quality, soap seems well fitted for dissolving oily or unctuous matters and viscidities in the human body; thereby opening obstructions, and digesting all the vessels it passes through. It is likewise a powerful menstruum for the calculus, or stone in the bladder; a solution of it in lime-water being one of the strongest dissolvents that can with safety be taken into the stomach; the virtue of this composition is considerably greater than the aggregate of the dissolving powers of the soap and lime-water when unmixed.

Socage, an ancient tenure, by which lands were held on condition of ploughing the lord’s lands, and doing the operations of husbandry, at their own charges.

Soccus, in antiquity, a kind of high shoe, reaching above the ankle, worn by comedians, as the cothurnus was by tragedians.

Society, in general, denotes a number of persons united together for their mutual affluence, security, interest, or entertainment.

The social principle in man is of such an expansive nature, that it cannot be confined within the circuit of a family, of friends, of a neighbourhood; it spreads into wider systems, and draws men into larger communities and commonwealths; since it is in these only, that the more sublime powers of our nature attain the highest improvement and perfection of which they are capable.
than two guineas annually. Ladies are also admitted members, and foreigners are likewise admitted as honorary or corresponding members. The money of the society is placed in the bank of England, in the name of the president and vice-presidents, three of whom are empowered to draw any from the society shall order to be paid. The society's office is opposite to Beauford buildings in the Strand, in London, where their meetings are held every Wednesday evening, from the second Wednesday in November, to the last Wednesday in May, and at other times every first and third Wednesday of every month.

Society for the reformation of manners, and putting in execution the laws against immorality and profaneness. It was set on foot about forty years ago, by five or six private persons in London, but is since exceedingly increased by numbers of all denominations. A particular body of the most considerable hereof, bear the expense of prosecutions, &c., without any contribution from the rest. These chiefly apply themselves to the prosecuting people for swearing, drunkenness, and prophaning the sabbath. Another body, of about fifty persons, apply themselves to the suppressing lewdness, and by them above five hundred lewd houses have been actually suppressed; a third body consists of confables; and a fourth of informers. Besides these, there are eight other regular mixed bodies of house-keepers and officers, who inspect the behaviour of the confables and other officers, assist in searching disorderly houses, seizing offenders, giving information, &c. There are several other societies of this kind at Bristol, Canterbury, Nottingham, &c.

Society for propagating the gospel in foreign parts, was instituted by king William, in 1701, for securing a maintenance for an orthodox clergy, and making other provisions for the propagation of the gospel in the plantations, colonies, frontiers, &c. To that end he incorporated the archbishops, several bishops, and other nobility, gentry, and clergy, to the number of ninety, with privilege to purchase two thousand pounds per year, inheritance and estates for lives or years, with other goods to any value. They meet yearly on the third Friday of February, to choose a president, vice-president, and other officers; and the third Friday in every month to transact business, and choose by lot persons to take subscriptions for the said funds, and of all money so received to give account to the lord chancellor, &c. They have a standing committee at the chamber-house, to prepare matters for the monthly meeting which is held at St. Martin's library.

Society for propagating Christian knowledge. This was begun in 1699, by some persons of worth, &c. Its original design was to propagate religion in the plantations, to secure the pious education of the poor at home, and to reclaim those that err in the fundamentals of Christianity. In the year 1701, they had procured considerable charities, and transmitted the same to the plantations, in libraries, bibles, catechisms, &c., with a voluntary maintenance for several ministers to be employed in the plantations; but the society for propagating the gospel in foreign parts being then instituted, they were incorporated by charter in the same, and thus discharged as a particular society from the further pursuit of that branch of their original design; whereupon they wholly turned themselves to the other, and are now very considerable by great accessions from the clergy and laity. They meet weekly to concert measures for raising charity for educating poor children, and setting up schools for that purpose, as also for the more regular disposal of books for the instruction of the ignorant, erroneous, &c.

For the other societies established by charter, see College, Company, Incorporation, and Stocks. Society, in Scots law. See Law, Tit. xxi. 5.

SOCII criminiis, in Scots law. See Law, Tit. xxxiii. 50.

SOCINIANs, in church-history, a sect of Christian heretics, so called from their founder Faustus Socinus, a native of Sicena in Italy. He, about the year 1574, began openly to declare against the Catholic faith, and taught, 1. That the eternal Father was the only God; that the Word was no more than an expression of the Godhead, and had not existed from all eternity; and that Jesus Christ was God no otherwise than by his superiority above all creatures who were put in subjection to him by the Father. 2. That Jesus Christ was not a mediator between God and men, but sent into the world to serve as a pattern of their conduct. 3. That the punishment of hell will last but for a certain time, after which the body and soul will be destroyed. And, 4. That it is not lawful for princes to make war. These four tenets were what Socinus defended with the greatest zeal. In other matters, he was a Lutheran or a Calvinist; and the truth is, that he did but refine upon the errors of all the antitrinitarians that went before him.

SOCOTORA, an island in the Indian ocean, about seventy miles long, and fifty broad: situate in E. long. 55°, N. lat. 11°.

SOCRATIC PHILOSOPHY, the doctrines and opinions, with regard to morality and religion, maintained and taught by Socrates. By the character of Socrates left us by the ancients, particularly by his scholar Plato, he appears to have been one of the best and greatest persons in all the heathen world. To him is ascribed the first introducing of moral philosophy, which is what is meant by that usual saying, "That Socrates "first called philosophy down from heaven to earth," that is, from the contemplation of the heavens and heavenly bodies, he led men to consider themselves, their own passions, opinions, faculties, duties, actions, &c. He wrote nothing himself; yet all the Grecian sects of philosophers refer their origin to his discipline, particularly the platonists, peripatetics, academicians, eunomians, &c., but the greatest part of his philosophy we have in the works of Plato.

SODA, or Heat of the stomach, in medicine, the name of a distemper compelling in a heat or troublesome burning about the pit of the stomach, or its left mouth which sometimes is extended the whole length of the esophagus, with a pressure or spasmodic contraction, usually attacking the patient by fits. See Medicine.

SODUBURY, a market-town of Gloucestershire, situated ten miles north-east of Bristol.

SODOMY, the unnatural crime of buggery, thus called from the city of Sodom, which was destroyed by fire for the same. The Levitical law adjudged those guilty of this execrable crime to death, and the civil law assigns the same punishment to it. Our law also makes it felony. There is no statute in Scotland against sodomy; the
libel of the crime is therefore founded on the divine law, and practice makes it punishable by burning alive.

SOFA, in the Turkish customs, a bench of wood raised from the ground about a foot high, and placed round a half or chamber for the people to sit down upon, or to lie along, and in that posture to take a view of what passes in the streets, &c. For these benches are surrounded with windows; they are covered with fine Turkish carpets; and upon that are placed cushions of fattin, flowered with gold or some other rich stuff.

SOFALA, the capital of the territory of that name in Africa, situated at the mouth of the river Sofala, in E. long. 35°, S. lat. 20°.

SOFFITA, or SOFFIT, in architecture, any plaster or ceiling formed of beams of flying cornices, the square compartments or pannels of which are enriched with sculpture, painting or gilding; such are those in the palaces of Italy, and in the apartments of Luxemburg at Paris.

SOFTENING, in painting, the mixing and diluting of colours with the brash or pencil.

SOGLIANA, a country of Asia, situated on the north side of the river Oxus, which separated it from the ancient Bactria, now a part of Ubbe Tartary.

SOHAM, a market-town of Cambridge, situated on a lake called Soham Meer, in the isle of Ely, fourteen miles north-east of Cambridge.

SOIL, in agriculture. See AGRICULTURE, p. 50.

SOISSONS, a city of France, in the province of the isle of France, situated on the river Ayle, fifty-five miles north-east of Paris.

SOL, the Sun, in astronomy, &c. See ASTRONOMY, p. 435.

SOL, in chemistry, is gold. See CHEMISTRY, p. 78.

SOL, in heraldry, denotes Or, the golden colour in the arms of foreign princes.

SOLÆUS, in anatomy. See ANATOMY, p. 209.

SOLANUM, in botany, a genus of the pentandria mono-gynia class. The corolla is rotated; the antherae are very close together, opening with a double pore at the points; and the berry has two cells. There are 30 species, two of them natives of Britain, viz. the nigrum, or common nightshade; and the dulcamara, or woody nightshade.

Common nightshade is used to allay inflammations.

Some years ago, the internal use of the solanum was much recommended by some writers, in cancerous cases, to leach ulcers, and scorfbaric eruptions: however, later experience has shown this simple to be not only of little or no efficacy in such cases, but to be attended with actual danger to the patient.

SOLAR, something belonging to the sun. See ASTRONOMY, p. 435.

SOLDANELLA, in botany, a genus of the pentandria monogynia class. The corolla is bell-shaped, and split into many segments. There is but one species, a native of Switzerland.

SOLDER, a metallic or mineral composition used in soldering or joining together other metals.

Solders are made of gold, silver, copper, tin, bismuth, and lead; usually observing, that in the composition there be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of solder, viz. solder of eight, where to seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four, and solder of three. It is the mixture of copper in the solder that makes solder to come always cheaper than flat. The solder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it, and pouring the bigness of a crown-piece upon a table; for if good, there will arise little bright shining stars therein. The solder for copper is made like that of the plumbers, only with copper and tin; for very nice works, instead of tin they sometimes use a quantity of silver. Solder for tin is made of two thirds of tin and one of lead: but where the work is anything delicate, as in organ pipes, where the juncture is scarce discernable, it is made of one part of bismuth and three parts of pewter.

SOLDERING, among mechanics, the joining and fastening together two pieces of the same metal, or of two different metals, by the fusion and application of some metallic composition on the extremities of the metals to be joined. See the last article.

To solder upon silver, brass, or iron: take silver, five penny-weight; brass, four penny-weight; melt them together for soft solder, which runs soonest. Take silver, five pennyweight; copper, three penny-weight; melt them together for hard solder. Beat the solder thin, and lay it on the place to be soldered, which must be first fitted and bound together with wire, as occasion requires; then take borax in powder, and temper it like ppp, and lay it upon the solder, letting it dry; then cover it with quick coals, and blow, and it will run immediately; take it presently out of the fire, and it is done. It is to be observed, that if any thing is to be soldered in two places, which cannot well be done at one time, you must first solder with the harder solder, and then with the soft; for if it be first done with the soft, it will unfolder again before the other is soldered. Let it be observed, that if you would have the solder run about the piece that is to be soldered, you must rub such places over with chalk.

In the soldering either of gold, silver, copper, and all the metals before-mentioned, there is generally used borax in powder, and sometimes rosin. As to iron, it is sufficient that it be heated red hot, and the two extremities thus hammered together, by which means they will become incorporated into one another.

SOLDIER, a military man lifted to serve a prince or state, in consideration of a certain daily pay.

SOLE, in the manage, a nail or foot of horn under a horse's foot, which is much more tender than the other horn that compasses the foot, and by reason of its hardnes is properly called the horn or hoof.

SOLEA, in ichthyology. See Pleuronectes.

SOLEÆE, among the Romans, a kind of sandals or flippers, which covered only the sole of the feet, and were bound on with thongs of leather, instead of which the women and the effeminate ones of the other sex tied them on with purple-coloured ribbons, or such as were variously adorned with gold and silver.

SOLECISM, in grammar, a false manner of speaking contrary to the use of language and the rules of grammar, either in respect of declension, conjugation, or syntax.

SELENIUM, in zoology, a genus of insects belonging to the order
order of vermes tectacea. The shell is oblong, bivalved, and opening at both sides; the cardo has a subulate reflected tooth, not inserted into the opposite valve. There are eleven species, distinguished by peculiarities in their shells.

SOLEPAING, in music, the naming or pronouncing the several notes of a song by the syllables ut, re, mi, fa, sol, &c. and in learning to sing it. See Music.

SOLICITOR, a person employed to take care of, and manage suits depending in the courts of law or equity.

There is also a great officer of the law, next to the attorney-general, who is styled the king's solicitor-general; who holds his office by patent, during the king's pleasure. The care and concern of managing the king's affairs, and has fees for pleading, besides other fees arising by patents, &c. He has his attendance on the privy council; and the attorney-general and he were anciently reckoned among the officers of the exchequer; they have their audience, and come within the bar in all other courts.

SOLID, a body whose parts are so firmly connected together, as not to give way, or slip from each other upon the smallest impression, in which sense, solid fluids opposed to fluid.

SOLIDAGO, in botany, a genus of the syngenesia polygamia superflua class. The receptacle is naked; the pappus is simple; the calyx is imbricated with flut scales. There are twelve species, two of them natives of Britain, viz. the virgaurea, or common golden rod; and the cambrica, or Welsh golden rod.

SOLIDITY, that property of matter, or body, by which it excludes all other bodies from that place which itself possesses. See Metaphysics.

SOLILLOQUY, a reasoning or discourse which a man holds with himself; or, more properly, according to Papias, it is a discourse by way of answer to a question that a man proposes to himself. Soliloquies are become very common things on the stage; yet can nothing be more unnatural, than an actor's making long speeches to himself, to convey his intentions to the audience. Where such discoveries are necessary to be made, the poet should rather take care to give the dramatic personages such confidents as may necessarily share their inoffin thoughts, by which means they will be more naturally conveyed to the audience: yet is even this a shift an accurate poet would not be found to have occasion for.

SOLITARY, something retired or in private, remote from the company or commerce of others of the same species.

SOLITARIES, a denomination of nuns of St. Peter of Alcantara, instituted in 1576, the design of which is to imitate the fiercer penitent life of that saint; thus they are to keep a continual silence, never to open their mouths to any body but themselves; employ their time wholly in spiritual exercises, and leave the temporal concerns to a number of maids, who have a particular superior in a separate part of the monastery. They always go bare footed, without sandals, gird themselves with a thick cord, and wear no linen.

SOLMS, the capital of the county of Solms, in the land-grave of Hesse-Cassel, in Germany, thirty-five miles north of Frankfort.

SOLON, in music, a term used in pieces consisting of several parts, to mark those that are to perform alone.

SOLON'S ISLANDS, a cluster of islands in the Pacific ocean, situated between 130° and 140° W. long., and between 7° and 12° S. lat.

SOLON'S SEAL, in botany. See Convallaria.

SOLOTHURN, one of the cantons of Switzerland, lying between those of Basli and Bern, the former on the north, and the latter on the south.

The city of Solothurn, capital of the said canton, is situated in E. long. 7° 15', and N. lat. 47° 18'.

SOLSTICE, in astronomy, that time when the sun is in one of the solstitial points; that is, when he is at his greatest distance from the equator. See Astronomy.

SOLVENT, the same with dissolvent. See Dissolvent.

SOLUTION, in chemistry, denotes an intimate mixture of solid bodies with fluids, so as seemingly to form one homogeneous liquor; the dissolving fluid is termed the dissolvent or menstruum. See Chemistry, paffim.

SOMERSETSHIRE, a county of England, situated on the Bristol channel, and bounded by Wiltshire on the east, by Dorsetshire on the south, and by Devonshire on the west; it is famous for the cloth manufacture.

SOMERTON, a market-town of Somersetshire, twelve miles south of Wells.

SOMME, a river of France, which running from east to west through Picardy, by Amiens and Abbeville, falls into the British channel near St. Vallery.

SONNAMULLI, in medicine, persons who walk in their sleep, otherwise called noctambuli.

SON, an appellation given to a male child, considered in the relation he bears to his parents.

SONATA, in music, a piece, or composition, intended to be performed by instruments only; in which sense, it stands opposed to cantata, or a piece designed for the voice.

SONCHUS, the sow-thistle, in botany, a genus of the syngenesia polygamia sequalis class. The receptacle is naked; the calyx is imbricated, and ventricose; and the pappus is plumose. There are ten species, three of them natives of Britain, viz. the iberica, or common sow-thistle; the arvenis, or tree sow-thistle; and the palustris, or marsh sow-thistle.

Sonchus is accounted cooling and attenuant, and according to the stranguries, as also in inflammations of all kinds, to be applied externally in the form of a cataplasm.

SONG, in poetry, a little composition, consisting of easy and natural verses, set to a tune in order to be sung.

SONG, in music, is applied in general to a single piece of music, whether composed for the voice or an instrument.

SONNA, a book of Mahometan traditions, wherein all the orthodox Mussulmen, or true believers, are required to believe.

SONNET, in poetry, a composition contained in fourteen verses, viz. two stanzas, or measures, of four verses each; and two of three; the eight first verses being all in three rhymes.

SONNETS, among the Mahometans, an appellation given to the orthodox Mussulmen, or true believers; in opposition to the several heretical sects, particularly the schismatics, or followers of Ali.

SOOT, a volatile matter, arising from wood, and other fuel, along with the smoke; or rather, it is the smoke itself, fixed and gathered on the sides of the chimney. See Chemistry, p. 158. and Agriculture, p. 49.
SOPHIST, a title given to the emperor of Persia; importing as much as wise, sage, or philosopher. There is no prince in the world whose authority is more absolute than that of the soplh of Persia.

SOPHISM, in logic, &c. an argument which carries much of the appearance of truth, and yet leads into error.

SOPHIST, a person who ufs sophisms, with a view to deceive those he would persuade or convince.

SOPHISTICATION, the adulterating any thing with what is not good or genuine; a practice too common in the making up medicines for sale; as also among vintners, distillers, and others, who are accused of softificating their wines, spirits, oils, &c. by mixing with them cheaper and coarser materials; and, in many cases, the cheat is carried on so artfully as to deceive the best judges.

SOPHOPRA, in botany, a genus of the decandria monogy clafs. The calix has five teeth, and is glibbous above; the corolla is papilionaceous, with the wings of the same length as the vexillum; and the cappole is a legumen. There are eight species, none of them natives of Britain.

SOPORIFIC MEDICINES, are those capable of procuring sleep, as opiates, &c. See OPIATES, &c.

SORBONNE, the house or college of the faculty of theology, in the university of Paris; sometimes also used for the faculij itself, because it usually assembles in the house of the forbonne.

SORBUS, in botany, a genus of the icofandria trigynia clafs. The calix consists of five leaves, and the corolla of five petals; and the berry contains three seeds. There are three species, two of them natives of Britain, viz. the domestica, or the true service or forb; and the aucuparia, quicken-tree, or mountain-ash.

SORCERY, the crime of witchcraft or divination by the aid of an evil spirit. See Witchcraft.

SORET, a province of the Hither India, lying northwards of Guzerat: its chief town is Jaganat.

SOREX, in zoology. See Mus.

SORITES, in logic, a species of reasoning, in which a great number of propositions are so linked together, that the predicate of the one becomes continually the subject of the next following, till at last a conclusion is formed by bringing together the subject of the first proposition and the predicate of the last. See LOGIC.

SOTERIA, in antiquity, sacrifices offered to the gods for delivering a person from danger; as also poetical pieces composed for the same purpose.

SOTOVENTO ISLANDS are situated on the coast of Terra Firma; the chief of which are Trinidad, Margareta, Tortuga, &c. They are also called the Leffer Antilles.

SOUBISE, a town of Guienne, in France. Situated on the river Charente, seventeen miles south of Rochelle.

SOUFFLAGE, a species of divination, performed by means of fortes or lots.

The fortes prenexit, famous in antiquity, consisted in putting a number of letters, or even whole words, into a urn; and then, after shuffling them together, they were thrown on the ground, and whatever sentences could be made out from them constituted the answer of the oracle.

Another kind of fortes consisted in taking some celebrated poet, as Homer or Virgil; and, opening the book, whatever presented itself first to the eye made the answer; and hence it got the name of fortes homericse, and fortes or lots.

The fortes prenexit, famous in antiquity, consisted in taking some celebrated poet, as Homer or Virgil; and, opening the book, whatever presented itself first to the eye made the answer; and hence it got the name of fortes homericse, and fortes or lots.

SOUGHS, among miners, denotes a passage dug underground, to convey off water from mines.

SOVEREIGN, in matters of government, is applied to the supreme magiftrate, or magiftrates, of an independent government or state; by reason their authority is only bounded by the laws of God, of nature, and the fundamental laws of the state; such are kings, princes, &c.

SOUL, a spiritual substance, which animates the bodies of living creatures; it is the principle of life and activity within them.

Various have been the opinions of philosophers concerning the subsistence of the human soul. The Cartelians make thinking the essence of the soul. Others again hold, that man is endowed with three kinds of souls, viz. the rational, which is purely spiritual, and infused by the immediate inspiration of God; the irrational, or sensitive, which is common to man and brutes; and lastly, the vegetative soul, or principle of growth and nutrition.

That the soul is an immaterial subsistence appears from hence, that its primary operations of willing and thinking have not only no connection with the known properties of body, but seem plainly inconsistent with some of its most essential qualities. For the mind discovers no relation between thinking and the motion and arrangement of parts.

As to the immortality of the human soul, the arguments to prove it may be reduced to the following heads: 1. The nature of the soul itself, its desires, sense of moral good and evil, gradual increase in knowledge and perfection, &c. 2. The moral attributes of God.

Under the former of these heads it is urged, that the soul, being an immaterial intelligent subsistence, does not depend on the body for its existence; and therefore may, nay, and must, exist after the dissolution of the body, unless annihilated by the same power which gave it a being at first. This argument, especially if the infinite capacity of the soul, its strong desire after immortality, its rational activity and advancement towards perfection, be likewise considered, will appear perfectly conclusive to men of a philosophical turn; because nature, or rather the God of nature, does nothing in vain.

But arguments drawn from the latter head, viz. the moral attributes of the Deity, are not only better adapted to convince men unacquainted with abstract reasoning, but equally certain and conclusive with the former: for as the justice of God can never suffer the wicked to escape unpunished, nor the good to remain always unrewarded; therefore, arguments drawn from the manifest and confvant prosperity of the wicked, and the frequent unhappiness of good men in this life, must convince every thinking person, that there is a future state wherein all will

SPANISH, a market-town of Lincolnshire, situated under the meridian of London, thirty miles south-east of Lincoln.
SPAN, a measure taken from the space between the thumb's end and the tip of the little finger, when both are stretched out. The span is estimated at three hand's breadths, or nine inches.
SPANDAW, a town of Germany, in the circle of Saxony, and Marquisate of Brandenburg, situated on the river Havel, eight miles north-west of Berlin.
SPANIEL, in zoology. See Canis.
SPAR, in natural history, a class of fossils, not inflammable nor soluble in water; when pure, it is pellucid and colourless, and imitating the appearance of crystal, but wanting its distinguishing characters; composed of plane and equable plates, not flexible nor elastic, not giving fire with steel, readily calcining in a small fire, and fermenting violently with acids, and wholly soluble in them.
The spars, in general, are found in the fissures of stones, and about mines. Derbyshire affords enough of them to supply the whole world; and the German mines afford yet larger quantities.
SPARADAPUM, in pharmacy. &c. a sort of cerecloth, called also tela Quarters, the form whereof is directed as follows. Take of the diaphalma plaster, and diachylon with the gums, each one pound; ceruse, half a pound; root of oris finely powdered, an ounce and a half. Mix these together, and whilst they are in fusion, dip them in soft worn-out linen rags, so that they may be covered with the plaster on each side; then take them out, spread them, and let them dry; and smooth the surfaces with

Vol. III. No. 94.
SPARTIUM, in botany, a genus of the moncecia triandria clafs. The amentum of both male and female is roundish; and the calyx of both consists of three leaves; neither of them have any corolla; the stigma of the female is bifid; and the drop is dry, and contains two seeds. There are two species, both natives of Britain, viz. the erectum, or great-bur-reed; and the natans, or leaf-bur-reed.

SPARROW, in ornithology. See Fringilla.

SPARROW-HAWK, in ornithology. See Falco.

SPARTIUM, in botany, a genus of the diadeiphia decan-

Speculum, in furgery, an inftrument for dilating a wound,

SPELL, in general, denotes the -'

SPELLING, in grammar, that part of orthography which
SPIE, a river of Scotland, which, running north-east, through Badenoch and Murray, falls into the German sea, east of the frith of Murray.

SPHELUS, in surgery and medicine, an absolute and perfect corruption or death of the parts. See Medicine and Surgery.

SPHENOID, in geometry, a solid, approaching to the figure of a sphere. The spheroid is generated by the entire revolution of a semi-ellipsoid about its axis.

SPHERICAL, in anatomy, something belonging to the sperm or seed. See Anatomy, p. 270.

SPERMACOCE, in botany, a genus of the tetrandria monogynia clafs. The corolla consists of one funnel-shaped petal; and it has two bidentated seeds. There are six species, none of them natives of Britain.

SPERMATIC, in anatomy, something belonging to the sperm or seed. See Seed.

SPERM-CASTI, a white flaky substance, prepared from the oil of a species of whale, called phystrer macrocephalus. See Physyter.

SPERMATIC, in anatomy, something belonging to the sperm or seed. See Anatomy, p. 270.

SPIE, a river of Scotland, which, running north-east, through Badenoch and Murray, falls into the German sea, east of the frith of Murray.

SPHACELUS, in surgery and medicine, an absolute and perfect corruption or death of the parts. See Medicine and Surgery.

SPEARANTHUS, in botany, a genus of the syngenefia class. The calyx consists of five segments, and the carpellae of the female of four; neither of them have any corolla; the styli are four; and there is one hard seed within the calyx. The species are two, none of them natives of Britain.

SPERGULA, in botany, a genus of the decandria pentandria class. There are five species, three of them natives of Britain, viz. the arvensis, or corn-spergule; the pentandria, or small spergule; and the nodosa, or knotted spergule.

SPERM, See Seed.

SPERM-CASTI, a white flaky substance, prepared from the oil of a species of whale, called physyter macrocephalus. See Physyter.

SPERMEL, in the glass-trade, an iron instrument, hooked at the end, and pointed, with which the workmen take the metal up out of the melting-pots, for proofs or essays, to see whether it be fit for work.

SPERGELOMBEGO, a town of Italy, in the territory of Venice, and province of Friuli: situated forty-five miles north of Venice.

SPILSBY, a market-town of Lincolnshire: situated twentyseven miles east of Lincoln.

SPINA VENTOSA, in surgery, that species of corruption of the bones which takes its rise in the internal parts, and by degrees enlarges the bone, and raises it into a tumour. See Surgery.

SPINACHIA, in botany, a genus of the dicocia pentandria class. The calyx is imbricated. There are two species, none of them natives of Britain.

SPINARANTHUS, in botany, a genus of the syngeneria class. The anthers are opearculated, and there is no calyx. The species are three, all natives of Britain, viz. the palustre, or grey bog-moss; the alpinum, or mountain bog-moss; and the arborescent, or creeping bog-moss.

SPIGNUS, in botany, a genus of the cryptogamia class. The antherae are apertor, and there is no calyptra. The species are three, all natives of Britain.

SPINEL, or Spinnet, a musical instrument, ranked in the second or third place among harmonious instruments.

SPINNING, the act or art of reducing silk, flax, hemp, wool, hair, or other matters, into thread. Spinning is either performed on the wheel with a distaff and spindle, or with other machines proper for the several kinds of working. Hemp, flax, nettle-thread, and the like vegetable matters, are to be wetted in spinning; silks, wool, &c. are to be spun dry, and do not need water; but there is a way of spinning silk as it comes off the cages or balls, where hot and even boiling water is to be used.

SPINOZISM, the doctrine of Spinoza, or atheism and pantheism proposed after the manner of Spinoza, who was born a Jew at Amsterdam.

The great principles of Spinozism, is, that there is nothing properly and absolutely existing besides matter and the modifications of matter; among which are even comprehended thought, abstract and general ideas, comparisons, relations, 'combinations of relations, &c.

The chief articles in Spinoza's system are reducible to thes. There is but one substance in nature; and that this only-substance is endowed with an infinite number of attributes, among which are extension and cognition; that all the bodies in the universe are modifications of this substance considered as it is extended, and that all the souls of men are modifications of the same substance considered as cogitative: that God is a necessary and infinitely perfect Being, and is the cause of all things that exist,
exist, but not a different being from them: that there is but one being and one nature, and that this nature produces within itself, by an immanent act, all those which we call creatures; and that this being is at the same time both agent and patient, efficient cause and subject, but that he produces nothing but modifications of himself.

SPIRAEA, in botany, a genus of the icofandria pentagymia class. The calix consists of five segments, and the corolla of five petals; and the capsule contains many seeds. There are eleven species, none of them natives of Britain.

SPIRAL, in geometry, a curve line of the circular kind, which, in its progress, recedes from its center.

SPIRAL, in architecture and sculpture, implies a curve that ascends, winding about a cone or spire, so as all the points thereof continually approach the axis. It is distinguished from the helix, by its winding around a cone, whereas the helix winds in the same manner around a cylinder.

SPIRE, in architecture, was used by the ancients for the base of a column, and sometimes for the auralt or tere. But among the moderns, it denotes a spire that continually diminishes as it ascends, whether conically or pyramidaly.

SPIRE, in geography, an imperial city of Germany, capital of a bishopric of the same name, and situated in the palatinate of the Rhine, fifteen miles south-west of Heidelberg: E. long. 8° 17', N. lat. 49° 16'.

SPIRIT, in metaphysics, an incorporeal being or intelligence; in which sense, God is said to be a spirit, as are angels and the human soul.

SPIRITiES, or ANIMAl SPIRiTiES, in physiology. See ANATOMY, p. 253, and there.

SPIRIT, in chemistry, a name applied to several very different substances. However, in general, it denotes any distilled volatile liquor that is not infipid, as phlegm, or pure water, not inflammable as oil; but under this general idea are comprehended liquors of quite opposite natures, some being acid, and others alkaline; which latter are such enemies to the former, that as soon as they are put together, they raise a violent effervescence, and grow hot: and to these may be added a third sort, called vinous or inflammable spirits; which, though very subtil or penetrative, are not manifestly either acid or alkaline. See CHEMISTRY, p. 69, 95, 161, &c.

SPIRiTuaL, in general, something belonging to, or partaking of, the nature of spirit. See SPIRIT.

SPIRiTUALITYiES of a bishop, are the profits he receives as a bishop, and not as a baron of parliament: such are the duties of his vifitation, presentation money, what arises from the ordination and institution of priests, the income of his jurisdiction, &c.

SPIrHEAD, a road between Portsmouth and the isle of Wight, where the Royal navy of Great Britain frequently rendezvous.

SPIrLLE, in physiology. See SALIVA.

SPIrTZBERGEN. See GREENLAND.

SPIrACLUM, in botany, a genus of the cryptogamia musci class. The calix of the male flower is smooth conic calyptra; the anthera are cylindric; and the receptacle coloured, membranaceous, and very large. There are four species, only one of them, viz. the ampliscaleum, a native of Britain.

SPIRiT, in metaphysics, an incorporeal being or intelligence; in which sense, God is said to be a spirit, as are angels and the human soul.

SPIRiT, in chemistry, a name applied to several very different substances. However, in general, it denotes any distilled volatile liquor that is not infipid, as phlegm, or pure water, not inflammable as oil; but under this general idea are comprehended liquors of quite opposite natures, some being acid, and others alkaline; which latter are such enemies to the former, that as soon as they are put together, they raise a violent effervescence, and grow hot: and to these may be added a third sort, called vinous or inflammable spirits; which, though very subtil or penetrative, are not manifestly either acid or alkaline. See CHEMISTRY, p. 69, 95, 161, &c.

SPLENiUS, a person affected with obstruction of the spleen.

SPLENiUS, in anatomy. See ANATOMY, p. 216.

SPLENt, or SPLINT, among farriers, a callous, inessential excrescence, breeding on the shank bone of horses. See Farriery, p. 573.

SPLiCiNg, in the sea-language, is the unwitting the ends of two cables or ropes, and working the several strands into one another by a fidd, so that they become as strong as if they were but one rope.

SPODiuM, in pharmacy, one of the fouleft recurrences of copper.

SPOTS, whatever is taken from the enemy in time of war.

SPOtting, in the lea-language, is said of a ship, which, being under sail in a storm at sea, is unable to bear it, and accordingly, called fiddclae and maculae.

SPOW, or WATER-SPOT, an extraordinary and dangerous meteor, observed at sea, and sometimes at land, called by the Latins typho and sipho. Its first appearance is in form of a deep cloud, the upper part of which is white, and the lower black: then from the lower part of this cloud hangs, or rather falls down, what is properly called the spout, in form of a conical tube, biggish at top; and under this tube, there is always a great boiling.
boiling and flying up of the water of the sea, as in a
jet d'eau. For some yards above the surface of the sea,
the water stands as a column or pillar, from the extreme
ity whereof it spreads and goes off, as in a kind of
smoke. Frequently, the cone descends so low, as to
touch the middle of this column, and continue for some
time contiguous to it; though sometimes it only points
to it, at some distance, either in a perpendicular or
oblique line. Frequently it is scarce distinguishable
whether the cone or the column appear the first, both
appearing all of a sudden against each other. But some-
times the water boils up from the sea to a great height,
without any appearance of a spout pointing to it, either
perpendicularly or obliquely. Indeed, generally, the
boiling or flying up of the water has the priority, this
always preceding its being formed into a column. Gen-
erally, the cone does not appear hollow, till towards
the end, when the sea-water is violently thrown up along
its middle, as smoke up a chimney. Soon after this, the
spout or canal breaks and disappears; the boiling up of
the water, and even the pillar, continuing to the half,
and for some time afterwards; sometimes till the spout
form itself again, and appear anew; which it sometimes
does several times in a quarter of an hour.

M. de la Pyme, from a near observation of two or
three spouts in Yorkshire, described in the Philosophical
Transactions, gathers, that the water-spout is nothing but
a gyration of clouds by contrary winds, meeting in a
point or centre; and there, where the greatest condensa-
tion and gravitation is, falling down into a pipe or great
tube, somewhat like Archimedes' spiral screw; and in
its working and whirling motion, absorbing and rai-
ning the water, in the same manner as the spiral screw does;
and thus destroying ships, &c.

SPRING, in ichthyology. See Clupea.

SPRING, in natural history, a fountain or source of water,
rising out of the ground. See Hydrostatics.

Spring, in mechanics, denotes a thin piece of tempered
steel, or other elastic substance; which, being wound up,
serves to put several machines in motion by its elas-
ticity, or endeavour to unbend itself; such is the spring of
a clock, watch, and the like.

SPRING-TIDE. See Astronomy, p. 473, &c.

SPRUNG. See Spongia.

SPUN, yarn, among sailors, is a kind of line made from
rop yarn, and used for seizing or fastening things to-
gether.

SPUR, a piece of metal, confining of two branches em-
passing a horseman's heel, and a rowel in form of a star,
advancing out behind to prick the horse.

SPURGE, in botany. See Euphorbia.

SPURGE LAUREL. See Daphne.

SPURKETS, in a ship, spaces between the upper and lower
futtocks, or betwixt the rungs fore and aft.

SPURRY, in botany. See Spergula.

SPUTUM, among physicians, denotes the same with the
saliva or spittle. See Saliva.

SPY, a person hired to watch the actions, motions, &c.

SQUADRON, in military affairs, denotes a body of horse
whose number of men is not fixed; but is usually from
one to two hundred.

SQUADRON OF SHIPS, a division or part of a fleet, com-
manded by a vice-admiral, or commodore.

SQUALUS, the shark kind, in ichthyology, a genus
belonging to the order of ammamia nantes. There are
five spiracula, one on each side of the neck; the body is
ob-
long, and somewhat cylindrical; and the mouth is situ-
ated in the anterior part of the head. There are 15 spe-
cies, all inhabitants of the ocean.

SQUAMARIA, in botany. See Lathraea.

SQUAMOUS, in anatomy, an appellation given to the spar-
ious or scale-like virtues of the skin, because composed of
squares or scales like those of fish. See Anatomy, p. 153.

SQUARE, in geometry, a quadrilateral figure, both equi-
lateral and equiangular. See Geometry.

SQUARE ROOT. See Arithmetick, p. 420.

SQUATINA. See Squalus.

STABLE, a place or house for horses, &c. furnished with
stalls and proper apartments to contain their food, &c.

STADTHOLDER, the principal governor or magistrate
of the United Provinces.

STADIUM, an ancient Greek long measure.

STAG, in zoology. See Sciurus.

STICK, in botany. See Scilla.

STINTING. See Strabismus.

STIRK, in zoology. See Sciurus.

STABLE, a place or house for horses, &c. furnished with
stalls and proper apartments to contain their food, &c.

STACHYS, in botany, a genus of the didynamia gymno-
perma class. The upper labium is vaulted, and the inferior
one reflected in the edges; the intermediate labium being
larger, and emarginated; and the flaminia are reflected
towards the sides. There are 12 species, three of them natives
of Britain, viz. the germanica, or base hore-hound; the flan-
mia, or hedge nettle; and the palusiris, or clown's gall, heal.

STADIUM, an ancient Greek long measure.

STADIUM was also the course or career wherein the
Greeks ran their races.

STADTHOLDER, the principal governor or magistrate
of the United Provinces.

The stadtholder seems to be impowered, either direc-
tly or by his influence, to change both the deputies, mag-
istrates, and officers, in every province and city. He is
president in the states of every province, though he has
not so much as a seat or vote in the states-general; but
as he influences the states of each province to send what
deputies he pleases to the states-general, he has, in effec-
t, the appointing the persons that constitute the states-
general, and may be deemed sovereign of the united pro-
vinces. The stadtholders had once a very great power.
We find one of their stadtholders appointing what towns
should send deputies or members to the assembly of the
states of Holland: but the stadtholdership was never he-
reditary till now, when in the year 1747 it was made so
in the family of Orange.
STAEHELINA, in botany, a genus of the family Polygonaceae. The receptacle is naked; the pappus is feathered; and the calyx is imbricated with scales, membranaceous, coloured, and reflected at the points. There are two species, none of them natives of Britain.

STAFF, an instrument ordinarily used to rest on in walking. The staff is also frequently used as a kind of natural weapon both of offence and defence, and for several other purposes.

STAFFORD, the county-town of Staffordshire, is situated one hundred and thirty miles north-west of London. It sends two members to parliament.

STAGGERS. See Farriery, p. 552.

STAINES, a town of Middlesex, situated nineteen miles south of London. It sends two members to parliament.

STAIR-CASE, in architecture, an ascent inclosed between walls, or a balustrade, consisting of stairs, or steps, with landing-places and rails, serving to make a communication between the several stories of a house. See Architecture, p. 360.

STALACTITE, in natural history, crystalline spars formed into oblong, conical, round, or irregular bodies, composed of various crusts, and usually found hanging in form of icicles from the roofs of grottos, &c.

STALBRIDGE, a market-town of Dorsetshire, situated eighteen miles north of Dorchester.

STALK, in botany, that part of a plant which rises immediately from the root, and which supports the leaves of the flowers and the fruit.

STALLION, or Stone-horse, in the menage, an ungelt horse, designed for the covering of mares, in order to propagate the species. See Equus.

STAMFORD, a borough-town of Lincolnshire, situated thirty-five miles south of Lincoln. It sends two members to parliament.

STAMINA, in the animal body, are defined to be those simple original parts, which exist first in the embryo, or even in the seed; and by whose distillation, augmentation, and accretion, by additional juices, the animal body, at its utmost bulk, is supposed to be formed.

STAMINEOUS, in botany, a term for those flowers of plants which have no petals or flower-leaves, but consist only of a number of stamens and pistils placed in a cup.

STAMP-DUTIES, certain impositions laid on all parchment and paper, on which deeds, grants, or other instruments, or any processes in law or equity, are ingrossed or written. These duties, when first granted, were from forty shillings for letters-patent, &c. to sixpence for the usual deeds; and one penny for declarations, pleadings, &c. They have been, in general, doubled and trebled, by subsequent statutes; and the common stamp now is the treble sixpenny. Persons writing or engrossing anything charged with the duty on parchment or paper, before it is stamped, or if it be marked with any lower duty than what is required, are liable to forfeit ½; and the deed shall not be deemed good in law, till such penalty is paid, and the same be stamped, &c.

STAMPALIA, an island of the Archipelago, about fifty miles in circumference, situated in E. long. 26° 30’, and N. lat. 36° 20’.

STANCHION, or Stanchions, in a ship, those pillars, which being set up piller-wise, do support and strengthen the waile-trees.

STAND, in commerce, a weight, from two hundred and a half to three hundred, of pitch.

STANDARD, in war, a fort of banner, or flag, borne as a signal for the joining together of the several troops belonging to the same body. See Flag, &c.

STANDARD, in commerce, the original of a weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try the weights used by particular persons in traffic. See Money.

STANDON, a town of Hertfordshire, situated under the meridian of London, and seven miles north of Hertford.

STANHOPE, a market-town of Durham, situated sixteen miles south of Durham.

STANLEY, a town of Gloucestershire, situated twelve miles south of Glocester.

STANNARIES, the mines and works where tin is dug and purified, as in Cornwal, Devonshire, &c. There are four courts of the stannaries in Devonshire, and as many in Cornwal; and great liberties were granted them by several acts of parliament in the time of Edward I. &c. though somewhat abridged under Edward III., and Charles I.

STANTON, a town of Lincolnshire, situated seventeen miles east of Lincoln, under the meridian of London.

STANZA, in poetry, a certain dated number of verses, generally containing a perfect sense, that ought to end with some lively and ingenious thought, or just and pertinent reflection.

STAPELIA, in botany, a genus of the pentandria tri-clas of plants. The plant is contorted, with a double star-like nectarium covering the fructification. There are two species, both natives of the Cape of Good Hope.

STAPES, in anatomy. See Anatomy, p. 296.

STAPHYLÆA, in botany, a genus of the pentandria tri-gynia clas. The calyx consists of five segments, and the corolla of five petals; the capsules are inflated and conuate; and there are two globular seeds. There are two species, both natives of the Cape of Good Hope.

STAPHYLINUS, in zoology, a genus of insects belonging to the order of coleoptera: the antennae are slender; the elytra are dimidiated, and cover the wings; and the tail is simple, and furnished with two oblong bladders. There are 17 species, principally distinguished by their colour.

STAPLE primarily signifies a public place or market, whether
Falling Stars, in meteorology, fiery meteors, which dart through the sky, in form of a star; being occasioned by a nitro-sulphurous matter, the common cause of all such meteors.

Star, in heraldry, a charge frequently borne on the shield, the garter, bath, and triple. See Garter.

Star-board, in the sea-language. denotes the right-hand side of a ship; thus they say, star-board the helm, or helm a star-board, when he that conds would have the men at the helm, or steering-wheel, put to the right-hand side of the ship.

Star chamber, a chamber at Westminster, so called from the part of the body; and some species have one of the rays bifid; so as to emulate the appearance of a six-rayed kind.

Star-chest. See Centaurea.

Starling. See Sturnus.

Stars. See Asterias.

Star shot, a gelatinous substance frequently found in vessels wherein wheat has been steeped in water; of which fevula, after separating the bran from it, by passing it through sieves, they form a kind of loaves, which being dried in the sun or an oven, is afterwards cut into little pieces, and so fold. The bell stalk is white, fiof, and friable, and easily broken into powder. Such as require fine stalk do not content themselves, like the stalk-men, with refuse wheat, but use the finest grain. The process is as follows: The grain being well cleaned is put to ferment in vessels full of water, which they expose to the sun while in its greatest heat, changing the water twice a day, for the space of eight or twelve days, according to the season. When the grain bursts easily under the finger, they judge it sufficiently fermented. The fermentation perfected, and the grain thus softened, it is put, handful by handful, into a canvas bag, to separate the flour from the husks, which is done by rubbing and beating it on a plank laid across the mouth of an empty vessel that is to receive the flour.

As the vessels are filled with this liquid flour, there is seen swimming at the top redish water, which is to be carefully fumed off from time to time, and clean water is to be put in its place; which, after flirring the whole together, is also to be strained through a cloth of sieve, and what is left behind put into the vessel with new water, and exposed to the sun for some time. As the fermentation thickens at the bottom, they drain off the water four or five times, by inclining the vessel, but without passing it through the sieve. What remains at bottom is the stalk, which they cut in pieces to get out, and leave it to dry in the sun. When dry, it is laid up for use.

Star-stone, in natural history, a name given to certain extraneous fossiliferous stones, in form of short, and commonly means, but crooked, columns, composed of several joints; each resembling the figure of a radiated star; with a larger or smaller number of rays in the different species; they are universally found of about an inch in length, and of the thicknees of a goose-quill. Some of them have five angles, or rays, and others only four, and in some the angles are equi-distant, while in others they are irregularly so; in some also they are short and blunt, while in others they are long, narrow, and pointed; and some have their angles so very short and obtuse, that at first sight they might be taken for entrochoasteries. The several joints in the same specimen are usually all of the same thicknees; this however is not always the case, but in some they are larger at one end, and in others at the middle, than in any other part of the body; and some species have one of the FOTHER MERCHANTS, &c. are obliged to bring their goods to be bought by the people, as the Greve, or the places along the Seine, for sale of wines and corn, at Paris, whether the merchants of other parts are obliged to bring those commodities.

Formerly the merchants of England were obliged to carry their wool, cloth, lead, and other like staple-commodities of this realm, in order to utter the same by wholesale; and these staples were appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Norwich, Welfminster, Canterbury, Chechester, Winchester, Exeter, and Bristol; in each whereof a public mast was appointed to be kept, and each of them had a court of the mayor of the staple, for deciding differences, held according to the law-merchant, in a summary way.

STAR, in astronomy. See Astronomy, passim.

Falling Stars, in meteorology, fiery meteors, which dart through the sky, in form of a star; being occasioned by a nitro-sulphurous matter, the common cause of all such meteors.

Star, in heraldry, a charge frequently borne on the shield, the garter, bath, and triple. See Garter.

Star-board, in the sea-language. denotes the right-hand side of a ship; thus they say, star-board the helm, or helm a star-board, when he that conds would have the men at the helm, or steering-wheel, put to the right-hand side of the ship.

Star chamber, a chamber at Westminster, so called from the part of the body; and some species have one of the rays bifid; so as to emulate the appearance of a six-rayed kind.

Star-chest. See Centaurea.

Starling. See Sturnus.

Start-point, a cape or promontory of Devonshire, in the English channel, twelve miles south of Dartmouth.

State, or estate, an empire, kingdom, province, or extent of country under the same government.

States, or Estates, a term applied to several orders or classes of people assembled to consult of matters for the public good.

Thus states-general is the name of an assembly consisting of the deputies of the seven United Provinces; these are usually thirty in number, some provinces sending two, others more; and whatever resolution the states-general take, must be confirmed by every province, and by every city and republic in that province, before it has the force of a law. The deputies of each province, of what number ever they be, have only one voice, and are esteemed as
as but one person, the votes being given by provinces. Each province prefides in the assembly in its turn, according to the order settled among them. Guelderland prefides first, then Holland, &c.

States of Holland are the deputies of eighteen cities, and one representative of the nobility, constituting the states of the province of Holland: the other provinces have likewise their states, representing their sovereignty, deputies from which make what they call the states-general. In an assembly of the states of a particular province, one dissenting voice prevents their coming to any resolution.

Statice, in botany, a genus of the pentandria trigyna class. The calix is one entire plaited leaf; the corolla consists of five petals; it has but one seed. There are 14 species, three of them natives of Britain, viz. the armoria, or sea gilly-flower; the limonium, or sea-lavender; and the reticulata, or matted sea-lavender.

Statics, that branch of mathematics which considers the motion of bodies arising from gravity. See Hydrostatics, and Mechanics.

Station, in geometry, surveying, &c., a place pitched upon to make an observation, take an angle, or the like.

Stationary, in astronomy, signifies the appearance of a planet, when it seems to remain immovable on the same point of the zodiac for several days. See Astronomy.

Stationary-days, in church-history, an appellation given to figures or statues of princes that were not kept with such rigour and strictness as Lent.

Stationary, in its general sense, signifies a law, ordinance, decree, &c. See Law, &c.

Statute, in our laws and customs, more immediately signifies an act of parliament made by the three estates of the realm: and such statutes are either general, of which the courts at Westminster take notice, without pleading them; or they are special and private, which last must be pleaded.

States of Holland are the deputies of eighteen cities, and one representative of the nobility, constituting the states of the province of Holland: the other provinces have likewise their states, representing their sovereignty, deputies from which make what they call the states-general. In an assembly of the states of a particular province, one dissenting voice prevents their coming to any resolution.

Stavanger, a port-town of Norway, in the province of Bergen, capital of the territory Stavenger, situated on the peninsula in the German ocean: E. long. 6° 30', N. lat. 59° 30'.

Stavoren, a port-town of the United-Netherlands, in the province of West Friesland, situated on a peninsula in the German ocean: E. long. 6° 30', N. lat. 59° 30'.

Steatites, in the history of fossils, a name given by
STEERING in navigation, the directing a vessel from one place to another by means of the helm and rudder. He is held the best steersman who cau[es the least motion in putting the helm over to and again, and who keeps the ship from making yaws, that is, from running in and out. See Navigation.

STEERING, on board a ship. The stemmen say the bowspirt or the beam head of a ship fleves, when it flands too upright, or not straight enough forward.

STEERINGAGE, on board a ship. That part of the ship next below the quarter-deck, before the bulk-head of the great cabin, where the fleersman stands in most ships of war. See the next article.

STEERING in navigation, the directing a vessel from one place to another by means of the helm and rudder. He is held the best steersman who causes the least motion in putting the helm over to and again, and who keeps the ship from making yaws, that is, from running in and out. See Navigation.

STEERING, on board a ship. The stemmen say the bowspirt or the beam head of a ship fleves, when it flands too upright, or not straight enough forward.
STERLING, a term frequent in British commerce. A pound, shilling, or penny Sterling, signifies as much as a pound, shilling, or penny of lawful money of Great Britain, as settled by authority. See Money.

STERN of a ship, usually denotes all the hindmost part of her, but properly it is only the outmost part abaft.

STERNBERG, a town of Germany, in the circle of Upper Saxony and marquise of Brandenburg, situated twenty-three miles north-east of Frankfort upon the Oder.

STERNHOYIDÆUS, in anatomy. See Anatomy, p. 233.

STERNUM, in anatomy. See Anatomy, p. 175.

STERNUTATORY, a medicine proper to produce sneezing. Sternutatives are of two kinds, gentle and violent. Of the first kind are betony, fage, marjoram, tobacco, and the whole fashionable tribe of snuffs. Of the latter kind are euphorbium, white hellebore, pellitory, &c.

STETIN, a city and port-town of Germany, in the circle of Silesia, on the river Oder: E. long. 14° 50', N. lat. 53° 30'.

STEVENAGE, a market-town of Hertfordshire, situated thirty miles north of London, and ten north-west of Hertford.

STEW, a small kind of fish-pond, the peculiar office of which is to maintain fish, and keep them in readiness for the daily use of the family, &c.

STEW, were also places anciently permitted in England to women of professed incontinency, for the proffer of their bodies to all comers. These were under particular rules and laws of discipline, appointed by the lord of the manor.

STEWARD, an officer appointed in another's (lead or jurisdiction. Of these there are various kinds. The greatest officer under the crown is the lord high steward of the king's household, who is the chief officer of the kings court, has the care of the king's house, and authority over all the officers and servants of the household, except such as belong to the chapel, chamber, &c.

STEWART, in Scots law. See Law, Tit. iv. 5.

STEWARTIA, in botany, a genus of the monadelphia polyandria class. The calyx is simple; the stigma is quinquescid; the berry has five lobes, and one seed. There is but one species, a native of Virginia.

STID, in zoology. See Alauda.

STIPA in botany, a genus of the triandria digynia class. The calyx consists of two valves, containing one flower; the exterior valve of the corolla terminates in an awn; and it is jointed at the base. There are seven species, only one of them, viz. the pennastrum, or feather-grass, a native of Britain.

STIFEND, among the Romans, signified the same with stipendiatii, in the civil law, the act of stipulating, that is, of treating and concluding terms and conditions to be inferred in a contract. Stipulations were anciently performed at Rome, with abundance of ceremonies; the first whereof was, that one party should interrogate, and the other answer, to give his consent, and oblige himself. By the ancient Roman law, no body could stipulate but for himself; but as the tabelliones were public servants, they were allowed to stipulate for their masters; and the notaries, succeeding the tabelliones, have inherited the same privilege.

STIRIA DUCHY, in Germany, is part of the circle of Austria.

STOCKS of the flocks, and a short history of the several companies*, describing the nature of their separate funds, the

In order to have a clear idea of the money-transactions of the several companies, it is necessary to know something of money in general, and the difference between that and the current species. See the article Money.

Money is the standard of the value of all the necessities and accommodations of life; and paper money is the representative of that standard to such a degree, as to supply its place, and to answer all the purposes of gold and silver coin. Nothing is necessary to make this representative of money supply the place of species, but the credit of that office or company who delivers it. which credit consists in its always being ready to turn it into species whenever required. This is exactly the case of the Bank of England; the notes of this company are of the same value as the current coin, as they may be turned into it whenever the possessor pleases. From hence, as notes are a kind of money, the counterfeiting them is punisheil with death as well as coining.

Of thefe a general account only was given under the words COMPANY, and BANK, as it would be necessary to resume them in connection with the present article, the better to illustrate it.

The method of depositing money in the bank, and exchanging it for notes (though they bear no interest) is attended with many conveniences; as they are not only safer than money in the hands of the owner himself, but as the notes are more portable and capable of a much more easy conveyance; since a bank note for a very large sum may be sent by the post, and, to prevent the designs of robbers, may, without damage, be cut in two, and sent at two or three different times. Or bills, called bank post-bills, may be had by application at the bank, which are particularly calculated to prevent losses by robberies, they being made payable to the order of the person who takes them out at a certain number of days after sight; which gives an opportunity to stop bills at the bank if they should be lost, and prevents their being so easily negotiated by strangers as common bank notes are: and whoever considers the hazard, the expense and trouble there would be in sending large sums of gold and silver to and from distant places, must also consider this as a very singular advantage. Befide which, another benefit attends them; for if they are destroyed by time, or other accidents, the bank will, on oath being made of such accident, and security being given, pay the money to the person who was in possession of them.

Bank notes differ from all kinds of stock in these three particulars. 1. They are always of the same value. 2. They are paid off without being transferred; and, 3. They bear no interest; while stocks are a share in a company’s funds, bought without any condition of having the principal returned. India bonds indeed (by some persons, tho’ erroneously, denominated stock) are to be excepted; they being made payable at six months notice, either on the side of the company or of the possessor.

Stocks of the flocks, and a short history of the several companies*, describing the nature of their separate funds, the

* Of these a general account only was given under the words COMPANY, and BANK, as it would be necessary to resume them in connection with the present article, the better to illustrate it.
ployed. But this term has been extended farther, though improperly, to signify any sum of money which has been lent to the government, on condition of receiving a certain interest till the money is repaid, and which makes a part of the national debt. As the security both of the government and of the public companies is esteemed preferable to that of any private person, as the flocks are negotiable and may be sold at any time, and as the interest is always punctually paid when due; so they are thereby enabled to borrow money on a lower interest than what could be obtained from lending it to private persons, where there must be always some danger of losing both principal and interest.

But every capital flock or fund of a company is raised for a particular purpose, and limited by parliament to a certain sum, it necessarily follows, that when that fund is completed, no flock can be bought of the company; though shares already purchased may be transferred from one person to another. This being the case, there is frequently a great disproportion between the original value of the shares, and what is given for them when transferred; for, if there are more buyers than sellers, a person who is indifferent about selling will not part with his share without a considerable profit to himself; and, on the contrary, if many are disposed to sell, and few inclined to buy, the value of such shares will naturally fall, in proportion to the impatience of those who want to turn their flock into specie.

These observations may serve to give our readers some idea of the nature of that unjustifiable and dishonest practice called flock jobbing, the mystery of which consists in nothing more than this: The persons concerned in that practice, who are denominated flock-jobbers, make contracts to buy or sell, at a certain distant time, a certain quantity of some particular flock, against which time they endeavour, according as their contract is, either to raise or lower such flock, by raising rumours and spreading fictitious stories in order to induce people either to sell out in a hurry, and consequently cheap, if they are to deliver flock, or to become unwilling to sell, and consequently to make it dearer, if they are to receive flock.

The persons who make these contracts are not in general possessed of any real flock; and when the time comes that they are to receive or deliver the quantity they have contracted for, they only pay such a sum of money as makes the difference between the price the flock was at when they made the contract, and the price it happens to be at when the contract is fulfilled; and it is no uncommon thing for persons not worth 100 l. to make contracts for the buying or selling 100,000 l. flock. In the language of Exchange Alley, the buyer in this case is called the Bull, and the seller the Bear.

Besides these, there are another set of men, who, though of a higher rank, may properly enough come under the same denomination. These are your great monied men, who are dealers in flock and contractors with the government whenever any new money is to be borrowed. These indeed are not fictitious, but real buyers and sellers of flock; but by raising false hopes, or creating groundless fears, by pretending to buy or sell large quantities of flock on sudden, by using the fore-mentioned set of men as their instruments, and other like practices, are enabled to raise or lower the flocks one or two per cent. at pleasure.

However, the real value of one flock above another, on account of its being more profitable to the proprietors, or any thing that will really, or only in imagination, affect the credit of a company, or endanger the government, by which that credit is secured, must naturally have a considerable effect on the flocks. Thus, with respect to the interest of the proprietors, a share in the flock of a trading company which produces 5 l. or 6 l. per cent. per ann. must be more valuable than an annuity with government security, that produces no more than 3 l. or 4 l. per cent. per annum; and consequently such flock must fall at a higher price than such an annuity. Though it must be observed, that a share in the flock of a trading company producing 5 l. or 6 l. per cent. per annum, will not fetch so much money at market as a government annuity producing the same sum; because the security of the company is not reckoned equal to that of the government, and the continuance of their paying so much per annum is more precarious, as their dividend is, or ought to be, always in proportion to the profits of their trade.

As the flocks of the East India, the bank, and South-Sea companies, are distinguished by different denominations, and are of a very different nature, we shall give a short history of each of them, together with an account of the different flocks each is possessed of; beginning with the East India company, as the first established.

Of the East India Company.

There is no trading company in Europe, the Dutch East India company excepted, which can be put in competition with this. Its was first established in the latter end of the reign of queen Elizabeth; and its privileges have been enlarged, or confirmed, by almost every monarch since. Its shares, or subscriptions, were originally only 50 l. sterling; and its capital only 360,891 l. 5 s. but the directors having a considerable dividend to make in 1676, it was agreed to join the profits to the capital, by which the shares were doubled, and consequently each became of 100 l. value, and the capital 739,781 l. 10 s.; to which capital, if 663,639 l. the profits of the company to the year 1685, be added, the whole flock will be found to be 1,703,492 l.

However, this company having sustained several losses by the Dutch, and the subjects of the great Mogul, was in a declining way at the Revolution, when the war with France reduced it so low, that it appearing scarcely possibly to be supported, a new one was erected. The merchants forming the new East India company received their charter in 1698, having, in consideration of the grant thereof, lent the government two millions at 8 per cent. per annum; and publishing their trade with vigour, they soon carried on twice the business that was ever done by the old company. But after the two companies had subsisted a few years in separate state, means were contrived to unite them; which was effected in 1702, when a new charter was granted them under the title of the United Company of Merchants trading to the East Indies.

To the two millions advanced by the new company, the united company in the 6th of queen Anne lent the government 1,200,000 l., which made their whole loan amount to 3,200,000 l. A further sum was also lent by the company in 1730, on a renewal of their charter, the interest of which is reduced to 3 per cent., and called the India 3 per cent. annuities.

As to India flock, it is of a quite different nature; for as that is not money put out to interest, but the trading flock
flock of the company; and the proprietors of the shares, instead of receiving a regular annuity, have a dividend of the profit arising from the company's trade; which, as it is more valuable, these shares generally fell at a price much above the original value.

As to the management of this united company, all persons without exception, natives and foreigners, men and women, are admitted members of it, and 500 l. in the flock of the company gives the owner a vote in the general court, and 2000 l. qualifies him to be chosen a director. The directors are 24 in number, including the chairman, and deputy chairman, who may be re-elected for four years successively. The chairman has a salary of 200 l. a year, and each of the directors 150 l. The meetings or courts of directors are to be held at least once a-week; but are commonly oftener, being summoned as occasion requires.

Out of the body of directors are chosen several committees, who have the peculiar inspection of certain branches of the company's business; as the committee of correspondence, a committee of buying, a committee of treasurers, a committee of warehouses, a committee of shipping, a committee of accounts, a committee of law-suits, and a committee to prevent the growth of private trade, &c. who have under them a secretary, cashier, clerks, warehouse-keepers, &c.

Other officers of the company are governors and factors abroad; some of whom have guards of soldiers, and live in all the state of sovereign princes.

Of the Bank of England.

The company of the bank was incorporated by parliament, in the 5th and 6th years of king William and queen Mary, by the name of the Governor and Company of the Bank of England, in consideration of the loan of 1,200,000 l. granted to the government, for which the subscribers received almost 8 per cent. By this charter, the company are not to borrow under their common seal, unless by act of parliament; they are not to trade, or suffer any person in trust for them to trade in any goods or merchandise; but they may deal in bills of exchange, in buying or selling bullion, and foreign gold and silver coin, &c.

By an act of parliament passed in the 8th and 9th year of king William III. they were empowered to enlarge their capital flock to 2,200,171 l. 10 s. It was then also enacted, that bank-stock should be a personal, and not a real estate; that no contract either in word or writing, for buying or selling bank-stock, should be good in law, unless registered in the books of the bank within seven days, and the stock transferred in 14 days; and that it should be felony, without benefit of clergy, to counterfeit the common seal of the bank, or any sealed bank-bill, or any bank-note, or to alter or erase such bills or notes.

By another act passed in the 7th of queen Anne, the company were empowered to augment their capital to 4,402,343 l. and they then advanced 400,000 l. more to the government, and in 1714 they advanced another loan of 3,500,000 l.

In the third year of the reign of king George I. the interest of their capital flock was reduced to 5 per cent. when the bank agreed to deliver up as many exchequer-bills as amounted to 2,000,000 l. and to accept an annuity of 500,000 l. and it was declared lawful for the bank to call from their members, in proportion to their interests in the capital flock, such sums of money as in a general court should be found necessary. If any member should neglect to pay his share of the moneys so called for, at the time appointed by notice in the London Gazette, and fixed upon the Royal Exchange, it should be lawful for the bank not only to stop the dividend of such member, and to apply it toward payment of the money in question; but also to stop the transfers of the share of such defaulter, and to charge him with an interest of 5 l. per cent. per annum for the money so omitted to be paid; and if the principal and interest should be three months unpaid the bank should have power to sell so much of the stock belonging to the defaulter as would satisfy the same.

After this the bank reduced the interest of the 2,000,000 l. lent to the government from 5 to 4 per cent. and purchased several other annuities, which were afterward redeemed by the government, and the national debt due to the bank reduced to 1,600,000 l. But in 1742, the company engaged to supply the government with 1,600,000 l. at 3 per cent. which is now called the 3 per cent. annuities, so that the government was now indebted to the company 3,200,000 l. the one half carrying 4, and the other 3 per cent.

In the year 1746, the company agreed that the sum of 986,800 l. due to them in the exchequer-bills unsatisfied, on the duties for licences to sell spirituous liquors by retail, should be cancelled, and in lieu thereof to accept of an annuity of 39,442 l. the interest of that sum at 4 per cent. The company also agreed to advance the further sum of 1,000,000 l. into the exchequer, upon the credit of the duties arising by the malt and land tax, at 4 per cent. for exchequer-bills to be issued for that purpose; in consideration of which, the company were enabled to augment their capital with 986,800 l. the interest of which, as well as that of the other annuities, was reduced to 3 l. 10 s. per cent. till the 25th of December 1757, and from that time to carry only 3 per cent.

And in order to enable them to circulate the said exchequer bills, they established what is now called bank circulation: the nature of which not being well understood, we shall take the liberty to be a little more particular in its explanation than we have been with regard to the other stocks.

The company of the bank are obliged to keep cash sufficient to answer not only the common, but also any extraordinary demand that may be made upon them; and whatever money they have by them, over and above the sum supposed necessary for these purposes, they employ in what may be called the trade of the company; that is to say, in discounting bills of exchange, in buying of gold and silver, and in government securities, &c. But when the bank entered into the above mentioned contract, as they did not keep unemployed a larger sum of money than what they deemed necessary to answer their ordinary and extraordinary demands, they could not conveniently take out of their current cash so large a sum as a million, with which they were obliged to furnish the government, without either lessening that sum they employed in discounting, buying gold and silver, &c. (which would have been very disadvantageous to them,) or inventing some method that should answer all the purposes of keeping the million in cash. The method which
which they chose, and which fully answers their end, was as follows.

They opened a subscription, which they renew annually, for a million of money; wherein the subscribers advance 4½ per cent, and enter into a contract to pay the remainder, or any part thereof, whenever the bank shall call upon them, under the penalty of forfeiting the 10 per cent. so advanced; in consideration of which, the bank pays the subscribers 4 per cent. interest for the money paid in, and ¾ per cent. for the whole sum they agree to furnish; and in case a call should be made upon them for the whole, or any part thereof the bank farther agrees to pay them at the rate of 5 per cent. per annum for such sum till they repay it, which they are under an obligation to do at the end of the year. By this means the bank obtains all the purposes of the case, receiving 6 per cent, for the money they advance, yet the company gains the sum of 23,500 l. per annum by the contract; as will appear by the following account.

The bank receives from the government for the advance of a million £ 30,000
The bank pays to the subscribers who advance 100,000 l. and engage to pay (when called for) 900,000 l. more — — 6,500

The clear gain to the bank therefore is 23,500

This is the state of the case, provided the company should make no call on the subscribers: which they will be very unwilling to do, because it would not only lessen their profit, but affect the public credit in general.

Bank-stock may not improperly be called a trading stock, since with this they deal very largely in foreign gold and silver, in discounting bills of exchange, &c. Beside which, they are allowed by the government very considerable sums annually for the management of the annuities paid at their office. All which advantages render a share in their stock very valuable, though it is not equal in value to the East India stock. The company make dividends of the profits half-yearly, of which notice is publicly given when those who have occasion for their money may readily receive it; but private persons, if they judge convenient, are permitted to continue their funds, and to have their interest added to the principal.

This company is under the direction of a governor, deputy-governor, and 24 directors, who are annually elected by the general court, in the same manner as in the East India company. Thirteen, or more, compose a court of directors for managing the affairs of the company.

The officers of this company are very numerous.

Of the South-Sea Company.

During the long war with France in the reign of queen Anne, the payment of the sailors of the royal navy being neglected, and they receiving tickets instead of money, were frequently obliged by their necessities to sell these tickets to various men at a discount of 40 l. and sometimes 50 l. per cent. By this and other means the debts of the nation unprovided for by parliament, and which amounted to 9,471,321 l. fell into the hands of these sufferers. On which, Mr Harley, at that time chancellor of the exchequer, and afterward earl of Oxford, proposed a scheme to allow the proprietors of these debts and deficiencies 6½ per cent. per annum, and to incorporate them in order to their carrying on a trade to the South Seas; and they were accordingly incorporated under the title of the Governor and Company of Merchants of Great Britain trading to the South-Sea and other parts of America, and for encouraging the Fishery, &c.

Though this company seemed formed for the sake of commerce, it is certain the ministry never thought seriously, during the course of the war, about making any settlements on the coast of South America, which was what flattered the expectations of the people; nor was it indeed ever carried into execution, or any trade ever undertaken by this company, except the Affiento, in pursuance of the treaty of Utrecht, for furnishing the Spaniards with negroes, of which this company was deprived by the late convention between the courts of Great Britain and Spain, soon after the treaty of Aix-la-Chapelle in 1748.

After this, some other sums were lent to the government in the reign of queen Anne at 6 per cent. In the third of George I., the interest of the whole was reduced to 5 per cent. and they advanced two millions more to the government at the same interest. By the statute of the 6th of George I., it was declared that this company might redeem all or any of the redeemable national debts, in consideration of which the company were empowered to augment their capital according to the sums they should discharge: and for enabling the company to raise such sums for purchasing annuities, exchanging for ready money new exchequer-bills, carrying on their trade &c. the company might, by such means as they should think proper, raise such sums of money as in a general court of the company should be judged necessary.

The company were also empowered to raise money on contracts, bills, bonds, or obligations under their common seal, on the credit of their capital stock. But if the sub-governor, deputy-governor, or other members of the company, should purchase lands or revenues of the crown upon account of the corporation, or lend money by loan or anticipation on any branch of the revenue, other than such part only on which a credit of loan was granted by parliament, such sub-governor, or other member of the company, should forfeit treble the value of the money so lent.

The fatal South Sea scheme, transacted in the year 1720, was executed upon the last mentioned statute. The company had at first set out with good success, and the value of their stock for the first five years had risen faster than that of any other company; and his Majesty, after purchasing 10,000 l. stock, had condescended to be their governor. Things were in this situation, when, taking advantage of the above statute, the South Sea bubble was projected. The pretended design of which was to raise a fund for carrying on a trade to the South Seas, and purchasing annuities, &c. paid to the other companies; and propostals were printed and distributed, shewing the advantages of the design, and inviting persons into it. The fund necessary for carrying it on, together with the profits that were to arise from it, were divided into a certain number of shares, or subscriptions, to be purchased by persons disposed to adventure therein. And the better to carry on the deception, the directors engaged to make very large dividends, and actually declared, that every 100 l. original stock would yield 50 l. per annum, which occasioned so great a rise of their stock, that a share of 100 l. was sold for upward of 1000 l. This was
in the month of July; but before the end of September it fell to £150 by which multitudes were ruined, and such a scene of distress occasioned as is scarcely to be conceived. But the consequences of this infamous scheme are too well known. We shall pass over all the other transactions of this company in the reign of King George I, as not material to our present purpose.

By a statute of the 6th of his late Majesty, it was enacted that from and after the 24th of June 1733, the capital stock of this company, which amounted to 14,651,103 l. 8s. v.d. and the shares of the respective proprietors, should be divided into four equal parts; three-fourths of which should be converted into a joint stock; attended with annuities, after the rate of 4 per cent. until redemption by parliament, and should be called The new South Sea annuities; and the other fourth part should remain in the company as a trading capital stock, attended with the residue of the annuities or funds payable at the exchequer to the company for their whole capital, till redemption; and attended with the same sums allowed for charges of management, and with all effects, profits of trade, debts, privileges and advantages belonging to the South Sea company. That the accomplishment of the company should twice every year, at Christmas and midsummer, or within one month after, state an account of the company's affairs, which should be laid before the next general court, in order to their declaring a dividend; and all dividends should be made out of the clear profits, and should not exceed what the company might reasonably divide without incurring any further debt; provided that the company should not at any time divide more than 4 per cent. per annum, until their debts were discharged; and that the South Sea company, and their trading stock, should, exclusively from the new joint annuities, be liable to all the debts and incumbrances of the company; and that the company should cause to be kept within the city of London, an office and books, in which all transfers of the new annuities shall be entered and signed by the party making such transfer, or his attorney; and the person to whom such transfer should be made, or his attorney, should underwrite his acceptance, and no other method of transferring the annuities should be good in law.

The annuities of this company, as well as the other, are now reduced to 3 per cent. This company is under the direction of a governor, sub-governor, deputy governor, and 21 directors; but no person is qualified to be governor, his Majesty excepted, unless such governor has, in his own name and right, 5000 l. in the trading stock; the sub-governor is to have 4000 l. the deputy 3000 l. and a director 2000 l. in the same stock. In every general court, every member having in his own name and right 500 l. in trading stock, has one vote; if 2000 l. two votes; if 3000 l. three votes; and if 5000 l. four votes.

The East India Company, the Bank of England, and the South Sea Company, are the only incorporated bodies to which the government is indebted, except the Million Bank, whose capital is only one million, constituted to purchase the reversions of the long exchequer-orders. The interest of all the debts owing by the government is now reduced to 3 per cent. excepting only the annuities for the years 1756 and 1758, the life-annuities, and the exchequer orders; but the South Sea company still continues to divide four per cent. on their present capital stock, which they are enabled to do from the profits they make on the

funds allowed to them for management of the annuities paid at their office, and from the interest of annuities which are not claimed by the proprietors.

As the prices of the different stocks are continually fluctuating above and below par; so when a person who is not acquainted with transactions of that nature, reads in the paper the prices of stocks, where bank-stock is marked perhaps 117 l. India ditto 134 a 134 l. South Sea ditto 97 l., & c. he is to understand that a 100 l. of those respective stocks fell at such a time for those several sums.

In comparing the prices of the different stocks one with another, it must be remembered, that the interest due on them from the time of the last payment, is taken into the current price; and the seller never receives any separate consideration for it, except in the case of India bonds, where the interest due is calculated to the day of the sale, and paid by the purchaser over and above the premium agreed for. But as the interest on the different stocks is paid at different times, this, if not rightly understood, would lead a person not well acquainted with them into considerable mistakes in his computation of their value; some always having a quarter's interest due on them more than others, which makes an appearance of a considerable difference in the price, when in reality there is none at all. Thus, for instance, old South Sea annuities fell at present for £85 or £85 10s. while new South Sea annuities fetch only £84 2s. or £84 15s. though each of them produce the same annual sum of £3 per cent. but the old annuities have a quarter's interest more due on them than the new annuities, which amounts to £1 s. the exact difference. There is, however, one or two cautions that will always make one species of annuities fell somewhat lower than another, though of the same real value; one of which is, the annuities making a small capital, and there not being for that reason so many people at all times ready to buy into it as into others where the quantity is larger; because it is apprehended, that whenever the government pays off the national debt, they will begin with that particular species of annuity the capital of which is the smallest.

A stock may likewise be affected by the court of chancery; for if that court should order the money which is under their direction to be laid out in any particular stock, that stock, by having more purchasers, will be raised to a higher price than any other of the like value.

By what has been said, the reader will perceive how much the credit and interest of the nation depends on the support of the public funds. While the annuities, and interest for money advanced, is there regularly paid, and the principal insured by both prince and people (a security not to be had in other nations) foreigners will lend us their property, and all Europe be interested in our welfare; the paper of the companies will be converted into money and merchandise, and Great Britain can never want cash to carry her schemes into execution.

In other nations, credit is founded on the word of the prince, if a monarchy; or that of the people, if a republic; but here, it is established on the interests of both prince and people; which is the strongest security; for however lovely and engaging honestly may be in other respects, interest in money-matters will always obtain confidence; because many people pay great regard to their interest, who have but little veneration for virtue.
STOICS, a faction of ancient philosophers, the followers of
Zeno, thus called from the Greek stoa, which signifies a
porch or portico, in regard Zeno used to teach under a
porch or piazza.

To the praise of the Stoics in general, it must be con-
fessed, that, less intent than other philosophers upon tri-
volution and often dangerous speculations, they devoted
their studies to the clearing up of those great principles
of morality which were the firmest supports of society;
but the dryness and stiffness that prevailed in their writ-
ings, as well as in their manners, disfigured most of their
readers, and abundantly lessened their utility. Zeno's chief
followers, among the Greeks, were Lucippus, Cleanthes,
Chryssippus, Diogenes Babylonius, Antipater, Panmortius,
Pomponius, and Epicurus; among the Romans, Cato,
Varro, Cicero, Seneca, the emperor Antoninus, &c. The
Stoics cultivated logic, physics, metaphysics, &c. but especi-
ely ethics. The principles of their dogmata, of the former
kinds, are, that there are certain cataleptias or comprehen-
sions, called innate ideas or principles, naturally found in
the mind; that God is the causal cause of the universe;
and, with the Platonists, that the world is an animal, by
reason of God's inhabiting and informing every part there-
of; that nature is an artificial fire tending to generation;
and that the world is at last to be destroyed by a con-
futation. As for the morality of the Stoics, it was couched
much in paradoxes; as, that a wise man is void of all pas-
sions, or perturbation of mind; that pain is no real evil, but
that a wise man is happy in the midst of torture, is al-
ways the same, and is always joyful; that there is none el-
se ought to be esteemed king, magistrate, poet, or philo-
osopher; that all wise men are great
men; that they are the only friends or lovers; that no-
thing can happen to them beyond their expectations; that
all virtues are inextricably connected together; that all good
things are equal, and equally to be desired; that good-
ness admits of no increase or diminution. They own but
one God, whom they however call by various names,
as Fate, Jupiter, &c. by which they did not mean vari-
ous things, but various powers and relations of the same
thing. Providence they expressed under the name Fate,
which Chryssippus defines to be a natural series or com-
position of things mutually following each other, by an
immutable nexus or tie, fixed from all eternity. They
held the immortality of the soul.

STOKEGOMER, a market-town of Somerfetshire, situ-
tated twenty-two miles west of Wells.

STOKESLY, a market-town of Yorkshire, situated thirty
miles north of York.

STOLBERG, a town of Germany, in the circle of Upper
Saxony, and territory of Thuringia, fifty-eight miles
north-west of Leipzig.

STOLE, a sacerdotal ornament worn by the Roman parlia-
priests over their surplice, as a mark of superiority in
their respective churches; and by other priests, over the
als, at celebrating of mass, in which case it goes a-cros-
the stomach, and by deacons, over the left shoulder,
scarf-wipe; when the priest reads the gospel for any one,
he lays the bottom of his stole on his head. The stole
is a broad swath, or flap of stuff, hanging from the neck
to the feet, with three croffes thereon.

Groom of the Stole, the eldest gentleman of his Majesties
bed chamber, whose office and honour it is to present
and put on his majesty's first garment, or shirt, every
morning, and to order the things in the chamber.

Order of the Stole, an order of knights instituted by the
kings of Arragon. Another military order, at Venice,
is called the order of the golden stole; thus called from
a golden stole, which those knights wore over their
shoulder, reaching to the knee, both before and behind,
and a half broad. None are raised to this order
but patricians, or noble Venetians.

STOMACH, in anatomy. See Anatomy, p. 258.

STOMACHIC, in pharmacy, medicines that strengthen
the stomach, and promote digestion, &c.

Stomachic corrobatives are such as strengthen the
tone of the stomach and intestines; among which are car-
minatives, as the roots of galangals, red gentian, zedoary,
pimpinella, calamus, aromaticus, and arum. Of barks
and rhinds, those of canella alba, ladafras, citrons, Seville
and China oranges, &c. Of spices, pepper, ginger,
cloves, cinnamon, cardamums, and mace.

STONES, in natural history, are defined to be essen-
tially compound foillis, not inflammable, nor soluble in water
or oil, nor at all ductile; found in continued strata, or beds,
of great extent; formed either of a congeries of small par-
ticles, in some degree resembling sand, and lodged in a smoo-
other cementitious matter; or else of this cementitious matter,
and the grit or sand-like particles, running together into
one smooth mass; or, finally, of granules cohering by con-
tact, without any cementitious matter among them; or com-
pounded of crytall or spar, usually debased by earth, and often
mixed with talc and other extraneous particles.

Of this class of foillis there are three orders; and un-
der these, eight genera.

The first order comprehends all the coarse, harsh, and
rough stones, of a lax texture, and composed of a visible
gritt, resembling sand in form, and usually immersed in
a cementitious matter, and of little natural brightenes;
scarce capable of any polish, and naturally mouldering
away in form of powder from the tools of the workmen.
The genera of this order are two, viz. the ammochida
and platanus; the former of which constitute our grey
and rough flates; and the latter comprehends most of the
stones used in building, particularly Portland stone.

The second order consists of stones moderately fine,
of a more compact and even texture, scarce dilligenu-
ble contruction, and affording no sand-like particles to
the view: of some natural brightenes, capable of a toler-
able polish, and flying off from the tools of the workmen
in form of small chips. Under this order are comprre-
hended the sympexia and degania.

The
The third order consists of flones of a very fine sub-
stance and elegant structure; naturally of a great bright-
ness, and capable of an elegant polish; composed of
granules of various shapes and sizes, but usually flattish,
sometimes more, sometimes less distinct; and, in some
species, running together into uniform masses, but never
lodged in any cementitious substance. Of this order are
the marbles, alabaster, porphyries, and granites.

Stone in the bladder. See Medicine, and Surgery.
Stone also denotes a certain quantity or weight of some
commodities.

A flone of beef, at London, is the quantity of eight
pounds: in Hertfordshire, twelve pounds; in Scotland,
sixteen pounds.

Stone chatter, in ornithology. See Motacilla.

Stonechenge, in antiquity. A famed pile or monu-
ment of huge flones on Salisbury plain, fix miles distant
from that city.

It consists of the remains of four ranks of rough flones,
ranged one within another, some of them, especially in
the outernot and third rank, twenty feet high, and
seven broad; sustaining others laid across their heads,
and fastened by mortises; so that the whole must have
anciently hung together.

Antiquaries are now pretty well agreed that it was a
British temple; and Dr Langwith thinks it might easily
be made probable, at least, that it was dedicated to the
sun and moon. Inigo Jones has given a fine scheme of
the work, and strives hard to persuade the world, that
it was Roman: but Dr Langwith, who took his mea-
sures on the spot, assures us he could by no means reco-

ncile them with that scheme.

Stoney-stratford, a market-town of Buckingham-
shire, fourteen miles north of Ailebury.

Stool, in medicine, an evacuation or discharge of the
faeces, &c. by the anus.

Stopper, in a ship, a piece of cable-laid rope, having a
wale-knot at one end, with a laniard fastened to it; and
the other end is spliced round a thimble in the ring-bolts
upon deck, and at the bits: its use is to stop the cable,
that it may not run out too fast; in order to which, they
make turns with the laniard about the cable, and the wale-
knot floats it, so that it cannot float away faster than is
necessary.

Storax, or Styrax, in natural history, a dry and solid
resin, of a reddish colour, and a peculiarly fragrant smell;
of which there are two kinds, the Styrax calamita, or
Styrax in tears, and the Styrax vulgaris; whereas the for-
mer is by far the purer and finer kind, imported in stariall
granules: it anciently used to be packed up in reeds, for

not formed of granules, but of one uniform consistence.

These are the two genuine kinds of storax; but nei-
ther of them is that met with in our shops, which is a
kind of saw-dust composed into lumps, by which so much of
the storax resin as will make the other matters hang
together. This is what our apothecaries use, under the
name of storax; but it is advisable to strain carefully
the pure resin from the fifth, and use no part of the latter.

The two genuine kinds of storax, which ought always
Vol. III. No 95.
STRAIT, is a narrow passage out of one sea into another.

STRABISMUS, squinting, a distortion of the eyes, whereby their pupils are turned from, instead of being directed toward objects at which they look: sometimes only one eye, but more frequently both are thus affected. See Medicine, p. 155.

STRAIN, in surgery, a violent extension of the sinews, or tendons, of some muscle.

STRAIT, is a narrow passage out of one sea into another, as those of Gibraltar and Magellan.

STRADES, in the sea-language, signify the uniform ranges of planks on the bottom, decks, and sides of ships; and the garboard-strake is that next the keel.

STRALSUND, a strong city and port-town of Germany, in the circle of Upper Saxony and duchy of Pomerania, subject to Sweden: E. long. 13° 22', and N lat. 54° 23'.

STRAND, signifies any shore of the sea, or bank of a great river; hence an immunity from paying customs on goods or vessels, was anciently expressed by strand and stream.

STRANDED, among seamen, is said of a ship that is driven ashore by a tempest, or runs on ground through ill fortune, and so perishes.

STRANGFORD, a town of Ireland, that gives name to a loch and bay in the county of Down and province of Ulster, situated nine miles east of Down.

STRANGURY, in medicine, a suppression of urine. See Medicine, p. 160.

STRAPADO, a kind of military punishment, wherein the criminal is hoisted up by a rope, and let down, so that, by the weight of his body in the fall, his arms are dislocated.

STRAPARS, or a saddle, are strong leather-thongs, nailed to the bows of a saddle, in order to make the girths, &c.

STRAPPY, among seamen, is said of a ship that is driven ashore by a tempest, or runs on ground through ill fortune, and so perishes.

STRASBURG, a free imperial city of Germany, capital of the landgraviate of Alsace, situated near the western bank of the Rhine, in E. long. 7° 35', and N lat. 48° 38'.

STRATA, in natural history, the several beds or layers of the earth, or bank of a great river; hence an immunity from paying customs on goods or vessels, was anciently expressed by strand and stream.

The time when these several strata were laid, was doubtfule at the creation: unless, with some great naturalists, as Steno, Dr. Woodward, &c. we suppose the globe of the earth to have been disfolded by the deluge.

STRATAGEM, in the art of war, any device for the deceiving and surprizing an enemy.

STRATEGUS, in Grecian antiquity, an annual officer among the Athenians, whereof there were two chosen, to command the troops of the flate.

STRATFORD, a populous market-town of Warwickshire, situated on the river Avon, six miles south of Warwick; remarkable for being the birth-place of the inimitable Shakespeare, and lately for the Jubilee held there in honour of his memory, September 1769.

STRATHNAVAY, a subdivision or district of the county of Sutherland, in Scotland, having the Caledonian ocean on the north and west.

STRATIFICATION, in chemistry, the ranging anything to be calcined in several layers or strata one above another.

STRATIOTES, in botany, a genus of the polyandra hexamyla class. The Ipomopsis conficts of two leaves, and the perianthium of three segments; the corolla has three petals, and the berry has six cells. There are two species, one of them, viz. the abores, water-aloe, or fresh-water lodd, a native of Britain.

STRATTON, a market-town of Cornwall, situated a little south of the Bristol channel, fourteen miles north-west of Launceston.

STRAWBERRY, in botany. See Fragaria.

STRAWBERRY TREE, in botany. See Arbutus.

STRENGTH, in physiology, the same with force, power.

STRENGTHENERS, in pharmacy, medicines that add to the bulk and firmness of the foIius; and such are all absorbent, agglutinant, and altringent medicines.

STRIE, in the ancient architecture, the same with the flutings of columns. See Flutes.

STRIATED LEAF, among botanists, one that has a number of longitudinal narrows on its surface.

STRIGONENSIS TERRA, earth of Strigonium, in the materia medica, a red earth, of the bole kind, found about the gold-mines at Strigonium in Hungary, and used in some places as an altringent and sudorific.

It is but of a coarse and impure texture, and lighter than most of the boles in colour; it is of a strong, dull red, and is of a tolerably smooth surface; it is apt to crumble to pieces between the fingers, and stains the skin in handling; it melts freely in the mouth, and has a remarkable smoothness, but very little altringency in its taste, and leaves a sensible grittiness between the teeth; it is sometimes veined and spotted with small molecules of an earth, like the whitish variegations of the red French bole.

STRIE, a measure of capacity, containing four bushels.

STRIE, among seamen, is a word variously used: when a ship, in a fight, or on meeting with a ship of war, sets down or lowers her top-sails, at least half-mast high, they say she strikes, meaning she yields, or submits, or pays respect to the ship of war. Also, when a ship touches ground, in shoal-water, they say she strikes. And, when a top-mast is to be taken down, the word of command is, Strike the top-mast, &c.

STRIX, in ornithology, a genus belonging to the order of accipitres. The bill is hooked, but has no cere or wax; the nostrils are covered with tereaceous leathers; the head is very large, as are also the ears and eyes; and the tongue is bent. There are twelve species, comprehending all the owl-kind. They are night-birds, and feed upon mice, bats, &c.

STROBILUS, among botanists. See Botany, p. 637.

STROMATEUS, in ichthyology, a genus belonging to the order of apodes. The head is compressed, the teeth in the jaws and palate; the body is oval, and slimy; and the tail is forked. There are two species.

STROMBOLI, one of the Lipari islands, fifty miles north of Messina.

STRONGOLI, a town of the Hither Calabria, in the kingdom of Naples, situated on the gulf of Taranto.

STROPE, in ancient poetry, a certain number of verses, including a perfect enjambement and making the first part of an ode.

STROUD, a market-town, nine miles south of Gloucester.
STYLE, in jurisprudence, the particular form or manner of proceeding in each court of jurisdiction, agreeable to the rules and orders established therein: thus we say the style of the court of Rome, of Chancery, of Parliament, of the Privy council, &c.

Old Style, the Julian manner of computing time, as the New Style is the Gregorian method of computation. See Astronomy, p. 490.

STYLET, a small dangerous kind of pox, which may be concealed in the hand, chiefly used in treacherous affimilations. The blade is usually triangular, and so slender that the wound it makes is almost imperceptible.

STYLITES, an appellation given to a kind of solitaries, who spend their lives seated on the tops of columns, to be, as they imagine, the better disposed for meditation, and even as low as the eleventh century. The founder of the order was St. Simon Stylites, a famous anchorite in the fifth century, who took up his abode on a column six cubits high; then on a second, of twelve cubits; and, at last, on another of thirty-six. The extremity of these columns were only three feet in diameter, with a kind of rail or ledge about it that reached almost to the girdle, somewhat resembling a pulpit. There was no lying down in it. The faqirs, or devout people of the East, imitate this extraordinary kind of life even to this day.

STYLOGLOSSUS, in anatomy. See Anatomy, p. 304.

STYLOHYOID, in anatomy. See Anatomy, p. 304.

STYLOGLOSSUS, in anatomy. See Anatomy, p. 304.

SUBMISSION, in Scots law. See Law, Tit. xxxii, 15.
SUBORDINATION, a relative term, expressing the degree of inferiority between one thing and another.
SUBORNATION of perjury, in Scots law. See Law, Tit. xxxiii, 55.
SUBPOENA, in law, a writ whereby all common persons, or those under the degree of peerage, may be called into chancery, in any case where the law cannot afford a remedy.
SUBREPTION, the act of obtaining a favour from a superior, by surplice or a false representation.
SUBREPTITIOUS, a term applied to a letter, licence, patent, or other act, fraudulently obtained of a superior, by concealing some truth, which, had it been known, would have prevented the concession or grant.
SUBROGATION, in the civil law, the act of substituting a person in the place, and entitling him to the rights of another.
SUBSCAPULARIS, in anatomy. See Anatomy, p. 156.
SUBSCRIPTION, in general, signifies the signature put at the bottom of a letter, writing, or instrument.
SUBSEQUENT, something that comes after another, particularly with regard to the order of time.
SUBSIDY, in law, signifies an aid or tax granted to the king, by parliament, for the necessary occasions of the kingdom; and is to be levied on every subject of ability, according to the rate or value of his lands or goods: but this word, in some of our statutes, is confounded with that of customs.
SUBSISTENCE, in the military art, is the money paid to the soldiers weekly, not amounting to their full pay; because their clothes, accoutrements, tents, bread, &c. are to be paid.
SUBSTANCE, something that we conceive to subsist of itself, independently of any created being, or any particular mode or accidents. See Metaphysics.
SUBSTANTIAL, in the schools, something belonging to the nature of subsistance.
SUBSTANTIVE, in grammar. See Grammar.
SUBSTITUTE, a person appointed to officiate for another, in case of absence or other legal impediment.
SUBSTITUTION, in the civil-law, a disposition of a testament, whereby the testator substitutes one heir for another, who has only the usufruit, and not the property of the thing left him.
SUBTRACTION, in arithmetic. See Arithmetic, p. 370.
SUBTRACTION, in algebra. See Algebra, p. 81.
SUBTENSE, in geometry, the same with the chord of an angle.
SUBSTRACTION, in arithmetick. See Arithmetic, p. 161. and Saccharum.
SUBTILE, in physics, an appellation given to whatever is extremely small, fine, and delicate; such as the animal spirits, the effluvia of odorous bodies, &c. are supposed to be.
SUBULARIA, in botany, a genus of the tetradyndromia filiculofa class. The pod is entire, oval, with oval concave valves; and the stylus is shorter than the pod. There is but one species, viz. the aquatica, or awl-wort, a native of Britain.
SUBULATED, something in the shape of an awl.
SUCCEDEANUM, in pharmacy, denotes a drug subtilized in the place of another, in medical composition.
SUCCESSION, in philosophy, an idea which we get by reflecting on that train of ideas constantly following one another in our minds when awake.
SUCCESSION, in Scots law. See Law, Tit. xxvii, 1, &c. xxviii, 1, &c.
SUCCESSOR, in law, one that succeeds, or comes in the place of another.
SUCCE NUM, in natural history. See Amber.
SUCCE SIA, in botany. See Scabiosa.
SUC Cory, in botany. See Cichorium.
SUC Cousus, a term used by some imaginary writers, for a demon who assumes the shape of a woman, and as such lies with a man; in which sense it stands opposed to incubus, which was a demon in form of a man, that they supposed to lie with a woman.
SUCCKERS, in gardening, the same with off-sides. See Off-sets.
SUC TION, the act of sucking or drawing up a fluid, as air, water, milk, or the like, by means of the mouth and lungs. See Pneumatics, and Hydrostatics.
SUDATORY, a name given by the ancient Romans to their hot or sweating-rooms; sometimes also called laconica.
SUDBURY, a borough-town of Suffolk, thirteen miles south of Bury. It sends two members to parliament.
SUDORIFIC, an appellation given to any medicine that causes or promotes sweat.
SUEZ, a port-town of Egypt, situated at the bottom of the Red-sea, seventy miles east of Cairo: it is from this town that the isthmus of Suez, which joins Africa to Asia, takes its name.
SUFFOCATION, in medicine, the privation of respiration, or breathing; which is sometimes occasioned by a congestion of blood in the lungs, so as to prevent the ingress of the air.
SUFFOLK, a county of England, bounded by Norfolk on the north, by the German-sea on the east, by Essex, from which it is separated by the river Minestingtree, on the south, and by Cambridge-shire on the west; being sixty-two miles long, and twenty-eight broad.
SUFFRAGAN, an appellation given to bishops with respect to archbishops, on whom they depend, and to whom appeals lie from the bishops' courts.
SUFFRAGE, denotes a vote given in an assembly, where something is deliberated on, or where a person is elected to an office or benefit.
SUFFRUTEX, among botanists, denotes an under-shrub, or the lowest kind of woody plants, as lavender, rue, &c.
SUGAR, in natural history, is properly the essential salt of the sugar-cane, as tartar is of the grape. See Chemistry, p. 157.
flank, or cane, being round, jointed, and two or three inches in diameter at the bottom: the joints are three or four inches alunder, and in a rich foil more: the leaves are long and narrow, and of a yellowish green colour; as is also the flank itself, the top of which is ornamented with a panicule, or cluster of arundinaceus flowers, two or three feet in length.

They propagate the sugar-cane, by planting cuttings of it in the ground in furrows, dug parallel for that purpose; the cuttings are laid level and even, and are covered up with earth; they soon shoot out new plants from their roots or joints: the ground is to be kept clear, at times, from weeds; and the canes grow so quick, that in eight, ten, or twelve months, they are fit to cut for making of sugar from them. The manner of doing it is thus: They cut off the reeds at one of the joints near the roots; they are then cleared of the leaves, and tied up in bundles, and sent to the mills, which are worked either by water or horses.

The sugar-mill is composed of three rollers of an equal fize, and all armed with iron plates, where the canes are to pass between them; only the middle roller is much higher than the right, to give the larger sweep to the two poles to which the horfes are yoked. This great roller in the middle is furnished with a cog full of teeth, which catch the notches in the two side rollers, and force them about to bruise the cane, which passes quite round the great roller, and come out dry and squeezed from all their juice; which runs into a vessel or back under the mill, and is thence conveyed through a narrow spout into the first boiler.

After the juice is let out of the first vessel, it is received into another; in which it is boiled more briskly, and scummed from time to time with a large kind of spoon, pierced with holes to let the liquor through, while it retains the scum and foulnefs separated from it in boiling: towards the end of this boiling, they throw into it a strong lixivium of wood-afhes, with some quick lime among it: this greatly promotes the separation of the foulnefs that yet remains among it; and, after it has boiled some time with this addition, they strain it off. The faeces left in the cloths make a kind of wine, when fermenting properly with water. The strained liquor, which is now tolerably clean, is let into a third boiler, in which it is boiled down to the confidence of sugar over a very brisk fire, the people who attend it continually stirring and scumming it.

Great caution is to be used that the boiling matter does not rise over the sides of the vessel, which would be of very dangerous consequence: they prevent this by taking up quantities of the boiling matter with a ladle, lifting it up high, and letting it run in again, and by now and then adding a small piece of batter, or fat of some kind, which takes down the bubbling almost instantaneously. They are very careful that no lemon-juice, or any other acid of that kind, comes near the vessels, a very small admixture of that being sufficient to keep the matter from granulating. When the liquor is boiled enough, which is known by its concreting on throwing a spoonful of it up into the air, it is then let out into a fourth vessel, under which there is a very gentle fire, only kept up that it may have leisure to granulate; when it has begun to granulate, it is let out of this last boiler into a kind of conic earthen vessels, open at both ends; the widest aperture is placed upwards, and the smaller end downwards, its aperture being stopped with a wooden plug. It is left in these vessels twenty-four hours to concreted; after this they are removed into sugar-houses, and are there arranged in regular order, with a vessel of earthen-ware under each; the plug is then taken out of the bottom aperture of each, and they are left in this condition for about forty days, that all the thick liquor, or melafles, may run from them: after they have stood thus long to drain of themselves, a quantity of clay is diluted, with water, into a thin past; and this is poured on the top of every parcel of sugar in the vessels, so as to cover it two or three inches deep.

This water, by degrees, all leaves the clay, and penetrating into the mafs of sugar, runs through it, and carries off yet more of this foul thick liquid with it, into the vessels placed underneath to receive it.

When the clay is quite dry, it is taken off, and the first preparation of the sugar is now finished; they take it out of the vessels, and, cutting it into lumps, which are of a dirty, brownish, or greyish colour, they put it up in hoglheads, and other casks, under the name of grey or brown sugar. The sugar, in this state, ought to be dry, not unctuous, and to have no taste of burning. The liquor which has run from the sugar in standing, is boiled to a confidence, and sold under the name of melafles or treacle; this affords, by fermentation, a very clear and good spirit.

This coarse sugar is afterwards refined to various degrees of purity by new solutions, and is fold at different prices, and under different names, according to the degree of purity it is brought to. Our sugar refiners first dissolve it in water, then clarify the solution by boiling with whites of eggs and desphumation; and after due evaporation pour it into moulds; where the fluid part being drained off, and the sugar concreted, its surface is covered with moist clay, as before. The sugar thus once refined, by repetition of the process becomes the double-refined sugar of the shops. The candy-sugar, or that in crystals, is prepared by boiling down solutions of sugar to a certain pitch, and then removing them into a hot room, with flicks placed across the vessel for the sugar to shoot upon; and these crystals prove of a white or brown colour, according as the sugar used in the process was pure or impure.

SUGILLATION, in medicine, an extravasation of blood in the coats of the eye, which at first appears of a reddish colour, and afterwards livid or black. If the disorder is great, bleeding and purging are proper, as are diuretics.

SUIT, in law, is used in different senses: as, 1. For an action, whether personal or real. 2. Suit of court, or suit-service, which is an attendance the tenant owes to his lord's court. 3. Suit-covenant, where a person has covenanted to do service in the court of the lord. 4. Suit-custum, which is where one and his ancestors have owed suit time out of mind. 5. It is used for a petition to the king, or any person of dignity; where a lord disclaims his tenant for suit, and none is due; in this case, the party may have an attachment against him to appear in the king's court. 6. Suit of the king's peace, is an action brought against a person for breach of the king's peace; as in the case of treasons, felonies, or trespasses.
SULPHUR. See Chemistry, p. 72, 118.
SULTAN, a title of honour given to the emperor of the Turks. The wife of a sultan is called sultana, and the favourite one hafita-sultana, i. e. the private sultana.
SUM, signifies the quantity that arises from the addition of two or more magnitudes numbers, or quantities together. See Arithmetic.
SUMACH, in botany. See Rhus.
SUMATRA, an island in the East Indian ocean, situated between 96° and 106° E. long, and between 5° 30' N. lat. and 5° 30' S. lat. extending from north-west to south-east, nine hundred miles long, and from one hundred to one hundred and fifty broad.
SUMMARY, in matters of literature. See Abridgment.
SUMMIT, the top or vertex of any body, or figure; as of a triangle, cone, pyramid, &c.
SUMMONS, in Scots law. See Law, Tit. xxx. 28.
SUN, in astronomy. See Astronomy, p. 435.
Sun-flower in botany. See Helianthus.
SUNDA-ISLANDS, those situated near the Straits of Sunda, in the Indian ocean; the chief of which are Borneo, Java, Sumatra, &c. See Borneo, &c.
SUNDAY, or the Lord's-day, a solemn festival observed by Christians on the first day of every week, in memory of our Saviour's resurrection.
This is the principal and most noted of the Christian festivals, and was observed with great veneration in the ancient church, from the time of the apostles, who themselves are often said to have met on that day for divine service. It is likewise called the Sabbath-day, as being subsituted in the room of the Jewish sabbath. See Sabbath.
The ancients retained the name Sunday, or dies solis, in compliance with the ordinary forms of speech, the first day of the week being so called by the Romans, because it was dedicated to the worship of the sun.
SUNDERLAND a port-town of Durham, situated on the German sea, at the mouth of the river Wear, ten miles north-east of Durham city.
SUNTUGOW, a territory in the circle of the upper Rhine in Germany, bounded by Allace on the north, by the river Rhine, which divides it from the Brugow, on the east; by Swirgland on the south; and by France-Compte on the west.
SUOVETAURILIA, an ancient Roman sacrifice, so called because it consisted of a pig (fas), a sheep, or rather ram (baciga), and a bull (taurus). They were all males, to denote the masculine courage of the Roman people. It was likewise called solitaurilia, because the animals offered were always (falsa) whole or uncut.
SUPERCARGO, a person employed by merchants to go on a voyage, and oversee their cargo, or lading, and dispose of it to the best advantage.
SUPERCILIUM, in anatomy. See Anatomy, p. 294.
SUPERCROGATION, in theology, what a man does beyond his duty, or more than he was commanded to do.
SUPERNUMERARY, something over and above a fixed number. In several of the offices are supernumerary clerks, to be ready on extraordinary occasions.
SUPPLEMENT, in matters of literature, an appendage or addition, to supply what is wanting therein.
SUPERSTITION, extravagant devotion, or religion wrong directed or conducted.
SUPERVISOR, a surveyor or overseer.
SUPERSTITION, in anatomy, the action of a supinator muscle, or the motion whereby it turns the hand so as that the palm is lifted up towards heaven.
SUPPLEMENT, in matters of literature, an appendage to a book, to supply what is wanting therein.
SUPPRESSED, in heraldry, a term applied to the uppermost quarters of a shield when divided into several quarters, these seeming as it were supported or sustained by those below. The chief is said to be supported when it is of two colours, and the upper colour takes up two thirds of it. In this case it is supported by the colour underneath.
SUPPORTERS, in heraldry, figures in an achievement placed by the side of the shield, and seeming to support or hold up the same. Supporters are chiefly figures of beasts or figures of human creatures, for the like purpose, as properly called tenants.
SUPPOSITORY, a kind of medicated cone, or ball, which is introduced to the anus for opening the belly. Suppo...
SUPREMACY, the superiority or sovereignty of the king.

Sponge with warm water. (£.) Some vinegar, wine, or Hungary water is performed on the veins that lie on the internal part of the arm is generally called an abscess. See Medicine and Surgery.

SUPPURATION, the second way wherein an inflammation terminates, being a conversion of the inflamed blood and the soft adjacent parts, as the vessels and fat, into pus, or matter: which disorder, when it has not yet found an opening, is generally called an abscess. See Medicine and Surgery.

SUPPULATIVES, or suppurating medicines, such as promot suppuratum. See the preceding article.

SUPRALAPSARY, in theology, a person who holds that God, without any regard to the good or evil works of man, has resolved, by an eternal degree, to save some and damn others. There are also called antelapsaries, and are opposed to sublapsaries and infralapsaries.

SURASPINATUS, in anatomy. See Anatomy, p. 196.

SUPPRESSION in law, the extirpation or annihilating of surcoat, a coat of arms to be worn over the body, and by much the most frequent in use at this present time. See Heraldry.

SURCOAT, a coat of arms to be worn over the body, and is also used for the sealing of letters, and other documents, where the application of the hand, and is also used for the sealing of letters, and other documents, where the application of the hand, and other disorders, where the application of the hand, afflit by proper instruments, is necessary.

OF PHLEBOTOMY.

We begin with the operation of phlebotomy: because it is of all the most general, performed in most parts of the body, and by much the most frequent in use at this present day. By phlebotomy, or bleeding, we here intend the opening a vein, by a sharp-edged and pointed instrument of steel, for extracting a proper quantity of blood, either for the preservation or recovery of a person's health.

It is commonly enough known, that the operation of bleeding in the arm is performed on the veins that lie on the internal part of the cubit. There are several things worthy the surgeon's notice in this operation; some of which regard the things which are to be done preparatory to bleeding, some in the operation itself, others immediately after the performance of it. Preparatory to bleeding you should have in readiness: (1.) A linen fillet, about an ell in length, and two fingers in breadth. (2.) Two small square billboard. (3.) Porringers or vessels to receive the blood. (4.) A sponge with warm water. (5.) Some vinegar, wine, or Hungarian water, to raise the patient's spirits if he should be inclined to faint. (6.) Two assistants, one to hold the porringer, the other to reach you anything that you shall want. (7.) You must place your patient upon a couch: or, if he is fearful of the operation, lay him upon a bed, left he should fall into a swoon. Lastly, the operator should be as expert in bleeding with his left hand as with his right: For,

SUPPRESSION in medicine, is generally used for a retention of urine or the menopause. See Medicine, p. 160, 162.

SURCULUS, in the anatomy of plants, a word used to express that part of the branching of the ribs of a leaf, which is of a middle kind between the great middle rib and the smallest reticular ramifications.

SURD. See Algebra, p. 95.

SURETY, in law, generally signifies the sum with bail. See Bail.

SURFACE See Superficies.

SURSEIT, in medicine, a sickness proceeding from the fermentation of a load at the stomach, usually attended with eruptions, and sometimes with a fever. See Medicine.

SURGE, in the sea-language, the same with wave. See Wave.

Also when heaving at the capstan, if the cable royal or messenger slips a little, they call it surging.

SURGERY, the art of curing all manner of wounds, and other disorders, where the application of the hand, afflicted by proper instruments, is necessary.

As you are ready at bleeding in the right arm with your right hand, so when you are to open the veins of the left arm, you will find it necessary to use your left hand.

Though the operation is to be performed at once, with one puncture; yet many things are to be observed in order to render it successful. First, it is necessary for the surgeon to inspect his patient's arm diligently, that he may see the course of the veins: he must then take hold of the arm, and extend it towards his breast, tucking up the sleeve about a hand's breadth above the bend of the cubit, where he must make his ligation, rolling the fillet twice round, and fastening it with a knot. The veins being compressed, and the blood being stopped in its return, they will enlarge, and lie fairer to the eye. When you have bound up the arm in this manner, you let it go for a small time till the veins grow turgid. You are then to lay hold of the arm again in the same manner as we directed before, and extend it to your breast, having an assistant ready with the vessel in his hand, at a convenient distance for receiving the blood.

You are now to examine which vein lies fairest, and is therefore most proper to be opened. For you must observe, that in the arm there usually appear three principal veins. The first is called Vena Cephalica and is found in the external part of the arm. The second is termed Basilica, and lies on the internal part of the arm: In the right arm it is also called Hepatica; in the left Splenicus. The third, which is obliquely situated between the former two, is called Mediana. The median and basilic veins, as they are larger than the cephalic, discharge a greater quantity of blood, but are attended with more danger in the operation:

Tappe, ten miles east of the Indian sea; in E. long. 72° 20', N. lat. 21° 30'.

SURCHARGE, the name with overcharge, and whatever is above that which is just and right.

SURCOAT, a coat of arms to be worn over the body armour.

The surcoat is properly a loose thin taffety coat, with arms embroidered or painted on it, such as is worn by heralds: anciently also used by military men over their armour, to distinguish themselves by.

SURCULUS, in the anatomy of plants, a word used to express that part of the branching of the ribs of a leaf, which is of a middle kind between the great middle rib and the smallest reticular ramifications.
For a considerable artery and the brachial nerve lie under the bicipital vein, and the tendon of the biceps muscle under the median. But as they lie farther to the eye, and therefore more frequently the subjects of the operations we are treating of than the cephalic vein, it is safer and more eligible for the less experienced surgeons to open the bicipital, or at least the median vein.

When you have determined which vein to open, you are to perform the operation on that part which presents itself fairest to you. But if the vein has frequently been opened, and the part which appears largest and fairest is full of cicatrices, you are not to open above, but below the cicatrices, by which means the blood will discharge itself more freely: For the part above is generally threatened by the cicatrices.

Before you apply the lancet to the skin, when the veins are not rifened, it will be proper to rub the arm below the bandage, which will drive the blood back towards the cubit, and render the veins more turgid. Whilst this is doing in the right arm, the surgeon should take hold of the patient's arm in such a manner that he may lay his thumb upon the vein he intends to open, to prevent the blood from flowing back, and to keep the vein from rolling. You are now to fix your eye upon that part of the vein which you intend to open, and taking the lancet with your right hand, so placed that the thumb and first finger may be fixed about the middle of the blade; the other fingers should rest gently upon the patient's arm, to prevent your hand from flipping.

Your lancet is now to be pushed lightly and carefully forward by your thumb and fore-finger, till it has penetrated through the coats of the vein; and at that instant to be raised a little upwards, in order to enlarge the orifice of the wound, which will give a freer passage to the blood. The most common and convenient size of an orifice is about twice the breadth of the back of an ordinary knife. You are to keep even between the two extremes of rashness and timidity in making the puncture. For as in one case you will only divide the common integuments, and so leave your work undone; in the other you will run the risk of wounding the artery, nerve, or tendon.

Your aperture being thus made, and the instrument drawn instantly back, the blood will then rush forth from the orifice either in a large or small stream. In the mean time the blood must be permitted to flow as long as it shall be judged useful or necessary; and if it should stop too soon, as it often may from too great a stricture of the bandage on the arm, it must be slackened a little, by which means the compressed artery being set at liberty, the blood will flow from the orifice as at first. If you find the orifice obstructed by too great a tension of the skin, or an intrusion of the membrana adiposa, you ought in that case to return the bit of fat, by pressing with the finger or a warm sponge, and to relax the skin by bending the arm a little. Lastly, if the orifice be obstructed by thick, gumous, or congealed blood, that impediment may be removed by wiping it with a sponge dipped in warm water.

But that the patient's arm may not become painful or languid, by holding it long extended, the surgeon should support it by the cubitus for a little while; and then give him a flick, or other cylindric body, to turn round in his hand, that by the contractions of the flexor and extensor muscles of the fingers, the course of the blood may be accelerated towards the cubitus: which will still be further promoted, if the patient urges a little voluntary cough.

When there seems to be a sufficient quantity of blood discharged, the ligature must then be immediately taken off from above the elbow, and the skin about the orifice must next be gently stroked or pressed together by the two fore-fingers of the left hand; by which means the lips of the divided vein are more easily compressed and closed. But while the surgeon is doing this with his left hand, he takes the smallest of the two compresses, and applies it upon the incision with his right hand: but so as to let what little blood may remain between the orifice and the vein, be discharged, before he imposes the compresses. Over the first or small compress he should impose another that is a little larger, pressing them both gently on the orifice with his left thumb, till the bandage is laid across.

Having applied your bandage, and drawn down the patient's sleeve over his arm; he should be ordered not to use it too early or violently, before the orifice is well closed, which might excite a fresh hemorrhage, an inflammation, suppuration, or other bad accident. And if the patient should faint away soon after the operation, it may be then convenient to wet his navel with Hungary water or vinegar; and to sprinkle some of the laft, or else cold water, in his face; and, especially in summer-time, to let in the fresh and cool air, by opening the windows, &c. Also, if any wine or cordial water be at hand, you may give the languishing patient a small draught thereof.

Of Bleeding in the Foot.

Bleeding in the foot is an operation of very old standing: it having been an observation made by the most ancient physicians, that phlebotomy in this part proved highly serviceable in most disorders of the head and breast, and for an obftruction of the menftrial and hemorrhoidal flux; upon which discharges greatly depended the healthy state of both sexes. For these reasons they therefore denominated those veins of the foot, Saphena and Cephalica: the laft of which extends itself from the internal ankle to the great toe; and the first, from the external malleolus to the smaller toes. But why one of them should be thought or denominated more cephalic than the other, there is not the least reason to be offered: since bleeding from either of them has altogether the same effect. Therefore, the surgeon should always open that which lies fairest and most conspicuous. But if the veins upon the metatarsus, or above of the foot, do not well appear, it may then be convenient to open one of those at the ankle, or about the calf or ham of the leg. Nor is the phlebotomist so liable to injure any of the tendons in the foot as he is upon the metatarsus.

For the more easy and successful apertion of these veins, the patient must first wash both feet well for some time in hot water; that when the veins become sufficienlly turgid, the surgeon may take his choice of that which presents itself either in the right or left foot, without paying any deference to the direction of right or left in any of the forementioned disorders. Having fixed upon the particular foot and vein, your ligature must be applied about two fingers breadth above the ankle; and then the patient must return it into the warm water, while the surgeon takes out and prepares his instrument or lancet. Then kneeling down on one knee, the surgeon takes out the patient's foot from the warm water, and having wiped it dry with a napkin, places it upon his other knee, or else upon a board laid over the vefel of hot water; and having wiped it dry with a napkin, places it upon his other knee, or else upon a board laid over the vefel of hot water; and, after having sufficiently dried it with a towel, he proceeds to the operation.
Of Bleeding in the Veins of the Forehead, Temples, and Occiput.

There are many physicians and surgeons, who think that bleeding by the veins of the forehead and temples is much more serviceable and expeditious in relieving all disorders of the head, such as violent pains, vertigo, delirium, melancholy, and raving madness, than the like discharge by veins more remote from the parts affected; judging that their vicinity renders them more capable of evacuating the offending matter of the disease. Before proceeding to cut the veins, an handkerchief or neckcloth ought to be drawn tight round the neck; that, by compressing the jugular vein, those branches of it may become more turgid and conspicuous. The vein being opened, the patient must hold down his head, that the blood may not trickle from his forehead into his eyes or mouth, when the stream does not spout out with sufficient force. If the blood does not stop after a due quantity is discharged, you must compress the orifice with your finger, and after wiping the forehead and face, apply a compress or two, and then your bandage. Bleeding from the occipital veins, which communicate with the lateral sinuses of the dura mater, is both by reason and experience proved to be serviceable in most disorders of the brain, where that part is overcharged with blood, which may be this way diverted and evacuated. The celebrated anatomist Morgagni especially recommends it, with scarification and cupping in those parts, for all lethargic and face, apply a compress or two, and then your bandage. The orifice with your finger; and, after wiping the forehead and temple, remove the ligature from the neck; upon which the blood stops without any danger of a fresh hemorrhage. Lastly, it must be acknowledged, that the patient faints away as readily after bleeding in the neck, as the jugular veins are safely and easily opened: but no danger follows from thence.

Of Bleeding in the Veins, called Ranula, under the Tongue.

It is very often found of no small service in a quinsy, or other inflammatory disorder of the neck, to bleed in the two small veins which run under the tip or end of the tongue; especially if a larger vein has been opened before, either in the neck, foot, or arm, whereby the inflamed and stagnated blood may be gradually evacuated. To bleed in these veins, a nick being made upon the neck as before, you then elevate the apex of the tongue with your left hand, while, with the lancet in your right, you circumspectly open first one, and then the other on each side; because the portion of one only will hardly ever discharge blood enough to give any considerable relief. When you judge a sufficient quantity of blood has run out of the mouth into your vessel, remove the ligature from the neck: upon which the flux usually stops of itself. But if it should still continue, let the patient take a little vinegar or Frontinio wine in his mouth: or else you may apply a bit of vitriol or alcohol, or a compress dip't in some astringent liquor, till the hemorrhage ceases; which can never be dangerous even without such topics.

Of Phlebotomy in the Penis.

Bleeding in the vena dorsalis penis usually surpasses the benefit of all remedies whatever in abating inflammatory disorders of this member. This large vein, which runs along the back or upper side of the penis, being generally pretty much dilated, and conspicuous in an inflammation of this part, may be incised either under the middle or back part of the penis; and kept bleeding till the member becomes flaccid, and a sufficient quantity of blood be discharged proportionable to the urgency of the symptoms. This done, you must apply a compress, and the bandage proper for the penis. But you must carefully endeavour to avoid injuring the arteries or nerves which enter the penis near this vein; for if not, your handage too strict; for by these means the inflammation and symptoms may turn out worse than before.
the progress of healing a large wound, when it is made with a sharp instrument, and the constitution is pure.

In this circumstance, the blood-vessels, immediately upon their division, bleed freely, and continue bleeding till they are either stopped by art, or at length contracting and withdrawing themselves into the wound, their extremities are shut up by the coagulated blood. The hemorrhage being stopped, the next occurrence, in about twenty-four hours, is a thin serous discharge; and, a day or two after, an increase of it, though somewhat thickened, and thickening in this state it continues two or three days without any great alteration, from which time the matter grows thicker and more offensive; and when the bottom of the wound fills up with little granulations of flesh, it diminishes in its quantity, and continues doing so till the wound is quite skinned over.

The first stage of healing, or the discharge of matter, is by ulcers called digestion; the second, or the filling up with flesh, incarination; and the last, or skimming over, cicatrization.

It is worth observing, that the loss of any particular part of the body can only be repaired by the fluids of that distinct part; and as in a broken bone, the callus is generated from the ends of the fracture, so, in a wound, is the cicatrix from the circumference of the skin only: Hence arises the necessity of keeping the surface even, either by pressure or eating medicines, that the eminence of the flesh may not refill the spaces of the skin in their tendency to cover the wound. This eminence is composed of little points or granulations called fungus, or proud flesh, and is frequently esteemed an evil, though in truth this species of it be the constant attendant on healing wounds; for when they are smooth, and have no disposition to flux out above their lips, there is a thicknes of flesh, and a cure is very difficultly effected. Since then a fungus prevents healing only by its luxuriance, and all wounds cicatrize from their circumference, there will be no occasion to destroy the whole fungus every time it rises, but only the edges of it near the lips of the skin; which may be done by gentle escharotics, such as lint dipr in a mild solution of vitriol, or for the most part only by dry lint, and a tight bandage, which will reduce it sufficiently to a level, if applied before the fungus have acquired too much growth. In large wounds, the application of corrosive medicines to the whole surface, is of no use; because the fungus will attain but to a certain height; when left to itself, which it will be frequently rising up to, though it be often walled; and as all the advantage to be gathered from it, is only from the evenness of its margin, the purpose will be as fully answered by keeping that under only, and an infinite deal of pain avoided from the continual repetition of escharotics.

From what has been said of the progress of a wound made by a sharp instrument, where there is no indisposition of body, we see the cure is performed without any interruption, but from the fungus; so that the business of surgery will consist principally in a proper regard to that point, and in applications that will the least interfere with the ordinary course of nature, which in these cases will be as much as act the least upon the surface of the wound; and agreeably to this we find, that dry lint only is generally the best remedy through the whole course of dressing; at first, it flops the blood with less injury than any flypick powders or waters; and afterwards, by absorbing the matter, which in the beginning of suppuration is thin and acrimonious, it becomes in effect a digestive: during incarnation it is the softest medium that can be applied between the roller and tender granulations, and at the same time is an easy compress upon the sprouting fungus.

Over the dry lint, may be applied a pledget of some soft ointment spread upon tow, which must be renewed every day, and preferred in its situation by a gentle bandage; though in all large wounds, the first dressing, after that of the accident or operation, should not be applied in less than three days, when the matter being formed, the lint separates more easily from the part; in the removal of which, no force should be used, but only so much be taken away as is loole and comes off without pain.

Of Inflammations and Abscesses.

As almost all abscesses are the consequences of inflammations, and these produce a variety of events, as they are differently complicated with other disorders, it will be proper first to make some inquiry into their disposition. Inflammations from all causes have three ways of terminating; either by dispersion, suppuration, or gangrene.

But though every kind of inflammation will sometimes terminate in different shapes, yet a probable conjecture of the event may be always gathered from the state of the patient’s health. Thus inflammations happening in a slight degree upon colds, and, without any foregoing indisposition, will most probably be dispersed: those which follow close upon a fever, or happen to a very hot habit of body, will generally impoverish: and those which fall upon very old people, or drophical constitutions, will have a strong tendency to gangrene.

If the state of an inflammation be such, as to make the dispersion of it safely practicable, that end will be best brought about by evacuations, such as plentiful bleeding and repeated purges: the part itself must be treated with emollients twice a day; and if the skin be very tense, it may be embozicated with a mixture of three fourths of oil of roses, and one fourth of common vinegar, and afterwards covered with ungunt Americana: or a soft ointment made of hogs wax and sweet oil, spread upon a fine rag, and rolled on gently. If after four or five days, the inflammation begin to subside, the purging-waters and manna may take place of other purges, and the embrocation of oil and vinegar be now omitted, or sooner, if it has begun to excoriate. The ointment of wax and oil may be continued to the last. During the cure a thin diet is absolutely necessary, and in the height of the inflammation the drinking of thin liquors is of great service.

Here we have supposed that the inflammation had so great a tendency to diffusion, as, by the help of proper affiduity, to terminate in that manner; but when it happens that the disposition of the tumour refists all ductinent means, we must then desist from any further evacuations, and assist nature in the bringing on a suppuration.

That matter will most likely be formed, we may judge from the increase of the symptomatic fever, and enlargement of the tumour, with more pain and pulsation; and if a small rigor come on, it is hardly to be doubted. Inflammations after a fever, and the small-pox, almost always suppurate; but these presently discover their tendency, or at least should be at first gently treated, as though we expected an impothisation. It is a maxim laid down in surgery,
surgery, that evacuations are pernicious in every circumstance of a disease, which is at last to end in suppuration: But as physicians do now acknowledge, that bleeding on certain occasions in the small-pox, is not only no impediment to the maturation, but even promotes it; so in the formation of abscesses, when the vesicles have been clotted, and the suppuration has not kindly advanced, bleeding has sometimes quickened it accordingly; but, however, this practice is to be followed with caution. Purges are, no doubt, improper at this time; yet if the patient be collyve, he must be afflicted with gentle enemias every two or three days.

Of all the applications invented to promote suppuration, there are none so easy as poultices; but as there are particular tumours very slow of suppuration, and almost void of pain (fuch, for instance, are some of the scrophulous swellings) it will be left troublesome in these cases to wear the gum-plasters, which may be renewed every four or five days only. Amongst the suppurative poultices, perhaps there is none preferable to that made of bread and milk softened with oil; at least the advantage of any other over it is not to be distinguished in practice. The abscesses may be covered with the poultice twice a day, till it come to that ripeness as to require opening, which will be known by the thinness and eminence of the skin in some part of it, a fluctuation of the matter, and generally speaking, an abatement of the pain previous to these appearances.

The figs of a gangrene are these: the inflammation loses its redness, and becomes dusky and livid; the tenesmus of the skin goes off, and feels to the touch flabby or emphysemous; vesicles filled with ichor of different colours spread all over it; the tumour subsides, and, from a dulcet complexion, turns black, the pufie quickens and sinks, and profuse sweats coming on, at last grow cold, and the patient dies.

To stop the progress of a mortification, the method of treatment will be nearly the same, from whatever cause it proceed, except in that arising from cold; in which case, we ought to be cautious not to apply warmth too suddenly to the part, if it be true, that in the northern countries they have daily conviction of gangrenes produced by this means, which might have been easily prevented by avoiding heat; nor, they carry their apprehension of the danger of sudden warmth so far as to cover the part with snow first, which does not appear often necessary to apply causticks; yet they are of molt use in cases where the skin is thin and inflamed: and we have reason to think the malignity of the abscess is of that nature as to prevent a quickness of incising; in which circumstance, if an incision only were made through the skin, little flaws would often form, and burrow underneath, and the lips of it lying loose and flabby, would become callous, and retard the cure, though the malignity of the wound were corrected: of this kind are venereal buboes, which notwithstanding they often do well by mere incision, yet when the skin is in the state we have supposed, the cautick is always preferable: but this method should be confined to venereal buboes; for those which follow a fever, or the small-pox, or the most part are curable by incision only. There are many scrophulous tumours, where the reasoning is the same as in the venereal: and even in great swellings, if the patient will not submit to cutting, and the surgeon is apprehensive of any danger in wounding a large vessel, which is often done with the knife, yet as this inconvenience is avoided by cautick, it may on such an occasion be made use of; however, in scrophulous swellings of the neck and face, unless they are very large, causticks are not advisable, since in that part of the body, with length of time, they heal after incision. Cauticks are of great service in destroying stubborn scrophulous indurations of the glands, also venereal indurations of the glands of the groin, which will neither diffuse nor suppurate; likewise in exposing carious bones, and making

In small abscesses, there is seldom a necessity for greater dilatation than a little orifice made with the point of a lancet; and in large ones, where there is not a great quantity of skin discoloured and become thin, an incision to their utmost extent will usually answer the purpose; or if there be much thin discoloured skin, a circular or oval piece of it must be cut away; which operation, if done dexterously with a knife, is much less painful than by cautick, and at once lays open a great space of the abscess, which may be dressed down to the bottom, and the matter of it be freely discharged; whereas, after a cautick, though we make incisions through the eflchar, yet the matter will be under some confinement; and we cannot have the advantage of dressing properly till the separation of the flough, which often requires a considerable time, so that the cure must be necessarily delayed; besides that the pain of burning continuing two or three hours, which a cautick usually requires in doing its office, draws such a friction upon the skin round the eflchar, as sometimes to indispose it very much for healing afterwards. In the use of cauticks, it is but too much a practice, to lay a small one on the most prominent part of a large tumour, which not giving sufficient vent to the matter, and perhaps the orifice too soon after growing narrow, leads on to the necessity of employing tents; which two circumstances more frequently make fistulas after an abscess, than any malignity in the nature of the abscess itself. The event would more certainly be the same after a small incision; but surgeons not depending so much on small openings by incision, as by cautick, do, when they use the knife, generally dilate sufficiently; whereas, in the other way, a little opening in the most depending part of the tumour usually satisfies them.

From this account of the method of opening abscesses, it does not appear often necessary to apply cauticks; yet they have their advantages in some respects, and are seldom so terrible to patients as the knife, though in fact they are frequently more painful to bear. They are of most use in cases where the skin is thin and inflamed: and we have reason to think the malignity of the abscess is of that nature as to prevent a quickness of incising; in which circumstance, if an incision only were made through the skin, little flaws would often form, and burrow underneath, and the lips of it lying loose and flabby, would become callous, and retard the cure, though the malignity of the wound were corrected: of this kind are venereal buboes, which notwithstanding they often do well by mere incision, yet when the skin is in the state we have supposed, the cautick is always preferable: but this method should be confined to venereal buboes; for those which follow a fever, or the small-pox, or the most part are curable by incision only. There are many scrophulous tumours, where the reasoning is the same as in the venereal: and even in great swellings, if the patient will not submit to cutting, and the surgeon is apprehensive of any danger in wounding a large vessel, which is often done with the knife, yet as this inconvenience is avoided by cautick, it may on such an occasion be made use of; however, in scrophulous swellings of the neck and face, unless they are very large, cauticks are not advisable, since in that part of the body, with length of time, they heal after incision. Cauticks are of great service in destroying stubborn scrophulous indurations of the glands, also venereal indurations of the glands of the groin, which will neither diffuse nor suppurate; likewise in exposing carious bones, and making
making large issues. The best cautick in use is a pall made with lime and lixivium capitale, which is to be prevented from spreading, by cutting an orifice in a piece of sticking plaster, nearly as big as you mean to make the eschar; which being applied to the part, the cautick must be laid on the orifice, and preferred in its situation by a few slips of plaster laid round its edges, and a large piece over the whole. When issues are made, or bones exposed, the eschar should be cut out immediately, or the next day: for if we wait the separation, we miscarry in our design of making a deep opening; since sloughs are flung off by the sprouting new flesh underneath, which fills up the cavity at the same time that it discharges the eschar; so that we are obliged afterwards to make the opening a second time with painful escharotic medicines. To make an issue, or lay a bone bare, this cautick may lie on about four hours; to destroy a large gland, five or six; and to open abscesses, an hour and a half, two hours, or three hours, according to the thickness of the skin; and what is very remarkable, notwithstanding its strength and sudden efficacy, it frequently gives no pain where the skin is not inflamed, as in making issues, and opening some few abscesses.

When an abscess is already burst, we are to be guided by the probe where to dilate, observing the same rules with regard to the degree of dilatation as in the other cases. The usual method of dilating, is with the probe, compafs, and indeed, in all abscesses, the generality of surgeons use the compafs, after having first made a puncture with a lancet: but as the knife operates much more quickly, and with less violence to the parts than compafs, which squeeze at the same time that they wound, it will be sparing the patient a great deal of pain to use the knife, where ever it is practicable, which is in almost all cases, except some fistula’s in ano, where the compafs are more convenient. The manner of opening with a knife, is by sliding it on a director, the groove of which prevents its being misguided. If the orifice of the abscess be so small as not to admit the director, or the blade of the compafs, it must be enlarged by a piece of sponge-tent; which is made by dipping a dry bit of sponge in melted wax, and immediately squeezing as much out of it again as possible, between two pieces of tile or marble; the effect of which is, that the loofe sponge being compessed into a small compafs, if any of it be introduced into an abscess, the heat of the part melts down the remaining wax that holds it together, and the sponge sucking up the moisture of the abscess, expands, and in expanding opens the orifice wider, and by degrees, so as to give very little pain.

The usual method of dressing an abscess, the first time, is with dry lint only; or if there be no flux of blood, with soft digestive spread on lint. If there be no danger of the upper part of the wound reuniting too soon, the dofts must be laid in loose; but if the abscess be deep, and the wound narrow, as is the case sometimes of abscesses in ano, the lint must be crammed in pretty tightly, that we may have afterwards the advantage of dressing down to the bottom without the use of tents, which, by refining the growth of the little granulations of flesh, in process of time harden them, and in that manner produce a fistula; so that, instead of being used for the cure of an abscess, they never should be employed but where we mean to retard the healing of the external wound, except in some little narrow abscesses, where, if they be not crammed in too large, they become as dofts, admitting of incarnation at the bottom; but care should be taken, not to infinate them much deeper than the skin in this case, and that they should be repeated twice a day, to give vent to the matter they confine. But tents do most good in little deep abscesses, whence any extraneous body is to be evacuated, such as small splinters of bone, &c.

The use of vulnerary injections into abscesses has been thought to bear so near a resemblance to the use of tents, that they both fell into disuse almost at the same time.

Over the dofts of lint may be laid a large pledget of tow spread with balsam, which will lie softer than a definative platter; for this, though designed to defend the circulation of wounds against inflammation or a fluxion of humours, is often the very cause of them; so that the dressings of large wounds should never be kept on by these plasters, where there is danger of such accidents. In this manner, the dressings may be continued, till the cavity is incarned; and then it may be cicatrized with dry lint, or some of the cicatrizing ointments, observing to keep the fungous down, as directed before.

In the course of dressing it will be proper to have regard to the situation of the abscess, and as much as possible to make the patient favour the discharge by his ordinary posture: and to this end also, as what is of greater importance than the virtue of any ointment, the discharge must be assisted by compafs and bandage; the compafs may be made of rags or platter; though the latter is sometimes preferable, as it remains immovable on the part it is applied to. The frequency of dressing will depend on the quantity of discharge: once in twenty-four hours is ordinarily sufficient; but sometimes twice, or perhaps three times, is necessary.

Of Ulcers.

When a wound or abscess degenerates into so bad a state as to render the methods of cure above laid down, and rules that completion which belongs to a healing wound, it is called an ulcer; and as the name is generally borrowed from the ill habit of the fore, it is a cullion to apply it to all sores that have any degree of malignity, though they be immediately formed without any previous abscess or wound; such are the venereal ulcers of the tonsils, &c.

Ulcers are distinguished by their particular disorders, though it seldom happens that the affections are not complicated; and when we lay down rules for the management of one species of ulcer, it is generally requisite to apply them to almost all others. However, the characters of most eminence are, the callous ulcer, the fistulous ulcer, and the ulcer with caries of the adjacent bone: the abundance of more known to surgeons, such as the putrid, the corrosive, the varicosus, &c. but as they have acquired their names from some particular affection, we shall speak of the treatment of them under the general head of ulcers.

It will be often in vain to pursue the best means of cure by topical application, unless we are assisted by internal remedies; for as many ulcers are the effects of a particular indisposition of body, it will be difficult to bring them into order, while the caufe of them remains with any violence; though they are sometimes in a great degree the discharge of the indisposition itself, as in the plague, small-pox, &c. But we see it generally necessary in the pox, the scurvy, obstructions of the menes, dropsies, and many other diseases, to give internals of great efficacy; and indeed, there are hardly any constitutions where ulcers are not assisted by some physical regimen. Those that are cancerous and
and scrophulous seem to gain the least advantage from phy-

cic; for if in their beginnings they have sometimes been very

much relieved, or cured, by salivation, or any other evacu-

tion, they are also often irritated and made worse by them;

so that there is nothing very certain in the effects of violent

medicines in these distempers. Upon the whole, in both

these cafes, the milk-diet, and gentle purgings with manna,

and the waters, seem to be most efficacious; though brisk

methods may be used with more safety in the evil than in the

cancer; and sometimes, particularly in young subjects, the

decocation of the woods is extremely beneficial for scrophu-

lous ulcers: but it has lately been attested by men of great

skill and veracity, that sea-water is more powerful than any

other remedy hitherto known, both for scrophulous ulcers,

and scrophulous tumours.

When an ulcer becomes foul, and discharges a nasty thin

ichor, the edges of it, in process of time, tuck in, and growing

skinned and hard, give it the name of a callous ulcer,

which, so long as the edges continue in that state, must

necessarily be prevented from healing: But we are not imme-

diately to destroy the lips of it, in expectation of a sudden

cure; for while the malignity of the ulcer remains, which

was the occasion of the callosity, so long will the new lips

be subject to a relapse of the same kind; however often the

external surface of them be destroyed: so that when we have

to deal with this circumstance, we are to endeavour to bring

the body of the ulcer into a disposition to recover by other

methods. It sometimes happens to poor laborious people,

who have not been able to afford themselves reft, that lying

a-bed will in a short time give a diversion to the humours of

the part, and the callous edges softening, will without any

great assistance shoot out a cicatrix, when the ulcer is grown

clean and filled with good flesh: the effect of a salivation is

generally the same; and even an issue does sometimes dif-
poe a neighbouring ulcer to heal: but though callosities be

frequently softened by these means, yet when the surface

of the ulcer begins to yield thick matter, and little granula-
tions of red flesh shoot up, it will be proper to quicken nature

of the ulcer begins to yield thick matter, and little granula-
tions of red flesh shoot up, it will be proper to quicken nature

and every attempt with escharoticks will be only a

repetition of pain to the patient without any advantage.

When the excrecence is cancerous, and does not rise

from a large cancer, but only from the skin itself, it has

been usual to recommend the actual cautery, but it is better
to cut away quite underneath, and dress afterwards with easy

applications. As to the treatment of incurable cancers

erations, after much trial, surgeons have at last discovered,

what gives the most ease to the fore is the most suitable

application; and therefore the use of escharoticks is not to

be admitted on any pretence whatsoever; nor in those parts

of a cancer that are corroded into cavities, must the precipi-
tate be made use of to procure digestion, or promote the

separation of the sloughs. The best way, therefore, is to

be guided by the patient what medicine to continue. Those

usually prefcribed are preparations from lead; but what we

have found most beneficial, have been sometimes dry lint

alone when it does not stick to the cancer; at other times,

lint dolfis spread with Bassifion or Cera. de Lapid. Calam.

and oftener than either with a Cerate made of oil and wax,

or the Sperm. Cet. ointment; and over all, a pledgit of tow

spread with the fame. Embrocating the neighbouring skin

and edges of it with milk, is of service; but the chief good

is to be acquired by diet, which should be altogether of milk

and things made of milk, though herbage may be admitted

also. Issues in the shoulders or thighs do also alleviate the

symptoms; and manna, with the purging waters, once, or

perhaps twice a-week, will serve to keep the body cool.

When ulcers or abscesses are accompanied with inflamma-

tion and pain, they are to be affilled with fomentations made

of some of the dry herbs, such as Roman wormwood, bay-

leaves, and rosemary; and when they are very putrid and

corrosive, which circumstances give them the name of foul

phagedenic ulcers, some spirits of wine should be added to

the fomentation, and the bandage be also dipt in brandy

and fomented.
S U R G E R Y.

or spirits of wine, observing in these cases where there is much pain, always to apply gentle medicines till it be removed.

When the pain and inflammation are excessive, bleeding and other evacuations will often be serviceable; and above all things, rest and a horizontal position: which last circumstance is of great importance to the cure of ulcers of the legs, that unless the patient will conform to it strictly, the skill of the surgeon will often avail nothing; for as the indig-nity of these foses is in some measure owing to the gravitation of the humours downwards, it will be much more beneficial to be laid along than sit upright, though the leg be laid on a chair; since even in this posture they will descend with more force, than if the body was reclined.

In ulcers of the legs, accompanied with varices or dilata-
tions of the veins, the method of treatment will depend upon the other circumstances of the fore; for the varix can only be affailed by the application of bandage, which must be continued a considerable time after the cure. The neatest bandage is the Irait leeching, which is particularly serviceable in this case; though, however, if the legs be oeodematus, or, if after the healing of the ulcers, they swell when the patient quits his bed, it may be worn with safety and advantage. There are instances of one vein only being various, which when it happens, may be destroyed by tying it above and below the dilatation, as in an aneurism; but this operation should only be practised where the varix is large and painful.

Ulcers of many years standing are very difficult of cure; and in old people the cure is often dangerous, frequently exciting an asthmatic, a diar-rhoea, or a fever, which destroys the patient, unless the fore break out again; so that it is altogether advisable to attempt the absolute cure in such cases, but only the reduction of them into better order, and less compains, which, if they be not malignant, is generally done with rest and proper care. The cure of those in young people may be undertaken with more safety; but we often find it necessary to raise a salivation to effect it, though, when completed it, does not always last; so that the prospect of cure in stubborn old ulcers, at any time of life, is but indifferent. In all these cases, however, it is proper to purge once or twice a-week with calomel, if the patient can bear it, and to make an issue when the fore is almost healed, in order to continue a dischage the constitution has been so long habituated to, and prevent its falling from the cicatrix, and bursting out again in that place.

When an ulcer or abscess has any sinus or channels opening and discharging themselves into the fore, they are called sinus ulcers. These sinus, if they continue to drain a great while, grow hard in the surface of their cavity, and then are termed fistula, and the ulcer a fistulous ulcer; also, if matter be discharged from any cavity, as those of the joints, abdomen, &c. the opening is called a sinus ulcer, or a fistula.

The treatment of these ulcers depends upon a variety of circumstances. If the matter of the sinus be thick, strict bandage and compres will sometimes bring the opposite sides of the sinus to a reunion: if the sinus grow turgid in any part, and the skin thinner, flowing a disposition to break, the matter must be made to pull more against that part, by plugging it up with a tent; and then a counter opening must be made, which proves often sufficient for the whole abscess, if it be not afterwards too much tented, which locks up the matter and prevents the healing; or too little, which will have the same effect; for dressing quite superficially, does sometimes prove, inAmbulances as tents, and for nearly the same reason, since suffering the external wound to contract into a narrow orifice before the internal one be incased, does almost as effectually lock up the matter as a tent: to preserve then a medium in these cases, a hollow tent of lead or silver may be kept in the orifice, which, at the same time that it keeps open, gives vent to the matter. The abscesses where the counter opening are made most frequently, are those of compound fractures, and the break; but the latter do often well without dilatation than the former, though it must be performed in both, if practicable, the whole length of the abscess, when after some trial the matter does not lessen in quantity, and the sides of it grow thinner; and if the sinuses be fistulous, there is no expectation of cure without dilatation. There are also a great many fistulous abscesses of the neck, that sometimes communicate by sinuses running under large indurations; in which instances, counter openings are advisable, and generally answer without the necessity of dilating the whole length; and indeed there are few abscesses in this distemper, which should be opened beyond the thickness of the skin. When abscesses of the joints discharge themselves, there is no other method of treating the fistula, but by keeping it open with the cauters already laid down, till the cartilages of the extremities of the bones being corrodcd, the two bones shoot into one another, and form an ankylosis of the joint, which is the most usual cure of ulcers in that part.

Gun-shot wounds often become fistulous ulcers, and then are to be considered in the same light as those already described; though surgeons have been always inclined to conceive there is something more mysterious in these wounds than any others: but their terribleness is owing to the violent contusion and laceration of the parts, and often to the admission of extraneous bodies into them, as the bullet, splinters, clothes, &c. and were any other force to do the same thing, the effect would be exactly the same as when done by fire-arms. The treatment of these wounds consists in removing the extraneous body as soon as possible; to which end the patient must be put into the same posture as when he received the wound: if it cannot be extracted by cutting upon it, which should always be practised when the situation of the blood-vessels, &c. does not forbid, it must be left to nature to work out, and the wound dressed superficially; for we must not expect, that if it be kept open with tents, the bullet, &c. will return that way; and there is hardly any case where tents are more pernicious than here, because of the violent tension and disposition to gangrene which presently ensue. To guard against mortification in this, and all other violently contused wounds, it will be proper to bleed the patient immediately, and soon after give a cynder; the part should be dressed with felt digesives, and the compres and roller applied very loofe, being first dip in brandy or spirits of wine. The next time the wound is opened, if it be dangerous, the spirituous fomentation may be employed, and after that continued till the danger is over. If a mortification comes on, the applications for that disorder must be used. In gun-shot wounds, it seldom happens that there is any effusion of blood, unless a large vessel be torn; but the bullet gives an echar, which usually separates in a few days, and is followed with a plentiful discharge; but when the wound...
come to this period, it is manageable by the rules already laid down.

When an ulcer with loose rotten flesh discharges more than the size of it should yield, and the discharge is oily and flaming, in all probability the bone is carious; which may easily be distinguished by running the probe through the flesh; and if so, it is called a carious ulcer. The cure of these ulcers depends principally upon the removal of the rotten part of the bone, without which it will be impossible to heal, as we sometimes even in little foci of the lower jaw, which taking their rise from a rotten tooth, will admit of exfoliation; but those produced by the evil, where the whole extremities of spongy parts of the bone are affected, are exceedingly dangerous, though all enlarged bones be not necessarily carious; and there are ulcers sometimes on the skin that covers them, which do not communicate with the bone and consequently do well without exfoliation: may, it sometimes happens, though the case be rare, that, in young subjects particularly, the bones will be carious to such a degree, as to admit a probe almost thro' the whole substance of them, and yet afterwards admit of a cure, without any notible exfoliation.

The method of treating an ulcer with a caries, is by applying a cautleick of the size of the scale of the bone that is to be exfoliated, and after having laid it bare, to wait till such time as the carious part can, without violence be separated, and then heal the wound. In order to quicken the exfoliation, there have been several applications devised; but that which has been most used in all ages, is the actual cautery, with which sponges burn the naked bone every day, or every other day, to dry up, as they say, the mucus, and by that means procure the separation: but as this practice is never of great service, and always cruel and painful it is now pretty much exploded. Indeed, from considering the appearance of a wound; when a scale of bone is taken out of it, there is hardly any question to be made, but that burning retards rather than hastens the separation; for as every scale of a carious bone is flung off by new flesh generated between it and the found bone, whatever would prevent the growth of these granulations, would also in a degree prevent the exfoliation; which must certainly be the effect of a red hot iron applied so close to it; though the circumfances of carious bones, and their disposition to separate, are so different from one another, that it is hardly to be gathered from experience, whether they will sooner exfoliate with or without the assistance of fire; sometimes in both methods, an exfoliation is not procured in a twelve month, and at other times it happens in three weeks or a month; however, if it be only uncertain whether the actual cautery be beneficial or not, the cruelty that attends the use of it should entirely banish it out of practice. It is often likewise, in these cases, employed to keep down the fungous lips that spread upon the bone; but it is much more painful than the charioteer's medicines; though there will be no need of either, if a regular compresse be kept on the dressings; or at worst, if a flat piece of the proper forge, of the size of the ulcer, be rolled on with a tight bandage, it will swell on every side, and dilate the ulcer without any pain.

Some caries of the bones are so very shallow, that they crumble intensibly away, and the wound fills up; but when the bone will neither exfoliate nor admit of granulations, it will be proper to scrape it with a rugine, or perforate it in many points with a convenient instrument down to the quick. In the evil, the bones of the carpus and tarsus are often affected, but their sponginess is the reason that they are seldom cured: so that when these, or indeed the extremities of any of the bones, are carious through their substance, it is adviseable to amputate: though there are instances in the evil, but more especially in critical abscesses; when after long discharging down, the splinters, and sometimes the whole substance of the small bones, have worked away, and a healthy habit of body coming on, the ulcer has healed; but these are so rare, that no great dependence is to be laid on such an event. The dressings of carious bones, if they are flaming, may be dissolved in the tincture of myrrh; or if there be of dry lint are easiest, and keep down the edges of the ulcer better than any other gentle applications.

Burns are generally esteemed a distinct kind of ulcers, and have been treated with a greater variety of applications than any other species of fore.

When burns are very superficial, not raising suddenly any vellecity, spirits of wine are laid to be the quickest relief; but whether they be more serviceable than embrocations with linseed oil, is uncertain, though they are used very much by some persons whose trade subjects them often to this misfortune. If the burn excoriates, it is easiest to roll the part up gently with bandages dipped in sweet oil; or a mixture of vinegar for法人, with the oil: when the excoriations are very tender, dropping warm milk upon them every dressing is very comfortable; or if the patient can bear to have flannels wrung out of it, applied hot, it may be still better: if the burn have formed eichares, they may be dressed with balsamic, though generally oil alone is easier; and in these fores, whatever is the caudal medicine will be the best digestible. There is great care necessary to keep down the fungus of burns, and heal the wounds smooth; to which end, the edges should be dressed with lint dippt in aqua virriil and dried afterwards; or they may be touched with the vitriol done, and the dressings be repeated twice a day. There is also a greater danger of ulceration from burns after the cure, than from other wounds; to obviate which, embrocations of neat's-foot oil, and bandage with stale boards to keep the part extended, are absolutely necessary, where they can be applied.

Explanation of Plate CLVII. fig. 1.

A director by which to guide the knife in the opening of abscesses that are burth themselves, or first punctured with a lancet. This instrument should be made either of steel, silver, or iron; but so tempered, that it may be bent and accommodated to the direction of the cavity. It is usually made quite straight; but that form prevents the operator from holding it firmly while he is cutting. The manner of using it is, by passing the thumb through the ring, and supporting it with the fore finger, while the straight-edged knife is to slide along the groove with its edge upwards, towards the extremity of the abscess.

B. The straight-edged knife, proper for opening abscesses with the assistance of a director; but which, in few other respects, is preferable to the round-edged knife.

C. A crooked needle, with its convex and concave sides sharp.
Surgery

When a wound is recent, and the parts of it are divided by a sharp instrument, without any farther violence, and in such a manner that they may be made to approach each other, by being returned with the hands, they will, if held in close contact for some time, reunite by inosculatation, and cement like one branch of a tree ingrafted on another. To maintain them in this situation, several sorts of sutures have been invented, and formerly practiced; but the number of them has of late been very much reduced. Those now chiefly described, are the interrupted, the glover's, the quilled, the twisted, and the dry sutures; but the interrupted and twisted, are almost the only useful ones; for the quilled suture is never preferable to the interrupted; the dry suture is ridiculous in terms, since it is only a piece of plaster applied in many different ways to reunite the lips of a wound; and the glover's, or uninterrupted stitch, which is advised in superficial wounds, to prevent the deformity of a scar, does rather, by the frequency of the stitches, occasion it, and is therefore to be rejected in favor of a compress and sticking plaster; the only instance where it should be used, is in a wound of the intestine.

Wounds are not fit subjects for suture, when there is either a contusion, laceration, loss of substance, great inflammation, difficulty of bringing the lips into apposition, or some extraneous body introducted into them; though sometimes a lacerated wound may be afficted with one or two stitches. It has formerly been forbidden to sew up wounds of the head; but this precaution is very little regarded by the moderns.

If we stitch up a wound that has none of these obstacles, we always employ the interrupted future, palling the needle two, three, or four times, in proportion to the length of it, though there can seldom be more than three stitches required.

The method of doing it is this: the wound being emptied of the grumous blood, and your assistant having brought the lips of it together, that they may lie quite even; you carefully carry your needle from without, inwards to the bottom, and fo on from within, outwards; using the caution of making the puncture far enough from the edge of the wound, which will not only facilitate the palling the ligature, but will also prevent it from eating through the skin and flesh; this distance may be three or four tenths of an inch: as many more stitches as you shall make, will be only repetitions of the same process. The threads being all palled, you begin tying them in the middle of the wound, though, if the lips are held carefully together all the while, as they should be, it will be of no great consequence which is done first. The most useful kind of knot in large wounds, is a single one first; over this, a little linen compres, on which is to be made another single knot; and then a slip-knot, which may be loosened upon any inflammation: but in small wounds, there is no danger from the double knot alone, without any compres to tie it upon; and this is most generally practised. If a violent inflammation should succeed, loosening the ligature only will not suffice; it must be cut through and drawn away, and the wound be treated afterwards without any future. When the wound is small, the lugs is it disturbed by dressing, the better; but in large ones, there will sometimes be a considerable discharge, and if the threads be not cautiously carried through the bottom of it, abscesses will frequently ensue from the matter being pent up underneath, and not finding issue. If no accident happen, you must, after the lips are firmly agglutinated, take away the ligatures, and dress the orifices which they leave.

It must be remembered, that during the cure, the future must be always afficted by the application of bandage, if possible, which is frequently of the greatest importance; and that sort of bandage with two heads, and a slit in the middle, which is by much the best, will in most cases be found practicable.

The twisted suture being principally employed in the hare lip, we shall reserve its description for the section on that head.

Of the Suture of Tendons.

Wounds of the tendons are not only known to heal again, but even to admit of sewing up like those of the fleshly parts,
parts, though they do not re-unite in so short a time. When a tendon is partly divided, it is generally attended with an excessive pain, inflammation, &c. in consequence of the remaining fibers being stretched and forced by the action of muscles, which necessarily will contract more when some of its resistance is taken away. To obviate this mischief, it has been hitherto an indisputable maxim in surgery, to cut the tendon quite through, and immediately afterwards perform the future. But this practice is not advisable; for though the division of the tendon afford present ease, yet the mere flexion of the joint will have the same effect: if, for example, it be a wound of a flexor tendon: besides, in order to few up the extremities of the tendon when divided, we are obliged to put the limb in such a situation, that they may be brought into contact, and even to sustain it in that posture to the finishing of the cure: if then, the posture will lay the tendon in this position, we can likewise keep it so without using the future, and are more sure of its not slipping away, which sometimes happens from any careless motion of the joint, when the stitches have almost worn through the lips of the wound; on which account, it is by all means advisable, in this case, to forbear the future, and only to favour the situation of the extremities of the tendon, by placing the limb properly.

But when the tendon is quite separated, and the ends are withdrawn from one another, having brought them together with your fingers, you may few them with a straight triangular pointed needle, paffing it from without inwards, and from within outwards in small tendons; about three tenths of an inch from their extremities, and in the *tendo Achillis* half an inch.

As the wound of the skin will be nearly traverse, it should not be raised to expose more of the tendon, but rather fewed up with it, which will conduct to the strength of the future. The knot of the ligature is to be made as in other wounds, and the dressings are to be the same: there is a sort of thin crooked needle that cuts on its concave and convex sides, which is very handy in the future of large tendons, and to be preferred to the straight one. During the cure, the dressings must be superficial, and the parts kept steady with pastboard and bandage: the small tendons reunite in three weeks, but the *tendo Achillis* requires six at least.

*Of the Gastroraphy.*

This word signifies no more than fewing up any wound of the belly; yet in common acceptance, it implies that the wound of the belly is complicated with another of the intestines. Now the symptoms laid down for distinguishing when the intestine is wounded, do not with any certainty determine it to be wounded only in one place; which want of information makes it absurd to open the abdomen in order to come at it: if so, the operation of fitching the bowels can only take place where they fall out of the abdomen, and we can see where the wound is, or how many wounds there are: if it happens that the intestines fall out unwounded, the burden of the surgeon is to return them immediately, without waiting for spirituous or emollient fomentations; and in case they puff up so as to prevent their reduction by the same orifice, you may with a knife or probe-sciar sufficiently dilate it for that purpose, or even prick them to let out the wind.

Upon the supposition of the intestine being wounded in such a manner as to require the operation, (for in small punctures it is not necessary,) the method of doing it may be this: Taking a straight needle with a small thread, you lay hold of the bowel with your left hand, and few up the wound by the glover's fitch, that is, by passing the needle through the lips of the wound, from within outwards all the way, so as to leave a length of thread at both ends, which are to hang out of the incision of the abdomen; then carefully making the interrupted future of the external wound, you pull the bowel by the small threads into contact with the peritoneum, in order to procure an adhesion, and tie them upon a small bolster of linen. In about six days, it is said the ligature of the intestine will be loofe enough to be cut and drawn away, which must be done without great force; in the interim, the wound is to be treated with superficial dressings, and the patient to be kept very still and low.

*Of the Bubonocele.*

When the intestine or omentum falls out of the abdomen into any part, the tumour in general is known by the name of *hermia*; which is farther specified either from the difference of situation, or the nature of its contents. When the intestine or omentum falls through the navel, it is called a *hermia umbilicalis*, or *exomphalos*; when through the rings of the abdominal muscles into the groin, *hermia inguinalis*; or if into the foramen, *ferotalis*: these two last, though the first only is properly fo called, are known by the name of bubonocele. When they fall under the *ligamentum Fallopian*, through the same passage that the iliac vessels creep into the thigh, it is called *hermia femoralis*. The bubonocele is also sometimes accompanied with a descent of the bladder: however, the case is very rare; but when it occurs, it is known by the patient's inability to urine, till the hernia of the bladder is reduced within the pelvis. With regard to the contents characterizing the swelling, it is thus distinguished: if the intestine only is fallen, it becomes an *enterocele*; if the omentum, (*epiplon*) *epiplocele*; and if both, *entero-epiplocele*. There is, besides these, another kind of hernia mentioned and described by the moderns, when the intestine or omentum is infinuated between the interlites of the muscles, in different parts of the belly: this hernia has derived its name from the place affected, and is called the *hermia ventralis*; and lastly, there have been a few instances, where the intestines or omentum have fallen thro' the great foramen of the ilium into the internal part of the thigh, between and under the two anterior heads of the triceps muscle.

All the kinds of hernias of the intestines and omentum, are owing to a preternatural dilatation of the particular orifices through which they pass, and not to a laceration of them.

The rupture of the groin, or *ferotum*, is the most common species of hernia, and in young children is very frequent; but it rarely happens in infancy, that any mischief arise from it. For the most part, the intestine returns of itself into the cavity of the abdomen, whenever the person lies down; at least a small degree of compression will make it. To secure the intestine when returned into its proper place, there are steel trusses now so artfully made, that by being accommodated exactly to the part, they perform the office of a bolster, without galling, or even fitting uneasy on the patient. These instruments are of so great service, that
were people who are subject to rupatures always to wear them, very few would die of this distemper: since it often appears, upon inquiry, when we perform the operation for the bubonoccele, that the necessity of the operation is owing to the neglect of wearing a trufs.

In the application of a trufs to these kinds of swellings, a great deal of judgment is sometimes necessary, and for want of it, we daily see trusses put even on buboes, induc- ted tertules, hydroctes, &c.

If there is a rupture of the integine only, it is, easily, when returned into the abdomen, supported by an instru- ment; but if of the omentum, notwithstanding it may be returned, yet the reduction felsion brings relief, unless there is only a small quantity of it; for the omentum will lie un- easily in a lump at the bottom of the belly, and, upon re- moval of the instrument, drop down again immediately; upon which account, seeing the little damage and pain there is in this kind of hernia, nothing need be used but a big trufs, to support the scrotum, and prevent possibly by that means the increase of the tumour. The difference of these tumours will be distinguished by the feel; that of the omentum feeling flaccid and rumpled, the other more even, flattulent, and springy.

Sometimes, in a rupture of both the integine and omen- tum, the gut may be reduced, but the omentum will still remain in the scrotum; and when thus circumstanced, a trufs must be used.

We have hitherto considered the rupture as moveable; but it happens frequently, that the integine, after it has passed the rings of the muscles, is partially inflamed, which enlarging the tumour, prevents the return of it into the ab- domen, and becoming every moment more and more strangLED, it soon tends to a mortification, unless we dilate the pasSages through which it is fallen, with some instrument, to suspend the scrotum, and prevent possibly by that means the increase of the tumour. The difference of these tumours will be distinguished by the feel; that of the omentum feeling flaccid and rumpled, the other more even, flattulent, and springy.

It rarely happens that patients submit to this incision be- fore the gut is mortified, and it is too late to do service; nor that there are instances of people surviving small gangrenes, and even perfectly recovering afterwards.

In mortifications of the bowels, when fallen out of the abdomen into the navel, it is not very uncommon for the whole gangrened integine to separate from the found one, so that the excrement must necessarily ever after be dis- charged at that orifice: there are likewise a few instances, where the rupture of the scrotum has mortified, and become the anus, the patient doing well in every other respect.

Before the performance of the operation for the bubono- ccele, it is only necessary to be done in the extremity of danger, the more methodical are to be tried; there are, such as will conduct to soothe the inflammation.

If, except the pleurisy, no disorder is more im- mediately relieved by plentiful bleeding than this. Clysters repeated, one after another, three or four times, if the fist or sore be either regained too long, or immediately re- turned, proves very efficacious; these are serviceable, not only as they empty the great intestines of their excrements and flatulences, which last are very dangerous, but they likewise prove a comfortable fomentation, by pulling thro' the colon all around the abdomen. The scrotum and groin musl, during the lay of the clyster, be bathed with warm fponges wrung out of a fomentation: and after the part has been well fomented, you must attempt to reduce the rub- ture: for this purpose, let your patient be laid on his back, so that his buttocks may be considerably above his head; the bowels will then retire towards the diaphragm, and give way to those which are to be pushed in. If, after endea- vouring two or three minutes, you do not find succeds, you may still repeat the trial.

If, notwithstanding these means, the patient continues in very great torture, though not so bad as to threaten an im- mediately mortification, we must apply some fome fort of poultice to the scrotum; such as equal parts of oil and vinegar made into a proper consists of oat-meal: after some few hours, the fomentation is to be repeated, and the other directions put in practice.

After all, should the pain and tenenencs of the part con- tinue, and hiccoughs and vomitings of the excresments suc- ceed, the operation must take place; for if you wait until a languid pulse, cold sweats, subfding of the tumour, and emphysematous feel come on, it will be most likely too late, as they are pretty sure symptoms of a mortification.

To conceive rightly of the occurrences in this operation, it must be remembered, that in every species of rupture, a portion of the peritoneum generally falls down with what- ever makes the hernia; which, from the circumstance of containing immediately the contents of the tumour, is called the sac of the hernia. Now, the portion of the peritoneum, which usuallly yields to the impulsion of the descending vif- cera, is that which corresponds with the inmost opening of the abdominal muscles, just where the membra pan cellularis peritonei begins to form the tunica vaginalis of the fpermatic cord; so that the sac with the vifcera infinuates them- selves into the tunica vaginalis of the fpermatic cord, and lie upon the tunica vaginalis of the tefticle: nevertheless, upon examination, the contents of the hernia are sometimes in contact with the tefticle itself; that is to say, within the tunica vaginalis of the tefticle. For some months during gestation, the teftes of the foetus remain in the abdomen; and when they descend into the tunica vaginalis, there is an immediate communication between the cavity of the abdo- men, and the cavity of the tunica vaginalis, which, in process of time, becomes obliterated by the coalition of the tunick with the cord; but if it happen, before the coalition be effected, that the integine or the omentum fall into the scrotum, they will necessarily remain in contact with the teftes.

From this description of the descent of the vifcera, it is evident that the herniary sac is contained within the tunica vaginalis, and ought to give the idea of one bag inclosing another: but in the operation, this distinction of coats does not always appear; for the herniary sac sometimes adheres so firmly to the tunica vaginalis, that together they make one thick coat: this adhesion may possibly result from the present inflammation of the parts, which has rendered the operation necessary.

The best way of laying your patient will be on a table about three feet four inches high, letting his legs hang down; then properly securing him, you begin your incision above the rings of the muscles, beyond the extremity of the tu- mour, and bring it down about half the length of the scro- tum, through the membra pan adiposa, which will require very little trouble to separate from the tunica vaginalis, and consequently will expose the rupture for the farther pro- cesses of the operation. If a large teftell is opened by the inci- sion, it must be taken up before you proceed further.

When
When the *tunica vaginalis* is laid bare, you must cut carefully through it and the *peritoneum*, in order to avoid pricking the intestines.

The *peritoneum* being cut through, we arrive to its contents, the nature of which will determine the next process: for if it is intestine only, it must directly be reduced; but if there is any mortified *omentum*, it must be cut off; in order to which it is advised to make a ligature above the part wounded, to prevent an hemorrhage; but it is quite needless, and in some meaure puerile, as it puckers up the intestine, and disfarms its situation, if made close to it.

When the *omentum* is removed, we next dilate the wound; to do which with safety, an infinite number of instruments have been invented: but there is none we can use in this case with so good management as a knife; and the finger in this operation is often a much better defence against pricking the bowels, than a director. The knife must be a little crooked and blunt at its extremity, like the end of a probe. Some surgeons perhaps may not be steady enough to cut dexterously with a knife, and may therefore perform the incision with probe-shears carefully introducing one blade between the intestine and circumference of the rings, and dilating upwards, and a little obliquely outwards. When the finger and knife only are employed, the manner of doing the operation will be by pricking the gut down with the fore-finger, and carrying the knife between it and the muscles, so as to dilate upwards about an inch, which will be a wound generally large enough: but if, upon examination, it shall appear that the intestine is strangulated within the *abdomen*, which may possibly happen from a contraction of the *peritoneum* near the entrance into the *fetum*; in that case, the incision must be continued through the length of the contracted channel, or the consequence will be fatal, notwithstanding the intestine be restored into the *fetum*: on this account the operator should pass his finger up the *fetum* into the abdomen, after the reduction of the gut, in order to discover whether it be safely returned into its proper place.

The opening being made, the intestine is gradually to be pulled into the *abdomen*, and the wound to be stitched up; for this purpose, some advise the quilted, and others the interrupted suture, to be passed through the skin and muscles; but as there is too much danger of the bowels falling out when a dressing and bandages are applied, and the patient all the white kept upon his back, but that it may be prevented by one or two short stitches through the skin only, it is by all means advisable to follow this method, since the security of a ligature in those tendinous parts may be dangerous.

Hitherto, in the description of the *bubonocele*, we have suppos'd the contents to be loose, or separato in the *fetum*: but it happens sometimes in an operation, that we find not only an adhesion of the outside of the *peritoneum* to the *tunica vaginalis*, and spermatique vessel, but likewise of some part of the intestines to its internal surface; and in this case there is so much confusion, that the operator is often obliged to extirpate the testes, in order to diffuse away and disentangle the gut; though if it can be done without calculation, it ought: however, this accident happens rarely, except in those ruptures that have been a long time in the *fetum* without returning: in which case the difficulty and hazard of the operation are so great, that, unless urged by the symptoms of an inflamed intestine, it should not be undertaken.

The dressing of the wound first of all may be with dry lint, and afterwards as directed under the head of wounds.

The operation of the *bubonocele* in women is nearly resembles that performed on men, that it requires no particular description: only in them the rupture is formed by the intestine or *omentum* falling down through the passage of the *ligamentum rotundum* into the groin, or one of the *labia pudenda*; where causing the same symptoms, as when obstructed in the *fetum*, it is to be returned by the dilatation of that passage.

**Of the Epiplocele.**

There have been a few instances where so great a quantity of the *omentum* has fallen into the *fetum,* that, by drawing the stomach and bowels downwards, it has excited vomitting, inflammation, and the same train of symptoms as happen in a *bubonocele*; in which case, the operation of opening of the *fetum* is necessary: the incision must be made in the manner of that for the rupture of the intestine, and the same rules observed with regard to the *omentum* that are laid down in the last section. It is necessary also, that the rings of the muscles should be dilated; or otherwise, though you have taken away some of the mortified part of the *omentum*, the rest that is out of its place, and tranquiled in the perforation, will gangrene also. The wound is to be treated in the same manner as that after the operation of the *bubonocele*.

**Of the Hernia Femoralis.**

This species of rupture is the same in both sexes, and formed by the falling of the *omentum* or intestine, or both of them, into the inside of the thigh, through the arch made by the *pubis* and *ligamentum Faltipiri*, where the saphenous and rendoms of the *fetum* and *iliacus internus* muscles pass from the *abdomen*. It is very necessary surgeons should be aware of the frequency of this disorder, which creates the same symptoms as other ruptures, and may first of all be treated by the same method: the manner of operating in the reduction is here too so exactly the same, with the difference of dilating the ligament instead of the rings of the muscles, that it would be a mere repetition of the operation for the *bubonocele* to give any description of it: only it may be observed, that the spermatique cord, as it enters into the *abdomen*, lies nearly transversely to the incision, and close in contact with the ligament; so that unless you make the dilatation obliquely upwards, instead of perpendicularly upwards, you will probably divide those vessels.

**Of the Exomphalos.**

This rupture is owing to a protrusion of the intestine, or *omentum*, or both of them, at the navel, and rarely happens to the subject of an operation: for though the case is common, yet most of them are gradually formed, from very small beginnings; and if they do not return into the *abdomen* upon lying down, in all probability they adhere without any great inconvenience to the patient, till some time or other an inflammation falls upon the intestines, which soon brings on a mortification, and death; unless, by great chance, the mortified part separates from the found one, leaving its extremity to perform the office of an *anus*; in this emergency, however, it is advisable to attempt the reduction, if called in at the beginning, though the universal adhesion of the *fetum* and its contents are a great obstacle to the success of the
the influence in which it is most likely to answer, is, when the rupture is owing to any strain, or sudden jerk, and is attended with these disorders which follow upon the irruption of a gut.

In this case, having tried all other means in vain, the operation is absolutely necessary; which may be thus performed: Make the incision somewhat above the tumour, on the left side of the navel, through the membrana adiposa, and then emptying the fat of its water, or mortifiedomentum, dilate the ring with the same crooked knife, conducted on your finger, as in the operation for the bubonocele; after this, return the intestines and omentum into the abdomen, and drees the wound without making any ligature but of the skin only.

Of the Hernia Ventralis.

The hernia ventralis, which sometimes appears between the recti muscles, is very large; but that tumour which requires the operation is seldom bigger than a walnut, and is a disease not so common as to have been observed by many but there are cases enough known, to put a surgeon upon inquiry after it. When the patient is suddenly taken with all the symptoms of a rupture, without any appearance upon inquiry after it. When the patient is suddenly taken with all the symptoms of a rupture, without any appearance

Explanalion of Fig. 2. Plate CLVII.

A. The round-edged knife, of a convenient size for almost all operations where a knife is used: the make of it will be better understood by the figure than any other description; only it may be remarked, that the handle is made of a light wood, as indeed the handles of all instruments should be, that the resistance to the blades may be better felt by the surgeon.

B. A pair of probe-scissors, which require nothing very particular in their form, but that the lower blade should be made as small as possible, so that it is strong, and has a good edge; because, being chiefly used in fistulas in ano, the introduction of a thick blade into the fistula, which is generally narrow, would be very painful to the patient.

C. The crooked knife with the point blunted, used in the operation of the bubonocele.

Of the Hydrocele.

The hydrocele, called also hernia aquosa, hydroscroti, and hydrostefis, is a watery tumour of the scrotum; which, notwithstanding the multiplicity of dilatations used by writers, is but of two kinds, the one when the water is contained in the tunica vaginalis, and the other when in the membrana cellularis scroti. This last is almost always complicated with an aniseke; which species of dropy is an extravasation of water lodged in the cells of the membrana adiposa; and when thus circumstanced, will not be difficult to be distinguished; besides that it is sufficiently characterized by the shining and softness of the skin, which gives way to the least impression, and remains pitted for some time. The penis is likewise sometimes enormously enlarged, by the inflation of the fluids into the membrana cellularis; all which symptoms are absolutely wanting in the dropy of the tunica vaginalis.

In the dropy of the membrana cellularis scroti, the puncture with the trocar is recommended by some, and little oriﬁces made here and there with the point of a lancet by others; or a small skene of silk passed by a needle through the skin, and out again at the distance of two or three inches, to be kept in the manner of a seton, till the waters be quite drained: but the two first methods avail very little, as they open but few cells; and the last cannot be so instructive in that respect as incisions, and will be much more apt to become troublesome, and even to gangrene.

Indeed it is not often proper to perform any operation at all upon this part, since the membrana cellularis scroti, being a continuation of the membrana adiposa, oriﬁces made through the skin in the small of the legs will effectually empty the scrotum; and this place ought rather to be pitched upon than the other, as being more likely to answer the purpose by reason of its dependency: however, it sometimes happens, that the waters fall in so great quantities into the scrotum, as, by difteading it, to occasion great pain, and threaten a mortification; the prepuce of the penis also becomes very often excessively dilated, and so twisted, that the patient cannot void his urine. In these two instances, an incision of three inches long should be made on each side of the scrotum, quite through the skin into the cells containing the water, and two or three of half an inch long, in any part of the penis, with a lancet or knife; all which may be done with great safety, and sometimes with the success of carrying off the disease of the whole body.

The dropy of the tunica vaginalis is owing to a preternatural discharge of that which is continually separating in a small quantity, on the internal surface of the tunick, for the moistening or lubricating the tefficle, and which collecting too fast accumulates and forms in time a swelling of great magnitude; this is what we take to be the other species of hydrocele, and the only one besides.

The hydrocele of the tunica vaginalis is very easily to be distinguished from the hydrocele of the membrana cellularis, by the preceding description of that species of dropy. We shall now explain how it differs from the other tumours of the scrotum, viz. the bubonocele, epiplocele, and enlarged tefficle. In the first place, it is seldom or never attended with pain in the beginning, and is very rarely to be imputed to any accident, as the hernia’s of the omentum and intestines are. From the time it first makes its appearance, it is very seldom known to appear or diminish; but generally continues to increase, though in some much faster than in others; in one person growing to a very painful diffusion in a few months, whilst in another it shall not be troublesome in many years; nay, shall cease to swell at a certain period, and ever after continue in that state without any notable disadvantage; though this last case very rarely happens. In proportion as it enlarges, it becomes more tense, and then is said to be transparent; indeed the transparency is made the chief criterion of the disease; it being constantly advised to hold a candle on one side of the scrotum, which it is said will shine through the other side, if there be water. But this experiment does not always answer, because sometimes the tunica vaginalis is very much thickened, and sometimes the water itself is not transparent; so that to judge positively if there be a fluid, we must be guided by feeling a fluctuation; and
and though we do not perhaps evidently perceive it, yet we may be persuaded there is a fluid of some kind, if we are once assured that the distension of the tunica vaginalis makes the tumour; which is to be distinguished in the following manner.

If the interstitial, or omentum, form the swelling, they will be soft and pliable, (unless inflamed;) uneven in their surface, particularly the omentum; and both of them extend themselves up from the serotum quite into the very abdomen: whereas, in the hydrocele, the tumour is tenser and smooth, and ceases before or at its arrival to the rings of the abdominal muscles: because the upper extremity of the tunica vaginalis terminates at some distance from the surface of the belly.

When the testicle is increased in its size, the tumour is rounder; and if not attended with an enlargement of the spermatic vessels, the cord may be easily distinguished between the swelling and abdomen; but without this rule of distinction, either the pain, or the very great hardness, will discover it to be a disease of the testicle.

As to the cure of this distemper by external applications, or internal means, little is to be expected; on which account, it is generally advisable to wait with patience until the tumour becomes troublesome; and then to tap it with a lancet or trocar. In opening with a lancet, it may possibly happen, that the orifice of the skin shall slip away from that of the tunica, and prevent the escape of the water to obviate which inconvenience, you may introduce a probe, and by that means secure the exact situation of the wound; but if the coats are very much thickened, it will be advisable to use the trocar, rather than the lancet. It is spoken of as an easy thing, to hold the testicle with the left hand, while we make the puncture with the right; but when the tunica vaginalis is very tense, it cannot well be distinguished: however, there is no danger of wounding it, if you make the puncture in the inferior part of the serotum. During the evacuation, the serotum must be regularly pressed; and after the operation, a little piece of dry lint and sticking plaster are sufficient.

This method of tapping is called the palliative cure; not but that it does now and then prove an absolute one. To prevent the relapse of this disease, surgeons prescribe the making a large wound, either by incision or caustic, that upon healing it afterwards, the firmness and contraction of the cicatrix may bind up the relaxed lymphatic vessels, and obstruct the further preternatural effusion of their contents; but this practice is generally attended with so much trouble, that, notwithstanding its success in the end, most surgeons prefer the palliative.

Of Castration.

This is one of the most melancholy operations in the practice of surgery, since it seldom takes place but in disorders into which the patient is very apt to relapse, viz. those of a febrirhus, or cancer: for under most of the symptoms described as rendering it necessary, it is absolutely improper; such as a hydrocele, abscesses of the testis, an increasing mortification, or what is sometimes understood by a farcocele; of which last it may not be amiss to say a word. In the utmost latitude of the meaning of this term, it is received as a fleshly swelling of the testicle itself, called likewise hernia canena; or in some enlargements, such as in a clam, more frequently hernia humoralis; but generally speaking, is considered as a fleshly excrecence formed on the body of the testis, which becoming exceedingly hard and tumefied, for the most part is supposed to demand extirpation, either by cutting or burning away the induration, or amputating the testicle. But this maxim too precipitately received, has very much misguided the practitioners of surgery.

It sometimes happens that the epidydymis is tumefied, independent of the testicle; and feeling like a large adventitious excrecence, answers very well to the idea most surgeons form of a farcocele: but not being aware of the different nature and texture of the epidydymis, they have frequently confounded its disorders with those of the testicle itself, and equally recommended extirpation in the induration of one or the other. But all indurations of the glandular part of the testicle not tending to inflammation and abscesses, generally, if not always, lead on to farcohus and cancers; whereas those of the epidymis seldom or never do. It is true, in spite of internal or external means, these last often retain their hardness, and sometimes suppurate, but however without much danger in either case.

Before castration, it is laid down as a rule to inquire whether the patient has any pain in his back, and in that case to reject the operation, upon the reasonable presumption of the spermatic vessels being likewise diseased; but we are not to be too hasty in this determination; for the mere weight of the tumour stretching the cord, will sometimes create this complaint. To learn the cause then of this pain in the back, when the spermatic cord is not thickened, let your patient keep his bed, and suspend his serotum in a bag-truss, which will relieve him, if disordered by the weight only; but if the spermatic cord is thickened or indurated, which rarely, when attended with a dilatation of the vessels of the serotum, is known by the Greek appellations cirrocele and varicocele, the case is desperate, and not to be undertaken.

But supposing no obstacle in the way to the operation, the method of doing it may be this: Lay your patient on a square table of about three feet four inches high, letting his legs hang down, which, as well as the rest of his body, must be held firm by the assistants. Then with a knife begin your wound above the rings of the abdominal muscles, that you may have room afterwards to tie the vessels, since for want of this caution operators will necessarily be embarrassed in making the ligature: then carrying it through the membrana adiposa, it must be continued downward, the length of it being in proportion to the size of the testicle.

If it is very small, it may be dissected away without taking any part of the serotum. If the testicle, for instance, weighs twenty ounces; having made one incision about five inches long, a little circularly, begin a second in the same point as the first, bringing it with an opposite sweep to meet the other in the inferior part, in such a manner as to cut out the shape of an oval whose smallest diameter shall be two inches: after this, dissect away the body of the tumour, with the piece of skin on it, from the serotum; first taking up some of the blood-vessels, if the hemorrhage is dangerous. Then pass a ligature round the cord, pretty near the abdomen, and if you have space between the ligature and testicle, a second about half an inch lower, to make the slippage of blood still more secure. The ligatures may be tied with what is called the surgeon's knot, where the thread is palled through the ring twice. This done, cut off the testicle a little underneath the second ligature, and pass a needle from the skin at the lower part of the wound through the skin at the upper part, in such a manner as to envelope in some
some degree the sound tactual, which will greatly facilitate and quicken the cure; or if one stitch will not answer the purpose, you may repeat it in such part of the wound where the skin on each side lies most loose.

In large tumours, it is advisable to cut away great part of the skin; for besides that the haemorrhage will be much less in this case, and the operation greatly shortened, the skin by the great distention having been rendered very thin, will great part of it, if not taken away, spackleate, and the rent be more prone to degenerate into a cancerous ulcer.

Of the Phymosis.

The phymosis signifies no more than such a straithness of the prepucce, that the glans cannot be denuded; which is the greatest it becomes troublesome, so as to prevent the egress of the urine, or conceal under it chances, or foul ulcers, quite out of the reach of application, is to be cut open. It sometimes happens, that children are born imperfect; in which case, a small puncture, dressed afterwards with a test, effects a cure. But this operation is chiefly practised in venereal cases, in order to expose chances either on the glans or within the prepucce itself: and here, if the prepucce is not very callous and thick, a mere incision will answer; which may be made either with the tiff harassing, or by slitting a knife between the skin and glans to the utmost extremity, and cutting it up; the last method is more easy than that of the cutting, but it is better to make the wound on the side of the prepucce than upon the upper part, for sometimes the great vessels on the dorsum penis afford a terrible haemorrhage; though the prepucce remains better slitted after an incision made in the upper part, and therefore is to be preferred by those who understand how to take up the vessels. In children it sometimes happens that the prepucce becomes very much contracted; and in that case, it is accidentally subiect to flight inflammations, which bring on some symptoms of the stone; but the disorder is always removed by the cure of the phymosis.

If the prepucce be very large and indurated, the opening alone will not suffice; and it is more advisable to take away the callosity by circumcision, which must be performed with a knife; and if the artery bleed much, it must be taken up with a small needle and ligature.

Of the Paraphymosis.

The paraphymosis is a disease of the penis, where the prepucce is fallen back from the glans, and cannot be brought forwards to cover it. There are many whose penis is naturally thus formed, but without any inconvenience; so that since the time of the Romans, (some of whom thought it indecent to have the glans bare,) it has not been usual to perform any operation upon that account; but we read the several processes of it described particularly by Celsus, who does not speak of it as an uncommon thing. Moit of the instances of this disease are owing to a venereal cause; but there are some where the prepucce is naturally very tight, which take their rise from a sudden retraction of it, and immediate enlargemen of the glans preventing its return. Sometimes it happens that the surgeon succeeds in the reduction immediately, by compressing the extremity of the penis, at the time he is endeavouring to advance the prepucce; if he does not, let him keep it suspended, and attempt again, after having somented, and used some emollient applications: but if, from the contraction below the corona glandis, there is so great a strititure as to threaten a gangrene, or even, if the penis is much enlarged by water in the membrane reticularis, forming tumours called crystallines, three or four small incisions must be made with the point of a lancet, into the strititure and crystallines, according to the direction of the penis; which in the first case will set free the obstruction, and in the other evacuate the water: the manner of dressing afterwards must be with fomentations, digestives, and the siberica Londinensis over the pledgits.

Of the Paracentesis.

This operation is an opening made into the abdomen, in order to empty any quantity of extravasated water, collected in that species of dropfy called the ascites; but as there is much more difficulty in learning when to perform than how to perform it, and indeed in some instances requires the nicest judgment, we shall endeavour to specify the distinctions which render the undertaking more or less proper.

There are but two kinds of dropsey; the ascites, called also leucophlegmacy, when the extravasated water swells in the cells of the membrane adiposa; and the ascites, when the water poises the cavity of the abdomen. In the first kind, the water is clear and limpid; but in the second, a little groffer, very often gelatinous and corrupted, and sometimes even mixed with fleshy concretions.

The operation of tapping is seldom the cure of the distemper: but dropsey, which are the consequence of a mere impoverishment of the blood, are less likely to return than those which are owing to any previous disorder of the liver; and it is not uncommon for dropseys that follow agues, haemorrhages, and diarrhoeas to do well; whereas in such as are complicate with a surrefous liver, there is hardly an example of a cure.

The water floating in the belly, is, by its fluctuation, to determine whether the operation be advisable; for if, by laying one hand on any part of the abdomen, you cannot feel an undulation from striking on an opposite part with the other, it is to be presumed there will be some obstacle to the evacuation. It sometimes happens, that a great quantity, or almost all the water, is contained in little bladders, adhering to the liver and the surface of the peritoneum, known by the name of hydatids; and the rest of it in different sized ones, from the degree of a hydatis, to the size of a globe holding half a pint or a pint of water. This is called the encysted dropsey, and from the smallness of its cysts makes the operation useful; but is not difficult to be distinguished, because there is not a fluctuation of the water, unless it is complicated with an extravasation.

When the fluctuation is hardly perceptible, (except the teguments of the abdomen are very much thickened by an ascites,) in all probability the fluid is gelatinous.

There is another kind of dropsey, which for the most part forbids the operation, and is peculiar to women, being feet in the body of one or both ovaries. There is no example of this species but what may be known by the hardness and irregularity of the tumour of the abdomen, which is nearly uniform in the other cases.

When the ovary is dropical, the water is generally deposited in a great number of cells formed in the body of it; which circumstance makes the fluctuation insensible, and the perforation useless; though sometimes there are only one or two.
two cells; in which case, if the ovary is greatly magnified, the undulation will be readily felt, and the operation be advisable.

When the ascites and anasarca are complicated, it is seldom proper to perform the operation, since the water may be more effectually evacuated by scarifications in the legs than by tapping.

Upon the supposition nothing forbids the extraction of the water, the manner of operating is this: Having placed the patient in a chair of a convenient height, let him join his hands so as to press upon his stomach; then dipping the trocar in oil, you stab it suddenly through the teguments, and, withdrawing the perforator, leave the waters to empty by the canula: the abdomen being, when filled, in the circumstance of a bladder distended with a fluid, would make it indifferent where to wound; but the apprehension of hurting the liver, if it be much enlarged, has induced operators rather to choose the left side, and generally in that part which is about three inches obliquely below the navel; if the navel protuberates, you may make a small puncture with a lancet in the skin, and the waters will be readily voided by that orifice, without any danger of a hernia succeeding; but it should be carefully attended to, whether the protuberance is formed by the water or an exomphalos; in which latter case, the intestines would be wounded, and not without the greatest danger. The surgeon neither in operating with the lancet, nor perforating with the trocar, need fear injuring the intestines, unless there is but little water in the abdomen, since they are too much confined by the membrane to come within reach of danger from these instruments; but it sometimes happens that when the water is almost all emptied, it is suddenly stopped by the intestines pressing against the end of the canula; in which case you may pull them away with a probe: during the evacuation, your attendants must keep pressing on each side of the abdomen, with a force equal to that of the waters being empty, lest the protuberance is formed by the water or an exomphalos, in which latter case, the intestines would be wounded, and not without the greatest danger. The surgeon neither in operating with the lancet, nor perforating with the trocar, need fear injuring the intestines, unless there is but little water in the abdomen, since they are too much confined by the membrane to come within reach of danger from these instruments; but it sometimes happens that when the water is almost all emptied, it is suddenly stopped by the intestines pressing against the end of the canula; in which case you may pull them away with a probe: during the evacuation, your attendants must keep pressing on each side of the abdomen, with a force equal to that of the waters before contained there; for by neglecting this rule, the patient will be apt to fall into faintings, from the weight on the abdomen, with a force equal to that of the waters being empty, leaves the superior ones of a hidden too empty, and thus interrupts the regular progress of the circulation. To obviate this inconvenience, the compression must not only be made with the hands during the operation, but be afterwards continued, by swathing the abdomen with a roller of flannel, about eight yards long, and five inches broad, beginning at the bottom of the belly, so that the intestines may be borne up against the diaphragm: you may change the roller every day till the third or fourth day, by which time the several parts will have acquired their due tone. For the drefsing a piece of dry lint and plaster suffices; but between the skin and roller it must be proper to lay a double flannel a foot square, dipp'd in brandy or spirits of wine.

This operation, though it does not often absolutely cure, yet it sometimes preserves life a great many years, and even a pleasant one, especially if the waters have been long collecting.

Explanation of Fig. 3. Plate CLVII.

A. A trocar of the most convenient size for emptying the abdomen when the water is not gelatinous. It is here represented with the perforator in the canula, just as it is placed when we perform the operation.

B. The canula of a large trocar, recommended in cases where the water is gelatinous.

C. The perforator of the large trocar.

The handle of the trocar is generally made of wood, the canula of silver, and the perforator of steel. Great care should be taken by the makers of this instrument, that the perforator should exactly fill up the cavity of the canula; for unless the extremity of the canula lies quite close and smooth on the perforator, the introduction of it into the abdomen will be very painful. To make it slip in more easily, the edge of the extremity of the canula should be thin and sharp; and that the canula should be of steel; for the silver one being of too soft a metal, becomes jagg'd or bruised at its extremity with very little use.

Of the Fistula in Ano.

The fistula in ano is an abscess running upon or into the integumentum rectum.

The piles, which are little tumours formed about the verge of the anus, immediately within the membrane interna of the rectum, do sometimes sappurite, and become the forerunners of a large abscess; also external injuries here, as in every other part of the body, may produce it; but from whatever cause the abscess arise, the manner of operating upon it will be according to the nature and direction of its cavity.

If the surgeon have the first management of the abscess, and there appear an external inflammation upon one side of the buttock only; after having waited for the proper maturity, let him with a knife make an incision the whole length of it; and in all probability, even though the bladder be affected, the lacerations of the wound, and the proper application of dressings lightly pressed in, will prevent the putrefaction of the integument, and make the cavity fill up like impol鞠imations of other parts.

If the fistula be continued to the other buttock, almost round the integument, the whole course of it must be dilated in like manner; hence, in such spongy cavities, a generation of fleas cannot be procured but by large openings; whence also, if the skin is very thin, lying loose and flabby over the fistula, it is absolutely necessary to cut it quite away, or the patient will be apt to sink under the discharge, which, in the circumstance here described, is sometimes exccellive. By this method, which cannot be too much recommended, it is amazing how happy the event is likely to be; whereas, from neglecting it, and trifling only to a narrow opening, if the discharge do not destroy the patient, at least the matter, by being confined, corrupts the gut, and infinuating itself about it, forms many other channels, which, running in various directions often baffle an operator, and have been the cause of a fistula being to generally esteemed very difficult of cure.

Here we have considered the impol鞠imation as poffessing a great part of the buttock; but it more frequently happens, that the matter points with a small extent of inflammation on the skin, and the direction of the fistula is even with the gut: in this case, having made a puncture, you may with a probe learn if it has penetrated into the intestine, by passing your finger up it, and feeling the probe introduced through the wound into its cavity; though, for the most part, it may
be known by a discharge of matter from the anus. When this is the state of the fistula, there is no hesitation to be made; but immediately putting one blade of the scissors up to the gut, and the other up the wound, snip the whole length of it. This process is as advisable when the intestine is not perforated, if the sinus is narrow, and runs upon or very near it; for if the abcefs be tented, which is the only way of dressing it while the external orifice is small, it will almost certainly grow callous; so that the safest means of cure, will be opening the gut, that proper applications may be laid to the bottom of the wound. However, it should be well attended to, that some patience pretty near the intestine neither run into nor upon it; in which case, they must be opened, according to the course of their penetration. There are abundance of instances, where the intestine is so much ulcerated, as to give free issue to the matter of the abcefs by the anus: but there are none where there is not, by the thinness and discolouration of the skin, or an induration to be perceived through the skin, some mark of its direction; which, if discovered, may be opened into with a lancet, and then it becomes the same case as if the matter had fairly pointed.

If the sinus into and about the gut are not complicated with an induration, and you can follow their course; the mere opening with scissors, or a knife guided on a director, will sometimes suffice; but it is generally safer to cut the piece of flesh surrounded by these inflations quite away, and, when it is callous, absolutely necessary, or the callousities must be walled afterwards by echinostick medicines, which is a tedious and cruel method of cure.

When the fistula is of a long standing, and we have choice of time for opening it, a dose of rhubarb the day before the operation will be very convenient, as it not only will empty the bowels, but also prove an antirheumatic for a while, and prevent the mischief of removing the dressings in order to go to stool.

It sometimes happens, that the orifices are so small, as not to admit the entrance of the scissors; in which case, sponge tents must be employed for their dilatation.

In performing these operations on the anus, no instruments are so handy as the knife and scissors; almost all the others which have been invented to facilitate the work are not only difficult to manage, but more painful to the patient: however, in those instances where the fistula is very narrow, and opens into the intestines, just within the verge of the anus, the syringotomy may be used with advantage; but where the opening into the gut is high, it cannot be employed without giving great pain.

The worst species of fistula is that communicating with the urethra, and sometimes through the prostate gland, with the bladder itself. This generally takes its rise from a former gonorrhoea, and appears externally first in perineum, and afterwards increases more towards the anus, and even sometimes into the groin, bursts out in various orifices, through the skin, which soon becomes callous and rotten; and the urine passing partly through these orifices, will often excite as much pain, and of the same kind, as a stone in the bladder.

This species of fistula, taking its rise from strictures of the urethra, is only manageable by the bougie: for so long as the urethra is obstructed, the cure of the fistula will be imperfect; but if the canal be opened by this application, it is amazing what obdurate indurations and foul sinuses will in consequence disappear; though there are some so callous and rotten, as to demand the knife and skilful dressings, notwithstanding the urethra should be dilated by the use of bougies.

Of the Puncture of the Perineum.

This operation is performed, when the bladder is under such a suppression of urine, as cannot be relieved by any gentler methods, nor, by reason of the obstruction in its neck or the urethra, will admit of the introduction of a catheter. The manner of doing it, as described by most writers, is by pulling a common trocar from the place where the external wound in the old way of cutting is made, into the cavity of the bladder, and so procuring the issue of the water through the canula; but others, refining upon this practice, have ordered an incision to be carried on from the fame part into the bladder, and then to infiltrate the canula: but both the methods are to be rejected, in favour of an opening a little above the os pubis; for besides that it is not easy to guide the instrument through the prostate gland into the bladder, the necessity of continuing it, in a part already very much inflamed and thickened, seldom fails to do mischief, and even to produce a mortification.

There is another method still more easy both to the patient and the operator; which consists only in emptying the bladder with a common trocar. and lopping the canula with a little cork, which is afterwards to be taken out as often as the patient has occasion to urine. The canula is to be continued in the bladder, till such time as the person finds he can void his urine by the natural passage.

In this operation the abdomen ought to be perforated about two inches above the os pubis; and if the patient be fat, the trocar should penetrate two inches, otherwise an inch and a half will be sufficient.

Of the Stone.

Stony concretions are a disagreeable incident to several parts of the body; but we shall treat only of those formed in the kidneys and bladder.

Small stones and gravel are frequently voided without pain; but sometimes they collect and become very large in the kidneys; in which case, a fit of the stone in that part is the cure, from the inflammation and pain occasioning convulsive twitches, which at last expel them. But in this disagreeable the patient is very much relieved by several kinds of remedies, such as the mucilaginous, the faponaceous, &c. some of which lubricate, and others both lubricate and stimulare. The sand, in passing through the ureters, is very much forwarded by the force of the urine. The ureters being very narrow as they run over the psoas muscle, and also at their entrance into the bladder, make the movement of the stone very painful and difficult in those parts; but there is seldom so much trouble after the first fit; for when once they have been dilated, they generally continue so. For the symptoms of a stone in the bladder, see Medicine, p. 122.

Of Searching.

The patient being laid on a horizontal table, with his thighs elevated and a little extended, place the sound with the concave part towards you, until it meets with some resistance in perineum, a little above the anus; then turning it without much force, pull it gently on into the bladder; and if...
if it meets with an obstruction at the neck, raise its extremity upwards, by inclining the handle of it towards you; or if it don't then slip in, withdraw it a quarter of an inch, and introducing your fore finger into the rectum, lift it up, and it will seldom fail to enter: there is some art in turning the found in the proper place of the urethra, which forgoons not vered in this operation cannot so well execute; therefore they may pass the instrument with the concave side always towards the abdomen of the patient, observing the fame rule at the entrance into the bladder as in the other method. The case of this obstacle, besides the rule of the urethra, and the reluctance of the verumontanum, is sometimes a small projection of the orifice of the bladder, in the urethra, like that of the ostium in the vagina, which occasions the end of the found to flip a little beyond it.

Though, upon searching, we are assured of a stone in the bladder, we are not, without further inquiry, to operate immediately; since there are sometimes obstacles which forbid the operation, either absolutely, or only for a certain time; among these, that of greatest consequence, is the gravel or stone in the kidneys. The objections of less weight, and which frequently are removed, are a fit of the stone, a cough, a hectic, and being emaciated by long pain; excessive hot or cold weather are likewise hindrances: But in extremity of danger, these last considerations may be disregarded.

Difference of age makes an extreme difference of danger, infants and young people almost always recovering; but still the operation is adviseable on those advanced in years, tho' it is not attended with near the same success. This operation is performed four several ways, all which we shall describe.

Of the Lesser Apparatus, or Cutting on the Gripe.

The most ancient way of cutting for the stone, is that described by Celsus, and known by the name of cutting on the gries; though, since the time of Johannes de Romans, it is also called cutting with the lesser apparatus, to distinguish it from his new method, which, on account of the many instruments employed in it, is called cutting with the greater apparatus. The manner of doing the operation is this: You first introduce the fore finger and middle finger of the left hand, dip't in oil, up the anus, and pressing softly with your right hand above the ostium, endeavor to bring the stone towards the neck of the bladder; then making an incision, on the left side of the perineum, above the anus, directly upon the stone, you turn it out through the wound, either with your fingers or a scoop.

This way of cutting was attended with many difficulties, for want of proper instruments to direct the incision, and extract the stone, when it lay beyond the reach of the fingers, which in a large bladder was frequently the case.

The wound of the bladder in this operation is made in the same place as is now practised in the later method; but it being impracticable on some subjects, and uncertain on all others, has made it universally exploded.

Of the Greater Apparatus, or the Old way.

This method of cutting, invented by Johannes de Romans, has at different times, and with different people, varied considerably in some of its proceedings, and particularly with regard to the use of certain instruments. What we shall describe, will be the manner in which it is now practised with all its improvements.

Having laid the patient on a square horizontal table, three feet four inches high, with a pillow under his head, let his legs and thighs be bent, and his heels made to approach his buttocks, by tying his hands to the bottom of his feet, with a couple of strong ligatures, about two yards long; and to secure him more effectually from struggling, pass a double ligature under one of his hams, and carry the four ligurs round his neck to the other ham; then passing the loop underneath it, make a knot by threading one of the single ends through the loop: After this, the thighs being widened from each other, and firmly supported by proper persons, you introduce the staff, having first dip't it in oil, which must be held by your assistant, a little leaning on the left side of the fomn in perineo; and beginning the external wound juft below the corrected, (which must be held out of the way,) you continue it downwards, to within two fingers breadth of the anus; then leaving that direction, you slip the knife forwards in the groove, pretty far into the bulbous part of the urethra; or, as there is some danger of wounding the rectum, in the continuation of the incision, you may turn the knife with the back towards it, and make this part of the incision from within outwards. Should a very large vesel be cut, it will be advisable to tie it before you proceed any farther in the operation. When the wound is made, slide the gorget along the groove of the staff into the bladder; and to do it with more safety, when the back of it is received in the groove, it will be proper to take the staff yourself in your hand; for if the assistant should, unwarily, either incline the handle of it too much towards you, or not refift enough to the force of the gorget, it is very apt to slip out of the groove, between the rectum and the bladder; which accident is not only inconvenient to the operator for the present, but is attended for the most part with very bad conquences. The gorget being pass'd, dilate the urethra and neck of the bladder with your fore-finger, and introduce the forces into the bladder, keeping them that till you touch the stone, when you must grasp it with a moderate force, and extract it by pulling downwards towards the rectum. Should you find a difficulty in laying hold of the stone, be careful to keep your forces in such a position, that they may open upwards and downwards, (not laterally,) which will very much facilitate the embracing of the stone, in case it should happen to be thin and flat.

Of the High Operation.

This method of cutting for the stone was first published in the year 1561, by Pierre Franco. About the year 1719, it was first done in England by Mr Douglas, and after him practised by others. The manner of performing it, with the improvements made since Franco's operation, is this: The patient being laid on a square table, with his legs hanging over, and fastened to the sides of it by a ligature pass'd above the knee; his head and body lifted up a little by pillows, so as to relax the abdominal muscles; and his hands held steady by some assistants; inject through a catheter into the bladder as much barley-water as he can bear, which in a man is often about eight ounces, and sometimes, twelve. For the more easily doing this, an ox's urether may be tied to the extremity of the syringe; and handle of the catheter,
the reflux of the water, must grasp the penis the moment the catheter is withdrawn, holding it on one side, in such a manner as not to stretch the skin of the abdomen; then with a round edged knife make an incision about four inches long, between the recti and pyramidal muscles, through the membrane adiposa, as deep as the bladder, bringing its extremity almost down to the penis; after which, taking a crooked knife, continue the incision into the bladder, carrying it a little under the os pubis, and immediately upon the water's flowing out, introduce the fore-finger of your left hand, which will direct the forceps to the stone.

This method was at first received with great applause in London; but after some trial was rejected, for the following inconveniences.

It sometimes happens that the bladder, notwithstanding the injection, still continues so deep under the os pubis, that the peritoneum being necessarily wounded first, the intestines push out immediately at the orifice, and the urine afterwards empties into the abdomen; in which case, hardly any recover. The injection itself is exceedingly painful; and however slowly the fluid be injected, it diffuses the bladder much more suddenly than the urine from the kidneys does, and so much faster than it can well bear, that it not only is seldom dilated enough to make the operation absolutely secure, but is sometimes even burst, or at least its tone destroyed by the daily dilatation. What adds to the danger here, is the possibility of meeting with a contracted indurated bladder; which is a circumstance sometimes attending on the stone, and indeed an exceedingly dangerous one in all the other methods; but would be frightful in this, by reason not only of the necessity of wounding the peritoneum, but of the difficulty of coming at the stone. If the stone be very small, it is hard to lay hold of it with the forceps, and in a fat man the fingers are not long enough for that purpose. If there are many little stones, it will scarce happen that more than one at a time can be extracted; and if the stone breaks, it not only is impracticable to take it all away in the operation, but also, from the supine posture of the patient, it will generally remain in the bladder; whereas, in the other methods, for the most part, it works itself out with the urine. But even supposing that the operation itself is prosperous, the confquences generally are very troublesome; for the urine seeping out at an orifice where there is no defect, spreads itself upon the abdomen, and makes very painful excoriations; though, what is still worse, it sometimes infiltrates itself into the cells between the bladder and abdominal muscles, and, together with the inflammation excited by the operation, brings on a suppuration there, which is always difficult to manage, and frequently mortal.

Of the Lateral Operation.

This method was invented by an ecclesiastic, who called himself Frere Jaques. He came to Paris in the year 1697, bringing with him an abundance of certificates of his dexterity in opening; and making his history known to the court, and magistrates of the city, he got an order to cut at the Hotel Dieu, and the Choisit, where he performed this operation on about fifty persons. His success did not answer the promises he had made.

The principal defect in his manner of cutting was the want of a groove in his staff; which made it difficult to carry the knife exactly into the bladder; nor did he take any care of his patients after the operation; so that for want of proper dressings, some of the wounds proved fistulous, and other ill consequences ensued.

Chelfelden, improving Frere Jaques's method, made use of the following, which is now the practice of most operators.

The patient being laid on a table, with his hands and feet tied, and the staff passed as in the old way, let your assistant hold it a little slanting on one side, so that the direction of it may run exactly through the middle of the left erector penis and accelerator prisma muscles; then make your incision through the skin and fat, very large, beginning on one side of the form in perineum, a little above the place wounded in the old way, and finding a little below the anus, between it and the tuberosity of the ischium; this wound must be carried on deeper between the muscles, until the profate be felt; when, searching for the staff, and fixing it properly, if it has slipped, you must turn the edge of the knife upwards, and cut the whole length of that gland from within outwards, at the same time putting down the rectum with a finger or two of the left hand; by which precautions the gut will always escape wounding; after which, the operation finishes nearly in the same manner as with the greater apparatus.

If, upon introducing the forceps, you do not perceive the stone readily, you must lift up their handle, and feel almost perpendicularly for it; since for the most part, when it is hard to come at, it lies in one of the sinuses sometimes formed on each side of the neck of the bladder, which projects forward in such a manner, that if the stone lie there, the forceps palls beyond it the moment they are through the wound; so that it would be impossible to lay hold of it, or even to feel it, if not aware of this circumstance.

When the stone breaks, it is much safer to take away the fragments with the forceps, than to leave them to be discharged with the urine; and if the pieces are very small, like sand, a scoop is the best instrument; though some prefer the injecting barley-water into the bladder, which suddenly returing, brings away the broken particles of the stone.

As there are hardly any instances of more stones than one, when the stone taken away is rough; so when it is smooth and polished in any part of it, it is almost a certain sign of others behind; on which account, an operator should be careful, in that case, to examine not only with his fingers, but some convenient instrument, for the remaining ones; though indeed, in all cases, it may be proper to examine the bladder after the extraction of the stone; because it is possible there may be a second stone, notwithstanding the first be rough.

The great inconvenience of the lateral operation is the haemorrhage which sometimes ensues in men; for in children the danger of it is not worth mentioning.

If in the operation any very large vessel of the external wound should be divided, it is advisable to tie it before the extraction of the stone; but the necessity of doing this, does not occur once in twenty times.

There is but one objection more of any consequence, which is the danger of wounding the rectum; and this is a very troublesome accident: But if the operator observes the rule laid down with regard to that article, it might always be avoided.

To
In this method the remarkable parts wounded by the knife are, the *musculus transversus penis*, *levator ani*, and *prostate gland*: In the old way, the urethra only is wounded, about two inches on this side the prostate, and the instruments are forced through the rent of the passage, which is composed of the bulbous part of the urethra, the membranous part of the urethra, the neck of the bladder, and prostate gland. This channel is so very narrow, that, till it be torn to pieces, the management of the forceps is exceedingly difficult; and it happens frequently, that from the tender texture of the membranous parts, the forceps are unwarly pushed through it between the *os pubis* and bladder; besides, in introducing the gorget upon the staff, it is apt to slip downwards between the rectum and bladder, both which inconveniences are avoided in the lateral operation. It is true, the wound made in the lateral method will not admit of the extraction of a large stone without laceration as well as in the old way: but in the one case, the laceration is small, and made after a preparation for it by an incision; and in the other, all the parts are torn without any previous opening, and which are so very tight, that the pain of the diffusion must necessarily be excessive. However, in both these operations, the surgeon must not grasp the stone with violence; and even in extracting, must, with both hands to the branches of his forceps, rehit their flatting so tight, as the compression from the lips of such a narrow wound would otherwise make them. The extraction of very large stones is much more impracticable with the greater apparatus than by this method, because of the smallness of the angle of the bones in that part where the wound is made; so that indeed it is necessary in almost all extractions to pull the stone downward towards the rectum, which cannot be done without great violence to the membranous parts, and even the separation of one from another; whence follow abscesses and sloughs about the wound, which is a circumstance not known in the lateral operation. Exsudates followed by suppuration and gangrene, sometimes spread themselves upon the serotum; and in short, all the inconveniences and ill symptoms which attend upon the lateral operation, except the haemorrhage, are in a more violent degree incident to the old way.

An inconvenience of urine is not common after the lateral operation, and a fetula seldom or never the consequence of it.

The manner of treating the patient after the operation, is pretty nearly this: If it happens that the vessels of the prostate bleed, dry lint, or lint dipped in some styptick water, such as *aqua vitiola*, must be applied to the part, and held there with a considerable degree of pressure for a few hours; or a silver canula of three or four inches long, covered with fine rag, may be introduced into the bladder, and left there two or three days, which seldom fails to stop the haemorrhage. The patient may also take an oseate. If the wound does not bleed, a little dry lint, or a pledget of digestive laid gently in it, is best. The place where the patient lies, should be moderately cool, as heat not only disposes the vessels to bleed afresh, but generally makes him low and faint. If, soon after the operation, he complains of a sickness at the stomach, or even a pain in that part of the abdomen near the bladder, it is not always a sign of a dangerous inflammation, but frequently goes off in half an hour: to afflict, however, in its removal, a fomentation put into an hog’s bladder, and applied pretty warm to the part in pain, will be of great service: if the pain increases, after two or three hours, the consequence is much to be feared; and in this case, bleeding, and emollient clysters, by way of fomentation to the bowels, are immediately necessary.

The first good symptom after the operation is the urine coming freely away, as we then know the lips of the bladder and prostate gland are not much inflamed. If the patient should become languid, and continue without any appetite, blisters prove beneficial; which may be applied with great safety, and little pain, as there is seldom or never any haemorrhage. About the third or fourth day a stool must be procured by a clyster; for it seldom comes naturally the first time, and this method must be continued as every man’s discretion shall guide him. As soon as the patient comes to an appetite, he should be indulged in eating light food; with this caution, that he do not eat too much at a time.

If, during the cure, the buttocks should be excoriated by the urine, let them be anointed with nutriment: the dressing from first to last is seldom any other than a soft digestive, or dry lint.

**Of the Stone in the Urethra.**

If a small stone be lodged in the urethra near the glands, it may often be pulled out with the fingers, or picked away with some instrument; but if it stops in any other part of the channel, it may be cut upon without any inconvenience. The best way of doing it, is to pull the prepuse over the glands, as far as you can; and then making an incision the length of the stone, through the teguments, it may be turned out with a little hook or the point of a probe: The wound of the skin slipping back afterwards, to its proper situation, and from the orifice of the urethra, prevents the issue of the urine through that orifice, and very often heals in twenty-four hours. This is a much less painful method of extracting stones from the urethra, than by any instruments that have hitherto been devised.

**Of the extraction of the Stone in Women.**

The extraction of the stone in women, will easily be understood, since the whole operation conforms in placing them in the same manner as men, and, without making any wound, introducing into the bladder a straight director, upon a gorget, and afterwards the forceps to take hold of the stone; all which may be done without difficulty, by reason of the shallowness of the urethra. If the stone proves very large, and in extracting draws the bladder forwards, it is advisable to make an incision through the neck of it, upon the stone; which not only will facilitate the extraction, but also be less dangerous than a laceration which will necessarily follow. The dressings are fomentations and emollient ointments, which should be applied two or three times a day, and the patient in other respects be treated like men who have undergone the operation for the stone.

**Explanation of Fig. 4. Plate CLVII.**

A. A found used in searching for the stone.

The size represented here is but a little too large for the youngest children, and may be used upon boys till they are thirteen or fourteen years of age; a larger should be employed between that age and adulthood, when one of about ten inches, in a right line from the handle to the extremity, is proper. This should be made of steel, and its extremity be round and smooth.
B. A staff fit for the operation on boys from eight to fourteen years of age. The staff for a man must be of the size of the found already described.

C. A staff something too big for the smallest children, but may be used upon boys from about four years of age to eight.

The staff has a groove on its convex side, which first serves as a direction where to cut, and afterwards receiving the beak of the gorget, guides it readily to the bladder. Care should be taken, in making the groove, that the edges of it be smoothed down, so that they cannot wound in passing through the urethra. The extremity should also be open; otherwise it will be sometimes difficult to withdraw the staff, when the gorget is introduced, and presses against the end of it.

These instruments are usually made with a greater bending than here represented, but this shape is more like to that of the urethra, and rather more advantageous for making the incision.

D. The yoke, an instrument to be worn by men with an incontinence of urine. It is made with iron, but for use must be covered with velvet. It moves upon a joint at one end, and is fastened at the other by catches at different distances placed on a spring. It must be accommodated to the size of the penis, and be taken off whenever the patient finds an inclination to make water. This instrument is exceedingly useful, because it always answers the purpose, and seldom galls the part after a few days wearing.

Explanation of Fig. 5. Plate CLVII.

A, A small catheter made of silver. This instrument is hollow, and serves to draw off the urine when under a suppression. It is also used in the high operation to fill the bladder with water. Near its extremity, are two orifices, through which the water passes into its cavity. Care should be taken that the edges of these orifices are quite smooth.

B. The knife used in cutting for the stone: it is the same already described: but it is improper to repeat the figure with the alteration of a quantity of tow twilled round it, which makes it easier to hold, when we perform the lateral operation, and turn the edge upwards to wound the prostate gland.

C. A female catheter, differing from the male catheter, in being almost straight; and something larger.

D. A silver-wire to pass into either catheter, for the removing any grumous blood or matter that clogs them up.

Explanation of Fig. 6. Plate CLVII.

A. The gorget used upon men in the lateral operation.

B. The gorget used upon children under five years of age in the lateral operation.

A gorget between the sizes of these two will be fit for boys from five years of age to fifteen or sixteen.

These instruments are hollow for the passage of the forceps into the bladder; and their handles lie flattening, that they may the more readily be carried through the wound of the prostate, which is made obliquely on the left side of it. The beak at the extremity of the gorget must be smaller than the groove of the staff which is cut upon, because it is to be received in the groove. Care should be taken, that the edges of the gorget near the beak are not sharp, leaf-like, instead of dilating the wound, as it ought, it should only cut on each side when introduced; in which case, it would be difficult to carry the forceps into the bladder.

C. A gorget, with its handle exactly in the middle; this shaped instrument is used in the old way. All the gorgets should be made of steel.

Explanation of Fig. 7. Plate CLVII.

A. The forceps for extracting the stone. These are represented a little open, that the teeth may be better seen within side.

This instrument must be of different sizes for different ages and stones, from the length of four inches to one of near a foot long; but the forceps of about eight inches long will be found most generally useful. The number necessary to be furnished with, will be four or five.

Great care should be taken by the makers of this instrument, that it move easily upon the rivet; that the extremity of the chops do not meet when they are shut; and particularly that the teeth be not too large, lest, in entering deep into the stone, they should break it. It is of consequence also that the teeth do not reach farther towards the joint than here represented, because a small stone, when received into that part, being held fast there, would dilate the forceps excessively, and make the extraction difficult; on which account, the inside of the blades near the joint should be smooth, that the stone may slip towards the teeth.

B. A director made of steel, used for the direction of the gorget, in the extraction of the stone from women.

C. A scoop to take away the stone when it is broken into small pieces like sand. This instrument is made of steel.

Of the Empyema.

The operation for the empyema generally implies an artificial opening made into the cavity of the thorax, by which we evacuate any fluid that lies there extravasated, and is become dangerous by its weight and quantity. The fluids described as necessary to be voided by this operation, are blood, matter, and water.

When blood is the fluid, supposed to require evacuation by this method, it is always extravasated through some wound of the vessels of the lungs or thorax, and being discharged in great quantities on the diaphragm, is said to oppress respiration, till let out by some convenient opening made in the most depending part of that cavity, which is the only kind of perforation into the thorax distinguished by the name of the operation for the empyema. But though this opening is universally recommended in the case here stated, yet we meet with few or no examples where it has been practiced for a mere extravasation of blood.

To empty the thorax, in a rupture of any vessels which open into it, bleeding is very necessary; which not only stops the hemorrhage, by abating the force of the circulation; but likewise, by unloading the vessels of their contents, makes them more fit to receive the extravasated fluid by absorption: gentle evacuations and hopes are also very serviceable, and a low diet is absolutely necessary.

The second circumstance in which this operation takes place, is a rupture of matter from the pleura mediastinum or lungs into the cavity of the thorax, where accumulating it at length proves fatal for want of a discharge. It is true, that the case occurs but very seldom, where the operation is necessary; because, in most abscesses of the thorax, the matter
mater is usually spit up as fast as it is generated; and in the
diffusion of such who have died of this species of consum-
tion, we rarely find much extravasated pus in the cavity,
though a great portion of the lungs be destroyed. However,
there are a few examples which require the operation: and
these may be distinguished by the following symptoms. The
patient is obliged to lie upon the diseased side, or, in cafe
there is matter in both cavities of the thorax, on his back;
because the mediastinum can seldom support the weight of
the incumbent fluid, without suffering great pain; but this
rule is not certain, it sometimes happens that the patient
can lie with ease on that side where there is no fluid. An-
other symptom of extravasated matter, is an evident un-
dulation of it, so that in certain motions it may be heard to
quaff. For the most part too, upon careful inquiry, an
edema, or at leat a thickening of some portion of the inter-
costal muscles, will be discovered, And lastly, if there be
much fluid, it will be attended with a preternatural expan-
sion of that side of the chest where it lies. When there-
fore these signs appear after a previous pleuritic or pulmona-
ry disorder, and the cave has been attended with the symp-
toms of a suppuration, it is most probably owing to a col-
cction of matter; though the patient will also labour under
a continual low fever, and a particular anxiety from the load
of fluid.

The left part of fluid faild to require issue from this opera-
tion is water, which however very seldom collects in such
manner as to become the proper subject of the operation:
for if the drophy of the thorax be complicated with an ana-
farca, or even afeptis, it is certainly improper; and indeed it
hardly ever takes place, but where the diftemper is single,
and takes its rise from the fame fides of disorders in the lymph-
atics of the pleura, as the hydrocele does from thofe of the
tunica vaginalis. The symptoms of this drophy are, a small
cough without fpritting, a little low fever from the diftur-
bance of respiration; fometimes too the water, by a fudden
jerk, may be heard to quaff; and, generally speaking, its weight
upon the diaphragm and mediastinum are fo troublesome as
to oblige the patient to ftoop forward, and to turn upon the
affected side when he lies down; for the fame reafon, when
there is water in both cavities of the thorax, he is forced to
lie on his back.

The manner of operating, whether it be for the discharge
of matter or water, is to pitch upon the moft depending part
of the thorax, which fame have fuppofed to be between the
eighth and ninthrib, and others between the ninth and tenth,
as the diftance from the vertebra that the depth of the
fein may not be an impediment to the perforation. This
difiance is determined to be about a hand's breadth: and here,
with a knife, fciilars, or trocar, we are ordered to make the
perforation; but in doing it there are a great many dif-
iculties. In fat perfons, it is not easy to count the ribs, and
the wound will be very deep, and troublesome to make; it
is hardly possible to escape wounding the intercostal artery,
which runs in this place between the ribs. But if the only
advantage proposèd by the situation of the wound be de-
rived from its dependency, the operation of discharging the
fluid will be as well anfwered by an opening between the
fifth and seventh rib, half way from the sternum towards
the spine; which, by laying ourselves down, becomes in effect
as depending an orifice, as the other in fitting up: and by an
opening made in this manner we avoid all the inconveni-
cies in the other method: For in this part of the thorax
there is very little depth of mueles; the artery lies conceal-
ed under the rib; and the diaphragm is at great distance.
The opening is beft made with a knife, and should be about
an inch long through the skin, and half an inch through the
subfacent muscles; though, to make the incifion with the risk
of wounded the lungs, it may be advisable to dilate it with
the blunt-pointed knife (as is practifed in the operation for
the bubonoccele) after having made a small puncture with a
common knife. The treatment of the wound will be accord-
ing to the nature of the difcharge. If, after a few days, there
appears no drain, you may let the orifice heal up; but if it
continues, it may be kept open with a fhort fifer canal,
until fuch time as an alteration in that circumftance will give
us leave to cicatrize with safety.

Of Encyftled Tumours.

These tumours borrow their names from a cyft or bag,
in which they are contained; and are farther dillinguifhed
by the nature of their contents: If the matter forming them
resembles milk-curds, the tumour is called atheroma; if it
be like honey, meliceris; and if composed of fat, or a
fucy fubfance, featoma. The two firft are not readily dif-
tinguifhed from one another, but their difference from the
featoma is eafily learnt by their softnefs and fuddnation.
Thfe tumours appear in every part of the body, and in pla-
ces where there are no glands.

The featoma is never painful untl by its weight it grows
troublefome, nor is it a mark of general indifpofition of body;
so that the extirpation feldoms fails of succefs. The fize of
fome of them is very large, frequently weighing five or fix
pounds, and there have been infances of their weighing above
fory.

When the featoma is irregular in its furface, with emi-
cencies and defpreffions, it is fucy; whereas the fat one has
for the moft part a uniform smooth outside. The operation
for the featoma will be underftood by the defcription of
that for the fchirrhus.

The atheroma is much more common than the meliceris;
at leat, if all encyfted tumours with matter not curdled, may,
in compliance with cuftom, be called fo: These are more
frequent, and grow larger than thofe where the matter is
curred, being often attendant on fcorphulous indifpofitions,
which makes them more difficult of cure.

The cyfts of these tumours, with the skin covering them,
after a certain period of growth, reftifting any further enlarge-
ment, do frequently inflame and break; but this opening is not
fo advantageous for the cure as extirpation by the knife, which
fhould be done in the infancy of the swelling. When the
tumours are no bigger than a small golden pippen, they may
be diffected away from under the skin, by making a ftraight
incifion only through it; but if they exceed this bulk, an
oval piece of skin must be cut through first, to make room
for the management of the knife and taking away the tumour;
in which cafe, it will be advifable to take off the upper por-
tion of the cyft with the skin; and then, by the help of a
hook, to diffect away as much of the remainder of it as can
be conveniently, which is a lefs painful and more feure me-
thod than deftroying it afterwards with efcharoticks. This
rule is to be obferved, when the cyft runs fo deep amongst
the interfices of the mufeles, as to make it impoffible to re-
move the whole of it, where, if we cut off a great quantity,
the refiually comes away in floughs and matter.

The ganglion of the tendon is an encyfted tumour of the

S U R G E R Y.

Vol. III. No. 96.
melliferous kind, but its fluid is generally like the white of an egg; when it is small, it sometimes disperses of itself; pre-
spire and sudden blows do also remove it; but for the most part it continues, unless it be extirpated. It is no uncom-
mon case to meet with this species of ganglion, running un-
der the ligamentum carpeale, and extending itself both up
the wrist and down to the palm of the hand. The cure of this
disorder cannot be effected but by an incision through its
whole length and dividing the ligamentum carpeale.

The dressing in these cases does not at all differ from the
general methods of treating wounds.

Of the Amputation of the Cancered and Scirrhous
Breast.

The success of this operation is exceedingly precarious,
from the great disposition there is in the constitution, after
an amputation, to form a new cancer in the wound, or some
other part of the body. When a scirrhous has admitted
of a long delay before the operation, the patient seems to
have a better prospect of cure without danger of a relapse,
than when it has increased very fast, and with acute pain.

The scirrhous may be distinguished, by its want of in-
flammation in the skin, its smoothness and slipperysets deep
in the breast, and generally by its prickling pain, which as
it is more or less, increases the danger accordingly; though
there are some few with little or none in the beginning: as
the tumour degenerates into a cancer, which is the worst
degree of scirrhous, it becomes unequal and livid, and the
vessels growing varicous, at last ulcerate.

In extirpating the scirrhus, if it be small, a longitudinal
incision will dilate sufficiently for the operation; but if
too large to be dissected out in that manner, an oval piece
of skin must be cut through first, the size of which is to be
proportioned to that of the tumour; for example, if the
dwelling is five inches long, and three broad, the oval piece
of skin cut away must be nearly of the same length, and
about an inch and a half in breadth. In taking off the
whole breadth, the skin may be very much preferred, by
making the wound of it a great deal less than the bulk of
the breast, which must be carefully cleared away from the
pectoral muscles. This is not difficult to do because all these
scirrhoues being enlarged glands, are encompassed with their
proper membranes, which make them quite distinct from
the neighbouring parts, and easily separable; at least this
is the case when the tumour is movable; for sometimes it adheres to the subjacent muscle, and that muscle to the
ribs; in which circumstance, the operation is impracticable.

When it is attended with knots in the arm pit, no service
of this part, without a fracture, will also occasion the same
factors: For this reason, the operation may take place
where the scull is not much offended, but only the vessels of
the dura mater, the pia mater, or the brain.

When the cranium is beaten inward, without any frac-
ture, it is called a depression; when very much broken, a
fracture; or if broken and beat in also, a fracture with de-
pression; if it is only cracked without depression, though
properly a fracture, it is called a fissure; if none of these
disorders appear, where there is a suspicion of them, the
symptoms are imputed to a concussion of the brain. These
are the four dispositions in use, and which fully comprehend
all the others.

The depression of the cranium without a fracture can
but seldom occur, and then it happens to children whose
bones are more pliable and soft than those of adults.

In blows of the cranium, requiring the use of the tre-
pan, the marks of a fracture are generally very evident,
since the scalp is often lacerated so much, as to expose it to
outburst. But if the wound of the scalp be so small, as only
to admit a probe, we must judge then by the feel of the
surface of the bone, using the caution of not mistaking a fa-
ture for a fracture.

If there be no wound of the scalp, you must press about
the
the head with your fingers, till the patient complains of some particular part, where in all likelihood the place affected, and, if the scalp there be separated from the cranium, is almost inallibility so. The symptoms of a fracture, are, a bleeding at the ears and nose, a lot of sepsis, vomitings, drowns, delirium, incontinence of urine and excrement; but what is most to be depended upon, is a depression of the bone, or a roughness on its surface; for all the other complaints not only happen to concussions, which do well without the application of a trepan, but likewise there are fractures not attended with any of them, or at least in a slight degree; so that these symptoms alone, without examination of the part affected, are but an uncertain rule to go by.

In concussions without a fracture, that produce the symptoms here laid down, and do well afterwards, the vessels of the brain and membranes are only inflamed and dilated; or if they are ruptured, they absorb the extravasated blood again; on which account, nature should be assisted by plentiful bleedings, clysters, and other evacuations, and so in all fractures where the patient is not trepanned immediately: however, although people with violent concussions do sometimes recover, it is so very seldom, that there can be no pretence, when they happen, for neglecting the trepan, but not being able to learn in what part the concussion is.

Writers dispute very much about the possibility of the centra fissure, or a fissure occasioned on the part of the head opposite to that on which the blow is given, or where the inner table is fractured while the outer one remains entire; but there are histories of cafes, which, if fairly stated, make it unquestionable; and this is most certain, that if the complaint be at a distance from where the blow was received, there can be no danger in scalping, and applying the trepan to that part where the pain is.

When we are affured of a fracture or depression, it is always advisable to trepan as soon as possible, in order to prevent the spreading of the abscesses, which seldom fails to follow upon the rupture of the vessels of the brain and membranes, and for the most part in a few days.

The manner of treating a fracture of the cranium, will be according to the nature of the fracture itself, and the injury of the scalp. If the wound of the head be torn into angles, perhaps cutting off the lacerated flaps will make room for the saw; if the bone be broken into several pieces, the pieces may be taken away with the forceps; or if some of the skull be also depressed, the removal of the pieces will, without perforating, make way for the elevator to raise the depressed part; but if the fracture be not complicated with a wound of the scalp, or the wound be too small to admit of the operation, which seldom fails to be the case, then the fracture must be laid bare, by taking away a large piece of the scalp.

Before the application of the trepan, it is to be remembered there are certain places on the skull where it cannot be used with so much safety as on others; the whole length of the sagittal fissure, down to the nose, is always mentioned as one where the perforation is dangerous, because of the spine of the os frontis, and the course of the superior longitudinal fissus under this part, which it is supposed would be necessarily wounded by the saw, and in consequence destroy the patient by the hemorrhage: but though a perforation may, contrary to the general opinion, be made over the fissus without offending it, and, even if it was wounded, the effusion of blood would not in all probability be mortal; yet at best it would be very troublesome; and since we are not frightened in that part of the cranium for room, it is advisable to forbear operating in this place. The bone fissus of the os frontis forbid the use of the trepan near the orbits of the eyes; therefore, if it should be depressed near those cavities, the surgeon must be careful to perforate either above, or on one side of the fracture; for sawing below it will only lead into the sinus, and answer no purpose in the design either of giving a discharge to the matter from the brain, or an opportunity to elevate the depression; nay, perhaps leave an incurable fistula, if the patient escapes with life.

The os occipitis being very uneven, both in its internal and external surface, makes trepanning there almost impracticable; besides, the great fissures run about so much of it, as hardly to afford space to perforate without danger of wounding them; but then it is so defended from injuries by its situation and strength, that fractures do not happen to it so often as to the other bones of the cranium; and when they do, for the most part they become so soon mortal, by affecting the cerebellum which it sustains, that the operation is seldom required in this case. Indeed the upper angle of this bone lies above the cerebellum, and, when fractured or depressed, is not attended with so immediate danger; but when this happens, the course of the longitudinal fissus down the middle of it, and the neighbourhood of the lateral fissures beneath it, make it advisable to trepan at the lower part of the os parietale, or at least upon or just below the lambdoidal future, so that the perforation of the os occipitis can hardly ever be proper.

Though wounds in the cerebellum are always mortal, yet great portions of the cerebrum have been carried off, or depressed, without any notable inconvenience. The places then unfit to admit the saw, are the three described; that is, the sagittal fissure; that part of the os frontis near the orbits of the eyes; and the os occipitis. But when a fracture happens in any other part above the ear, there is no objection to the operation. When there is only a small fissure without any depression or motion in the bone, the trepan may be applied on the fissure itself, which will more readily give vent to the blood or matter underneath, than if made at a distance. If the fissure be large, and the bone weakened or depressed, the trepan must be applied on one side of it, but so as to make it a part of the circumference of the sawed piece; if the fracture run upwards, it will be eligible always to perforate near its bottom, because the dependency of the orifice will give better issue to the matter, though the ill-grounded apprehension of the brain falling out there has made many eminent surgeons contradict this rule in their practice. If, by making one orifice, you cannot raise all the depressed part, you must make a second and a third, and continue doing so, till you have reduced the whole cranium even; there is frequently occasion to repeat it twice or thrice; and it has been done twelve times, nay oftener, with success; which shews the little danger there is, either in sawing the skull, or exposing the dura mater and brain, when the pressure is taken off. Indeed the mischief of laying the brain bare is so small, compared with a concussion of it, or an abscess from pent-up matter, that those fractures of the skull, where the bone is broken into splinters the whole extent of it, and can be taken away, much more readily do well, than a simple fissure only, where the abscess cannot discharge itself freely; for which
which reason, though the depressed fracture may be raised by the means of one orifice, yet, if it is of a considerable length, it will be almost absolutely necessary to make one or two more openings, for the convenience of dischage; since, for want of this, we see abscesses increase daily in their quantity of matter, and at the end of a few weeks carry off the patient.

In concussions of the brain without a fracture of the cranium, if the trepan be applied, and vast discharges ensue, it will be also convenient to make more perforations into the abscess and the neighbourhood of the abscess, the situation of which will be easily guessed by the direction of the stream of matter. And here it is to be observed, that abscesses, which ensue from a concussion are generally more extensive and dangerous than those which accompany a fracture with depresion: for in a fracture, the yielding of the bone destroys, in a great degree, the force of the striking body, and prevents any violent commotion of the brain; so that what the brain suffers results chiefly from the pressure of the incumbent bone, and the laceration of the vessels, near the fracture: whereas, when the cranium refists the shock, all, or great part of the cerebrum suffers the concussion, and is often impollumated or inflamed almost in its whole dimension.

The manner of trepanning is this: Having fixed your patient's head steady, either on the bolster of a bed, or by placing him in a low chair; with the pin of your faw, mark the center of the piece of bone to be taken out; then with the perforating trepan, make an orifice deep enough to receive the pin, which being fixed in it, will prevent the faw from flipping; and thus you are to continue sawing, till the imprefion made will preserve the steadiness within it: the pin, when it is to be taken away, for fear of its wounds the brain before the faw has entered through the cranium, which it would do at last, because of its projection. In working through the bone, the teeth of the faw will begin to clog, by that time you arrive to the diplone; wherefore a brush must be ready to clean it every now and then; and with a pointed probe you must clear away the dust in the circle of the trepanned bone, observing if it be deeper on one side than the other, to lean afterwards on that side where the impreffion is leaft, that the whole thickness may be sawed through at the same time. To do all this with less interruption, it will be proper to have two faws of exactly the fame diameter, that an attendant may be brushing one while you operate with the other. We are advised to saw boldly till we come to the diplone, which, it is said, will always distinguish itself by the bloodstains. But, however, this is not a certain mark to go by: for though, where there is a diplone, it will manifest itself by its bloodstains, yet sometimes the faw is so very thin as not to admit of any; in which case, if an operator should push on his instrument in expectation of meeting with this subflance, he would unwarily wound the brain. This is not very often the case; but, however, often enough to put a man on his guard, and make him inquire whether the bone be loose after a little sawing, which is the only rule we go by when we have paffed through the diplone, and may as well be attended to before coming at it, without any considerable loss of time. When it is quite sawed through, and lies loose, it may be taken away with the forces contrived for that use; and if the lower edges of the orifice, next to the dura mater, are splintered, they may be scraped smooth with a lenticular.

These are the chief processes of the operation of the trepan. The only thing remaining to be done, is, with an elevator introduced at the orifice, to raise the depresion, or broken splinters, if they cannot otherwise be laid hold of, and to draw out the grumous blood, or any other extraneous body. If the dura mater be not wounded or torn, an incision must be made through it, to give way to the blood or matter, which almost certainly lie underneath it, if the symptoms have been bad, and done has been discharged from between the cranium and dura mater: Though it has been lately observed that an abscess will sometimes be formed in the substance of the brain; and therefore, if the puncture of the dura mater does not procure an evacuation of the matter, and the symptoms of a suppuration are still urgent, it will be advisable to make a small incision with a lancet into the brain itself.

We have used the word trepan all along, for the sake of being better understood; but the instrument here recommended is a trephine; the advantages of which, as also that of a cylindrical faw, or one nearly cylindrical, are described in the explanation of the copper-plate.

With regard to the dressings of these wounds, it is very certain, that as the greatest part of the evil proceeds from the quantity and pressure of the matter, whatever approaches towards the nature of a tent, and increases its quantity and pressure by locking it up, must be pernicious. Therefore the use of all lyndows whatever should be excluded. The best application, too, of spirits of wine, which is so commonly advised, cannot be proper, as they are not only unfit for inflammations in general, but also clog up the vesicles of the dura mater and brain, and stopping the suppuration, sometimes produce a gangrene. Since then a close application is inconvenient, and, whatever good there may be in topical medicines, it cannot for the most part be communicated to the abscesses, by reason of its extent beyond the orifice, the best remedy will be dry lint only, which must be laid on hourly to give vent to the matter, and be repeated twice a day till the discharge is lessened, when once in twenty-four hours will be sufficient to the diminishing of the cure, which will be something retarded by the exfoliations that sometimes follow this operation. The patient afterwards may wear a plate of tin upon the ear, to defend it from blows or any accidental injury.

Explanation of Fig. 1. Plate CLVIII.

A. The perforator, commonly called the perforating trepan. With this instrument, an orifice is usually made for the reception of the pin, on the centre of the piece of bone that is to be taken away, in the operation of trepanning; though if the pin be very sharp, and project but little beyond the teeth of the faw, as in that marked with the letter B, the perforator would be needless; but as the point of the pin presently grows blunt with use, and, in that case, it is difficult to fix the pin, it is advisable to have this instrument in readiness. It is also handy for boring into the substance of the bone, in order to promote a granulation of flesh on their surfaces. When it is made use of, it must be received and fastened in the handle C.

B. The crown, or faw of the trepan, with the pin appearing just beyond the extremities of the teeth. The shape of this faw is cylindrical.

C. The handle of the foregoing instrument, called the trephine; which is much preferable to the trepan, (an instrument like a wimble used by joiners,) because of the great
great convenience of holding it, and leaning on one side or other of the saw, as we find it necessary. The tenon however, though allowed to be unhandy, is the instrument most used by surgeons in other parts of Europe, upon the supposition of its working quicker than the trephine.

The trephine here represented is of such a shape as to make it a convenient elevator, for which purpose the extremities of it are made rough.

D, A key to take out the pin E, when the saw has made an impression deep enough to be worked without the help of it.

**Explanation of Fig. 2. Plate CLVIII.**

A, A convenient forceps to take out the circular piece of bone, when it does not stick to the saw: the contrivance by which they readily lay hold of it, is to make the extremities that are to grasp it, with an arch of the same circle as the saw is made. Upon one of the handles, there is added a little elevator, to lift up any small splinter of bone.

B, A lenticular: the fore-part of its blade is sharp, in order to scrape the lower edge of the orifice of the cranium, in case any splinters should remain after the operation; and the button at its extremity receives the durt, that it may not fall on the brain; but there is seldom any occasion for this instrument.

C, A rudge or raspatories, for scraping bones in order to promote granulations of flesh. The handles of these two last instruments are wood, whereas every part of the others should be made of steel.

**Of the Cataract.**

The cataract, called by the Latins suffitfo, is a disease of the crystalline humour, rendering the whole body of it opaque, so that the rays of light, which, in the natural state of its transparency, were transmitted to the tunica retina, become now totally intercepted, and produce no effect. This is pretty nearly the account delivered down to us by Hippocrates and the ancient Greeks, who likewise knew it by the name of glaucoma.

Anatomists have frequently disputed the eyes of persons under this disorder after their death, and have found it to be always an opacity of the crystalline humour, agreeably to the definition of a glaucoma: so that by consequence we must understand the words cataract and glaucoma as synonymous terms.

The general criterion of the fitness of cataracts for the operation, is taken from their colour; the pearl coloured, and those of the colour of burned iron, are esteemed proper to endure the needle; the white are suppos’d milky, the green and yellow horne and incurable.

The depression of a cataract of any colour would be the cure, if that alone was the dilater of the eye: but it generally happens, that the yellow cataracts adhere to the iris so firmly as to become immovable; besides, when they follow in consequence of a blow, which is often the case, either the cells of the vitreous humour are so much disturbed and broken, or the retina affected, that a degree of blindness will remain, though the cataract be depressed.

To judge whether the cataract adheres to the iris, if you cannot at once distinguish it by your sight, flit that of the patient’s eye, and rub the lids a little: then suddenly opening it, you will perceive the pupil contract, if the crystalline humour does not prevent the action by its adhesion: And when this is the case in any kind of cataract, the operation can hardly be advised.

Another consideration of the greatest moment, before undertaking the cure, is to be an advising of the right flare of the tunica retina: which is very readily learnt, where there is no adhesion of the cataract, from the light falling between the iris and crystalline humour, which if the eye is not sensible of, it is a certain indication of another malady, and absolutely forbids the operation. Generally, this cataract takes its rise from head-aches, convulsions, and nervous disorders.

When none of these objections forbid the operation, it may be thus done: Having placed your patient in a convenient light, and in a chair suitable to the height of that you yourself sit in, let a pillow or two be placed behind his back. In such a manner, that the body bending forward, the head may approach near to you; then inclining the head a little back, upon the breast of your assistant, and covering the other eye so as to prevent its rolling, let the assistant lift up the superior eye-lid, and yourself depress a little the inferior one. This done, strike the needle through the tunica conjunctiva, something less than one tenth of an inch from the cornea, even with the middle of the pupil, into the posterior chamber, and gently endeavour to depress the cataract with the flat surface of it. If, after it is dislodged, it rises again, though not with much elasticity, it must again and again be pushed down. If it is membranous; after the discharge of the fluid, the pellicle must be more broke and depressed: if it is uniformly fluid, or exceedingly elastic, we must not continue to endanger a terrible inflammation, by a vain attempt to succeed. If a cataract of the right eye is to be couched, and the surgeon cannot use his left hand so dexterously as his right, he may place himself behind the patient, and use his right hand.

We have not recommended the speculum oculi, because, upon the discharge of the aqueous humour through the puncture, the eye, being somewhat emptied, more readily admits of the depression of the crystalline humour, than when depressed upon by the instrument.

As to the method of treating the succeeding inflammation, bleeding and other gentle evacuations are found absolutely necessary.

**Of Cutting the Iris.**

There are two cases where this operation may be of some service; one when the cataract is from its adhesion immovable; and the other, when the pupil of the eye is totally closed up by a disorder of the muscular fibres of the iris, which gradually contracting the orifice, at last leaves the membrane quite imperforate. This last disordered has hitherto been deemed incurable. The adhesion of the cataract has been considered as a species of blindness not to be relieved: but Mr Cheffelden has invented a method of making an artificial pupil, by slititng the iris, which may relieve in both the instances here stated.

In doing this operation, the patient must be placed as for cousing, and the eye kept open and fixed by the speculum oculi, which is absolutely necessary here; then introducing the knife in the same part of the conjunctiva you wound in cousing, insinuate it with its blade held horizontally, and the back of it towards you, between the ligamentum ciliare and circumference of the iris, into the anterior chamber of the eye; and after it is advanced to the farther side of it,
make your incision quite through the membrane; and if the operation succeeds, it will upon wounding fly open, and appear a large orifice, though not so wide as it becomes afterwards.

The place to be opened in the iris, will be according to the nature of the disease: if the membrane itself be only affected with a contraction, the middle part of it; which is the natural situation of the pupil, must be cut; but if there be a cataract, the incision must be made above or below the cataract, though it is more eligible to do it above.

The contracted iris, from a paralytic disorder, is so often complicated with an affection of the retina, that the success is very precarious in this case. This operation has answered well in adhesions of the crystalline humour, though not so often as might be expected; for this success is very precarious in this case. This operation has answered well in adhesions of the crystalline humour, though not so often as might be expected; but even there.

**Explanation of Fig. 3. Plate CLVIII.**

A. The couching needle, the broad part of which towards the point is flat on one side; but on the other is a little convex to give it more substance and strength.

The handle of this instrument is white-ivory, inlaid with a streak of black in that part of it lying even with the convex surface of the blade: The meaning of which is, that by holding the handle with the stroke upwards, we may possibly guide to depress the membrane of a milky cataract with the flat surface, though the substance of the cataract swimming in the eye obscures the needle, and prevents its being directed in a proper position by the light.

B. A speculum oculi, which is made to open or shut by an iron button sliding along a slit in the handle. This instrument is composed of one piece of steel, in such a manner that it would fly open by its elasticity, if the two branches of the handle were not confined by the button. The circle of it should be covered with velvet, to make it lie softer on the eye-lids.

C. The knife for cutting the iris, the blade of which has two edges, resembling a lancet, which are more advantageous than one only, in cutting the cornea for the extraction of the cataract.

**Of the Fistula Lachrymalis.**

The fistula lachrymalis is generally understood to be such a disorder of the canals leading from the eye to the nose, as obstructs the natural progress of the tears, and makes them trickle down the cheek: but this is only the first and mildest stage of the disease. In the next, there is a mucus resembling matter, and afterwards matter itself discharged with the tears from the puncta lachrymalia, and sometimes from an orifice broken through the skin between the nose and angle of the eye. The last and worst degree of it is, when the matter of the abscesses, by its long continuance, has not only corroded the neighbouring soft parts, but also affected the subjacent bone.

Monseur Annell, a French surgeon, recommends in the recent fistula, to pass a small probe through one of the puncta lachrymalia into the fascus and nose, in order to break the concretions which were supposed to make the obstruction, and with a small pipe and syringe to throw an injection through the other, in order to wash them away.

The manner of operating in those cases where perforation is not required, is this: Supposing the abscesses not broken, chafe a time when it is most turgid with matter; and to his end, you may shut the patient's eye the day before, and lay little slips of plaster upon one another across the lids, from about the puncta lachrymalia to the internal angle; which compressing their channels, and preventing the flux of the matter that way, will heap it up in the bag, and indicate more certainly the place to be cut. If the abscess is already open, the orifice and probe will inform you where to enlarge: then placing the patient in a seat of convenient height for the management of your hand; with a small incision-knife dilate from the upper part of the bag, down to the edge of the orbit, without any regard to the tendon of the orbicularis muscle, or fear of wounding the blood-vessels; though if you see the vessels, it is proper to shun them. The length of this incision, will be near four tenths of an inch. It has been advised, in opening the bag, to introduce a small probe through one of the puncta into its cavity, to prevent wounding the posterior part of it. But this excess of care may be more troublesome than useful; since, in far large a vessel, a very small share of dexterity is sufficient to avoid the mistake. In making this incision, care must be had, not to cut too near the junction of the eye-lids, because of the deformity of the succeeding scar; though the clearer eye or even, contraction of the skin in that part, after the operation, is generally owing to the use of the cautery, and not to the wound of the tendon of the orbicularis muscle; for this last is necessarily from its situation always cut through, but without any inconvenience, because of the firm cicatrix afterwards that fixes it strongly to the bone.

When the bag is open, it is to be filled with dry lint, which the next day may be removed, and exchanged for a dose of a hot diast in a hot digestible medicine; this must be repeated every day once or twice, according to the quantity of the discharge; now and then, when the matter is not good, using the precipitate medicine, and from time to time a sponge-tent, to prevent the too sudden reunion of the upper part of the abscesses. When the discharge begins to lessen, it will be proper to pass a small probe, a small bougie, or silver wire, through the nasal duct into the nose, every time it is drest, in order to dilate it a little, and make way for the tears and matter which by their drain will continue to keep it open. This method must be followed till the discharge is nearly over; and then dressing superficially with dry lint, or any drying application, the wound will feel safe and healing. After the care, in order to prevent a relapse, it will be proper, for a few weeks, to wear the compressing instrument represented in the copperplate.

When the bone is bare, and the fistula requires perforation, the perforator is not to be carried down the ductus ad nasum, for fear of boring into the sinus maxillaris; but more internally towards the nose, which will bleed freely, it properly wounded. The wound afterwards should be dressed with Joshils, in the manner above described, and the probe or silver wire be every day passed through the ductus ad nasum. Left, after the cure of the abscesses, it should still remain obstructed; and if, upon trial, the duct should be so filled up as not to admit the wire, it will be right to keep open the perforation into the nose with a small tent, till the discharge is almost quite ceased.

**Explanation of Fig. 4. Plate CLVIII.**

A. The eye, with the skin of the eye-lids denuded, in order to show the orbicularis muscle: the white streak running from the inner angle of the eye toward the nose is the tendo a.
tendon of the orbicularis muscle. At a little distance from
the internal angle, on the edge of the eyelids may be
observed two black spots, which are the orifices of the
lacrimal channels, and called the puncta lachrymalia.

B. The exact dimension of the lacrymal channels and
bag; the pricked line represents the edge of the orbit.

C. A small incision-knife, more handy than a larger for
opening the bag.

D. The perforator to destroy the os unguis, if ever it
should happen to be necessary.

E. An iron instrument made thin and pliable, to set even
on the forehead, and for use covered with velvet: the holes
at the three extremities receive two pieces of ribband, by
which it is fastened on the forehead: the button at the end
of the screw is to be placed on the fascus lachrymalis, and
the screw to be twisted till the button makes a considerable
preasure on the bag: the button should be covered with vel-
et, and a little compresa of plaster be laid on the bag be-
fore it is applied, to prevent the skin from being galled by
the preasure. The little branch of iron which receives the
screw must be soft enough to admit of bending, otherwise
it will be difficult to place the button exactly on the bag.
This instrument is for the left eye only; it should be worn
night and day in the beginning of a hiltula, and after a hiltula
has been healed by incision; but as the succusses depends upon
the exact situation of the button upon the bag, it should be
carefully looked after.

Of Bronchotomy.

The operation of bronchotomy is an incision made in the
aerina artesia, to make way for the air into the lungs,
when respiration is obstructed by any tumour comprizing the
larynx, or some other disorder of the glottis and aorpa
arteria, without any apparent tumour.

The manner of doing it is, by making a longitudinal in-
cision through the skin, three quarters of an inch long, op-
posite to the third and fourth ring of the trachea, if you
have the choice of the place; and when you cannot make
it so high, the rule will be to wound a little below the
tumour; it is always advised to pinch up the skin for this
proceed, which however may be left to the discretion of the
surgeon. When the skin is cut through, you must make a
small transverse incision into the wind-pipe, and immediately
introduce a silver crooked canula near half an inch long,
with a couple of little rings at the top of it, through which
a ribband may be passed round the neck, to keep it fixed in
the wound.

The method of dressing will be easily understood; since,
after the patient can breathe by the natural passage, if you
withdraw the hollow tent, the wound will become a simple
one, and, notwithstanding its penetration through a carri-
lage into a large cavity, require a superficial application
only.

Of the Extirpation of the Tonsils.

These glands sometimes grow so large and ferruous as
to become incurable, and even to threaten suffocation if not
extirpated. The manner of doing this operation formerly,
was by cutting them off: but the almost constant consequence
of this wound was a violent bleeding, and sometimes too
a mortal one; on which account it is rejected in favour of
the ligature, which is not only void of danger, but also sel-
dom fails of cure.

If the basis of the tonsil is smaller than the upper part,
you may pass the ligature by tying it to the end of a probe,
bent into the form of an arch, and set into a handle; which
being carried beyond the gland, and round it, is to be
brought back again: this done, you may easily tie it by the
means of an instrument of Mr. Chefelden's contrivance, which
holds one end of the string on the side of the tonsil next the
throat, while you make the knot by pulling the other with
the right hand quite out of the mouth, as will be easily un-
derstood by the draught in the copper-plate. Should it
happen that the tonsils are conical, so that the ligature will
necessarily slip over its extremity when we attempt to tie;
in this case, he has recommended an instrument like a crook-
ed needle, set in a handle, with an eye near the point,
threaded with a ligature, which is to be thrust through the
bottom of the gland, and being laid hold of with a hook,
the instrument is to be withdrawn; then pulling the double
ligature forwards, it must be divided, and one part be tied
above, and the other below the tumour: the knots are to
be always double, and the ligature to be cut off pretty near
them.

If after four or five days they slip, or seem to have mort-
tised the tonsil only in part, you must repeat the whole
operation; and if it fail a second time, you must even repeat
it again.

This kind of extirpation is more practised in large piles,
that are esteemed incurable. When the piles are within the
intestines, you must place your patient over a fomenta-
tion in a clofetooj, and have a crooked needle with a
double ligature ready to pass through them, when by drain-
ing they are pulled out of the anus (for sometimes the in-
testine will return suddenly,) and tie above and below as in
the instance of the tonsil. Sometimes the piles are of that
shape as to admit a single ligature to be tied round them
without the help of a needle, which is less painful. If there
are several, you must only tie one or two at a time; for the
pain of the ligature is excessive, and would be intolerable
if many were tied at once: however, every five or six days,
the operation may be repeated till all are extirpated, and
the parts must be kept supple by some emollient ointments.

When the piles are small, they may safely and with much
less pain be cut off.

The uvula is subject to so great a degree of relaxation
sometimes, that it almost chokes the patient: the readieli
cure is cutting off all but half an inch of it, which may be
done at one time with a pair of scissors (particularly curved
for that purpose,) laying hold of it with a forceps, left it
should slip away.

Explanation of Fig. 5 Plate CLVIII.

A. The bent probe fixed in a handle, with the ligature
made of the same thread as the ligatures for tying the blood-
veins.

B. The iron instrument for tying the tonsils.

This instrument is also of great service in extirpating, by
ligature, a species of ferruous that sometimes grows from the
neck or cavity of the uterus.

C. The needle with the eye towards the point, for pas-
fing the ligature through the tonsil, when the basis is larger
than the extremity.

D. A canula made of silver to be used in the empyema.

E. A canula to be used in bronchotomy.

To keep the canulas in their place, small ribbands may
be
be paffed through the rings of them, and carried round the body and neck; or they may be held by a ligature run through, and faftened to a hole cut in a piece of focking plaiter, which is to be laid on each side of them.

Of the Polyopus.

The polyopus of the nofe is laid to be an excrecence of flesh, spreading its branches amongst the laminae of the os ethmoidis, and through the whole cavity of one or both noffils. It happens very often to both sides of the nofe at once; and in that cafe is very troublesome, almost suffocationating the patient, at leaft making expiration very difficult. The intent of the operation is the removal of this obfcacle.

Polyopi arise from the membrane spread upon the laminae spongiosa, nearly paffed in the fame manner as the hydatids of the body; in one kind of dropy, do from the surface of the liver; or as ganglions from the tendons, borrowing their coats from a production of its fibres and vessels: If they appear soft, and of the colour of the foam of the blood, in all likelihood they are formed of fuch a fort of water contained in cylinders, which, upon breaking the membrane, leaves fo little hold for the instrument, that but a small part of it can be extracted afterwards. This polyopus is to be left to happen, before the operation be undertaken, which in ferfs of time it generally will do. In the next degree of confidence, they retain pretty nearly the fame colour, and are often partly watery, and partly of a vitcid texture, which though not tenacious enough to admit of drawing them out by the roots, may at fever 1 attempts be taken away by bite. The next degree of confidence, is that which is neither fo soft as to be squeezed to pieces, nor fo hard and bittte as to scrape, or adhere to the membrane with that force as not to admit of separation: this is the moft favourable one. The laff, is hard and firrhous, adhering fo tight as to tear rather than separate in the extraction, and sometimes even tends to degenerate into a cancer: This polyopus is very difficult of cure.

The polyopus sometimes dilates to that degree, as not only to extend beyond the os palati, and hang over the orophagus and trachea; but also spreading into the sinus maxillae, so exactly fills up every interstice of the nofe, as to obstruct the lower orifice of the ductus ad nafum, and prevent the defcent of the teardrops, which neceffarily muft return thro' the puncta lacrimalia; and sometimes they grow fo enormoufly large, as even to alter the fhape of the bones of the face.

When the polyopus appears in the throat, it is always adviceable to confcrt it that way; it being found, by experience, more ready to loofen when paffed in that direction, than by the nofe. To this end, it would be right, before undertaking the operation, to let your patient lie fupine two or three hours, which will bring it down farther down; for the body of the polyopus does not universally adhere, and will by its weight stretch out the fibres by which it is connected to the nofe; nay, there are infences, where by a little effort, fuch as haffing, they have drop quite off.

The method of extracting it is by a pair of forceps, with a flit at their extremities for the better hold, which muft be introduced into the noffill about an inch and a half, to make more sure of it towards the roots; then twifling them a little from one fide to the other, you muft continue in that action, while you pull very gradually the body of the polyopus. If it break, you muft repeat the extrication as long as any remains, unlefs it is attended with a violent haemorrhage, which is an accident that sometimes follows upon the operation, and seldom happens when the extraction is fccurrous: However, the surgeon is not to be alarmed at the appearance of an immoderate effufion the moment after the separation; for, generally speaking, the effusions collapse very soon again; but if they do not, dry hift, or lint dipht in some flypluck, will readily flop it.

After the extirpation, it has been ufual, in order to prevent a relapse, to drefs with efacbroticks powders, and even to burn with the actual cautery; but neither the one or the other can be of great service in this cafe, and both are painful and dangerous. If ever the ufe of corrosive medicines is advisable, it fhou'd be for destroying the remainder of a polyopus which cannot all be taken away; and then the efacbroticks may be better conveyed to the part by a long tube, than a fettom paffed through the nofe and mouth, which is difficult to do without hurting the patient, and very nasty to bear.

Of the Hare Lip.

This difeafe is a fiffure in the upper lip, with want of subftance, and is a natural defect; the patient being always born with it, at leaft that species of hare-lip which requires the following operation. The cure is to be performed by the twifled future. There are many lips, where the lods of subftance is fo great, that the edges of the fiffure cannot be brought together, or at all where they can but jift touch, in which cafe it need not be advifed to forbear the attempt: it is likewise forbidden in infants, and with reafon if they fuck; but otherwife it may be undertaken with great fafety, and even with more probability of fuccefs than in others that are older.

It is not uncommon for the roof of the mouth to be fiffed likewife; but this is no objection to the operation, if the skin of the lip is loofe enough to admit of re union: and it may be remarked, that the fiffure of the palate, in length of years, closes surprifingly in fome cafes.

The manner of doing it is this. You firt with a knife separate the lip from the upper jaw, by dividing the ftrafum between it and the gums; and if the dentes incerti projeft, as is ufual in infants, they muft be cut out with the fame knife; then with a thin pair of frafton fciptas take off the callous edges of the fiffure the whole length of it, obferving the rule of making the new wound in ftraight lines, because the fides of it can never be made to correspond without this caution. For infence, if the hare lip had the shape a, Plate CLVIII. fig. 5 the incifion of the edges muft be continued in ftraight lines till they meet in the manner represented by b, ibid. The two lips of the wound being brought exactly together, pafs a couple of pins, one pretty near the top, and the other as near the bottom, through the middle of both edges of it, and secure them in that situation by twifling a piece of waxed thread crofs and round the pins feven or eight times; you muft then cut off the points, and lay a small bolifter of plaiter underneith them, to prevent their scratching; but when the lower part only of the hare lip can be brought into contact, it will not be proper to ufe more than one pin.

The pins are made three fourths of their lengths of silver, and the other part towards the point of ftee; the silver pin is not quite fo offenive to a wound as a bras or fteel one; but
but a steel point is necessary for their easier penetration, which indeed makes them pass so readily, that there is no need of any instrument to assist in pulling them through. The practice of bolstering the cheeks forward does little or no service to the wound, and is very unsafe to the patient. The manner of dressing will be to remove the applications which are quite superficial, as often only as is necessary for cleanliness. The method is to deforb the third day, and afterwards to do it every day, or every other day: It is not at all requisite to dress between the jaw and lip where the frenulum was wounded, there being no danger that an inconvenient adhesion should ensue. In about eight or nine days the parts are usually united, and in children much sooner, when you must gently cut the threads, and draw out the pins, applying upon-the orifice a piece of plaster and dry lint. It will be proper, in order to withdraw the pins more easily, to daub the ligatures and pins with warm water, and also moisten them with sweet oil, two or three days before you remove them, which will wash off the coagulated blood, that would otherwise fall them so hard to the ligature as to make the extraction painful.

Of the Wry Neck.

The operation of cutting the wry neck is very uncommon, and is never to be practised but when the disorder is owing to a contraction of the masseterous muscle only; as it can answer no purpose to fet that muscle free by dividing it, (which is all that is to be done,) if the others in the neck are in the same state; and more especially if it has been of long standing from infancy; because the growth of the vertebrae will have been determined in that direction, and make it impossible to set the head upright.

When the case is fair, the operation is this. Having laid your patient on a table, make a transverse incision thro' the skin and fat, something broader than the muscle, and not above half an inch from the clavicle; then passing the probed razor with care underneath the muscle, draw it out and cut the muscle. The great vessels of the neck lie underneath; but when we are aware of their situation, the danger of wounding them may be avoided. After the incision is made, the wound is to be cleansed with dry lint, and always dressed so as to prevent the extremities of the muscle from re-uniting; to which end they are to be separated from each other as much as possible by the assistance of a supporting bandage for the head, during the whole time of the cure, which will generally be about a month.

Explanation of Fig. 6. Plate CLVIII.

A. The instrument called the probe razor to cut the mas
toides muscle in the wry neck, and is sharpened only about half its length at that end where the blade is broad.

B. The two pins with the twisted future, used in the hare-lip.

C. The polypus forceps, with one of the rings open for the reception of the thumb, which would be cramped in pulling the forceps with much force, if it were received in the same fort of ring as in the other handle.

Of the Aneurism.

This is a disease of the arteries, in which, either by a preternatural weakness of any part of them, they become excessively dilated, or by a wound through their coats, the blood is extravasated amongst the adjacent cavities. The first species of aneurism is incident to every part of the body, but does not often happen, except to the curvature of the aorta, which is subject to this disorder from the extraordinary impulse of the blood on that part: from the curvature, it runs upwards along the carotids or subclavians, generally increasing, till by its great diffusion it is ruptured, and the patient dies.

There are several histories given of aneurism of the curvature of the aorta; in some of which, the vessel has been so excessively dilated, as to pose off a great space of the upper part of the thorax; and the most curious circumstance to be gathered from them is, that the spot of the vessel which is weakest, and where the disease begins, generally gives way in such a manner to the force of the blood continually pushing it outwards, as to form a large pouch or cyst, with coats nearly as thick as those of the artery itself. However, the thickness of the coats of these cysts will last but to a certain period; for when the vessels of the coats can no longer conform to the extension, the circulation grows languid, the cyst becomes thinner at its apex, and soon after bursts.

The symptoms of this aneurism, are a strong pulsatian against the sternum and ribs; every pulse of the heart; and, when it extends above the sternum, a tumour with pulsation. Upon dissection, the ribs, sternum, and clavicle, are sometimes found cavernous, from the obstruction of the vessels of the pericardium, which are pressed by the tumour.

What we have spoken of hitherto, has been only the aneurism of the thorax from an internal disorder; aneurism of the extremities, are for the most part owing to wounds, though when they happen of themselves, they differ very little from the description given of that in the thorax. The further symptoms of them are (besides pulsation) the tumour's being without discoloration of the skin; its subsiding when pressed by the hand, and immediately returning when the hand is taken away; though, if it be upon the point of bursting, the skin will grow inflamed, and the coagulated blood in the cyst will sometimes make the pulsation much less perceptible.

This species of aneurism may sometimes be supported a great number of years, if we rejoin its dilatation by proper bandage; but if we do not, there is danger of its bursting, and, if it be pretty large, of rotting the adjacent bones.

A found artery wounded through part of its external coat would in all probability produce nearly the same appearances as where the whole coat is weakened from an internal indisposition; and this most likely is the case after bleeding in the arm, when it has not been immediately perceived that the artery was pricked, and the tumour has begun to form some days after the puncture; though the common appearance of an aneurism from the wound of a lancet, is a discharge of blood first through the orifice of the skin, and, upon being dropped from bleeding outwardly, an infusion of it among all the muscles as far as it can spread, in the shoulder and arm: here, the arm grows livid from the ecchymosis, and the blood coagulating to the confidence of flesh, prevents any sensible pulsation. The cyst which arises near the orifice of the artery is formed by the cellular capsula developing the vessels of that part, and a portion of the aponeurosis of the biceps muscle, which admitting of some extravasated blood underneath it, become excessively thickened and expanded. These membranes must make the cyst, otherwise we could not, upon opening the tumour in the o.
peration, discover so readily the puncture; or if the coats of the artery made it, we could not separate it distinctly from the vessel, which would be always dilated above and below the cyst, as we see in other aneurisms.

There are some few instances of small aneurisms and punctures of the artery from bleeding, doing well by bandage; but they almost all require the operation at last, which is to be performed nearly in the same manner in every part; and supposing it in the bend of the arm, is to be done after the following method.

Having applied the tourniquet near the shoulder, and laid the arm in a convenient situation, make an incision on the inside of the biceps muscle, above and below the elbow a considerable length, which, being in the course of the artery, will discover it as soon as you have taken away the coagulated blood, which must be all removed with the fingers, the wound being dilated sufficiently for that purpose. If the orifice does not readily appear, let the tourniquet be loosened, and the effusion of blood will direct you to it; then carefully carrying a crooked needle with a ligature under it, tie the vessel just above the orifice; and pulling the needle again, make a second ligature below it, to prevent the return of the blood, and leave the intermediate piece of the vessel to slough away without dividing it. To avoid wounding or tying the nerve in making the ligature, the artery may be cleared away from it first, and held up with a hook; but should the nerve be tied with the artery, no great inconvenience would ensue from it. After the operation, the arm must be laid easy, on a pillow in bed, and the wound be treated in the common method, keeping it in that posture a fortnight or three weeks, especially if it should swell much, and not digest kindly.

In doing this operation, it will be proper to have the amputating instruments ready, lest it should be impracticable to tie the artery; and even after having tied it, the arm must be carefully watched; and in case of a mortification, it may be taken off.

Of Amputation.

A spreading mortification has been always esteemed to be principally a cause for amputation, that it is a fashion with writers to treat of the nature of a gangrene previous to the description of this operation. However, this operation is spoken of as frequently unsuccessful; and in length of time, its want of success has been so unquestionably confirmed by repeated experiments, that some of the most eminent practitioners make that very circumstance an exception to the operation, which so few years since was the great inducement; and the maxim is, never to extirpate till the mortification is absolutely stopt, and even advanced in its separation.

Gangrenes may be produced two ways; either by indisposition of body, or by accident in a helpless state: for as the life of a part depends upon the circulation of its fluids, whatever shall make the circulation cease, will inevitably occasion a gangrene. Thus a mere compres preventing the course of the blood, as effectually causes a mortification as any indisposition in the fluids or vessels.

It frequently happens in old age, that the arteries of the lower extremities offury; which destroying their elasticity, must in consequence produce a gangrene in the toes first, and afterwards in the limb nearly as high as where the operation terminates; so that in mortifications arising from this cause, we at once fee why amputation, during their increase, is of so little service, unless performed above the ulceration; but we have no way to judge where the incision ends, but by the inference we make from the gangrene's stopping. Hence we may learn the propriety of our modern practice in this case.

If by any accident the limb has been injured to that violent degree as to begin to mortify, it will be no more fit to operate here till it stops, than in the other instance; because all parts that are mortified have lost the disposition to become so, before the effect is produced: and cutting off a limb, half an inch above the absolute dead skin, is generally leaving a part behind, with the seeds of a mortification in it; so, unless we can be sure the vessels are not affected in the place of amputation, which will be hard to know but from the consequence, the operation will be useless.

Sometimes the fluids of the body are so vitiated, as to lose their proper nutritious qualities: and the limb becomes gangrened, not from any alteration in its vessels, but chiefly from its situation, which being at a great distance from the heart, will be more prone to feel the ill effects of a bad blood than any other part, as the circulation is more rapid in the extremities; and it seems not very improbable, that in some dispositions of the blood, a mortification may also be a kind of critical discharge. When therefore a gangrene arising from either of these causes, is running on, amputation above it will for the most part be useless, since it is only removing one degree of the effects of the bad juices, and leaving them in the same state to produce the like mischief in other parts. Thus we see, after amputations on this account, the gangrene sometimes fall on the bowels, or the other extremities: from which observation we may conclude it not safe to amputate, till the fluids are altered; and this alteration will presently discover itself by the stopping of the mortification.

Gunshot wounds, compound fractures, and all sudden accidents requiring amputation, are attended with the best success if immediately performed. Disorders of the joints, ulcers of long standing, and all scrophulous tumours, do sometimes return on other parts after the operation. When a leg is to be amputated, the manner of doing it is this.

Lay your patient on a table two feet six inches high, which is much better than a low seat, both for securing him steady, and giving yourself the advantage of operating without flopping, which is not only painful, but inconvenient in the other situation. While one of the assistants holds the leg, you must roll a strip of fine rag half an inch broad, three or four times round it, about four or five inches below the inferior extremity of the patella: This being pinned on, is to serve as a guide for the knife, which without it perhaps would not be directed so dexterously. The manner of rolling has always been perpendicular to the length of the leg; but having sometimes observed, that though the amputation at first be even, yet afterwards the gastrocnemius muscle contracting, draws back the inferior part of the stump more strongly than the other muscles can do the rest of it; in order to preserve the regularity of the cicatrix, allow for this excess of contraction, and make the circular incision in such a manner that the part of the
wound which is on the calf of the leg is a little farther from the ham than that on the shin is from the middle of the patella.

In the mean time, one of your assistants must carry a strong ligature round the thigh, about three or four inches above the patella, which pulling through a couple of slits in a square piece of leather, he must twist with a tourniquet, till the artery is sufficiently compressed, to prevent any great effusion of blood; and to do it more effectually, he may lay a bolster of tow or linen under the ligature, upon that part where the artery creeps. It will also be a little more easy to the patient, to carry a compres of linen three or four times double, round the thigh, on that part where the ligature is applied, in order to prevent it from cutting the skin.

The course of the blood being stopped, you must begin your incision just below the linen roller, on the under part of the limb, bringing your knife towards you, which at one sweep may cut more than the semicircle; then beginning your second wound on the upper part, it must be continued from the one extremity to the other of the first wound, making them but one line. These incisions must be made quite through the membraa adipofa, as far as the muscles; then taking off the linen roller, and an assistant drawing back the skin as far as it will go, you make your wound from the edges of it when drawn back, through the flesh to the bone, in the same manner as you did through the skin. Before you saw the bones, you must cut the ligament between them, with the point of your knife; and the assistant who holds the leg while it is sawing, must observe not to lift it upwards, which would clog the instrument; and at the same time, not to let it drop, left the weight of the limb should fracture the bone, before it is quite sawed thro'.

In amputating below the knee, it is of advantage to stand on the inside of the leg; because the tibia and fibula lie in a position to be sawed at the same time, if the instrument be applied externally; whereas, if we lay it on the inside of the leg, the tibia will be divided first, and the fibula afterwards; which not only lengthens the operation, but is also apt to splinter the fibula when it is almost sawed thro', unless the assistant be very careful in supporting it.

When the leg is taken off, the next regard is to be had to the flowing the blood, which must be effectually done before the patient is put to bed, or there will be great danger of bleeding again, when the fever is excited, and the vessels of the stump dilated, both which happen a very little while after the operation. There is no method for this purpose so secure, as taking up the extremities of the vessels with a needle and ligature in the following manner. As soon as the amputation is performed, the assistant must loosen the tourniquet for a moment, upon which the orifices of the arteries will appear by the title of the blood. The operator having then fixed his eye upon one of the largest vessels, palls a crooked needle through the flesh, a little more than a quarter of an inch above the orifice, and about the same depth, in such a direction as to make nearly one third of a circle round the vessel; then withdrawing the needle, he a second time passes it into the flesh and out again, in the same manner and about the same distance below the orifice of the vessel. By this means, the thread will almost encompass the vessel, and when it is tied (which should be done by the surgeon's knot) will necessarily inclose it within the stricture. All the considerable arteries are to be taken up in the same manner; that is, the tourniquet is to be loosened in order to discover the vessels, and then the needle is to be passed round. This is a much better way than using the artery forceps, where the vessels are apt to slip away out of the ligature: and as to the tourniquet applications, their want of safety is so well known, that the use of them, in hemorrhages from large vessels, is almost universally rejected; though it is thought by several surgeons who have experienced the virtue of agaric, that it will be found to be a more powerful astringent than any hitherto discovered.

It sometimes happens in a large lump, that ten or more vessels require tying; which done, you must apply loose dry lint to the wound; or in case the small vessels bleed plentifully, you may throw a handful of flour amongst the lint, which will contribute to the more effectual stopping up their orifices. Before you lay on the pledget, you must bind the lump, and begin to roll from the lower part of the thigh down to the extremity of the lump. The use of this roller is to keep the skin forwards, which, notwithstanding the steps already taken to prevent its falling back, would in some measure do so, unless sustained in this manner. The dressing may be secured by the crois cloth and gentle bandage; and the method of treating the wound may be learnt from what has been laid with respect to recent incised wounds.

In amputating the thigh, the first incision is to be made a little more than two inches above the middle of the patella. After the operation, a roller should be carried round the body, and down the thigh, to support the skin and flesh: this is also the most proper bandage, as abscesses will sometimes form in the upper part of the thigh, which cannot discharge themselves conveniently with any other; it being almost impracticable to roll above the abscesses, unless we begin from the body.

The amputation of the arm or cubit differs so little from the foregoing operations, that it will be but a repetition to describe it. However, it must be laid down as a rule, to preserve as much of the limb as possible, and, in all amputations of the upper limbs, to place your patient in a chair.

The amputation of the fingers and toes is better performed in their articulation, than by any of the other methods: for this purpose, a straight knife must be used, and the incision of the skin be made not exactly upon the joint, but a little towards the extremity of the fingers, that more of it may be preferred for the easier healing afterwards; it will also facilitate the separation in the joint, when you cut the finger from the metacarpal bone, to make two small longitudinal incisions on each side of it first. In these amputations, there is generally a vessel or two that require tying, and which often prove troublesome when the ligature is omitted.

It may happen that the bones of the toes, and part only of the metatarsal bones, are carious; in which case, the leg need not be cut off, but only so much of the foot as is done off: a small spring-faw is better to divide with here, than a large one. When this operation is performed, the heel and remainder of the foot will be of great service, and the wound heal up safely.

Explanation of Fig. 7 Plate CLVIII.

A. The figure of the amputating knife. The length of the blade and handle should be about thirteen inches.
B. The figure of the saw used in amputating the limbs. The length of the handle and saw should be about seventeen inches.

Of Luxations.

A Bone is said to be luxated or dislocated, when it is moved out of its place or articulation, so as to impede its proper motion and office.

Luxation of the Nose.

It sometimes happens, that the bones of the nose are separated from each other, or distorted out of their natural places, by some violent blow or fall. When such an accident happens, it is several ways discovered: as, (1.) By the sight, when we behold the deformed position of the nose; or, (2.) By feeling; or lastly, (3.) By the ear, when the patient perceives with what difficulty the patient draws his breath through his nostrils.

When this case happens, the patient is to be speedily placed in a high chair, that an attendant may stand behind and hold his head firm, in a proper posture: the surgeon is then to introduce with one hand, a thick probe, a goose-quill, or little flicke shaped for the purpose, up the nostril internally, by which means the depressed parts of the nose may be thrust into their places: in the mean time he applies his other hand externally, to guide and direct the parts which are moved from within: this being done, there is scarce anything else required but to let a bit of flocking plaster lie upon the nose at the same time.

Of a Dislocation of the Lower Jaw.

The lower jaw is indeed seldom luxated, because it is held firm by strong ligaments and muscles, by whose assistance it is retained in two sinuses in the bafes of the cranium: but when it is by accident forced out from thence, it may chance to be on one side only, or else on both, being then thrust directly forwards: and this happens most frequently from opening the mouth too wide in yawning; though it has sometimes been occasioned by a violent blow or fall. If it be luxated on both sides, the chin will incline downward, and the jaw will be thrust very forward: but if only on one side, the chin will be inclined toward the opposite side; the elapted little head of the jaw not being capable of dislocation but forward and inward; for the processes of the bones of the cranium prevent the jaw from being dislocated backwards.

The lower jaw is chiefly known to be luxated on one side, when the chin is dislocated on the opposite side: for that part to which the chin inclines, is the found; but that from whence it recedes, is the luxated one: the mouth in this case gapes wider than usual, so that the patient cannot shut it, nor eat with his teeth; the lower range of teeth being projected beyond, and on one side the upper: but when the jaw is luxated on both sides, then the mouth not only gapes wide and open, but the chin also hangs down, and is thrown directly forwards; so that the patient cannot shut his mouth, speak diligently, or even swallow anything without much difficulty.

When the jaw is cut only on one side, and the face recent, the cure is usually not so very difficult; but when both heads are dislocated, and not presently restored to their places, it always occasions the worst of symptoms, as pains, inflammations, convulsions, fevers, vomitings, and at length death itself.

When this kind of luxation happens, the patient is to be directly seated on a low stool, so that an attendant may hold his head firm against his breast. Then the surgeon is to thrust his two thumbs as far back into the patient's mouth as he well can; but they are first wrapped round in a handkerchief, to prevent them from slipping or being hurt; and his other fingers are to be applied to the jaw externally: when he has got firm hold of the jaw, it is to be strongly pressed, first downwards, then backwards, and lastly upwards, but so as that they may be all done in one instant; by which means the elapted heads of the jaw may be very easily shoved into their former cavities.

If the jaw be out on one side only, every thing must be done in the same manner: but the luxated side of the jaw must be forced more strongly downward and backward than the found one.

Of Luxations of the Head and Spine.

The luxations which happen in the spine and vertebra of the back are generally imperfect ones. For it appears from an accurate consideration of the structure and articulation of these bones, that none of the vertebra can be entirely displaced without being fractured, and also compressing or wounding the spinal marrow, which must produce danger of infant death. Even the imperfect luxations of these bones are very dangerous: which happen either between the two superior vertebra of the neck and the head, or else between the rest of the vertebra, when they are forced from each other.

Such as have a luxation between the head and upper vertebra, seldom escape being carried off by a speedy and sudden death: for in this case the tender medulla which joins immediately with the brain, and is lodged in the spine, the brain itself, and the nerves which arise beneath the occiput, are too much distended, compressed, or lacerated; the two condyloide processes of the occiput usually slip out of their glenoide sinuses in the first vertebra of the neck, when a person falls headlong from a high place, from off a ladder, from on horseback, or when he receives a violent blow upon his neck: they dying very suddenly in this case, are vulgarly said to have broke their neck, though there is generally no more than a luxation: yet it sometimes happens that the vertebra of the neck are really fractured. If life should remain after such a luxation, which very rarely happens, the patient's head is commonly dislocated with his chin close down to his breast, so that he cannot swallow any thing, nor speak, nor even move any part that is below his neck: therefore, if speedily assistance be not had, death ensues, from the compressure or hurt of the medulla.

But to repulse this unwelcome messenger, the patient is to be immediately laid flat upon the ground or floor: then the surgeon kneeling down with his knees against the patient's shoulders, is to bring them together so as to contain the patient's neck between them: this done, he quickly lays hold of the patient's head with both his hands, and strongly pulling or extensing it, he gently moves it from one side to the other; till he finds, by a noise, the natural position of the neck, and the remission of the symptoms, that the dislocation is properly reduced: by this method the surgeon retains the patient firm between his knees, and
performs the extension and reduction between his hands.

It will be proper, in order to prevent a tumor, and restore the stretched ligaments of the neck to their former vigour, to bathe it with ag. Hungar, fp. vin. camph: or some other strengthening spirit applied warm, as also compresses dipped in the same: the patient should bleed, and rest gently for some days, till the neck be found sufficiently strong and well.

With respect to the rest of the vertebrae of the back, they are seldom moved quite out of their places, unless they are fractured, they being retained, for the greatest part, by adhering to the adjacent ligaments and muscles: therefore the luxations which happen among them are usually imperfect; no more being displaced than their two upper or lower processes, and they often but on one side; and this happens sometimes to one of the spinal vertebrae, and sometimes to more. But it is here to be briefly observed, that it is usual to include among the number of luxated vertebrae, that which is found and firm, but intersepted by others which are not so: thus whenever the upper vertebrae of the loins from the left of the back, and lowermost vertebrae of the loins next the os sacrum, are luxated, we con monly lay and reckon there are five vertebrae out of their places; when, strictly speaking, only the two outermost or the uppermost and lowermost of those vertebrae are disturbed, the three middle ones retaining their natural situation and connection.

The signs common to luxations in the spine dorso are chiefly the following: the back itself is found to be crooked or unequal, after the external violence has been inflicted; the patient can neither stand nor walk, and his whole body seems to be paralytic; the parts which are beneath the luxated vertebrae are nearly without all sense and motion; the excrements and urine cannot be discharged, or else they are sometimes emitted involuntarily; the lower extremities grow dead by degrees; and, at length, death itself follows: but these symptoms vary in proportion to the degree of violence in the luxation.

Luxations of the spinal vertebrae are very difficult to reduce. The following seems to be the most suitable method of reducing luxations of the vertebrae: when the apophyses of the vertebrae are dislocated on both sides, the patient is to be laid leaning upon his belly over a calk, drum, or some other gibbous body; then two assistants are successively to press down both the ends of the luxated spine, on each side; by which means the bones of the spine will be set free from each other, lifted or pulled up in the form of an arch, and so gradually extended. This done, the surgeon presses down the luxated vertebrae, and at the same time nimbly lifts up the inferior part of the body upwards: and by this means the luxated vertebrae are sometimes commodiously reduced into their right places: but, if success should not attend the first time, the method should be repeated two or three times more.

It seems proper, after the vertebrae are reduced, to bathe the spine with fp. vin or to lay on compresses dipped in fp. vin. camph. Afterwards the patient is to be laid in a soft and even bed; bleeding, and bathing the weak parts with strengthening spirits, are to be used as there may be occasion.

Of Luxations of the Os Coccyx, and Ribs.

The os coccyx may be thrust inwards by a violent fall or blow, and it is often pushed outwards in hard birth. When this happens, it is usually attended with violent pain and inflammation about the lower part of the spine, affections form in the inter-sixum rectum, and the fauces are constipated or suppressed. To discover the luxation of this bone the more readily, we have recourse to the use of our hands and eyes, as well as to the knowledge of the forementioned symptoms: nor is the replacing this bone very difficult, if attempted by a careful and expert surgeon; for if it be thrust outwards, it must be depressed into its right place by the thumb, after which may be applied compresses dipped in warm wine, or its spirit, made broad above, and narrow below, to fill up the posterior sinus of the nates; and these may be held on by the T bandage; but that part of this bandage which comes between the thighs should be flat, and placed so that the patient may go to stool without undoing the bandage, and to prevent the bone from being by that means displaced again.

When the os coccyx happens to be luxated inwards, the first finger is to be introduced into the anus. After it has had its nail cut and been dipped in oil, it must be thrust as far as possible, that it may the more readily drive out the depressed bone; the other fingers being applied externally, are to conduct the bone into its right position: when this has been done, it will be proper for the patient to rest some time upon the bed; and when he sits up, it should be in a chair with a hole in its bottom, left the affected part should be otherwise compressed or disturbed.

The ribs are indeed sometimes, though but seldom, dislocated; for upon the assault of some external violence, it is not uncommon for them to be displaced either upwards, downwards, inwards, or outwards. They cannot be easily reduced outwards, because prevented by the vertebral processes, and refitted by very thick and strong muscles: but when they are drove into the cavity of the thorax, they not only lactate the pleura, but do generally great injury to the contained parts; in consequence whereof arise most sharp pains, inflammations, difficulty of breathing, cough, ulcers, immobility, and many other dangerous symptoms of the like nature.

When the rib is dislocated either upwards or downwards, in order to replace it conveniently, the patient is to be laid on his belly upon a table, and the surgeon must strive to reduce the luxated rib into its right place with his hands; or, the arm of the disordered side may be suspended over a gate or ladder, and while the ribs are thus stretched up from each other, the heads of such as are luxated may be pulled into their former seat.

But these luxations wherein the heads of the ribs are forced into the thorax, are generally found to be much the most difficult to reduce; since neither the hand, nor any other instrument, can be applied internally to direct the luxated heads of the ribs: in this case it seems proper to lay the patient on his belly over some gibbous or cylindric body, and to move the fore part of the rib inwards towards the back, slacking it sometimes; for thus generally the head of the luxated ribs slips into its former place: but if this method of cure will avail nothing, and the deplorable condition of the patient requires speedy help, we have no remedy left but incision, and endeavouring to replace the luxated head of the rib with the fingers, pliers, or little hooks. In the mean time, where the symptoms are not very urgent, and the heads of the ribs but little displaced, it is advisable neither to cut the flesh, nor violently force the ribs; be
The clavicles may be dislocated either from the top of the sternum, or processus acromion of the scapula, by some external violence, as a fall, blow, or by pulling it with the hand both inward and outward, without at all moving or bending the scapula; as when the pronation and supination of the hand is made thereby. Both these bones of the cubitus are so articulated with the lower head of the os humeri, that large protuberances are received into deep cavities or grooves, and the whole involved and relieved with exceeding strong ligaments; so that notwithstanding the cubitus may be luxated in all four directions, outward, inward, forward, and backward, yet it is but seldom that it suffers a perfect or entire dislocation, unless the upper part of the ulna, called olecranon, be broken, or the ligaments of the cubitus much weakened, by some very great external violence.

If the cubitus be luxated backward, which is the most frequent of all others, then the arm becomes crooked and shorter, and it cannot be extended. In the inward part of the bend of the arm, the head of the humerus may be observed to stick out; in the back part of the same, the head of the ulna or olecranon will be protuberant, and between both bones will appear a sinus under the olecranon, be broken, or the ligaments of the cubitus much weakened, by some very great external violence.

Of a Luxation of the Cubitus.

The cubitus, consisting of two bones, the ulna and the radius, is articulated by ginly synovial joints. The connection of these bones is such, that the ulna or cubitus, as being the least, or the distal bone, and seated in the inferior part of the arm, does of itself perform the whole flexion and extension of the arm; yet it cannot perform that motion without carrying the radius along with it; so that the radius always follows the ulna in flexion and extension; but, on the other hand, the radius may be turned along with the hand both inward and outward, without at all moving or bending the ulna; as when the pronation and supination of the hand is made thereby. Both these bones of the cubitus are so articulated with the lower head of the os humeri, that large protuberances are received into deep cavities or grooves, and the whole involved and relieved with exceeding strong ligaments; so that notwithstanding the cubitus may be luxated in all four directions, outward, inward, forward, and backward, yet it is but seldom that it suffers a perfect or entire dislocation, unless the upper part of the ulna, called olecranon, be broken, or the ligaments of the cubitus much weakened, by some very great external violence.

As soon therefore as the luxation is discovered in the humerus, the safest way will be to fix the patient on the floor, or on a low stool. Two strong assistants are to be placed on each side the patient: one of which should secure his body, and, if possible, the scapula too, that it may not give way to the extension; while the other lays firm hold of the luxated arm with both his hands, a little above the cubitus, gradually and strongly extending it. But before that extension be made, the surgeon himself should have a large napkin, of sufficient length, tied at the ends, and hung about his neck so that the knot may be behind; but the other part of the napkin must hang over his breast; then the patient's arm must be put through the napkin up to the shoulder, and the surgeon at the same time lays hold of the head of the humerus with both his hands; this done, he orders the assistant to extend the limb sufficiently, and in the mean time he himself elevates the head of the patient's humerus by the napkin about his neck, directing it with his hands, till it slip into its former cavity in the scapula.

Of a Luxation of the Cubitus.

The cubitus, consisting of two bones, the ulna and the radius, is articulated by ginly synovial joints. The connection of these bones is such, that the ulna or cubitus, as being the least, or the distal bone, and seated in the inferior part of the arm, does of itself perform the whole flexion and extension of the arm; yet it cannot perform that motion without carrying the radius along with it; so that the radius always follows the ulna in flexion and extension; but, on the other hand, the radius may be turned along with the hand both inward and outward, without at all moving or bending the ulna; as when the pronation and supination of the hand is made thereby. Both these bones of the cubitus are so articulated with the lower head of the os humeri, that large protuberances are received into deep cavities or grooves, and the whole involved and relieved with exceeding strong ligaments; so that notwithstanding the cubitus may be luxated in all four directions, outward, inward, forward, and backward, yet it is but seldom that it suffers a perfect or entire dislocation, unless the upper part of the ulna, called olecranon, be broken, or the ligaments of the cubitus much weakened, by some very great external violence.

As soon therefore as the luxation is discovered in the humerus, the safest way will be to fix the patient on the floor, or on a low stool. Two strong assistants are to be placed on each side the patient: one of which should secure his body, and, if possible, the scapula too, that it may not give way to the extension; while the other lays firm hold of the luxated arm with both his hands, a little above the cubitus, gradually and strongly extending it. But before that extension be made, the surgeon himself should have a large napkin, of sufficient length, tied at the ends, and hung about his neck so that the knot may be behind; but the other part of the napkin must hang over his breast; then the patient's arm must be put through the napkin up to the shoulder, and the surgeon at the same time lays hold of the head of the humerus with both his hands; this done, he orders the assistant to extend the limb sufficiently, and in the mean time he himself elevates the head of the patient's humerus by the napkin about his neck, directing it with his hands, till it slip into its former cavity in the scapula.
S U R G E R Y.

As soon as the reduction has been by these means effected, the articulation must be bound up with a proper bandage, and the arm is to be afterwards suspended in a napkin or fling about the neck: but care must be taken, that the bandage be not suffered to be on too long, nor the arm to be kept all the time still, without some gentle motion.

On Luxations of the Hand, Carpus, Metacarpus, and Fingers.

Notwithstanding the hand is very accurately connected to the two preceding bones, and particularly to the radius, by means of the carpus and strong ligaments, yet it sometimes suffers luxation in all four directions; but it is generally not so easy to be luxated on either side, as forward or backward, because of the two processes of the radius and ulna, which guard it on each side. The hand is said to be luxated forwards or inwards, when it recedes from the muscles which bend the fingers; to be luxated backwards, when it departs from the muscles which extend the fingers: much also in the same manner, the hand is judged to be luxated outward, when the carpus makes a tumor near the thumb, and a cavity near the little finger; to be luxated inward, when the contrary happens.

It seems to be the safest way immediately to reduce what is displaced; and that this may succeed the better, two things are to be chiefly regarded: (1.) That the luxated hand be sufficiently extended by two assistants, one of which is to lay hold of the hand, and the other of the humerus, pulling in opposite directions: (2.) That the part of the extended hand, where the flexus is, be placed on a table, or some other flat body, that whatever flicks up may be depressed: by which method the hand, in whatever part luxated, may be very readily reduced into its natural seat.

It also sometimes happens, that one or two of the eight little bones of the carpus are luxated and dislocated from their natural seat by some external violence. When this happens, there will be perceived a tumor in one part, and a cavity in another, which may be also felt by the fingers; besides, violent pains will be felt by the patient. For the rest, as this kind of luxation is very easily discovered, partly by the sight, and partly also by feeling; so, when it is recent, it is almost as readily cured, letting the hand be extended in the manner we before proposed, and the dislocated bone be afterwards forced into its place.

The four small bones, which are found in the metacarpus or palm of the hand, may be sometimes luxated from the carpus itself, to which their upper parts are connected; which usually happens from some external violence. The two bones which are placed in the middle between the two other external ones, cannot be dislocated to either side; as the two external ones which sustain the first and little fingers cannot be luxated inwardly, but are more easily driven outward: though each of them may be luxated on the fore or back part of the hand. But which ever of these happens, the particular disorder may be discovered and examined by feeling and inspecting, and the cure may be carried on in altogether the same method which we directed before.

Lastly, The bones of the fingers, to which we join those of the thumbs, are liable to luxation at each of their articulations, and that in several directions. But these accidents, if recent, are both very easy to discover and cure: for the ligaments being not very robust, the fat and muscles thin, and the flexures of the articulations shallow, render the extension very easy, and the reduction of them into their former places may be done very readily. While one hand of the surgeon extends the finger, he thrives with his other to replace the bones in their natural seat.

Of a Luxation of the Thigh.

Very rare is it that the head of the thigh-bone is displaced out of its acetabulum; though formerly it was supposed to be pretty frequent, physicians taking a fracture thereof for a luxation, the reason whereof may be taken from the articulation itself: (1.) How very deep is the fiesus, called by the ancients fiesus coxæ, and by the moderns acetabulum, into which the head of the thigh-bone is received. (2.) With what a broad concave cartilage is almost the whole head of that bone covered. (3.) How strong are the ligaments with which it is stiffened. (4.) How greatly it is defended with exceeding stout and thick muscles. (5.) But how very brittle is the neck of this bone beyond any other part thereof: from all which it appears, that the neck must be far more frequently and easily broke, especially in adults, than its head dislocated: and though something of this kind may sometimes happen, so as to make the head of the thigh-bone flip out of its acetabulum; yet that generally proceeds more from internal than external causes: for we find it has been observed by very skilful physicians, that the ligaments of the thigh-bone, though very strong, may be by various causes, and particularly by a flux of humours, so relaxed and weakened, as to let the head of that bone flip spontaneously out of its acetabulum; so that it should seem no great wonder if the thigh should be sometimes luxated even while the patient lies in bed, without any external violence, so that when they rise, one leg appears longer or shorter than the other, and seems as if it were unhinged.

But this case does not happen so easy in robust adults, as in such as are more young and tender.

Whenever the said head of the thigh-bone is thrust out, it is almost always wholly displaced, so as to make a perfect luxation. The exact roundness of this head, with the great force of the circumjacent muscles, and the narrowness of the fides of the acetabulum, will not admit the bone to be dislocated a little way only; for as soon as the head of this bone is thrust up to the edge of the acetabulum, it must unavoidably either turn quite out, or else fall back again into its right place.

The thigh is usually luxated four ways; upward, downward, backward, and forward: but it is most frequently dislocated downwards and inwards, towards the large foramen in the os pubis: for besides that the cartilaginous defence on the lower part of the acetabulum is not so high as the reff, the ligamentum rotundum is found to give way more easily in that part than any other: and lastly, the adjacent muscles are found to be weakest in their resistance on this part, being insufficient to keep the head of this bone from flipping out; and then there is a certain eminence in this edge of the acetabulum, which keeps the head of the os femoris from falling back again into its right place: but if the head of this bone be dislocated outwards, it generally slips upwards at the same time; it being scarce possible but the very strong muscles of the thigh must then draw the bone upwards, and then there is no eminence there, in the edge of the acetabulum, to resist the head of the bone in that passage; but should it at any time be luxated by an external
ternal force, there must certainly be a rupture of the round ligament.

When the thigh is dislocated forwards and downwards, which is what usually happens, the leg hangs straddling outward, and is longer than the other; also the knee and foot turn outwards; the head of the bone itself will be felt near the lower part of the inguen and os pubis; sometimes there is a suppression of urine in this case; when some nerve, which communicates with the bladder, is violently compressed; in the buttck may be perceived a cavity, from the external force, there must certainly be a rupture of the round ligament.

Whenever the thigh is luxated backward, the patient is to be placed flat on a table, with his face downward; and the thigh is to be extended in directly the same manner, but a little more strongly than we just now proposed; and the reduction is to be effected afterwards by the surgeon's hands, an assistant in the mean time extending the limb, and turning it inwards; by this means the head of the thigh-bone generally slips very readily again into its acetabulum.

Of a Luxation of the Patella and Knee, or Tibia and Fibula.

The patella is usually luxated mostly on the internal or external side of the joint; but whenever the knee is perfectly luxated, the patella can scarce avoid being displaced at the same time, because of its strong connexion to the thigh and tibia.

The reduction of a luxated patella is usually no very great difficulty, if the patient be laid flat on his back upon a table or bed, or if he be laid in that posture upon an even floor, so as that the leg may be pulled out filant by an assistant; for then the surgeon may firmly grasp the patella with his fingers, and afterwards press it strongly into its right place; which may be also effected if the patient stands upright: when this is done, there remains nothing but carefully to bind up the disordered part, and to let the patient rest quietly for some days, sometimes gently bending and extending his leg to prevent it from growing stiff, till the pains are gone off, and the limb has recovered its former strength.

A luxation of the knee is properly so, when the tibia recedes from under the femur. The leg is sometimes luxated from the bals of the thigh-bone, either on the out or inwards, or backwards; seldom or never forwards, unless it be forced and driven very violently that way; because forwards, the patella is bound against the articulation, by the very strong tendons of the muscles which extend the leg; nor is it easy for the bones of the leg to be wholly displaced from that of the thigh, so as to make a perfect luxation; by reason of the great strength of the ligaments, and the two deep sinues which receive the head of the thigh-bone.

As this kind of luxation is very easy to discover from the thin covering of the joint, with the tumors and cavities which follow; so, when it is discovered, it is as difficult to make a perfect cure thereof, without letting the bones join together; or leaving some stiffsness in the knee; which first accident is usually called an ankylosis.

When the knee is but slightly luxated, the patient is to be seated on a bed, bench, or table, and one assistant holds the thigh firm above the knee, and the other extends the leg; but the surgeon in the mean time replaces the bones by his hands and flings if necessary, or pushes it by the application of his knee into its natural place.

Sometimes the fibula is separated by some external violence from the thigh-bone, and is then distorted either upward or downward: and this generally happens, when the foot has been luxated outward; therefore, when this is the case, there is need of extension. The bone is to be first restored...
reflored to its natural place, and then properly bound up.

Of a Luxation of the Foot and Ankle.

The ankle may be sometimes luxated either in jumping, running, or walking; and that in all four directions, inward, outward, backward, and forward. Which of these ways it happens to be luxated, may be discovered by the particular posture of the joint.

The ankle is more or less difficult to reduce, in proportion to the violence of the cause by which it is luxated. But the most ready way of reducing a luxation of the ankle is to place the patient upon a bed, chair, or table, letting the leg and foot be extended in opposite directions by two assistants, while the surgeon drives to reduce the ankle with his hands and fingers. When the foot is by this means once replaced, it is proper to bind it up carefully, after it has been well bathed with oxycrate and salt, advising the patient to keep to his bed a good while, till the disfigure and its symptoms quite leave him.

SURSOLID, in arithmetick and algebra, the fifth power, or fourth multiplication of any number or quantity considered as a root. See Arithmetick and Algebra.

SURVEYING, the art or act of measuring land; that is, of taking the dimensions of any tract of ground, laying down the same in a map or draught, and finding the content or area thereof. See Geometry, p. 699.

SURVEYOR, a person who hath the overfright and care of considerable works, lands, or the like. Surveyor likewise denotes a gauger; as also a person who surveys lands, and makes maps of them.

SURVIVOR, in law, signifies the longest liver of joint tenants, or of any two persons jointly interested in a thing.

SUS, in zoology, a genus of the decandria pentagy. See Arthopoda. The calyx consists of six leaves; and the corolla of five petals; and there are five roundish seeds. There is but one species, a native of America.

SURMOUNTED, in heraldry, is when one figure is laid over another. As the pile surmounted of a chevron in Plate CXLVII, fig. 17.

SURREPTITIOUS. See Subreptitious.

SURREY, a county of England, bounded by the river Thames, which separates it from Middlesex, on the north; by Kent, on the east; by Suffolk, on the south; and by Berkshire, on the west; being thirty-four miles long, and twenty-one broad.

SURROGATE, in law, denotes a person that is substituted, or appointed in the room of another.

SUSDAL, a city of the province of Moscow, in Russia, one hundred miles north-east of Moscow.

SUSSEX, a county of England, bounded by Surrey and Kent on the north, by another part of Kent on the east, by the English channel on the south, and by Hampshire on the west; being sixty-five miles long, and twenty-nine broad.

SUTHERLAND, a shire of Scotland, bounded by Caithness on the north, by the German sea on the east, by the English channel on the south, and by Caithness on the west.

SUTTON GOLEFIELD, a market-town twenty miles north-west of Warwick.

SUTTER, in anatomy. See Anatomy, p. 152.

SWABBER, an inferior officer on board ships of war, whose employment it is to see that the decks are kept neat and clean.

SWABIA, a circle of the German empire, bounded by Bavaria and the palatinate of the Rhine on the north, by Bavaria on the east, by Switzerland and Tyrol on the south, and by the river Rhine, which separates it from Alsace, on the west; being one hundred and thirty miles long, and one hundred and ten broad.

SWALE, a river of Yorkshire, which rising on the confines of Wiltmoreland, runs south-east through Yorkshire, and falls into the Ouse.
SWEDEN, one of the most northerly kingdoms of Europe, bounded by Norwegian Lapland on the north, by Russia on the east, by the Baltic sea on the south, and by Norway on the west; being upwards of eight hundred miles from north to south, and five hundred from east to west.

SWEET, in the wine-trade, denotes any vegetable juice, whether obtained by means of sugar, raisins, or other foreign or domestic fruit, which is added to wines, with a design to improve them.

SWERIN, a town of lower Saxony, in Germany, capital of the duchy of Mecklenburg; and situated on the lake of Swerin: E. long. 11° 30', and N. lat. 54°.

SWERTIA, in botany, a genus of the pentandria digynia class. The corolla is rotated, and there are nectariferous pores at the bases of the different laciniae of the corolla; the capsule has one cell, and two valves. There are five species, only one of them, viz. the perennis, or marsh gentian, a native of Britain.

SWIMMING, the art or act of sustaining the body in water, and of moving therein; in which action the air-bladder and fins of fishes bear a considerable part.

SYMBOL, a sign or representation of something moral, by the figures or properties of natural things. Hence symbols are of various kinds, as hieroglyphics, types, enigmas, parables, fables, &c.

SYMPHISIS, in anatomy. See Anatomy, p. 148.

SYMPHONY, in music, properly denotes a concord of several sounds agreeable to the ear, whether vocal or instrumental, called also harmony.

SYMPHYTUM, in botany, a genus of the pentandria digynia class. The limbus of the corolla is tubular and cleft. There are three species, only one of them, viz. officinale, or comfrey, a native of Britain. The root is used in the medicine.

SYMPHYTUM, in botany, a genus of the pentandria digynia class. The limbus of the corolla is tubular and somewhat ventricose, the sauces being cloased with fubulate radii. There are three species, only one of them, viz. officinale, or comfrey, a native of Britain. The root of the comfrey is a fine mucilage.

SYMPHYSIS, in anatomy. See Anatomy, p. 148.

SYMPHYTUM, in botany, a genus of the pentandria digynia class. The limbus of the corolla is tubular and somewhat ventricose, the sauces being cloased with fubulate radii. There are three species, only one of them, viz. officinale, or comfrey, a native of Britain. The root of the comfrey is a fine mucilage.

SYMPHYTUM, in botany, a genus of the pentandria digynia class. The limbus of the corolla is tubular and somewhat ventricose, the sauces being cloased with fubulate radii. There are three species, only one of them, viz. officinale, or comfrey, a native of Britain. The root of the comfrey is a fine mucilage.

SYMPHYTUM, in botany, a genus of the pentandria digynia class. The limbus of the corolla is tubular and somewhat ventricose, the sauces being cloased with fubulate radii. There are three species, only one of them, viz. officinale, or comfrey, a native of Britain. The root of the comfrey is a fine mucilage.
SYNDIC, in government and commerce, an officer in department.

SYNCOPE, fainting, in medicine, a deep and sudden loss of consciousness.

SYNECDOCHE, in rhetoric, a kind of trope, frequent among orators and poets. There are three kinds of synecdoche. By the first, a part is taken for the whole; as the point for the sword, the roof for the house, the hills for the ship, &c. By the second, the whole is used for a part. By the third, the matter whereof the thing is made is used for the thing itself; as steel for sword, silver for money, &c. To which may be added another kind, when the species is used for the genus, or the genus for the species.

SYNEDRION, a word introduced into medicine by the empirics, who mean by it a concourse of symptoms.

SYNÉCDOCHE, in rhetoric, a kind of trope, frequent among orators and poets. There are three kinds of synecdoches. By the first, a part is taken for the whole; as the point for the sword, the roof for the house, the hills for the ship, &c. By the second, the whole is used for a part. By the third, the matter whereof the thing is made is used for the thing itself; as steel for sword, silver for money, &c. To which may be added another kind, when the species is used for the genus, or the genus for the species.

SYNACHUS, or Synocha, in medicine, a term used by Paracelsus, and synonymous with the word Synoecia.

SYNAGOGUE, a particular assembly of Jews met to perform the offices of their religion. Also the place wherein they meet.

SYNAX, in grammar, a contraction of syllables, performed principally by suppressing some vowel or diphthong at the end of a word, on account of another vowel or diphthong at the beginning of the next. As ill' ego, for ille ego, &c.

SYNARTHROSIS, in anatomy. See Anatomy, p. 148.

SYNCHONDROSIS, in anatomy. See Anatomy, p. 148.

SYNCHRONISM, denotes the happening of several things in the same time.

SYNCOPE, fainting, in medicine, a deep and sudden loss of consciousness.

SYNCOPTATION, in rhetoric, denotes the happening of several things in the same time, whereby the distinction of the several times or parts of the measure is interrupted.

SYNCOPE, fainting, in medicine, a deep and sudden loss of consciousness, wherein the patient continues without any sensible heat, motion, sense, or respiration, and is seized with a cold sweat over the whole body, and all the parts turn pale and cold as if dead. See Medicine, p. 157.

SYNCOPE, in grammar, an elision or retrenchment of a letter or syllable out of the middle of a word, as calidus for calidus.

SYNOD, in altrenomy, a conjunction, or concourse of bodies, and the like.

SYNODAL, signifies also a meeting, or assembly of ecclesiastical persons, concerning matters of religion.

SYNODALS, were pecuniary rents, commonly of two shilling, paid to the bishop, or archdeacon, at the time of their Easter visitation, by every parish priest.

SYNODICAL, something belonging to a synod; thus synodal epistles are circular letters written by the synods to the absent prelates and churches, or even those general ones directed to all the faithful, to inform them of what had passed in the synod.

SYNODESIA, in Greek antiquity, a feast celebrated at Athens, in memory of Theseus's having united all the petty communities of Attica into one single commonwealth, the feat whereof was Athens, where all the assemblies were to be held. This feast was dedicated to Minerva; and, according to the school of Thucydides, it was held in the month of Metagitation.

SYNONYMOUS, is applied to a word or term that has the same import or signification with another.

SYNOVIA, in medicine, a term used by Paracelsus, and synonymous with the word Synovia.

SYNOPSEIS, a seat of heretics, who maintained, that there was but one nature and one subsistence in Jesus Christ.

SYRACUSE, a city and port-town of Sicily, in the province of Val de Noto, situated on a fine bay of the Mediterranean sea, on the east coast of the island: in 37° 55' N lat. 15° 15' E. It was the seat of the Levantine commerce, and the like.

SYRAX, a part of Asiatic Turkey, bounded by Natalia and Turcomania, on the north; by Diarbec or Mesopotamia on the east; by Arabia and Palestine on the south; and by the Levant-sea on the west. The Turks divide Syria into three beglerbeglies, or vice-royalties, viz. those of Aleppo, Tripoli, and Damascus; and the like.

SYRINIA, in botany, a genus of the diandria monogynia class. The corolla consists of four segments, and the capsule has two cells. There are two species, both natives of Peria.

SYRINGE, a well known instrument, serving to imbibe or convey a quantity of fluid, and to squirt or expel the same with violence.

SYRINGA, in botany, a genus of the diandria monogynia class. The corolla consists of four segments, and the capsule has two cells. There are two species, both natives of Peria.
TABARCA, an island on the coast of Barbary, in Africa.

TABAGO, one of the Caribbee islands in the American ocean, one hundred and twenty miles south of Barbadoes: W. long. 59°, N. lat. 11° 30'.

TABARCA, an island on the coast of Barbary, in Africa, fifty miles west of Tunis: E. long. 8°, N. lat. 36° 30'.

TABASCO, the capital of a province of the same name, situated on the bay of Campeachy, at the mouth of the river tabasco, one hundred and sixty miles south-west of Campeachy: W. long. 95°, N. lat. 11° 30'.

TABBYING, the palling a silk or fluff under a calender, derived to dissolve slowly, and generally made agreeable to the palate.

TABBY, in commerce, a kind of rich silk which has undergone the operation of tabbying. See the next article.

TABBYING, the palling a silk or fluff under a calender, the rolls of which are made of iron or copper, variously engraved, which bearing unequally on the stuff renders the surface thereof unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABELLA, tablet, in pharmacy, is much the same with our notaries-public, who are often called tabelliones in our ancient law-books.

TABELLIO, in the Roman law, an officer or scrivener, much the same with our notaries-public, who are often called tabelliones in our ancient law-books.

TABELLIO, in the Roman law, an officer or scrivener, called tabelliones in our ancient law-books.

TABERNACLE, among the Hebrews, a kind of building, in the form of a tent, set up, by express command of God, for the performance of religious worship, sacrifices, &c. during the journeying of the Israelites in the wilderness; and, after their settlement in the land of Canaan, made use of for the same purpose till the building of the temple of Jerusalem. It was divided into two parts, the one covered, and properly called the tabernacle; and the other open, called the court. The curtains which covered the tabernacle were made of linen, of several colours, embroidered. There were ten curtains, twenty-eight cubits long and four in breadth. Five curtains fastened together made up two coverings, which covered all the tabernacle. Over these there were two other coverings; the one of goat-hair, and the other of sheep skins. The holy of holies was parted from the rest of the tabernacle by a curtain made fast to four pil lars, standing ten cubits from the end. The length of the whole tabernacle was thirty-two cubits, that is, about fifty feet; and the breadth twelve cubits, or nineteen feet. The court was a spot of ground one hundred cubits long, and fifty in breadth, inclosed by twenty columns, each twenty cubits high and ten in breadth, covered with silver, and standing on copper bases, five cubits distant from each other: between which, there were curtains drawn, and fastened with hooks. At the east end was an entrance, twenty cubits wide, covered with a certain hanging loofe.

Feast of Tabernacles, a solemn festival of the Hebrews, observed after harvest, on the fifteenth day of the month Tisri, instituted to commemorate the goodness of God, who protected the Israelites in the wilderness, and made them dwell in booths, when they came out of Egypt. On the first day of the feast, they began to erect booths of the boughs of trees, and in these they were obliged to continue seven days. The booths were placed in the open air, and were not to be covered with cloths, nor made too close by the thickness of the boughs; but left that the fun and the stars might be seen, and the rain descend through them.

TABERNÆMON'TANA, in botany, a genus of the pentandria monogynia class. It has two horizontal follicles; and the seeds are pulpy. There are three species, all natives of America.

TABES, or Consumption. See Medicine, p. 103.

TABLATUR, in music, is, in general, when, to express the sounds or notes of a composition, we use the letters of the alphabet, or any other characters not used in the modern music.

Laws of the Twelve Tables, were the first set of laws of the Romans, thus called, either by reason the Romans then wrote with a stylus on thin wooden tablets covered with wax; or rather, because they were engraved on tables, or plates of copper, to be exposed in the most noted part of the public forum. After the expulsion of the kings, as the Romans were then without any fixed or certain sytem of law, at least had none simple enough to take in the various cases that might fall between particular persons, it was resolved to adopt the best and wisest laws of the Greeks. One Hermodorus was first appointed to...
to translate them, and the decemvirs afterwards compiled and reduced them into ten tables. After a world of care and application, they were at length enacted and confirmed by the senate and an assembly of the people, in the year of Rome 303. The following year they found something wanting therein, which they supplied from the laws of the former kings of Rome, and from certain customs which long use had authorized: all these being engraved on two other tables, made the laws of the twelve tables, so famous in the Roman jurisprudence, the source and foundation of the civil or Roman law.

TABLES of the law, in Jewish antiquity, two tables on which were written the decalogue, or ten commandments, given by God to Moses on Mount Sinai. See Decalogue.

Table, in mathematics, a system of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations.

Astronomical Tables, are computations of the motions, places, and other phenomena of the planets.

TABORITES, a branch or sect of the ancient Huffleites. They carried the point of reformation farther than Hufs had done, rejected purgatory, auricular confession, the use of baptism, transubstantiation, &c. They reduced the seven sacraments of the Romanists to four, viz. baptism, the eucharist, marriage, and ordination.

TABRISTAN, a province of Persia, situated on the north of the Caspian sea, having the province of Asfar bat on the east, and Gilan on the west; being part of the ancient Hycrania.

TACAMAHACA, in pharmacy, a solid resin, improperly called a gum, in the shops: it is of a fragrant and peculiar smell, and is of two kinds; the one called the shell-tacamahaca, which is the finest; the other, which is an inferior kind, being termed rough-tacamahaca, or tacamahaca in grains.

Some greatly commend tacamahaca in disorders of the breast and lungs; but, at present, it is very rarely used internally. Externally, however, it is in repute for softening tumours, and mitigating pain and aches.

TACK, in a ship, a great rope having a wale-knot at one end, which is seized or fastened into the clew of the sail; so is reeved first though the chiefe-trees, and then is brought through a hole in the ship's side. Its use is to carry forward the clew of the sail, and to make it stand close by a wind: and whenever the sails are thus trimmed, the main-tack, the fore-tack, and mizen-tack, are brought close by the board, and haled as much forward on as they can be.

TACK, in Scots law. See Law, Tit. xiii. 8, &c.

TACK-ABOUT, in the sea-language, is to turn the ship about, or bring her head about, so as to lie the contrary way.

TACKLE, among sea-men, denotes all the ropes or cordage of a ship, used in managing the sails, &c.

TACTICS, in the art of war, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions.

TADCASTER, a market-town of Yorkshire, ten miles south west of York.

TADORMA, in ornithology. See ANAS.

TADPOLE, a young frog, before it has disengaged itself from the membranes that envelope it in its first stage of life. See RANA.

TENIA, in zoology, a genus of insects, belonging to the order of vermes zoophyta; the body of which is of an oblong form, and composed of evident joints or articulations, in the manner of the links of a chain, with a mouth and visera in each joint; so that the joints, which are exceedingly numerous, are in some measure so many distinct animals, and can live independent of each other.

There are four species; the folium, or tape-worm, is found in the bowels of men, and filhes, and frequently extends to many yards in length. See Medicine, p. 160.

TENIA, in architecture, a member of the Doric capital, resembling a square fillet, or regret; it serves instead of a cymatium.

TAPPETY, in commerce, a fine smooth silken stuff, remarkably glossy.

TAGESES, in botany, a genus of the fungenia polygama superflux class. The receptacle is naked; the papus has five straight awns; the calix consists of one tubulouis leaf with five teeth; and there are five perisephalous scales in the radius. The species are three, all natives of America.

TAGUS, the largest river of Spain; which, taking its rise on the confines of Aragon, runs south west through the provinces of New Catalonia and Extremadura; and passing by the cities of Aranjuez, Toledo, and Alcantara, and then crossing Portugal, forms the harbour of Lisbon, at which city it is about three miles over; and about eight or ten miles below this, it falls into the Atlantic ocean.

TAJACU, in zoology, a species of hog. See Sus.

TAIL, the train of a beast, bird, or fish; which, in land animals, serves to drive away flies, &c. and in birds and fishes, to direct their course, and affist them in ascending or descending in the air or water.

TAILZIE, in Scots law. See Law, Tit. xxviii. 8, &c.

TAINE, a port-town of Ross-shire, in Scotland, situated on the south side of the frith of Sutherland, seven miles north of Cromarty: W. long. 3° 38', N. lat. 58°.

TALC, in natural history, a large class of fossil bodies, composed of broad, flat, and smooth lamine or plates, laid evenly and regularly on one another; easily filings, according to the size of these plates, but not all so in any other direction; flexible, and elastic; bright, shining, and transparent; not giving fire with steel, nor fermenting with acid menstrua, and retaining the force of a violent fire without calcining.

TALENT, money of account among the ancients. Among the Jews, a talent in weight was equal to 60 maneh, or 113 lb. 10 oz. 1 dwt. 10½ gr.

TALIO, lex taliouis, a species of punishment in the Mosaic law, whereby an evil is returned similar to that committed against us by another; hence that expression, eye for eye, tooth for tooth.

TALISMANS, magical figures cut or engraved with superficialious observations on the charateristics and configurations of the heavens, to which some astrologers have attributed wonderful virtues, particularly that of calling down celestial influences. The talismans of Samothrace, so famous of old, were pieces of iron formed into certain images, and set in rings; these were esteemed preservatives...
TANNING is the art of preparing raw hides or skins for the hand of the currier; or for immediate use, without any further operation.

The first part of this definition includes all leather used for the upper part of shoes, coaches, coach harness, saddle-leather, &c. and the last, the manufacture of bin or backs, &c.

We shall first give a general account of the process of manu-
manufacturing leather comprehended under the first part of the definition; and then explain separately the particular operations comprehended under the general processes.

When the hide or skin is received raw from the hand of the butcher, it is thrown into a water-dub or other piece of water, to cleanse it from the blood and gore; after which, the horns and tail are cut off: then it is put into the lime, and wrought there according to the directions given below; from thence it is wrought into the bate, and cleansed there from the lime, &c. It is next transferred to the ooze; and when properly filled, according to the directions on that head, it is conveyed to the tann-pit, where it is tanned; which when properly filled, according to the directions given below; the horns and tail are cut off: then it is put into the lime, and wrought there according to the directions given below; from thence it is wrought into the bate, and cleansed there from the lime, &c. It is next transferred to the ooze; and when properly filled, according to the directions on that head, it is conveyed to the tann-pit, where it is tanned; which finishes the process.

Before we proceed, it will be necessary to give a short view of the nature and structure of leather, which will contribute to explain the reason of the different operations it passes through.

All hides or skins, when received from the hand of the butcher, are a bundle of connected tubes, somewhat resembling a honeycomb fixed on a basis; on the flesh-side, of an extreme close texture; but all open on the hair or grain side. These tubes contain a fatty or mucilaginous kind of matter; which, if allowed to remain in a fluid state, would corrupt the leather, and, if dried in the hide, would not only occasion a crisp or hardness in the leather, and be easily softened by moisture; but would also, in the course of tanning, in a great measure oppose every substance that can be applied to consolidate and preserve the hide from corruption.

To extract this matter; to swell and expand the pores as much as they can bear, without a diffusion of parts, in order to increase the thickness, and the more easily to re-fill or introduce a matter less subject to changes from drought and moisture; to preserve the fibres that compose the leather from putrefaction; and to consolidate the whole into one durable mass; are the ends proposed by the several operations of tanning.

The extraction of the matter contained in the pores being the first aim of the tanner, the first step is to open and expand the fibres, that the matter may be the more easily ejected, in order to give room for the subsequent reception of the tan. This is done by common laked lime infused in water, and is made up in a pit built with stone, of a length sufficient to contain a packing hide, but seldom so broad as to allow it to lie at its full breadth. The hides are generally treated in the lime in the following manner. They are thrown into a lime-dub, of a weak or flack complexion at first; where they are drawn out and thrown in twice or thrice every day, for a few days. They are then conveyed to a lime of a stronger quality, and drawn as before, though perhaps not so often; once in a day, or once in two days when they are further advanced, may suffice. After they have lain there for ten or fourteen days, the strength of the lime may be increased, or they may be carried to one of a stronger nature, where they are drawn and returned as before till they be completely limed.

As the hastening and retarding the operation in particular cases may be necessary; and as it is material for the quality of the leather, that the lime should make an equal impression upon the hide; or rather, if possible, that the weaker parts should be saved, and the stronger more exposed; the following observation may be of use. In most yards there

are from 20 to 40 hides or upwards wrought in a lime at a time. When these hides are all thrown in, they must necessarily be made to lie spread out upon one another, as close as possible, to take up little room. By this means those that are near the bottom of the pit will be squeezed so closely together by the pressure of the superior hides, that the water, the medium by which the lime is communicated to them, will be almost entirely excluded from acting upon the body of the hide, while the bellies and other outer skirts will be exposed to its full force. For this reason, it is necessary to change their position often, that the different parts of the hides may have nearly the same opportunity of being impregnated with the lime; and in this view, since drawing in the limes is necessary, it is also evident, that no prejudice can accrue to the leather from the frequent repetition of it, but may be greatly hurt if it is neglected. The often drawing of leather must not only bring on the operation more equally, but must at the same time quicken the effect of the lime, as the exposure of the hide to the air and lime by turns will give it an opportunity of acting with greater force. Besides, the workman has it in his power, every time the dub is drawn, either to add new strength to it (if necessary) by giving more lime, or to make it exert the strength it already possesses by stirring or raking the lime from the bottom. Thus the workman has it greatly in his power to accelerate or retard the operation as he shall think proper. Small leather ought to be drawn oftener than large, as it is not so able to resist the strength of the lime. During very hot weather the lime will operate more quickly than in cold; therefore the workman ought to pay a stricter attention to the state of his limes at that time, and draw oftener. The rays of the sun, if allowed to act any time on the leather when it is in the draught, will greatly hurt it.

From the above hints, the workman will be enabled to form some judgment how to vary his work according to the different circumstances that may occur. And here it would seem requisite, that some directions should be given for knowing when the leather is sufficiently limed. But it is impossible to convey ideas in an intelligible manner by words, which can only be acquired by practice and frequent observation. Only we may observe in general, as the hide becomes limed, it leaves the original raw fleshly appearance, has more of the appearance of being boiled, and becomes more plump and fpongy. But all these appearances are the more visible in proportion as the leather is over-done; and therefore it would be extremely dangerous for a person without experience to truft to the above marks. However, though the time taken to perform this operation may be much varied; yet the ordinary time for a middling hide is from 4 to 6 weeks, and so in proportion for larger and smaller leather.

The hide is now stripped of its hair, and all the slimy fatty stuff separated from the leather that is found adhering to the flesh-side; the first of which operations is called hairing, and the last fleshing. After which, as it is the workman's aim to discharge the matter contained in the pores of the leather, as also the particles of lime that may have infinuated themselves during the liming; and as the lime will be found to have communicated a degree of elasticity to the fibres, and a tenacious quality to the matter; it is necessary to unbrace and relax the fibres, and bring the matter-
to be ejected into a greater state of fluidity before we attempt to repel it. An infusion of hen or pigeon dung and water, (which is called a bait,) has been found to be the most effective thing for answering the above end. Into this infusion the hides are thrown promiscuously, where they are drawn in the same manner as directed in the article of liming; and in proportion to the draughts given, the strength of the leather, trim of the bait, &c. the workman will find his point gained from 4 to 8 days: he will find the leather reduced to a soft mellow confidence without any corruption or decay of parts, the matter more fluid and less tenacious, and easily separable from the hide upon working it on the beam with the tanner's knife: but as once working cannot purify the hide, the workman must soak it in water, and work it on the beam, alternately, such a number of times as his judgment shall direct, in order to purge it thoroughly; and as it was observed before, that all the pores of the leather were open on the grain-side, most of the work should be applied on that side. As a putrefaction or corruption of the parts, or an extention of the fibres beyond their proper tone, can never be remedied when once begun, the over-doing or undue management either in baiting or liming, must be equally fatal. To obtain the ends proposed by these two operations, and at the same time to guard against their bad effects, require more experience and knowledge in the nature of leather than any other operation it has afterwards to go through.

Of Oozing.

The hide, when ready for the oozes, ought to be nothing but a bundle of empty tubes void of all fluid matter; that is, composed of nothing but what is called the solids of the hide, without any decay or corruption.

It is now the tanner's business to fill these tubes or pores with a more durable matter, in order to support the fabric of the leather; which is the end of oozing. A number of different substances have been tried for this purpose; but none are equal to oak-bark. This bark, after it is thoroughly dried, is pounded, or rather bruised with a mill or other instrument; the powder is sifted out for the purpose of making up oozes, which is only an infusion of this powder in common water; an old or exhausted ooz (if not begun to corrupt) may be renewed by adding more bark, according to the strength of the oooze required. This liquor is deposited in a number of handlers or duders, (as they are called,) as occasion requires, and the hides are thrown promiscuously into it, where they must be drawn and returned much in the same manner as directed in the article of liming, and carried from a weaker to a stronger ooze as the leather shall require, till they are found to be sufficiently filled. It will be found, that the finer particles of the bark will infinuate themselves into the pores of the leather, and lodge there; and at the same time the astringent quality will strengthen and brace the fibres, and bring them again to their proper tone, after their relaxed state in the bait, which will make the leather appear to swell, and feel plump and soft. Here again no rule can direct an inexperienced person to know when a hide is properly oozed; and indeed some kinds of leather require a greater and some a lesser degree of it, according to the purpose for which it is intended; but in general, there is left danger in oozing plentifully than in being sparing of it, as it always adds to the weight and beauty of the leather. A middling hide may be oozed in three weeks, and sooner or later in proportion to the strength of the ooze, the number of draughts, and heat of the weather.

Of Lopping, or what is more properly called Tanning.

This part of the operation is designed to preserve the fibres from corruption, and at the same time to consolidate the whole into one compact body; or, in some few cases, it may be called lignifying the hide, (if the term may be allowed.) This must evidently be the work of time, as the nature of the fibres must be in a great measure changed, and the new-imbibed matter incorporated and consolidated with them. In order to perform this, the hides are spread out at their full breadth and length in a vat, and a stratum of beat bark thrown between each of them. This vat holds at first as much liquor as will just cover the hides; and in this situation they are allowed to lie till the strength of the bark is thought to be exhausted, which is commonly from four to six weeks; and the operation is repeated till the hides are sufficiently tanned, and which is generally from two to four times, according to the strength of the leather. The bark should be ronder beat, and more given to the lop, for large hides than small ones; and consequently larger leather should lie longer in the lop.

Of Currying.

The leather, when only tanned, is not sufficiently soft and pliable to answer a number of purposes. The currier's province is to reduce the leather to the proper thickness, pliability, and colour, requisite for the different uses to which it is applied; and though there is a material difference in the method of manufacturing the several kinds, and a good deal of dexterity required; yet what could be here said of them would be of little use to those who are unacquainted with the business. We shall therefore reduce all we are to lay on this subject to a general detail of the process.

The leather, after it has dripped some time from the tan-pit, is shaved on an upright beam with a knife whose edge is turned on the one side, and with which the currier can take down the leather in the same manner as a wright can take a shaving from a piece of wood with his plane. After the currier has thus levelled the hide or skin to his purpose, (which is always done on the flesh-side,) he spreads it out on a stone or table made for the purpose, and there scores it on the grain-side from all the loose tan, and other fluff that may hurt the beauty of the grain. He then puts on a certain quantity of oil on both grain and flesh side, for the purpose of softening the fibres, and at the same time making them tough, and hangs it up to dry. When it is sufficiently dry, there is a thin shaving again taken off the flesh-side, in order to clean or brighten it up; and then it is rubbed backward and forward upon a table by the currier with a nicked or furrowed board, keeping the leather always doubled at the place where he rubs, till it be made soft and pliable to his intention. This last part of the operation is properly called Currying, and it is from this that the business gets its name. As to the colour, the leather is fair or dark in proportion to the quantity of oil laid on, if the tanning has been properly performed, and the currier do not neglect some material part of his duty. Curriers seldom dye any colour but black, which is done with copperas and a very little logwood.

latter may be brought, by habit, to relish what at first excited loathing and disgust; yet it does not seem to have been the intention of nature, that the generality of mankind should acquire by custom and experience those sentiments and perceptions which are necessary to their preservation. It is otherwise with the intellectual taste: its formation requires time, instruction, and experience. A young man uninstructed in the arts of music and painting, let his natural sensitiveness be ever so quick and lively, will not immediately distinguish, in a grand concert of music, the various parts whose connection and relation constitute the elegance and charm of the composition; nor will he perceive in a picture the gradations of light and shade, that harmony of colours, that correctness of design, which characterizes a finished piece; but in process of time, and also by degrees, he learns both to hear and to see in a more perfect manner. The same uninstructed person will find a variety of emotions arise in his mind the first time he is present at the representation of a fine tragedy: but he will neither perceive the dexterity of the author in maintaining the unity; nor that exquisite art by which the drama is managed, that no person enters upon the scene nor quits it without an evident reason; nor yet that full more nice and difficult art of making the various subordinate interests terminate and centre in one, which absorbs them all. Thus the only force of habit and reflection, that he will distinguish these several objects of taste, and feel delightful sensations from circumstances of which formerly he had little or no idea.

Elegant and able artists may communicate their feelings and their discernment to others, and thus excite taste in a nation, which, without them, had never known its refined pleasures. By frequently contemplating the works of great and eminent masters in the various arts, the powers of nature arise into taste; and we imbibe, as it were, the spirit of those illustrious men, so as to come at length to look at a gallery of paintings with the eyes of a Le Brun, a Poussin, or a Le Sueur; nay, we even read works of learning and genius with a portion of that spirit that appears in their composition.

If, in the first periods of the culture of the arts and sciences, it has sometimes happened, that a whole nation have been unanimous in the praise of authors full of defects, and whom succeeding ages have beheld with indifference, and even with contempt; the reason is, that these authors had natural beauties which were perceived by all, while that just discernment that was necessary to distinguish their numerous defects, and which is left to the gift of nature, than the result of taste, habit, and reflection, was as yet acquired by none. Thus Lucilius, who had been in the highest reputation among the Romans, sunk into oblivion when Horace arose; and Regnier was universally admired by the French, until Boileau appeared; and if there are several ancient authors, who have maintained their credit, notwithstanding the absurdities that are to be found in every page of their writings, it must be the authors of those nations, among whom no judicious and correct writer has appeared to open their eyes, like Horace among the Romans, and Boileau among the French.

It is a common saying, that there is no disputing about tastes; and if by the taste here be understood the palate, which loves certain aliment and revolts others, the maxim is just; because it is needless to dispute about what cannot be corrected, or to attempt reforming the constitution and mechanism of organs merely corporeal. But the maxim is false and pernicious, when applied to that intellectual taste which has for its objects the arts and sciences. As these objects have real charms, so there is in reality a good taste which perceives them, and a bad one which perceives them not; and there are certain methods by which we may often correct those mental defects which produce a depraved taste. But it must be granted, at the same time, that there are certain phlegmatic spirits, which nothing can enflame; and also certain distorted intellects, which it is impossible to rectify; with such therefore, it is in vain to dispute about tastes, because they have none at all.

In many things taste seems to be of an arbitrary nature, and without any fixed or uniform direction, such as in the choice of dress and equipage, and in every thing that does not come within the circle of the finer arts. In this low sphere it should be distinguished by the name of fancy, rather than taste. In this sphere it is fancied, rather than taste, that produces such an endless variety of new and contradictory modes.

The taste of a nation may degenerate and become extremely depraved; and it almost always happens, that the period of its perfection is the forerunner of its decline. Artists, through the apprehension of being regarded as mere imitators, strike out into new and uncommon paths, and turn aside from the beautiful simplicity of nature, which their predecessors invariably kept in view. In these efforts there is a certain degree of merit, which arises from industry and emulation, and calls a veil over the defects which accompany their productions. The public, fond of novelty, applauds their invention; but this applause is soon succeeded by fatigue and disgust. A new set of artists start up, invent new methods to please a capricious taste, and depart still further from nature than those who first ventured from its paths into the wilds of fancy. Thus the taste of a people degenerates into the grossest corruption. Overwhelmed with new inventions, which succeed and efface each other with incredible rapidity, they scarcely know where they are, and call back their eager and anxious desires towards the period when true taste reigned under the empire of nature. But they implore its return in vain; that happy period cannot be recalled; it departs, however, in the custody of certain choice spirits, the sublime pleasures of true taste, which they cherish and enjoy in their little circle, remote from the profane eye of the depraved and capricious multitude. There are vassal countries, where taste has not yet been able to penetrate. Such are those uncivilized nations, where civil society has never been brought to any degree of perfection, where there is little intercourse between the sexes, and where all representations of living creatures in painting and sculpture are severely prohibited by the laws of religion. Nothing renders the mind so narrow, and so little, if we may use that expression, as the want of social intercourse; this confines its faculties, blunts the edge of genius, damns every noble passion, and leaves it in a state of languor and inactivity very principles that could contribute to the formation of true taste. Besides, where several of the finer arts are wanting, the rest must necessarily languish and decay, since they are inseparably connected together, and mutually support each other. This is one reason, why the Asiatics have never excelled in any of the arts; and hence also it is that true taste has been confined to certain countries in Europe.
TAW (880) TAW

TAW (889) TAW

TATA, or SIND, the capital of a province of the same name in the Hither India, in Asia, situated at the mouth of the Indus: E. long. 68°, N. lat. 25° 45'.

TAT-TOO, a beat of a drum at night, to advertise the soldiers to retreat or repair to their quarters in their garrisons, or to their tents in a camp.

TAU, or Taw, in heraldry, an ordinary in figure of a T, supposed to represent St. Andrew's crofs, or a cross potent, the top part cut off. See CROSS.

TAVASTUS, the capital of the province of Tavastia, in the territory of Finland in Sweden, situated eighty-four miles north-east of Abo: E. long. 24°, N. lat. 61° 20'.

TAUDENT, or Tau'ra, in the sea-language, signifies the name as plait, or fast: thus, to fast taught the throuts on stays, is to make them more light and stiff.

TAVISTOCK, a borough of Devonshire, thirty-two miles south-west of Exeter. It sends two members to parliament, and gives the title of marquis to the noble family of Ruffels dukes of Bedford.

TAUNTON, a borough of Somersetshire, twenty miles south-west of Wells. It sends two members to parliament.

TAURIS, or Tabris, a city of Persia, four hundred miles north of Tifhan: E. long. 46° 30', N. lat. 38° 20'.

TAURUS, the bull, in zoology. See Bos.

TAURUS, in astronomy. See Astronomy, p. 847.

TAUTOLOGY, a needless repetition of the same thing in different words.

TAWING, or Taw (889), the art of dressing skins in white, so as to be fit for divers manufactures, particularly gloves, &c.

All skins may be tawed: but those chiefly used for this purpose are lamb, sheep, kid, and goat skins.

The method of tawing is this: Having cleared the skins of wood or hair, by means of lime, they are laid in a large vat of wood or flone, set on the ground full of water, in which quick-lime has been skimed; wherein they are allowed to lie a month or six weeks, according as the weather is more or less hot, or as the skins are required to be more or less soft and pliant.

While they are in the vat, the water and lime is changed twice, and the skins are taken out and put in again every day; and when they are taken out for the last time, they are laid all night to soak in a running water, to get out the greatest part of the lime; and in the morning are laid together by fives one upon another, upon the wooden leg and are scraped and rubbed one after another, to get the flesh off from the fliny side, with a cutting two-handled instrument called a knife; and then they are cut off the legs, (if they are not cut off before) and other superficial parts about the extremities. Then they are laid in a vat or pit with a little water, where they are fulfilled with wooden pelles, for the space of a quarter of an hour; and then the vat is filled up with water, and they are rinsed in it.

In the next place, they are thrown on a clean pavement to drain, and afterwards cast into a fresh pit of water, out of which they rinse them well, and are laid again on the wooden leg, fix at a time, with the hair-side outwards; over which they rub a kind of whetstone very briskly, to soften and fit them to receive four or five more preparations, given them on the leg, both on the flesh-side and the hair-side, with the knife, after the manner above-mentioned.

After this they are put into a pit of water and wheaten-bran, and stirred about in it with wooden poles, till the bran is perceived to stick to them, and then they are left: as they rise of themselves to the top of the water by a kind of fermentation, they are plunged down again to the bottom; and at the same time fire is set to the liquor, which takes as easily as if it were brandy, but goes out the moment the skins are all covered.

They repeat this operation as often as the skins rise above the water; and when they have done riling they take them out, lay them on the wooden leg, the fliny side outwards, and pass the knife over them to scrape off the bran.

Having thus cleared them of the bran, they lay the skins in a large baker, and load them with huge stones to promote their draining; and when they have drained sufficiently, they give them their feeding, which is performed after the manner following:

For one hundred of large sheep-skins, and for smaller in proportion, they take eight pounds of alum, and three of sea-salt, and melt the whole with water in a vessel over the fire, pouring the dissolution out, while yet lukewarm, into a kind of trough, in which is twenty pounds of the finest wheat flower, with the yecks of eight dozen of eggs; all of which is formed of kind of paste, a little thicker than children's pap; which, when done, is put into another vessel, to be used in the following manner.

They pour a quantity of hot water into the trough in which the paste was prepared, mixing two spoonfuls of the paste with it; to do which they use a wooden spoon, which contains just as much as is required for a dozen of skins: and when the whole is well diluted, two dozen of the skins are plunged into it; but they take care that the water be not too hot, which would spoil the paste and burn the skins.

After they have lain some time in the trough, they take them out, one after another, with the hand, and stretch them out; they do twice; and after they have given them all their paste, they put them into tubs, and there full them afresh with wooden pelles.

Then they put them into a vat, where they are suffered to lie for five or six days, or more; then they take them out in fair weather, and hang them out to dry on cords or racks; and the quicker they are dried the better: for if they be too long a drying, the salt and alum within them are apt to make them rise in a grain, which is an essential fault in this kind of dressing.

When the skins are dry, they are made up into bundles, and just dip in fair water, and taken out and drained; and being thrown into an empty tub, and after having lain some time are taken out and trampled under foot.

Then they draw them over a flat iron-instrument, the top of which is round like a battoedere, and the bottom fixed into a wooden block, to stretch and open them; and having been opened, they are hung in the air upon cords to dry; and being dry, they are opened a second time, by pulling them again over the same instrument.

In the last place they are laid on a table, pulled out, and laid smooth, and are then fit for sale.

TAX, a tribute rated upon every town, which formerly...
TEA, or Thea, in botany, a genus of the polyandria mono-
cycous. A shrub grows to five or six feet high, and is very
vigorously. The leaves are about an inch long, near half an
inch broad, serrated, and terminating in a point. The
corolla consists of five petals, inserted into the receptacle; and the
gynoecium consists of three segments; the female has no stigmas; and the berry
contains one seed. There are two species, both natives of China.

This shrub grows to five or six feet high, and is very
vigorously. The leaves are about an inch long, near half an
inch broad, serrated, and terminating in a point. The
traders in tea distinguish a vast many kinds of it, as they
differ in colour, flavour, and the size of the leaf. To
evaluate the several subdistinguishions were endless; the
common green tea has somewhat small and crumpled leaves,
much convoluted, and closely folded together in the dry-
ing. Its colour is a dusty green, its taint agreeable. It gives the water a strong yel-
lowish green colour. The fine green has larger leaves,
less rumpled and convoluted in the drying, and more
fresh and agreeable, yet more agreeable taste than the for-
der. It gives a pale-green colour to water. To this
kind are to be referred all the higher priced green teas,
the hyson, imperial, &c. The bohea consists of much
smaller leaves than either of the other, and those more
crumpled and closely folded than in either. It is of a
darker colour than the other, often blackish; and is of
the smell and taint of the others, but with a mixed sweet-
ness and astringency. The green teas have all somewhat
of the violet-flavour: the bohea has naturally somewhat of
the rose-flavour. The leaves when gathered are dryed
with great caution, partly by the help of heat, partly
by the air, and when thoroughly prepared will keep a
long time fresh and good. Every parcel, when dryed,
though gathered promiscuously, is separated, according
to the largeness and smallness of the leaves, into three
or four different kinds, each of which is of a different
price, and has its different name. The bohea tea is ga-
thered before the leaves are perfectly opened, and is
made to undergo a greater degree of heat in the curing,
to which its colour and peculiar flavour is in a great mea-
sure owing.

Tea, moderately and properly taken, acts as a gentle
affluent and corroborative.

TEA, in botany. See ANAS.

TEANS, a lymph or aqueous humour, which is subtle,
lipid, and a little saltish: it is separated from the arte-
rial blood by the lachrymal glands, and small gland-
ulous grains on the inside of the eye-lids. See ANATO-
MY, p. 294.

TENETH, the tenth month of the Jewish ecclesiastical
year, and fourth of the civil. It answers to our month
of December.

TECKLENSBURG, a city of Germany, in the circle of
Westphalia, capital of a county of the same name, thir-
teen miles south-west of Olmbrug, subject to its own
count: E. long. 7° 20', N. lat. 52° 21'.

TECHNICAL, expresses somewhat relating to arts or
sciences: in this sense, we say technical terms.

TE DEUM, the name of a celebrated hymn, used in the
Christian church, and so called because it begins with
these words, Te Deum laudamus: "We praise thee, O
God." It is sung in the Romish church, with great pomp
and solemnity, upon the gaining of a victory, or other
happy event.

TEES, a river which rises on the confines of Cumberland;
and running eastward divides the county of Durham
from Yorkshire, and falls into the German sea below
Stockton.

TEFLIS, the capital of Persia; Georgia in Asia, situate on
the river Kura, or Cyrus, three hundred miles north of
Tbilissi, and as many south of Astracan: E. long. 47°
20', N. lat. 43°.

TEGAPEATAN, a port-town of the hither India, in Asia,
near Cape Comorin, eighty miles south of Cochin, and
a hundred and fifty north-west of Colombo in Ceylon: E.
long. 76°, N. lat. 8°.

TEGUMENT, any tiling that surrounds or covers ano-
ther.

TEHAMA, one of the divisions of Arabia Felix in Asia,
situate on the Red-sea, between the provinces of Mecca
and Hadramut.

TEINTS and Semi-teints, in painting, denotes the fe-
veral colours used in a picture, considered as more or less
bright, deep, thin, or weakened, and diminifhed,
&c. to give the proper relief, softness, or diftance, &c.
of the several objects.

TEISSE, or Teys, a river of Hungary, which rises in the
Carpathian mountains; and running from east to west,
passes from Tokay; then turning south, passes by Zol-
neck and Segedin; and having joined the river Merih, falls
into the Danube, opposite to Salankam.

TELEMON, a name given to those figures or half figures
of men so commonly used, instead of columns or pilasters,
to support any member in architecture, as a balcony, or
the like.

TELEPHIUM, in botany, a genus of the pentandria tri-
gynia class. The calyx consists of five leaves; and the
corolla of five petals, inserted into the receptacle; and the
capsule has one cell and three valves. The species are
two, none of them natives of Britain.
TELESCOPE. See Optics, p. 421.

TELESIN, a province of the kingdom of Algiers, in Africa, situated on the confines of the empire of Morocco.

TELLER, an officer of the exchequer, in ancient records called tallier. There are four of these officers, whose duty is to receive all sums due to the king, and to give the clerk of the pells a bill to charge him therewith. They likewise pay all money due from the king, by warrant from the auditor of the receipt; and make weekly and yearly books, both of their receipts and payments, which they deliver to the lord treasurer.

TELICHERRY, a port-town on the Malabar coast, in the Hither India, thirty miles north of Calicut: E. lon. 75° N. lat. 12°.

TEMESWAER, the capital city of the Bannat of Temeswaer, lately annexed to Hungary, sixty miles north-east of Belgrade: E. long. 22°, N. lat. 45° 55'.

TEMPERAMENT, among physicians, denotes the same conformation of the human body, whereby it may be denominated hot, cold, moist, dry, bilious, sanguine, phlegmatic, melancholy, &c.

TEMPLARS, a religious order instituted at Jerusalem, about the year 1118. Some religious gentlemen put themselves under the government of the patriarch of Jerusalem, renounced property, made the vow of celibacy and obedience, and lived like canons regular. King Baldwin assigned them an apartment in his palace. They had likewise lands given them by the king, the patriarch, and the nobility, for their maintenance. At first there were but nine of this order, and the two principal persons were Hugo de Paganis, and Geoffrey of St Omers. About nine years after their institution, a rule was drawn up for them, and a white habit assigned them, by pope Honorius II. About twenty years afterwards, in the popedom of Eugenius III. they had red crosses sewed upon their cloaks, as a mark of distinction; and in a short time they were increased to about three hundred, in their convent at Jerusalem. They took the name of Knights Templars, because their first house stood near the temple dedicated to our Saviour at Jerusalem. This order, after having performed many great exploits against the infidels, became rich and powerful all over Europe; but the knights, abusing their wealth and credit, fell into great disorders and irregularities. Many crimes and enormities being alleged against them, they were proscribed in France, Italy, and Spain; and at last, the pope, by his bull of the 22d of May 1312, given in the council of Vienna, pronounced the extinction of the order of Templars, and united their estates to the order of St John of Jerusalem.

TEMPLE, a general name for places of public worship, whether pagan, Christian, or otherwise. But the word, in a restrained sense, is used to denote the places, or edifices, in which the pagans offered sacrifice to their false gods.

TEMPORAL, a term generally used for secular, as a distinction from ecclesiastical. Thus we say temporal lords, and spiritual or ecclesiastical lords.

TEMPORUM OSSA. See Anatomy, p. 155

TENAILLE, in fortification. See Fortification, p. 619.

TENANT, one that holds lands or tenements of some lord, or landlord, by rent, fealty, &c. See TACK.

TENBURY, a market-town of Worcestershire, fifteen miles north-west of Worcester.

TENBY, a port-town of Pembroke-shire, situated on Bristol channel: W. long. 4° 45', N. lat. 51° 40'.

TENEBRIO, a genus of insects belonging to the ordercoleoptera. The left joint of the antennae is roundish; the breast is somewhat convex, and margined; and the elytra are hard. There are 33 species, principally distinguished by their colour.

TENEDOS, one of the smallest islands of the Archipelago, situated near the coast of Jaffa, west of the ruins of Troy. E. long. 27°, N. lat. 39° 30'.

TENEMENT, property signifies a house; but in a larger sense it is taken for any house, land, rent, or other thing, which a person holds of another.

TENERIF, one of the largest of the Canary Islands, situated in the Atlantic Ocean: W. long. 17°, N. lat. 28°, being about 130 miles in circumference. It is a fruitful island, abounding in corn, wine, and oil; though pretty much incumbered with mountains, of which the most remarkable is that called the Pico of Tenerif, being one of the highest mountains in the world, in the form of a sugar-loaf, the white top whereof may be seen at sea upwards of one hundred miles.

TENES, a province of the kingdom of Algiers, in Africa.

TENEBRUS, in medicine, a name given by medical writers to a complaint which is a continual desire of going to stool, but without any stool being ready to be voided. This is usually attended with some tumour, sometimes with a very considerable one, in the part. This is properly no primary disease, but merely a symptomatic one, and differs in degree according to the disea on which it is an attendant.

TENOR, or Tenour, the purport or content of a writing or instrument in law, &c.

Action of proving the Tenor, in Scots law. See Law, Tit. xxx. 22.

TENOR, in music, the first or principal part, or that which is the ordinary pitch of the voice, when neither raised to a treble, nor lowered to a bass.

TENSE, in grammar, an inflection of verbs, whereby they are made to signify, or distinguish the circumstance of time, in what they affirm. See Grammar.

TENT, in surgery, a roll of lint worked into the shape of a sugar-loaf, the white top whereof may be seen at sea upwards of one hundred miles.

TENT, in surgery, a roll of lint worked into the shape of a sugar-loaf, the white top whereof may be seen at sea upwards of one hundred miles.

TENT, in grammar, an inflection of verbs, whereby they are made to signify, or distinguish the circumstance of time, in what they affirm. See Grammar.

TENT, in surgery, a roll of lint worked into the shape of a sugar-loaf, the white top whereof may be seen at sea upwards of one hundred miles.

TENT, in surgery, a roll of lint worked into the shape of a sugar-loaf, the white top whereof may be seen at sea upwards of one hundred miles.

TENT, in surgery, a roll of lint worked into the shape of a sugar-loaf, the white top whereof may be seen at sea upwards of one hundred miles.

TENT, in surgery, a roll of lint worked into the shape of a sugar-loaf, the white top whereof may be seen at sea upwards of one hundred miles.
TERM, in general, signifies much the same with boundary or limit.

TERM, in law, is generally taken for a limitation of time or estate: as a lease for term of life, or years.

TERM, in grammar, denotes some word or expression of a language.

TERM in the arts, or Term of art, is a word which, besides the literal and popular meaning which it has, or may have, in common language, bears a further and peculiar meaning in some art or science.

TERMINALIA, in antiquity, feasts celebrated by the Romans, in honour of the god Terminus.

TERMINATION, in grammar, the ending of a word, or last syllable thereof.

TERNATE, the northernmost of the Molucca or Clove islands, in the possession of the Dutch.

TERRA. See Geography, and Astronomy.

Terra firma, in geography, is sometimes used for a continent, in contradistinction to islands.

Terra del Fuego, an island of South America, from which it is separated by the straits of Magellan.

Ter R/E FILIUS, Son of the Earth, & student of the Romans, in honour of the god Terminus.

TERRENN, at a town of Artois, in the French Netherlands, and thereby the tenant was, at his own expense, obliged to follow his lord into the wars. Knight's service and chivalry; when lands were held of the king, or mefnal lord, to perform service in war. Burgage tenure; land held of the lord of the burrow, at a certain rent.

Terrier is also used for a small hound. See Canis.

TERIER, a book, or roll, wherein the several lands, either of a private person, or of a town, college, church, &c. are described. It should contain the number of acres, and the site, boundaries, tenants names, &c. of each parcel.

TERRIER, in geography, an appellation given to our globe, because consisting of land and water.

TERRAQUEOUS, in geography, an appellation given to the great magnetical globe which we inhabit.

TERRAQUEOUS, in geography, an appellation given to the great magnetical globe which we inhabit.

TERRAQUEOUS, in geography, an appellation given to the great magnetical globe which we inhabit.

TERRAQUEOUS, in geography, an appellation given to the great magnetical globe which we inhabit.

TERRESTRIAL, something partaking of the nature of earth, or belonging to the globe of the earth: thus we say, the terrestrial globe, &c.

TERRIA, in botany. See Pistacia.

TERIES, in anatomy. See Anatomy, p. 195.

TERGOWISCO, the capital of Wallachia, in European Turkey, eighty miles south-east of Hermannstadt in Transylvania: E. long. 26° 30', N. lat. 45° 35'.
made of curious square marbles, bricks, or tiles, called telesela, from the resembling dice.

Tessin, a river of Italy, which, taking its rise in the Alps, runs through the country of the Grisons and the lake Maggiorn; and then, turning south-east through the Milanese, passes by Pavia, and falls into the Po, a little below that city.

Test, a vessel of the nature of the coppers, used for large quantities of metals at once.

Test-liquor, a liquor used by dealers in brandies, to prove whether they be genuine, or mixed with home-spirit.

Testo, in antiquity, was particularly used among the poets, &c. for the ancient lyre; by reason it was originally made by its inventor Mercury, of the black or hollow shell of the Testudo aquatica, or sea-tortoise, which he accidentally found on the banks of the river Nile.

The Americans find so good account in catching turtle, that they have made themselves very expert at it: they watch them from their nests on shore, in moon-light; and, before they reach the sea, turn them on their backs, and leave them till morning; when they are taken much in the same manner as

Testudo, in antiquity, was a kind of cover or screen which the soldiers, e.g. a whole company, made themselves of their bucklers, by holding them up over their heads, and standing close to each other.

This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above, when they went to the assault.

Testudo was also a kind of large wooden tower, which moved on several wheels, and was covered with bullocks hides split, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams.

It was called testudo, from the strength of its roof, which covered the workmen as the shell does the tortoise.

Tetanus, in medicine, a convulsive motion that makes any part rigid or inflexible.

Tethys, a genus of fossils belonging to the order of vermes mollusca. The body is oblong, stiffly, and without feet; the mouth consists of a cylindrical proboscis under the duplicate of a lip; and there are two foramina at the left side of the neck. The species are two, both inhabitants of the ocean.

Tetbracoa, botany, a genus of the polyandria class. The calix consists of six leaves; and there are four capsules. There is but one species, a native of America.

Tetrachord, in the ancient music, a concord consisting of four degrees or intervals, and four terms or sounds; called also by the ancients diatessaron, and by us a fourth.

Tetradrachma, in natural history, the name of a genus of fofils, of the class of the felenitae, expressing a rhomboidal body, consisting of fourteen planes.

The characters of this genus are, that the bodies of it are exactly the same form with the common felenite; but that each of the end-planes is divided into two; and there are, by this means, eight of these planes, instead of four.

Tetradriapason, a musical chord, otherwise called a quadruple diapason, or eighth.

Tetradynamia, botany. See Botany, p. 635.

Tetraedron, in geometry, one of the five regular or platonic bodies or solids, comprehended under four equilateral and equal triangles.

Tetragrammaton, a denomination given by the Greeks to the Hebrew name of God, Jehovah, because consisting of four letters.

Tetragonia, in botany, a genus of the icosaedria pentagynia class. The calyx consists of four segments; it has no corolla; and the drupa has four fides, and four cells.

There are two species, both natives of Ethiopia.

Tetragonotheca, in botany, a genus of the Jyngea polygynia superficula class. The receptacle is pellaeous; it has no pappus; and the calyx consists of one leaf, divided into four plain segments. There is but one species, a native of Virginia.

Tetragrammaton, a denomination given by the Greeks to the Hebrew name of God, Jehovah, because consisting of four letters.

Tetrandria, in botany. See Botany, p. 635.

Tetrao, in ornithology, a genus of birds, of the order of gallinacea, distinguished by having the part of the forehead near the eyes naked and papillate. There are 20 species, distinguished principally by their colour, their having rough or naked feet, &c.
TETS.APETALOUS, in botany, an epithet given to flowers that consist of four single petals or leaves.

TETRAPHARMACUM, signifies any remedy consisting of four ingredients.

TETRAPTERA, a name given to insects which have four wings.

TETRAPOTOTE, in grammar, a name given to such defective nouns as have only four caes; such are visis, pecudis, fordis, &c. being deprived of the nominative and vocative singular.

TETRAPHARMACUM, in natural history, the name of a genus of herbs, influenced in their shape by an admixture of particles of tin, and found in form of broad-bottomed pyramids of four sides.

TETRARCH, a prince who holds and governs a fourth part of a kingdom. Such originally was the import of the title tetrarch; but it was afterwards applied to any petty king or sovereign.

TETRASTYLE, in the ancient architecture, a building, and particularly a temple, with four columns in its front.

TETUAN, a town of the empire of Morocco, situated about eight miles from the bay of that name, just within the straits of Gibraltar: W. long. 6° 35′, N. lat. 35° 40′.

TEUCRIUM, in botany, a genus of the polyandria monogynia class. The corolla consists of five waved petals; and the drupa has a double-celled nucleus. There is but one species, a native of America.

TEULONIC, something belonging to the Teutons, an ancient people of Germany, inhabiting chiefly along the coasts of the German ocean: thus, the Teutonic language is the ancient language of Germany, which is ranked among the mother tongues. The Teutonic is now called the German or Dutch.

TEUTONIC ORDER, a military order of knights, established towards the close of the twelfth century, and thus called as consisting chiefly of Germans or Teutons. The origin, &c. of the Teutonic order, is said to be this. The Christians, under Guy of Lusignan, laying siege to Acre, or Acon, a city of Syria, on the borders of the Holy Land, some Germans of Bremen and Lubeck, touched at Land, some Germans of Bremen and Lubeck, touched at Lechtle in the county of Bucks, and falls into the Isis at Dorchester.

THANE, or Thain, a name of an ancient dignity among the English and Scots, or Anglo-Saxons. Skene makes thane to be a dignity equal to the son of an earl. Camden will have it, that thanes' were only dignified by the offices they bore. There were two kinds or orders of thanes; the king's thanes, and the ordinary thanes. The first were those who attended the king in his courts, and who held lands immediately of the king. The ordinary thanes, or the thani minores, were the lords of the manors, who had particular jurisdiction within their limits, and over their own tenants; they changed their names for that of barons, and hence their courts are called courts-baron to this day.

THANE, a little island of ealt Kent, formed by the branches of the Stour and the sea.

THAPSIA, in botany, a genus of the pentandria digynia class. The fruit is oblong, and surrounded with a membrane. There are four species, none of them natives of Britain.

THAWING, the resolution of ice into its former fluid state, by the warmth of the air, &c. See FREEZING.

THEA, in botany. See TEA.

THEATINES, a religious order in the Roman church, called
THEOLOGIA, in botany, a genus of the pentandria class. The calyx consists of five petals; the nectarium is bell-shaped; and the fruit is a woody cortex, of an unequal surface, with five ridges. There are two species, both natives of America.

THEOCRACY, in matters of government, a (late government, by a single person, who is never took from his place by his own will, but never lapses from his place, unless by death or his own consent. This form of government is mentioned in Scripture, as existing among the ancient Egyptians. It was also practiced among the Greeks and Romans.

THEODOLITE, a mathematical instrument much used in surveying. See Geometry, p. 701.

THEOGONY, the branch of the heathen theology, which taught the genealogy of their gods.

THEOLOGY. See Religion.

THEOPHRASTA, in botany, a genus of the pentandria class. The corolla is bell-shaped, and the capsule has one round large cell, and one seed. There are two species, a native of America.

THEOREM, a speculative proposition, demonstrating the properties of any subject.

THEORETIC, something relating to theory, or that terminates in speculation. See Theory.

THEORY, in general, denotes any doctrine which terminates in speculation alone, without considering the practical uses and application thereof.

THERAPEUTIC, a term applied to those who are wholly employed in the service of religion. This general term has been applied to particular sects of men, concerning whom there have been great disputes among the learned.

THERAPEUTICS, that part of medicine which acquaints us with the rules that are to be observed, and the medicines to be employed in the cure of diseases.

THERAPY, certain images, or superstitions figures, mentioned in scripture. Some Jewish writers tell us, the theraphim were effigies of human heads, placed in niches, and consulted as oracles. Others say, they were talismans, or figures of metal, cast and engraved under certain aspects of the planets; to which they ascribed extraordinary effects.

THERIACA ANDROMACHIA, a compound medicine, made in the form of an electuary.

THERMÆ, artificial hot baths, much used by the Romans.

THERMOMETER, an instrument for measuring the increase and decrease of the heat and cold of the air, by means of the elastic and expansive power of bodies of the fluid kind. See Pneumatics, p. 486.

THERMAL, artificial hot baths, much used by the Romans.

THESSALY, now called Epirus, a province of European Turkey.

THESSALY, now called Epirus, a province of European Turkey.

THESSALY, now called Epirus, a province of European Turkey.

THESSALY, now called Epirus, a province of European Turkey.

THESSALY, now called Epirus, a province of European Turkey.

THESSALY, now called Epirus, a province of European Turkey.

THESSALY, now called Epirus, a province of European Turkey.

THESSALY, now called Epirus, a province of European Turkey.

THESSALY, now called Epirus, a province of European Turkey.

THETFORD, the county-town of Norfolk, situated twenty-five miles south-west of Norwich. It sends two members to parliament.

THEURGY, a name given to that part of magic called white magic, or the white art. Those who have written of magic have divided it into three kinds: the first is theurgy, as operating by divine means: the second, natural magic, performed by the powers of nature: and the third, necromancy, which they imagined proceeded from invoking demons.

THIBET, one of the most powerful of the Tartar kingdoms, having China on the east, and India on the west.

THIGH, in anatomy. See Anatomy, p. 200.

THIMBLE, an instrument made of brass, iron, etc., put on the finger to thrust a needle through any cloth, silk, etc. used by all seamstresses, tailors, etc.

THINKING, a general name for any act or operation of the mind. See Logick, and Metaphysics.

THIRLAGE. See Law, Tit. xvi. 12.

THIRSK, a borough-town in the north-riding of York-
fire, situated on the river Swale, sixteen miles north-west of York. It sends two members to parliament.

THIRST, an uneasy sensation, arising from a deficiency in the saliva to moisten the inward parts of the mouth; hence arises a strong desire for drink; it is a symptom generally attending feverish disorders.

THISTLE, in botany. See Carduus.

THIRST, an uneasy sensation, arising from a deficiency in the saliva to moisten the inward parts of the mouth; hence arises a strong desire for drink; it is a symptom generally attending feverish disorders.

THISTLE, in botany. See Carduus.
THORNBURY, a market-town of Gloucestershire, situated twenty miles south-west of Gloucester.

THORNY-IsLAND, an island made by the branches of the Thames formerly, where Westminster-abbey now stands.

THORN-BY, a market-town of Gloucestershire, situated twenty miles south-west of Gloucester.

THORNEY-ISLAND is also an island situated in a bay of the East channel, between Chichester and Portsmouth.

THOUSAND, or Toulouse, a city of France, capital of France, situated on a bay of the Mediterranean sea; E. long. 5°, and N. lat. 43° 39'.

TOULON, or Toulon, a port-town of Provence, in the city of Languedoc, situated on the river Garonne; E. long. 5°, and N. lat. 43° 40'.

THRONE, a royal seat, or chair of state, enriched with ornaments of architecture and sculpture, raised on one or more steps, and covered with a kind of canopy. Such are the thrones in the rooms of audience of kings and other sovereigns.

THROWSTER, one who prepares raw silk for the weaver, by cleaning and twisting it.

THRUSH, in ornithology. See Turdus.

THULE, of the ancients, supposed to be the islands of Orkneys.

THUMB, in anatomy, one of the parts or extremities of the hand. See Anatomy, p. 121.

THUMMIM. See Urim.

THUNDER, a noise in the regions of the air, excited by sudden flashes of lightning. See Electricity, p. 480, 484.

THURINGIA LANDGRAVATE, one of the divisions of the circle of Upper Saxony, in Germany, having the Duchy of Magdeburg on the north, and Franconia on the south.

THURSDAY, the fifth day of the Christian week, but the sixth day of that of the Jews.

THURSO, a port-town of Caithness, in Scotland, situated on the Caledonian ocean, fifteen miles south-west of Dunblane.

THYATIR, a genus of the monochlaennidia class. The calix is aamentum, that of the female a strobilus; neither of them have any corolla; there is one pistillum, and one nut surrounded with an emarginated wing. The species are three, all natives of warm countries.

THYMUS, in botany, a genus of the thymus class. The calix is bilabiated, and the falk is shut up with hairs. There are eight species, two of them natives of Britain, viz. the serpillum, or common thyme; and the acinos, or wild basil.

THYMY, in anatomy. See Anatomy, p. 278.

THYROARYTENOIDES, in anatomy. See Anatomy, p. 301.

THYROIDE CARTILAGE. See Anatomy, p. 300.

THYRSUS, in antiquity, the sceptre which the poets put into the hand of Bacchus. And wherewith they furnished the menades in their bacchanalia.

TIARA, an ornament or habit wherewith the ancient Persians covered their head; and which the Armenians, and kings of Pontus, still wear on medals; these last, because descended from the Persians.

TIAHA is also the name of the pope's triple crown.

TIBER, a great river of Italy, which runs through the pope's territories, passing by Perugia and Orvieto; and having visited Rome, falls into the Tuscian sea at Ollia, fifteen miles below that city.

TIBIA, in anatomy. See Anatomy, p. 183.

TIBIALIS, in anatomy. See Anatomy, p. 209.

TIDES. See Astronomy, p. 473.

TIDE-WAITERS, or TIDESMEN, are inferior officers belonging to the customs-house, whose employment it is to watch or attend upon ships, until the customs be paid: they get this name from their going on board ships, on their arrival in the mouth of the Thames or other port, and so come up with the tide.

TIEND, in Scots law. See Law, Tit. xvii. i., &c.

TIERCE, or TIRCE, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or forty-two gallons.
TIGER, in zoology. See Felis.

TIGRIS, a large river of Turky in Asia, which, rising in the mountains of Armenia, runs southward, dividing Dar- 
beek or Mopotamia, from Cursedian or the ancient Af- 
Syria; and having passed by Budagh, joins the Euphrates 
in Eyraea Arabic, or the ancient Chaldea.

TILBURY, a fortres in the county of Essex, situated on 
the river Thames, opposite to Gravesend, twenty miles 
east of London.

TILLIA, in botany, a genus of the polyandria monogynia 
class. The corolla consists of five petals, and the calix of 
five segments; the berry is dry, and round, with five 
cells, and five valves. There are two species, only one 
of them, viz. the Europaea, or lime-tree, a native of 
Britain.

TILLIANA, in botany, a genus of the hexandria mo-

TILTLE. See Agriculture, p. 54.

TILT. in mullick, is an affection of found, whereby we de-
nominate it long or short, with regard to its continuance 
in the same degree of time. See Music.

TIMOR, and illand in the Indian ocean, situated between 
120° and 126° of east long, and between 8° and 10° 
fouth lat.

TIN (83) TOB

TIN, or TIT, or CUEVIOI-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quauncungn, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
scid between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat terra, &c.

TIT designation of dignity or quality, given to 
princes, and other persons of distinction.

TITMOUSE, in ornithology. See Parus.

TITUBATION, a kind of libration, or shaking, which the 
doth thus, for quacunquae, Virgil lays, que 

TITREM, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.

TITULO, or CHEVIOT-MOUNTAINS, are high hills on the 
bottom of hell.

TINTURIE, in grammar, a figure whereby a compound word 
is separated into two parts, and one or more words pla-
ced between them: thus, for quacunquae, Virgil lays, que 
que quauncung vacat tertae, &c.
TOMB, includes both the grave or sepulchre wherein ade-

TOLUIFERA, in botany, a genus of the decandria mono-

TOLU, a port-town of Terra Firma, situated on a bay of

TOLERATION, in matters of religion, is either civil or

TOLEN, the capital of Amuria, in Asia: E. long. 37°, and

TOCKAY, a city of Hungary, seventy miles north-east of

TOILET, in general any small instrument, used for making other more complex instruments and machines, as in most operations in the mechanic arts.

TOOL, among mechanics, denotes in general any small instrument, used for making other more complex instruments and machines, as in most operations in the mechanic arts.

TOISE, a French measure containing six of their feet, or

TOILS, snare or nets used by hunters for catching wild

TOOSES, See ANATOMY, p. 188.

TOGA, in Roman antiquity, a wide woolen gown, or

TOLEDO, a city of New Castile, in Spain; the archbi-

TOLEN, the capital of an island of the same name, in the province of Zealand, in the United Netherlands, situated four miles north-west of Bergen-op-Zoom.

TOLLENON, among the Romans, a warlike machine.

TOLU, a port-town of Terra Firma, situated on a bay of the North-Sea, an hundred miles south-west of Carthage.

TOLUM, in matters of literature, denotes a bound book, or writing that just makes a volume.

TOMENTUM, among botanists, the downy matter which grows on the leaves of some plants.

TONE, or TONE, in music, a property of sound, where-

TOPARCHY, a little state or sovereignty, consisting only of

TONGUE, in anatomy. See ANATOMY, p. 304.

TONGUE, in mosaic, a particular manner of laying or clipping the hair of ecclesiastics or monks.

TOMAE, in matters of literature, denotes a bound book, or writing that just makes a volume.

TOPIC.
TOPICAL MEDICINES, are the same with external ones, or those applied outwardly to some diseased and painful part, such as plasters, cataplasm, ungents, &c.

TOPOGRAPHY, a description or draught of some particular place, or small tract of land; as that of a city or town, promontory or tenement, field, garden, house, castle, or the like; such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

TORNE, the capital of Torne Lapmark, a province of Sweden, situated at the mouth of the river Torne, at the bottom of the Bothnic gulf, upon a little Aland made by Toricelli, a disciple of the great Galileo, which has been already explained in the Treatise of Pneumatics, p. 485.

TORBAY, a fine bay in the English channel, a little east of Dartmouth.

TORCELLA, a port town of Catalonia, in Spain, situated at the mouth of the river Ter, in E. long. 2° 50', and N. lat. 42°.

TORCELLO, in chemistry, is the roasting or scorching of a body by the fire, in order to discharge a part either unnecessary or hurtful in another operation; as sulphur is thus discharged from an ore, before the metal can be obtained to advantage.

TORCH, a luminous used in several church-ceremonies, funerals, &c. and more usually called flambeau.

TORCH-THISTLE, in botany. See CACTUS.

TORDYLIUM, in botany, a genus of the pentandria dicoum clafs. The calyx consists of eight segments, and the corolla of four petals; the seeds are roundish, naked, and fixed to a small dry receptacle. There are two species, both natives of Britain, viz. the latifolium, or purple-flowered great baffard parsley; and the nodosum, or knotted parsley.

TORUS, in architecture, a large round moulding, used in the bases of columns.

TORIFES, in the history of England, a faction or party, opposed to the whigs. See WHIGS.

The Tories are great flickers for the prerogative of the crown, as the whigs are for the liberties and privileges of the people; though, in truth, the principles of the moderate people of both parties do not greatly differ.

TORMENTILLA, in botany, a genus of the icofandria gynia clafs. The calix consists of eight segments, and the corolla of four petals; the seeds are roundish, naked, and fixed to a small dry receptacle. There are two species, both natives of Britain, viz. the erecta, or tormentil; and the reptans, or creeping tormentil.

Tormentil-root has an auffere styptic taste, accompanied with an aromatic flavour: it is one of the most agreeable and efficacious vegetable astringents.

TORNOADO, a sudden and vehement gulf of wind from all quarters, which is suddenly from mountains, whereon there have been great rains, or an extraordinary thaw of snow.

TORRE, in armorics, about the heads of moors, &c.

TORREFACTION, in chemistry, is the roasting or scorching of a body by the fire, in order to discharge a part either unnecessary or hurtful in another operation; as sulphur is thus discharged from an ore, before the metal can be obtained to advantage.

TORDYLIUM, in botany, a genus of the pentandria dicoum clafs. The calix consists of eight segments, and the corolla of four petals; the seeds are roundish, naked, and fixed to a small dry receptacle. There are two species, both natives of Britain, viz. the latifolium, or purple-flowered great baffard parsley; and the nodosum, or knotted parsley.

TORTURE, a grievous pain inflicted on a criminal, or person accused, to make him confess the truth.

TOTNESS, a borough-town of Devonshire, twenty-three miles south-west of Exeter. It sends two members to parliament.

TOUCAN, in ichthyology. See RAMPHASTOS.

Toucan, in aeronautics, P. 487.

TOUCAN, in ichthyology. See RAMPHASTOS.

TOUCAN, in aeronautics, P. 487.

TOUCH-NAIL, among alchemists, refiners, &c. little bars of gold, silver, and copper, combined together in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark it leaves on the touchstone with those of the bars.

TOUR, a luminary used in several church-ceremonies, funerals, &c. and more usually called flambeau.

TOURNIER, among alchemists, refiners, &c. little bars of gold, silver, and copper, combined together in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark it leaves on the touchstone with those of the bars.

The metals usually tried by the touchstone, are gold, silver, and copper, either pure, or mixed with one another in different degrees and proportions, by fusion. In order to find out the purity or quantity of base metal in these various admixtures, when they are to be examined they are compared with these needles, which are mixed in a known proportion, and prepared for this use. The metals of these needles, both pure and mixed, are all made into laminae or plates, one twelfth of an inch broad, and of a fourth part of their breadth in thickness, and an inch and half long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it.

The black rough marbles, the basaltites, or the softer kinds of black pebbles, are the most proper for touchstones.

Now the method of using the needles and stone is this: the piece of metal to be tried, ought first to be wiped well with a clean towel, or piece of soft leather, that you may the better see its true colour; for from this alone an experienced person will, in some degree, judge beforehand what the principal metal is, and how and with what debaup.
TRACT, in geography, an extent of ground, or a portion TOXICODENDRON, in botany. See Rhus.

TOWN, a place inhabited by a considerable number of people.

TOURNEQUET, in surgery, an instrument made of rollers, compresses, screws, &c. for compressing any wounded part, so as to stop haemorrhages. See Surgery.

TOWER, a tall building, confiding of several stories, usually of a round form, though sometimes square or polygonal.

Towers are built for fortresses, prisons, &c. as the Tower of London, the Tower of the Baffie, &c.

TOWN, a place inhabited by a considerable number of people, being of a middle size between a city and village.

TOXICODENDRON, in botany. See Rhus.

TOZZIA, in botany, a genus of the didynamia angiofermae clasi. The calix has five teeth; and the capsule is round, with one cell, containing a single seed. There is but one species, a native of Switzerland.

TRACHEA, in anatomy. See Anatomy, p. 300.

TRAÇHELIUM, in botany. See Anatomy, p. 300.

TRACHEUM, in botany. See Anatomy, p. 300.

TRACHUS, in anatomy. See Anatomy, p. 295.

TRAGUS, in anatomy. See Anatomy, p. 295.

TRAGUS, in botany. See Anatomy, p. 295.

TRAGIA, in botany, a genus of the moncecia tetrandria clasi. The calix of the male consists of three segments, that of the female of five; neither of them have any corolla; the stylus is trifid; and the capsule has three cells, with solitary seeds. There are five species, none of them natives of Britain.

TRAGOPHTON, in botany, a genus of the fungusca polygamia equalis clasi. The receptacle is naked; the calix is simple, and consists of many leaves; and the pappus is feathered. There are eleven species, two of them natives of Britain, viz. the pratenfe, or yellow goat's-beard; and the porsefolium, or purple goat's-beard.

TRAGUS, in anatomy. See Anatomy, p. 295.

TRAJAN COLUMN, a famous historical column erected in Rome, in honour of the emperor Trajan. It is of the Tuscan order, though something irregular; its height is eight diameters, and its pedestral Corinthian: it was built in a large square there, called Forum Romanum. Its base consists of twelve flones, of an enormous size, and it is raised on a fole, or foot of eight steps; within side is a stair-case, illuminated with forty four windows. It is 140 feet high, which is thirty-five short of the Antonine column, but the workmanship of the former is much more valuable. It is adorned from top to bottom with baso-relievo's, representing the great actions of that emperor against the Dacian.

TRAJECTORY of a comet, is its path or orbit, or the line it describes in its motion. See Astronomy, p. 444.

TRAIN, a line of gun-powder, laid to give fire to a quantity thereof, in order to do execution by blowing up earth, works, buildings, &c.

TRAIN OF ARTILLERY, includes the great guns, and other pieces of ordnance belonging to an army in the field.

TRAIN-OIL, the oil procured from the blubber of a whale by boiling.

TRAINING, or TRAGING, in mineralogy, a term used by the miners, to express the tracing up the mineral appearances on the surface of the earth to their original place, and there finding a mine of the metal they contain. See Mine.

TRALOS MONLES, a province of Portugal, bounded by Spain on the north-east; by the province of Beira on the south; and by Entreminho Douro on the west.

TRANSACTION, an accommodation of some business.
or dispute between two parties, by a mutual and voluntary agreement between them.

TRANSCENDENTAL, or Transcendent, something elevated, or raised above other things; which paffes and transcends the nature of other inferior things.

TRANSCRIPT, a copy of any original writing, particularly that of an act, or instrument, inferred in the body of another.

TRANSFER, in commerce, &c. an act whereby a person surrenders his right, interest, or property in any thing moveable or immoveable to another.

TRANSFORMATION, in general, denotes a change of form, or the assuming a new form different from a former one. The chemists have for a long time been seeking the transformation of metals; that is, their transmutation, or the manner of changing them into gold.

TRANSFUSION, the act of pouring a liquor out of one vessel into another.

TRANSGRESSION, an offence against some law, or a breach or violation thereof.

TRANSILVANIA, a principality bounded by the Carpathian mountains, which divide it from Poland on the north; by Moldavia on the east; by Wallachia, and part of Hungary, on the south; and by another part of Hungary on the north; being about 120 miles long, and almost as many broad; and lying between 22 and 25 degrees east long., and between 45 and 48 of north lat.

TRANSIT, in astronomy, signifies the passage of any planet, just by, or over a fixed star, or the sun, and of the moon in particular, covering or moving over any planet.

TRAVEL, or Transverse, in general, denotes something that goes athwart another, from corner to corner: thus bends and bars, in heraldry, are transverse pieces or bearings: the diagonals of a parallelogram or a square, are transverse lines.

TRAPA, in botany, a genus of the tetrandria monogynia class. The corolla consists of four petals; and the calix of four segments; and the nut has four spines opposite to one another. There is but one species, a native of Asia.

TRAPAZIUM, in geometry, a plane figure contained under four unequal right lines.

TRAPEZIUS, in anatomy. See Anatomy, p. 193.

TRANSPORTATION, the act of conveying or carrying a thing from one place to another.

TRANSUMPTION, in law. See Law, Tit. xxxii. 27.

TRAVELLER, in navigation, is a compound course, wherein several different successive courses and distances are known. See Navigation.

TRAUESTY, a French term, derived from the verb traverser, to disguise one's self, or to appear in masquerade; and hence, travelly is applied to the disfiguring of an author, or the translating him into a style and manner different from his own, by which means it becomes difficult to know him.

TREACLE. See Theriaca.

Some also give the same treacle to melasses.

TREASON, in general, signifies betraying; but is more particularly used for the act or crime of impiety to one's lawful sovereign. See Law, Tit. xxxiii. 9.

TREASURE, in general, denotes a store or stock of money in reserve.

TREASUREER, an officer to whom the treasure of a prince or corporation is committed, to be kept, and duly dispensed of.

The lord high treasurer of Great Britain, or first commissioner of the treasury, when in commission, has under his charge and government all the kings revenue, which is kept in the exchequer. He holds his place during the king's pleasure, being inlittuated by the delivery of a white staff.
TRESPASS, in law, signifies any transgression of the law, and in his gift and disposition are all the officers of the custody in the several parts of the kingdom; executors in every county are nominated by him; he also makes leaves of the lands belonging to the crown.

TREASURY, the place wherein the revenues of a prince are received, preferred, and disbursed.

Lords of the Treasury. In lieu of one single director and administrator of his majesty’s revenues under the title of lord high treasurer, it is at present thought proper to put that office in commission, i.e. to appoint several persons to discharge it with equal authority, under the title of lords commissioners of the treasury.

TREATISE, a set discourse in writing on any subject. A treatise is supposed more express, formal, and methodical than an essay, but less so than a system.

TREATY, a covenant between two or more nations; or the several articles or conditions stipulated and agreed upon between sovereign powers.

TREBLE, in music, the highest or acutest of the four parts in symphony, or that which is heard the clearest and shrillest in a concert.

TREE, the first and largest of the vegetable kind, considered as the foundation and support of all others.

TREBLE, in music, the highest or acutest of the four parts in symphony, or that which is heard the clearest and shrillest in a concert.

TREBLE, in botany. See Menyanthes.

TREFOIL. See Trifolium.

TREFOIL. See Trifolium.

TREFOIL. See Trifolium.

TREFOIL. See Trifolium.

TREFOIL. See Trifolium.

TREMOR, an involuntary shaking, chiefly of the hands and head, and sometimes of the feet, and sometimes of the tongue and heart.

TRENCHES, in fortification, are ditches cut by the besiegers, that they may approach more securely to the place attacked; whence they are also called lines of approach.

TRENT, a province of Germany, in the circle of Austria, situated on the Alps, which divides Italy from Germany, and sometimes reckoned part of Italy; it is bounded by Tyrol on the north, by the territory of Venice on the east and south, and by the country of the Grisons on the west, being seventy miles long and fifty broad, subject to the house of Austria.

TRENT is also the name of one of the largest rivers in Great Britain, rising in the moor-lands of Staffordshire, and running south-east by Newcastle Under Line, divides that country almost into two equal parts; then entering Derbyshire, turns about to the north-east; and having run the whole length of Nottinghamshire, continues its course due north; at last joining the river Ouse, and several others, it changes its name to that of Humber, and falls into the Germain sea below Hull.

TREPAN. See Surgery, p. 664.

TRESPASS, in law, signifies any transgression of the law, under treason, felony, or misprison of either; but it is most commonly used for any wrong or damage that is done.

TRESPASS, in law, signifies any transgression of the law, under treason, felony, or misprison of either; but it is most commonly used for any wrong or damage that is done.

TRESPASS, in law, signifies any transgression of the law, under treason, felony, or misprison of either; but it is most commonly used for any wrong or damage that is done.

TRESURE, in heraldry, a diminutive of an orle, usually held to be half the breadth thereof. See it represented in Plate CXVII. fig. 20.

TRET, in commerce, an allowance made for the wafte, or the dirt, that may be mixed with any commodity, which is always four pounds in every hundred and four pounds weight.

TRIAL, in law, the examination of a cause, civil or criminal, according to the laws of the land, before a proper judge; or, it is the manner and order observed in the hearing and determining of causes.

TRIANGLE, in geometry, a figure of three sides and three angles. See Geometry, p. 686.

TRIANGULARIS, in anatomy. See Anatomy, p. 306.

TRIBBE, in antiquity, a certain quantity or number of persons, when a division is made of a city or people into quarters or districts.

TRIBRACHYS, in ancient poetry, a foot consisting of three syllables, and those all short, as Melius.

TRIBULUS, in botany, a genus of the decandria monogynia class. The calix consists of five segments, and the corolla of five open petals; it has no stamens; and there are five gynoecia, bristly capsules, containing many seeds.

There are four species, none of them natives of Britain.

TRIBUNAL, in general, denotes the seat of a judge, called in our courts bench.

TRIBUNE, among the ancient Romans, a magistrate chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls.

The tribunes of the people were first established in the year of Rome 259. The first design of the creation was to shelter the people from the cruelty of usurers, and to engage them to quit the Aventine mount, whither they had retired in displeasure.

Their number, at first, was but two; but the next year, under the consuls of A. Polthamus Aruncius and Caflius Vifcellitus, there were three more added; and this number of five was afterwards increased by L. Trench to ten. The appellation tribune was given them, by reason they were at first chosen out of the tribunes of the army.

Military Tribun, an officer in the Roman army, who commanded in chief over a body of forces, particularly the division of a legion, much the same with our colonel, or the French mestre de camp.

TRIBUTARY, one who pays tribute to another, in or- dinary.

TRIBUTARY, one who pays tribute to another, in ordi- nary.

TRIBUTARY, one who pays tribute to another, in ordi- nary.

TRIBUTARY, one who pays tribute to another, in ordi- nary.

TRIBUTARY, one who pays tribute to another, in ordi- nary.

TRIBUTARY, one who pays tribute to another, in ordi- nary.

TRIBUTE, a tax or impound, which one prince or state is obliged to pay to another as a token of dependence, or in return to live in peace with him, or share in his protection.

TRIBUNAL, a seat of a judge, called in our courts bench.

TRIBUNE, among the ancient Romans, a magistrate chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls.

The tribunes of the people were first established in the year of Rome 259. The first design of the creation was to shelter the people from the cruelty of usurers, and to engage them to quit the Aventine mount, whither they had retired in displeasure.

Their number, at first, was but two; but the next year, under the consuls of A. Polthamus Aruncius and Caflius Vifcellitus, there were three more added; and this number of five was afterwards increased by L. Trench to ten. The appellation tribune was given them, by reason they were at first chosen out of the tribunes of the army.

Military Tribun, an officer in the Roman army, who commanded in chief over a body of forces, particularly the division of a legion, much the same with our colonel, or the French mestre de camp.

TRIBUTARY, one who pays tribute to another, in order to live in peace with him, or share in his protection.

TRIBUTE, a tax or impost, which one prince or state is obliged to pay to another as a token of dependence, or in virtue of a treaty, and as a purchase of peace.

TRICEPS, in anatomy. See Anatomy, p. 205.

TRICHOSTEMA, in botany, a genus of the didynamia class. The upper lip of the corolla is divided; and the stamens are very long. There are two species, both natives of America.

TRICUSPIDES valve, in anatomy. See Anatomy, p. 279.
TRIGONOMETRY.

TRIGONOMETRY is that part of geometry which teaches how to measure the sides and angles of triangles.

Trigonometry is either plane or spherical, according as the triangles are PLANE or SPHERICAL; of each wherein we shall treat in order.

PLANE TRIGONOMETRY.

Plane Trigonometry, or that which teaches the measurement of plane triangles, is commonly divided into rectilinear and oblique-angular.

Of Rectangular Plane Trigonometry.

If in any right-angled triangle, ABC (Plate CLIX, fig. 1. n° 1.) the hypotenuse be made the radius, and with that a circle be described on the one end, A, as a centre; then, it is plain, that BC will be the sine of the angle BAC; and if with the same distance, and on the end B as a centre, a circle be described, it is plain, that AC will be the sine of the angle ABC; therefore, in general, if the hypotenuse of a right-angled triangle be made the radius, the two legs will be the sines of their opposite angles.

Again, if in a right-angled triangle DEF (ibid. n° 2.) one of the legs, as DF, be made the radius, and on the extremity D (at one of the oblique angles, viz. that which is formed by the hypotenuse and the leg made radius) as a centre, a circle be described; it is plain, that the other leg, EF, will be the tangent of the angle at D, and the hypotenuse DF will be the secant of the same angle. The same way, making the leg EF the radius, and on the center E describing a circle, the other leg DF will become the tangent of the angle at E, and the hypotenuse DE the secant of the same.

The chord, sine, tangent, &c. of any arch, or angle, in one circle, is proportional to the chord, sine, tangent, &c. of the same arch in any other circle: from which, and what has been said above, the solutions of the several cases of rectangular trigonometry naturally follow.

Since trigonometry consists in determining angles and sides from others given, there arise various cases; which being seven in rectangular trigonometry, are as follow.

CASE I. The angles, and one of the legs, of a right-angled triangle being given, to find the other leg.

Example. In the triangle ABC (ibid. n° 3.) right-angled at B, suppose the leg AB=36 equal parts, as feet, yards, miles, &c. and the angle A=33° 30'; required the other leg BC, in the same parts with AB.

1. Geometrically: Draw AB=36, from any line of equal parts; upon the point B, erect the perpendicular BC; and, lastly, from the point A, draw the line AC, making with AB an angle of 33° 30'; and that line produced will meet BC in C, and so constitute the triangle. The length of BC may be found by taking it in your compasses, and applying it to the same line of equal parts that AB was taken from.

II. By calculation: First, by making the hypotenuse AC radius, the other two legs will be the sines of their opposite angles, viz. AB the sine of C, and BC the sine of A. Now, since the sine, tangent, &c. of any arch in one circle is proportionable to the sine, tangent, &c. of the same arch in any other circle, it is plain the sines of the angles A and C in the circle described by the radius AC, must be proportional to the sine of the same arches or angles, in the circle, that the table of artificial sines, &c. was calculated for; so the proportion for finding BC will be

S: C :: A: B C

1. i.e. as the sine of the angle C in the tables, is to the length of AB (or line of C in the circle whose radius is AC) so is the sine of the angle A in the tables, to the length of BC.
TRIGONOMETRY.

BC (or line of the same angle in the circle whose radius is AC.) Now the angle A being 33° 40', the angle C must be 56° 20'; therefore looking in the table of artificial sines, &c, for the sines of the two angles, and in the table of logarithms for the logarithm of 86 the given leg, we shall find, by proceeding according to the foregoing proportion, that the required leg BC is 57.28; and the operation will stand as follows:

| 4.93450 | AB 86 |
| 9.74380 | S A 33° 40' |
| 11.67830 | S C 56° 20' |
| 1.75802 | BC 57.28 |

Secondly, making AB the radius, it is plain BC, the leg required, will be the tangent of the given angle A; and so the proportion for finding BC, when AB is made the radius, will be:

$$ R : \tan A :: A B : B C $$

First, making AC the radius, we shall have the following proportion for finding AC, viz.

| 9.82352 | T A 33° 40' |
| 1.93450 | AB 86 |
| 11.75802 | Rad. 90° |

Lastly, by supposing BC the radius, it is plain that AB will be the tangent of C, and the proportion for finding BC will be as follows:

$$ \tan C : T C :: A B : B C $$

Case II. The angles and one of the legs given, to find the hypotenuse.

Example: In the triangle ABC, (ibid. n° 4.) suppose AB 124, and the angle A 34° 20'; consequently the angle C 55° 40', required the hypotenuse AC, in the same parts with AB.

1. Geometrically: This case is constructed after the same manner with the former; and the hypotenuse, AC; is found, by taking its length in your compasses, and applying that line to the same line of equal parts from which AB was taken.

2. By calculation: First, making AC the radius, we shall have the following proportion for finding AC, viz.

| 9.91686 | to the sine of C 55° 40' |
| 1.00000 | to AB 124 |
| 2.09342 | to AC 150.2 |

Secondly, making AB the radius, we have this proportion, viz.

| 10.00000 | i.e. as the radius 90° |
| 10.08314 | to the secant of A 34° 20' |
| 2.09342 | so is AB 124 |
| 2.17656 | to AC 150.2 |

This may also be done, without the help of the secants; for since $$ R : \sec C :: A C : A B $$

| 9.91686 | is to sec C 55° 40' |
| 10.00000 | so is AB 124 |
| 2.09342 | to AC 150.2 |

Thirdly, making BC the radius, we have the following proportion, viz.

| 10.16538 | i.e. as the tangent of C 55° 40' |
| 10.24872 | is to sec C 55° 40' |
| 2.09342 | so is AB 124 |
| 2.17656 | to AC 150.2 |

This likewise may be done without the help of secants; for since $$ T C : \sec C :: A B : A C $$

| 9.91686 | where no secants do appear; and it coincides with that in the first supposition of this case, fo we shall not repeat the operation.

Case III. The angles and hypotenuse given, to find either of the legs.

Example. In the triangle ABC, (ibid. n° 4.) suppose the hypotenuse AC 146, and the angle A 36° 25', consequently the angle C 53° 35', required the leg AB.

1. Geometrically: Draw the line AB at pleasure, and make the angle B A C equal to 36° 25'; then take AC equal to 146 from any line of equal parts; lastly, from the point C, let fall the perpendicular CB, on the line AB. So the triangle is constructed, and AB may be measured from the line of equal parts.

2. By calculation: First, making AC the radius, we shall have the following proportion, viz.

| 10.00000 | i.e. As radius 90° |
| 9.90565 | to the sine of C 53° 35' |
| 2.09342 | so is AB 124 |
| 2.17656 | to AC 150.2 |

This may also be done without the help of secants; for since $$ R : \sec A :: A C : A B $$

| 9.90565 | where no secants do appear; and it coincides with that in the first supposition of this case, so we shall not repeat the operation.

R: Co-S, A:: A C : A B,
Case IV. The two legs being given, to find the angles.

Example. In the triangle ABC, (ibid. n° 5.) suppose AB 94 and BC 56, required the angles A and C.

I. Geometrically: Draw AB equal to 94, from any line of equal parts; then from the point B raise BC perpendicular to AB, and take BC from the former line of equal parts equal to 56; lastly, join the points A and C with the straight line AC: so the triangle is constructed, and the angles may be measured by a line of chords.

II. By calculation: First, supposing AB the radius, we have this analogy, viz.

\[
\frac{AB}{BC} = \frac{R}{\tan \alpha}
\]

i.e. as AB 94 1.97313

is to BC 56 1.74819

to the radius 90° 10.00000

to the tangent of A 47° 9.77506

Secondly, making BC the radius, we have this proportion, viz.

\[
\frac{BC}{BA} = \frac{R}{\sin \alpha}
\]

i.e. as BC 56 1.74819

is to AB 94 1.97313

to the radius 90° 10.00000

to the sine of C 13° 10.22494

Case V. The hypotenuse and one of the legs given, to find the angles.

Example. In the triangle DEF, (ibid. n° 6.) suppose the leg DE = 83, and the hypotenuse DF = 126; required the angles D and F.

I. Geometrically: Draw the line DE = 83 from any line of equal parts; and from the point E raise the perpendicular EF: then take the length of DF = 126, from the same line of equal parts; and setting one foot of your compasses in D, with the other cross the perpendicular EF in E; lastly, join D and F; and the triangle being thus constructed, the angles may be measured by a line of chords.

II. By calculation: First, supposing DF the radius, we have this proportion, viz.

\[
\frac{DF}{DE} = \frac{R}{\cos \alpha}
\]

i.e. as DF 126

is to DE 83 2.10037

to the radius 90° 1.91908

to the sine of F 12° 9.81871

Secondly, by supposing DE the radius, we have this proportion, viz.

\[
\frac{DE}{DF} = \frac{R}{\sec \alpha}
\]

i.e. as DE 83

is to DF 126 2.10037

to the radius 90° 1.91908

to the secant of D 48° 10.18582

This may be done without the help of secants; for since R = sec. Co-S. = R, the foregoing analogy will become this, viz.

\[
\frac{DF}{DE} = \frac{R}{\cos \alpha}
\]

which gives the same answer with that deduced from the first supposition.

Case VI. The two legs being given, to find the hypotenuse.

Example. In the triangle ABD, (ibid. n° 7.) suppose the leg AB = 64, and BD = 56: required the hypotenuse.

I. Geometrically: The construction of this case is performed the same way as in the fourth case, and the length of the hypotenuse is found by taking it in your compasses, and applying it to the same line of equal parts that the two legs were taken from.

II. By calculation: This case being a compound of the fourth and second cases, we must first find the angles by the fourth, thus:

\[
\frac{AB}{DB} = \frac{R}{\tan \alpha}
\]

i.e. as the leg AB 64 1.80618

is to the leg DB 56 1.74819

to the radius 90° 10.00000

to the tangent of A 47° 9.77506

Then by the second case we find the hypotenuse required thus:

\[
\frac{S, A}{R} : \frac{BD}{AD}
\]

i.e. as the sine of A 47° 10.22494

is to the radius 90° 10.00000

to the leg BD 56 1.74819

to the hypoten. AD 83.05 1.92956

This case may also be solved after the following manner, viz.

From twice the logarithm of the greater

fide AB

subtract the logarithm of the lesser

fide BD

and there remains 1.86417

the logarithm of 73.15; to which adding the lesser side BD, we shall have 189.15, whose logarithm is 2.11093

to which add the logarithm of the lesser

fide BD

and the sum will be

3.89512

the half of which is

1.9256

the logarithm of the hypotenuse required.

Or it may be done by adding the square of the two sides together, and taking the logarithm of that sum, the half of which is the logarithm of the hypotenuse required; thus, in the present case, the square of AB (64) is 4096

the square of BD (56) is 3136

the sum of these squares is 7232

the logarithm of which is 3.85926

the half of which is 1.92963

to the logarithm of 85.05, the length of the hypotenuse required.

Case VII. The hypotenuse and one of the legs being given, to find the other leg.

Example. In the triangle BGD, (ibid. n° 8.) suppose the leg BG = 87, and the hypotenuse BD = 142; required the leg DG.

I. Geometrically: The construction here is the same as in case V; the same things being given; and the leg DG is found by taking its length in your compasses, and applying that to the same line of equal parts the others were taken from.

II. By calculation: The solution of this case depends upon the 1st and 5th; and first we must find the oblique angles by case 5th thus:

\[
\frac{DB}{BG} = \frac{R}{\sin \alpha}
\]

i.e. as the hypoth. DB 142 2.15229

is
is to the leg $BG$; its radius $\theta$; to the fine of $D$, $90^\circ$; to the fine of $G$, $97.8723$

Then by case 1st, we find the leg $DG$ required, thus:

$$R : S, B : B : D : D : G,$$

i.e., as radius $90^\circ$, to the fine of $B$, $52^\circ$, 13', $9.89781$, to the hypotenuse $DB$, $142$, $2.15229$, to the leg $DG$, $112.2$, $2.05010$

The leg $DG$ may also be found in the following manner, viz.

To find the log of the sum of the hypotenuse and the given leg, viz. $2.35984$

add the logarithm of their difference, viz. $55$, $1.74036$

and their sum is $4.10020$

and the half of that is $2.05010$

the log of $112.2$ the leg required.

Or it may be done by taking the square of the given leg from the square of the hypotenuse, and the square root of the remainder the leg required: thus, in the present case,

The square of the hypotenuse $(142)$ is $20164$

The square of the leg $BG$ $(87)$ is $7569$

Their difference is $12595$

Whole logarithm is $4.10020$

The half of which is $2.05010$

which answers to the natural number $112.2$ the leg required.

Thus have we gone through the seven cases of right-angled plane trigonometry; from which we may observe, 1. That to find a side, when the angles are given, any side may be made the radius. 2. To find an angle, one of the given sides must of necessity be made the radius.

Of Oblige Angled Plane Trigonometry.

In oblique-angled plane trigonometry, there are six cases; but before we shew their solution, it will be proper to preface the following theorems.

Theorem I. In any triangle $ABC$ (ibid. fig. 2. n° 2.) the sides are proportional to the sines of the opposite angles; thus, in the triangle $A B C$, $A B : B C : C A : S, C : S, A$, and $A B : A C : B C : S, B : S, A$.

Demonstration. Let the triangle $ABC$ be inscribed in a circle; then, it is plain (from the property of the circle) that the half of each side is the sine of its opposite angle: but the sides of these angles, in tabular parts, are proportional to the sines of the same in any other measure; therefore, in the triangle $ABC$, the sine of the angles will be as the halves of their opposite sides; and since the halves are as the wholes, it follows, that the sides of the angles are as their opposite sides; i.e., $S, C : S, A : A B : B C$, &c.

Theorem II. In any plane triangle, as $ABC$ (ibid. n° 2.) the sum of the sides, $AB$ and $BC$, is to the difference of these sides, as the tangent of half the sum of the angles $BAC$, $ABC$, at the base, is to the tangent of half the difference of these angles.

Demon. Produce $AB$; and make $BH$ equal to $BC$; join $HC$, and from $B$ let fall the perpendicular $BE$; through $B$ draw $BD$ parallel to $AC$, and make $HF$ equal to $CD$.

Vol. III. N° 98.
and an angle opposite to one of them being given, to find
the angle opposite to the other.

Example. In the triangle ABC (ibid. n° 4.) suppose
AB=156, BC=34, and the angle C (opposite to AB)=56°
30'; required the angle A, opposite to BC.

2. Geometrically: Draw the line AC, and at any point
of it, suppose C, make the angle C=56° 30'; then take
CB=84, and with the length of 156 = AB taken in your
compasses from the same scale of equal parts, fixing one
point in B, with the other cross AC in A. Lastly, join
A and B; so the triangle is constructed, and the required
angle A may be measured by a line of chords.

3. By calculation: We have, by theor. 1, the following
proportion for finding the angle A, viz.

\[
\frac{AB}{BC} = \frac{S, C}{S, A}.
\]

\[
\frac{156}{84} = \frac{S, C}{S, A}.
\]

\[
S, C = 9.99250, \quad S, A = 2.06850.
\]

This gives

\[
A = 56° 30'.
\]

Case II. The angles, and a side opposite to one of them,
being given, to find a side opposite to another.

Example. In the triangle HBG (ibid. n° 5.) suppose
the angle H=46° 15', and the angle B=54° 22'; consequently
the angle G=79° 30', and the leg HB=125, required
HG.

Geometrically: Draw HB=125, from any line of equal
parts, and make the angle H=46° 15', and B=54° 22',
then produce the lines HG and BG till they meet one an-
other in the point G; so the triangle is constructed, and HG
is measured by taking its length in your compasses, and ap-
plying it to the same line of equal parts that HB was taken
from.

2. By calculation: By the first of the preceding theorems,
we have this analogy for finding HG, viz.

\[
\frac{HB}{HG} = \frac{S, G}{S, B}.
\]

\[
\frac{125}{HG} = \frac{S, G}{S, B}.
\]

\[
\]

This gives

\[
HG = 62° 45'.
\]

Case III. Two sides and an angle opposite to one of them
given, to find the third side.

Example. In the triangle KLM (ibid. n° 6.) suppose
the side KL=126 equal parts, and KM=130 of these parts,
and the angle L (opposite to KM) = 63° 20', required the
side ML.

1. Geometrically: The construction of this case is the
same as that in Case I, (there being the same things given
in both,) and the leg ML may be measured by applying
it to the same line of equal parts that the other two were
taken from.

2. By calculation: The solution of this case depends up-
on the two preceding ones; and, first, we must find the other
two angles by Case I, thus:

\[
\frac{MK}{S, L} = \frac{S, K}{KL}.
\]

\[
\frac{130}{63° 20'} = \frac{9.99250}{9.93759}.
\]

Then by Case II, we have the required leg ML, thus:

\[
\frac{S, L}{S, K} = \frac{MK}{ML}.
\]

\[
\frac{126}{63° 20'} = \frac{9.99250}{9.93759}.
\]

The leg ML=118.2, required.

N. B. The greater angle is always that subtended by
the greater side; thus, in the present case, the greater angle C,
is subtended by the greater side AD; and the lesser angle
D is subtended by the lesser side AC.

Case V. Two sides and the contained angle being given,
to find the third side.

Example. In the triangle BCD (ibid. n° 8.) suppose
BC=154, BD=133, and the angle B=56° 03'; required the
side CD.

1. Geometrically: The construction of this case is the
same with that of the last, and the length of DC is found
by taking its length in your compasses, and applying it to
the same line of equal parts that the two legs were taken
from.

2. By calculation: The solution of this case depends up-
on the second and fourth; and, first, we must find the angles
by the last case; thus:

\[
\frac{BC}{CD} = \frac{S, A}{S, D}.
\]

\[
\frac{154}{CD} = \frac{S, A}{S, D}.
\]

So is CD 180°.

S, D = 9.99250, \quad S, A = 2.06850.

This gives

\[
CD = 54° 30'.
\]

Their sum is 229°.

And their difference is 23°.

The sum of the three angles A, D, and C, is 180°.

The angle A is 54° 30'.

Their sum is 229°.

And half their sum is 62° 45'.

Then by theor. 2. we have the following proportion, viz.

\[
\frac{AD}{AC} = \frac{S, C}{S, A}.
\]

\[
\frac{AD}{AC} = \frac{9.99250}{2.06850}.
\]

This gives

\[
AD = 72° 30'.
\]

So is KM=130, of them by theorem 3 thus:

\[
\frac{KM}{KL} = \frac{S, L}{S, K}.
\]

\[
\frac{130}{63° 20'} = \frac{9.99250}{9.93759}.
\]

Thus

\[
KL = 62° 45'.
\]

And the sum is the greater angle C = 79° 47'.

Again from half their sum, viz.

\[
KL = 62° 45'.
\]

Take half their difference, viz.

\[
KL = 11° 02'.
\]

And there will remain the lesser angle D = 51° 43'.

So is KM 130.

To ML 118.2.

Case IV. Two sides and the contained angle being given,
to find the other two angles.

Example: In the triangle ACD (ibid. n° 7.) suppose
AC=103, AD=126, and the angle A=54° 30'; required the
angles C and D.

1. Geometrically: Draw AD=126, and make the angle
A=54° 30'; then set off 103 equal parts from A to C:
lastly, join C and D; and so the triangle is constructed,
and the angles C and D may be measured by a line of chords.

2. By calculation: The solution of this case depends up-
on the second and third of the preceding theorems; and, first, we must find the sum and difference of the sides, and half
the sum of the unknown angles, thus:

The leg AD is 126.

The leg AC is 103.

Their sum is 229.

And their difference is 23.

The sum of the three angles A, D, and C, is 180°.

The angle A is 54° 30'.

Their sum is 229°.

And half their sum is 62° 45'.

Then by theor. 2. we have the following proportion, viz.

\[
\frac{AD}{AC} = \frac{S, C}{S, A}.
\]

\[
\frac{126}{103} = \frac{S, C}{S, A}.
\]

This gives

\[
AC = 72° 30'.
\]

So is KM=130, of them by theorem 3 thus:

\[
\frac{KM}{KL} = \frac{S, L}{S, K}.
\]

\[
\frac{130}{63° 20'} = \frac{9.99250}{9.93759}.
\]

Thus

\[
KL = 62° 45'.
\]

And the sum is the greater angle C = 79° 47'.

Again from half their sum, viz.

\[
KL = 62° 45'.
\]

Take half their difference, viz.

\[
KL = 11° 02'.
\]

And there will remain the lesser angle D = 51° 43'.

So is KM 130.

To ML 117.2.

\[
\frac{126}{117.2} = \frac{S, C}{S, A}.
\]

\[
\frac{126}{117.2} = \frac{9.99250}{2.06850}.
\]

This gives

\[
\]

Secondly, we must find the angles C and D.

Example: In the triangle BCD (ibid. n° 8.) suppose
BC=154, BD=133, and the angle B=56° 03'; required the
side CD.

1. Geometrically: The construction of this case is the
same with that of the last, and the length of DC is found
by taking its length in your compasses, and applying it to
the same line of equal parts that the two legs were taken
from.

2. By calculation: The solution of this case depends up-
on the second and fourth; and, first, we must find the angles
by the last case; thus:

\[
\frac{BC}{CD} = \frac{S, A}{S, D}.
\]

\[
\frac{154}{CD} = \frac{S, A}{S, D}.
\]

So is CD 180°.

S, D = 9.99250, \quad S, A = 2.06850.

This gives

\[
CD = 54° 30'.
\]
Is to their difference 21 1.32222
So is the tangent of half the sum of
the angles D and C 61° 58' 10.27372
To the tangent of half their difference 7° 50' 9.13806
So by theorem 2, we have the angles D and C thus:
To half the sum of the angles D and C 61° 58'
Add half their difference 7° 50'

And the sum is the greater angle D 69° 08'
Also, from half the sum 61° 58'
Take half the difference 7° 50'

And there remains the lesser angle C 54° 08'
Then by Case II, we have the following analogy for finding DC the leg required, viz.

S. C : BD : : S. B : DC.

i. e. As the sine of C 54° 08' 9.90869
To BD 133 2 1.21835
So is the sine of B 56° 03' 9.91883
To DC 136.2 2 1.39099

CASE VI. Three sides being given, to find the angles.

Example: In the triangle ABC (ibid. n° 8.) suppose AB=156, AC=185.7, and BC=84; required the angles A, B, and C.

I. geometrically: Make AC=185.7 from any line of equal parts; and from the same line taking 156=AB in your compasses, fix one foot of them in A, and with another sweep an arch; then take 84=BC in your compasses, and fixing one foot in C, with the other sweep an arch, which will cross the former in B: lastly, join the points B and A, and B and C; so the triangle will be constructed, and the angles may be measured by a line of chords.

II. by calculation: Let fall the perpendicular, BD, from the vertex B, upon the base AC; which will divide the base into two segments AD and DC, the lengths whereof may be found by theorem 4. thus:

As the base AC 185 7 2 26893
To the sum of the sides AB and BC 240 2 32801
So is the difference of the sides 72 1 85733

To the diff. of the segments of the base 93 1 06871
And having the sum of the segments viz. the whole base, and their difference, we find the segments themselves, by theorem 3. thus:

To half the sum of the segments 92.8 2 19312
And half their difference 46.5 1 24395
Also from half the sum of the segment 92.8
Take half their difference 46.5

The remainder is the lesser segment DC 46.3

Now the triangle ABC is divided, by the perpendicular DB, into two right-angled triangles, ADB and DBC; in the first of which are given the hypothenus AB=156, and the base AD=139.3, to find the oblique angles, for which we have (by Case V. of rectangular trigonometry) the following analogy, viz.

As AB 156 2 19312
To AD 139.3 2 14395
So is the radius 90° 10 00000

To the co-sine of the angle A 26° 40' 9.95083

Also the angle C is found by the same cafe, thus:

As BC 84 1 92428
To CD 46.3 1 66538
So is the radius 90° 2 00000

To the co-sine of C 56° 30' 9.74120
Having found the two angles A and C, we have the third, B, by taking the sum of the other two from 180, thus:

The sum of all the three angles is 180°
The sum of A and C is 83° 10'

The angle B is 96° 50'

All the proportions used for the solutions of the several cases in plain trigonometry, may be performed by the scale and compass. On the scale there are several logarithmic lines, viz. one of numbers, another of fines, and one of tangents, &c.

And the way of working a proportion by these is this, viz. extend your compasses from the first term of your proportion, found on the scale, to the second; and with that extent, fixing one foot in the third term, the other will reach the fourth term required.

SPHERICAL TRIGONOMETRY.

Spherical Trigonometry is the art whereby, from three given parts of a spheroidal triangle, we discover the rest; and, like plane trigonometry, is either right-angled, or oblique-angled. But before we give the analogies for the solution of the several cases in either, it will be proper to premise the following theorems.

THEOREM I. In all right-angled spherical triangles, the sine of the hypothenuse: radius :: sine of a leg: sine of its opposite angle. And the sine of a leg: radius :: tangent of half the sum: radius.

Demonstration. Let EDAFG (ibid. fig. 3.) represent the eighth part of a sphere, where the quadrantal planes EDFG, EDBC, are both perpendicular to the quadrantal plane ADFB; and the quadrantal plane ADGC is perpendicular to the plane EDFG; and the spherical triangle ABC is right-angled at B, where CA is the hypothenuse, and BA, BC, are the legs.

To the arches GF, CB, draw the tangents HF, OB, and the lines GM CI on the radii DF DB; also draw BL the sine of the arch AB, and CK the sine of AC; and then join IK and OL. Now HF, OB, GM, CI, are all perpendicular to the plane ADFB. And HD, GK, OL, lie all in the same plane ADGC. Also FD, IK, BL, lie all in the same plane ADGC. Therefore, the right-angled triangles HDF, CIK, ODL, having the equal angles HDF, CKI, OLB, are similar. And CI : DG :: GM : CI; that is, as the sine of the hypothenuse: radius :: sine of a leg: sine of its opposite angle. For GM is the sine of the arc GF, which measures the angle CAB. Also, LB : FD :: BO : FI; that is, as the sine of a leg: radius :: tangent of the other leg: tangent of its opposite angle, Q. E. D.

Hence it follows, that the sines of the angles of any oblique spheroidal triangle ACD (ibid. n° 2.) are to one another, directly, as the sines of the opposite sides. Hence it also follows, that, in right-angled spheroidal triangles, having the same perpendicular, the sines of the bases will be to each other, inversely, as the tangents of the angles at the bases.

Theorem
Theorem II. In any right-angled spherical triangle ABC (ibid. n° 3.) it will be, As radius is to the co-sine of one leg, so is the co-sine of the other leg to the co-sine of the hypotenuse.

Hence, if two right-angled spherical triangles ABC, CBD (ibid. n° 2) have the same perpendicular BC, the co-sines of their hypotenuses will be to each other, directly, as the co-sines of their bases.

Theorem III. In any spherical triangle it will be, As radius is to the co-sine of one leg, so is the co-sine of the other leg to the co-sine of the hypotenuse.

Hence, if two right-angled spherical triangles ABC, CBD (ibid. n° 2) have the same perpendicular BC, the co-sines of their hypotenuses will be to each other, directly, as the co-sines of their bases.

Theorem IV. In any right-angled spherical triangle it will be, As radius is to the co-sine of the hypotenuse, so is the tangent of either angle to the co-tangent of the other angle.

As the sum of the sines of two unequal arches is to their difference, so is the tangent of half the sum of those arches to the tangent of half their difference: and, as the sum of the co-sines is to their difference, so is the co-tangent of half the sum of the arches to the tangent of half the difference of the same arches.

Theorem V. In any spherical triangle ABC (ibid. n° 4 and 5.) it will be, as the co-tangent of half the sum of half their difference, so is the co-tangent of half the base to the tangent of the distance (DE) of the perpendicular from the middle of the base.

Since the last proportion, by permutation, becomes co-tang. \( \frac{AC+BC}{2} \) : co-tang. AE : : tang. \( \frac{AC-BC}{2} \) : tang. DE; and as the tangents of any two arches are, inversely, as their co-tangents; it follows, therefore, that tang. AE : tang. \( \frac{AC+BC}{2} \) :: tang. \( \frac{AC-BC}{2} \) : tang. DE, or, that the tangent of half the base is to the tangent of half of the sum of the sides, as the tangent of half the difference of the sides to the tangent of the distance of the perpendicular from the middle of the base.

Theorem VI. In any spherical triangle ABC (ibid. n° 4) it will be, as the co-tangent of half the sum of the angles at the base, is to the tangent of half of their difference, so is the tangent of half the vertical angle to the tangent which the perpendicular CD makes with the line CF bisecting the vertical angle.

**TRINGA**, in ornithology, a genus of birds belonging to the order of grallae. The beak is somewhat cylindrical, and as long as the head; the nostrils are linear; and there are four toes on the feet, the hind one confling of one joint, and elevated above the ground. There are 23 species, principally distinguished by their colour.

**TRINGLE**, in architecture, a name common to several little square members or ornaments, as reglets, pilasters, and plat-bands. It is more particularly used for a little member fixed exactly over every triglyph, under the plat-band of the architrave, from whence the gable or pendant drops hang down.

**TRINIDAD**, or Trinity-island, is situated in the Atlantic or American ocean, between 60° and 63° of west longitude, and between 9° and 11° of north latitude; it is about ninety miles long, and sixty broad.

**TRINIDAD**, a port-town of Mexico, in America, situated in the province of Guatemala, an hundred and twenty miles south-east of the city of Guatemala: W. long. 94°, N. lat. 15°.

**TRINITARIANS**, those who believe in the Trinity; those who do not believe therein, being called antitrinitarians. Trinitarians also denote an order of religious instituted at Rome in the year 1198, under the pontificate of Innocent III. The founders were John de Matha, and Felix de Valois. His holiness gave them permission to establish this order for the deliverance of captives, who groaned under the tyranny of the infidels: he gave them, as a habit, a white gown ornamented with a red and blue cross. After the death of the two founders, pope Honorius III. continued the order, and their rule was approved by his successor Clement IV. in 1267. At first they were not permitted to eat fish, and, when they traveled, were to ride only upon asses. But their rule was corrected and mitigated by the bishop of Paris, and the abbots of St. Victor and St. Genevieve, who allowed them to eat any kind of food, and to use horses. This order possesses about two hundred and fifty convents in thirteen different provinces, six of which are in France, namely, France, Normandy, Picardy, Champagne, Languedoc, and Provence; three in Spain, viz. New Castile, Old Castile, and Aragon; one in Italy, and one in Portugal. There was formerly the province of England, where this order had forty-three houses; that of Scotland, where it had nine; and that of Ireland, where it had fifty-two; besides a great number of monasteries in Saxony, Hungary, Bohemia, and other countries. The convent of Cerfroy in France is head of the order.

**TRINITY**, in theology, the ineffable mystery of three persons in one God; Father, Son, and Holy Spirit.

**TRINITY SUNDAY**, a festival observed on the Sunday next after Whitunday, in honour of the holy Trinity. The observance of this festival was first enjoined in the council of Arles, anno 1260.

**Fraternity of the Trinity**, a religious society instituted at Rome by St. Philip Neri, in 1548. These religious were appointed to take care of the pilgrims who came to visit the tombs of St. Peter and St. Paul. The society originally consisted of only fifteen religious, who assembled on the first Sunday of every month, in the church of St. Saviour del Campo, to hear the exhortations of the founder; after whose death pope Paul IV. gave the fraternity the church of St. Benedict, near which they have since built a large hospital, for the reception of pilgrims. The fraternity is one of the most considerable in Rome, and most of the nobility of both sexes have been members thereof.

**TRIO**, in music, a part of a concert wherein three persons sing; or more properly a musical composition consisting of three parts.

**TRIONES**, in astronomy, a sort of constellation or assemblage of several stars in the uria minor, commonly called Charles's wain.

**TRIOPTERIS**, in botany, a genus of the decandria trigynia...
TRIP, a fea-term. A ship is said to bear her top-sails a- 
trip, when she carries them hoisted up to the highest.

TRIPHTHONG, in grammar, an assemblage or concourse of 
three vowels in the same syllable, as cue.

TRIPLE, in music, is one of the species of measure or 
time. See Music.

TRIPOD, in antiquity, a famed sacred seat or stool, sup-
ported by three feet, whereon the priests and fibyls were 
placed to render oracles. It was in the tripod that the 
gods were said to inspire the Pythians with that divine 
fury and enthusiasm wherewith they were seized at the 
delivery of their predictions.

TRIPOLI, a state of Africa, which including Barca, is 
bounded by the Mediterranean sea on the north, by 
Egypt on the east, by Nubia and Bilgdugerd on the south, 
and by Tunis on the west; extending along the shore of 
the Mediterranean from the north-west to the south-east 
about a thousand miles, but scarce two hundred miles 
broad in any place. The city of Tripoli, being the ca-
scription: E. long. 14° 1/2, N. lat. 33° 30'.

TRIQUETRUS, among botanists, expresses a fruit or leaf 
that has three sides or faces all flat.

TRIJEMIS, in antiquity, a gally with three ranks of oars 
on a side.

TRISMEGISTUS, an epithet or surname given to one of 
the two Hermes, or Mercuries, kings of Thebes in E-
ypt, who is said to be contemporary with Moses.

TRISPASTON, in mechanics, a machine with three pul-
leys, or an assemblage of three pulleys for raising of great 
weights.

TRISYLLABLE, in grammar, a word consisting of three 
syllables.

TRITICUM, in botany, a genus of the triandria digynia 
class. The calix consists of six segments; and there 
are three seeds, with a double membranous wing. There 
is but one species, a native of Jamaica.

TRITON, a sea demi-god, held by the ancients to bean of-
fury and enthufiasms with which they were seized at the 
delivery of their predictions.

TRITON, in zoology, a genus belonging to the order of 
the sea-fish. The victims were slain. In the mean time all 
the temples were open, and all the altars loaded with offer-
ings and incense; games and combat were celebrated in 
the public places, and rejoicings appeared everywhere.

TRIUMPH, in Roman antiquity, a public and solemn ho-

TRIUMPH, was decreed by the Senate to a general, upon 
the conquering of a province, or gaining a signal victory. 
The day appointed for the ceremony being arrived, scath-
folds were erected in the forum and circus, and all the 
other parts of the city, where they could best behold the 
pomp; the Senate went to meet the conqueror without 
the gate called Capena or Triumphalis, and marched back 
in order to the capitol; the ways being cleared and clean-
fed by a number of officers and attendants, who drove away 
such as thronged the passage, or struggled up and down.

The general was clad in a rich purple robe, interwoven 
with figures of gold, setting forth his great exploits; his 
bufkins were befit with pearl; and he wore a crown, 
which at first was only laurel, but afterwards gold; in 
one hand he bore a branch of laurel, and in the other a 
truncheon. He was drawn in a magnificent chariot, ad-
dorned with ivory and plates of gold, drawn usually by 
two white horses; though sometimes by other animals, 
as that of Pompey, when he triumphed over Africa, by 
elephants; that of Marc Antony, by lions; that of He-
liogabalus, by tygers; that of Aurelian, by deer, &c.

His children were at his feet, and sometimes on the cha-
riot-horses. The procession was led up by the musicians, 
who played triumphal pieces, in praise of the general: 
these were followed by young men, who led the victims 
to the sacrifice, with their horns gilded, and their heads 
adorned with ribbands and garlands; next came the carts 
and wagons, loaded with all the spoils taken from the 
enemy, with their horers, chariots, &c. these were fol-
lowed by the kings, princes, and generals, who had been 
taken captives, loaded with chains: after these appeared 
the triumphal chariot, before which, as it passed, they 
all along threw flowers, and the people, with loud ac-
clamations, called out 'Io triumphi!' The chariot was 
followed by the Senate, clad in white robes; and the Sen-
ate by such citizens as had been set at liberty or rans-
fomed: and the procession was closed by the priests and 
their officers and utensils, with a white ox led along for 
the chief victim. In this order they proceeded through 
the triumphal gate, along the via sacra, to the capitol, 
where the victims were slain. In the mean time all the 
temples were open, and all the altars loaded with offer-
ings and incense; games and combat were celebrated in 
the public places, and rejoicings appeared everywhere.

TRIUMVIR, one of three persons who govern absolutely, 
and with equal authority, in a state. It is chiefly applied 
to the Roman government: Caesar, Pompey, and Crassus 
were the first triumvirs, who divided the government am-
ongst them. There were also other officers, called 
triumvirs; as the triumviri or trefviri capiteles, who were 
the keepers of the public goal; they had the office of pu-
nishing malefactors; for which purpose they kept eight 
boys under them.

TRIUMVIRATE, an absolute government, administered 
by three persons with equal authority. See the preced-
ing article.

TROCHANTER, in anatomy. See Anatomy, p. 181.

TROCHE, in pharmacy, a sort of medicine, made of glu-
tinous substances, into little cakes, and afterwards ex-
sected.
TROCHÆUS, in the Greek and Latin poetry, a foot consisting of two syllables, the first long, and the second short.

TROCHILUS, in ornithology, a genus belonging to the order of peregrines. The beak is tubular and thread-shaped, with a tubular apex, and longer than the head, the superior mandible thrusting the inferior; the tongue is thread-shaped; and the feet are fitted for walking. This genus comprehends all the humming birds, which are the smallest of birds, and are distinguished by their colour and the shape of their bills.

TROCHLEA, one of the mechanical powers, usually called a pulley. See Mechanics.

TROCHLEARES, in anatomy. See Anatomy, p. 290.

TROCHLOIDES, in the ancient geography, a people of Ethiopia, said to have lived in caves under ground. Pom. Mela gives a strange account of the Troglodytes: he says, they did not know properly speak as shrieks, and that they lived on serpents.

TROJA, or Trojan games, were games said to be instituted by Ascanius, son of Aeneas, and afterwards kept up by the Romans with great solemnity. They were celebrated by companies of boys, neatly dressed, and furnished with little arms and weapons, who muttered in the public circus. They were chosen, for the most part, out of the noblest families of Rome, and the captain of them had the honourable title of princeps juventutis, being sometimes next heir to the empire, and seldom less than the son of a principal senatus.

TROIS RIVIÈRES, a town of North America, in the province of Canada, situated on the river of St. Laurence, fifty miles south of Quebec; W. long. 75° 6', and N. lat. 46° 45'.

TRONAGE, an ancient customary toll, paid for weighing of wool. This word is particularly mentioned in a charter granted to the mayor and citizens of London; in which city there is an officer called tronator, who has the business of it.

TRONCONNE, in heraldry, denotes a crofs, or other thing, cut in pieces and dismembered, yet so as all the pieces keep up the form of a crofs, though set at a small distance from one another.

TROOP, a small body of horse or dragoons, about fifty or sixty, sometimes more, sometimes less; commanded by a captain. Each troop, besides a captain, has a lieutenant, coronet, quarter-mater, and three corporals, who are the lowest officers of a troop.

TROPEÁOLUM, in botany, a genus of the octandria monogynia class. The calix consists of one calcarated leaf; and the corolla of five unequal petals; and there are three dry berries. The species are three, natives of Peru.

TROPE, in rhetoric, a kind of figure of speech, whereby a word is removed from its first and natural signification, and applied with advantage to another thing, which it does not originally mean; but only stands for it, as it has a relation to or connection with it: as in this sentence, God is my rock. Here the trope lies in the word rock, which being firm and immovable, excites in our minds the notion of God's unfailling power, and the steady support which good men receive from their dependence upon him.

TROPHY, among the ancients, a pile or heap of arms of a vanquished enemy, raised by the conqueror in the most eminent part of the field of battle.

TROPICS, in astronomy. See Astronomy, p. 469.

TROUT, in ichthyology. See Salmo.

TRUSS, a bundle, or certain quantity of hay, drawn, or certain quantity or measure: thus, a tub of tea contains about sixty pounds; thirty-six trusses make a load.

TRUSS is also used for a sort of bandage or ligature, made of flax, or the like matter, wherewith to keep up the parts in those who have hernias or ruptures.

TRUSTEE, one who has an estate, or money, put or committed to another for the use of another.

TRUTH, a term used in opposition to falsehood, and applied to propositions which answer, or accord, to the nature and reality of the thing whereof something is affirmed or denied.

TUB, in commerce, denotes an indeterminate quantity or measure: thus, a tub of tea contains about sixty pounds; a tub of camphor from fifty-six to eighty pounds.

TUBE, in general, pipe, conduit, or canal; a cylinder hollow within, either of lead, iron, wood, glass, or other matter, for the air, or some other fluid, to have a free passage or conveyance through.

TUBERCLE, in botany, a kind of round turgid root, in form of a knob or turnip.

The plants which produce such roots are hence denominated tuberose, or tuberous, plants.

TUBERCLES, among physiicians, denote little tumours which suppurate and discharge pus, and are often found in the lungs, especially of consumptive persons.

TUBIPORA, a genus of sub-marine plants, belonging to the cryptogamia class, of the hardnefs of coral, and consisting of cylindrical tubes rising from a thin crust of the same sort of matter with themfelves.

TUBULI ACTIFIÆRI, in anatomy. See Anatomy, p. 277.

TUCUMAN, the south-west division of the province of La Plata, or Paraguay, in South America.

TULIPA, in botany, a genus of the hexandria monogynia class. The corolla is bell-shaped, and consists of six petals; it has no styli. There are three species, none of them natives of Britain.

TUMEFACIUNT, the act of swelling or rising into a tumour.

TUMOUR, in medicine and surgery, a preternatural rising
**TUN**, a large vessel or cask of an oblong form, biggest in the middle, and diminishing towards its two ends, gilt about with hoops, and used for storing several kinds of merchandise, for convenience of carriage; as brandy, oil, sugar, flins, hats, &c. This word is also used for certain vessels of extraordinary bigness, serving to keep wine in for several years.

Tun is also a certain weight whereby the burden of ships, &c. are esteemed.

**TUNBRIDGE**, a town of Kent, situated thirty-three miles west of Canterbury, much resorted to on account of its excellent waters.

**TUNICA**, a kind of waistcoat, or under garment, in use amongst the Romans. They wore it within doors by itself, and abroad under the gown. The common people could not afford the toga, and so went in their tunics, whence Horace calls them popellus tonicas.

**TUNICA**, in anatomy, is applied to the membranes which invest the vessels, and divers others of the less solid parts of the body; thus the interlines are formed of five tunics, or coats.

**TUNNAGE** is used for a custom or imposition, payable to the chandize, for convenience of carriage; as brandy, oil, with hoops, and used for flowing several kinds of merchandise, for several years.

**TURBO**, in zoology, a genus of insects belonging to the order of vermes testacea. This is an animal of the snail kind; the shell consists of one spiral solid valve; and the aperture is orbicular. There are 49 species, distinguished by peculiarities in their shells.

**TURBO**, in ichthyology. See **PLEURONECTES**.

**TURCICA TERRA, TURK-EARTH**, in the materia medica, a very fine bole or medicinal earth, dug in great plenty in the neighbourhood of Adrianople, and used by the Turks as a sudorific and astringent, and famous among them in pestennial diseases.

**TURCOSE**, in natural history, an ore of copper.

There are, indeed, two kinds of turcois; the one a true and genuine ore of copper; the other the bones of animals tinged to a beautiful blue colour, by having been buried in places where copper-ore has been near them.

**TURCOSIA**, a very extensive empire, comprehending some of the richest countries in Europe, Asia, and Africa.

Turk in Europe, comprehends Romania, Bulgaria, Serbia, Bosnia, Ragusa, Wallachia, Moldavia, Bessarabia, Budzak, Crim, and little Tartary, with Albania, Epirus, Macedonia, Thebaly, and all the ancient Greece, with its numerous islands. See **ROMANIA**, &c.

Turk in Asia, comprehends Napoleon, Diarbeck, Syria. Turcomania, and part of Georgia and Arabia.

And Turk in Africa, comprehends the fruitful and extensive country of Egypt.

**TURMERIC**, in the materia medica, the root of a plant, called by botanists curcuma. See CURCUMA.

**TURNEP**, in botany, a species of brassica. For the culture of them, see **AGRICULTURE**, p. 67.

**TURNER**, in botany, a genus of the pentandria trigynia class. The calyx is funnel-shaped, and consists of five segments; there are five petals inserted into the calyx; the ligums are divided into many parts; and the capsule has one cell. There are three species, none of them natives of Britain.

**TURNING**, a branch of sculpture, being the art of fashioning hard bodies, as brass, ivory, wood, &c. into a round or oval form, in a lathe.
TURPENTINE, a transparent sort of resin, flowing either naturally or by incision from several unctuous and resinous trees, as the terebinth, larch, pine, fir, &c.

The turpentine of Chio or Scio, which is the only genuine kind, and that which gives the denomination to all the rest, is a whitish resin, bordering a little on green, very clear, and a little odoriferous; drawn by incision from a tree called terebinthus, very common in that island, as also in Cyprus, and some parts of France and Spain.

The uses of turpentine in medicine are innumerable. It is a great vulnerary, and very detergent, and as such is prescribed in abscesses, ulcers, &c. It promotes expectoration, and as such is prescribed in diseases of the lungs and breast; but it is most famous for clearing the urinary passages, and as such prescribed in obstructions of the reins, in gonorrhoea, &c.

Oil of Turpentine. There are two kinds of oil drawn from turpentine, by distillation; the first white, the second red, both esteemed as balsams proper for the cure of wounds, chilblains, &c. But they are so little used among us, that it is not easy to procure either of them.

What is commonly sold under the name of oil of turpentine, or etherial oil, is only a distillation of the resinous juice of the tree, fresh as it is gathered. It is used with success in the cure of green wounds, as also by the painters, farriers, &c. To be good, it must be clear and pellucid as water, of a strong penetrating smell, and very inflammable.

TURRITIS, in botany, a genus of the tetradynamia filiquora class. The pod is very long, and angular; the calyx is connivent and ered; and the corolla is ered.

TUSSILAGO, in botany, a genus of the pyngenefia poly-gama superflua class. The receptacle is naked; the pappus is simple; the scales of the calyx are equal, and somewhat membraneous. There are nine species; three of them natives of Britain, viz. the farfara, or common colt's foot; the hybrida, or long-stalked butter-bur; and the petiolaris, or common butter bur.

The common colt's foot is recommended in coughs, and other disorders of the breast and lungs.
VAIRY, in heraldry, expresses a coat, or the bearings of a coat, when charged or chequered with vair: and hence, vairy-cuppy, or vairy-taffy, is a bearing composed of pieces representing the tops of crutches. See Plate CXLVII. fig. 22.

VALE, proper signifies a sheath, or scabbard: and the term vagina is used, in architecture, for the part of a terminus, because resembling a sheath, out of which the flature seems to issue.

VAGINA, in anatomy, a large canal, formed of a robust or strong membrane, and reaching from the external orifice, or os pudendii, in women, to the uterus. See Anatomy.

VAGUM, or PAR VAGUM. See Anatomy. 249.

VAIR, in heraldry, a kind of fur, consisting of divers little pieces, argent, and azure, resembling a Dutch U, or a bell glass. See Plate CXLVII. fig. 21.

VAiry, in heraldry, expresses a coat, or the bearings of a coat, when charged or chequered with vair: and hence, vairy-cuppy, or vairy-taffy, is a bearing composed of pieces representing the tops of crutches. See Plate CXLVII. fig. 22.

VALENCIA, the capital of a province of the same name, in Spain, situated in a fine plain on the river Guadalavia, W. long. 24°, N. lat. 39° 20'.

VALENTINIANS, in church-history, a sect of Christian heretics, who sprung up in the 11th century, and were so called from their leader Valentinus.

The Valentinians were only a branch of the Gnostics, who realized or personified the platonic ideas concerning the deity, whom they called Ploroma, or plenitude. Their syllem was this: the first principle is Bythos, i.e., depth, which remained many ages unknown, having with
it Enroe or thought, and Sige or silence; from these sprang the Nouns, or intelligence, which is the only Ion, equal to, and alone capable of comprehending, the Bythos; the sister of Nouns they called Alethia, or truth: and these constituted the first quaternity of xions, which were the source and original of all the rest: for Nouns and Alethia produced the world and life: and from these two proceeded man and the church. But besides these eight principal xions, there were twenty two more: these formed Sophia, being desirous to arrive at the knowledge of Bythos, gave herself a great deal of unisearch, which created in her Anger and Fear, of which she was born Matter. But the Horos, or bounder, stopt her, preferred her in the pleroma, and reflored her to her perfection. Sophia then produced the Christ and the Holy Spirit, which brought the xions to their last perfection, and made one of them contribute their utmost to form the Saviour. Here Enthyme, or thought, dwelling near the Pleroma, perfected by the Christ, produced every thing that is in the world, by its divers pations. The Christ sent into it the Saviour, accompanied with angels, who delivered it from its pations, without annihilating it; for the self was formed corporeal matter. And in this manner did they romance, concerning God, nature, and the mysteries of the Christian religion.

VALERIANA, in botany, a genus of the triandria monogynia class. It has no calix; the corolla consists of one petal, gibbous at the base, and situate above the fruit. There are 20 species, three of them natives of Europe, viz. the officinalis, or great wild valerian, whose root is alexipharmic, fadorific, and diuretic; the dioica, or harsh valerian; and the locusta, or lamb-lettuce.

VALET, a French term, used as a common name for all domestic men servants, employed in the more servile offices, as grooms, footmen, coachmen, &c.

VALETUDINARY, among medical writers, denotes a person of a weak and sickly constitution, and frequently out of order.

VALID, in law, an appellation given to acts, deeds, transactions, &c. which are clothed with all the formalities requisite to their being put into execution.

VALLADOLID, a city of Old Spain, in Spain, eighty-six miles north-west of Madrid: W. long. 4° 50', and N. lat. 41° 36'.

VALLINGIN, the capital of a county of the same name, in Switzerland, situated near the lake of Neuchattel, twenty five miles north-west of Bern.

VALLISNERIA, in botany, a genus of the dioica diandria class. The spadix both of male and female consists of two segments, and the corolla of three petals; the spadix of the male is covered with floccules; the spadix has one cell, containing many seeds; and there are three styli. There is but one species, a native of Italy.

VALOIS, a duchy of France, situated on the three great rivers, the Seine, the Marne, and the Oise.

VALUE, in commerce, denotes the price or worth of any thing.

VALUED RENT, in Scots law. See Law, Tit. xii. 6.

VALVE, in hydraulics, pneumatics, &c. is a kind of lid, or cover, of a tube or vessel, so contrived as to open one way; but which, the more forcibly it is pressed the other way, the closer it shuts the aperture; so that it either admits the entrance of a fluid into the tube or vessel, and prevents its return; or admits its escape, and prevents its re-entrance.

VALVE, in anatomy, a thin membrane applied on several cavities and vessels of the body, to afford a passage to certain humours going one way, and prevent their reflux towards the place from whence they came.

VAN, a term derived from the French avant, or avanti, signifyng before, or foremost of any thing; thus we say, the van-guard of an army, &c.

VANDALIA, the ancient name of the countries of Mecklenburg and Pomerania, in Germany.

VANELLUS, in ornithology. See Tringa.

VAPOUR, in philosophy, the moist and most volatile particles of bodies, separated by heat, and raised into the atmosphere. See Rain.

VAPOURS, in medicine, a disease properly called hyps, or the hypochondriacal disease, and in men particularly the spleen. See Medicine, p. 148.

VARI, in medicine, little hard and ruddy tumours, which frequently infect the faces of young persons of a hot temperament of body.

VARIATION, in geography and navigation, is the deviation of the magnetic needle, in the mariner's compass, from the true north point, towards either the east or west; or it is an arch of the horizon, intercepted between the meridian of the place of observation and the magnetic meridian. See Navigation.

VARIEGATION, among botanists and florists, the act of streaking or diversifying the leaves, &c. of plants and flowers with several colours.

Variegation is either natural or artificial. Of natural variegation there are four kinds: the first having itself in yellow spots here and there in the leaves of plants called by gardeners the yellow bloach. The second kind, called the white bloach, marks the leaves with a great number of white spots or stripes; the white streak passing the surface of the leaves, usually accompanied with other marks of a greenish white, that lie deeper in the body of the leaves. The third, and most beautiful, is where the leaves are edged with white, being owing to some disorder in the juices, which it has the natural complection or verdure of the plant. The fourth kind is that called the yellow edge.

Artificial variegation is performed by inarching or inoculating a striped or variegated plant into a plain one of the same sort; as a variegated common jessamin into a plain, common, Spanish, Brazil, or Indian jessamin.

A single bud or eye, Mr Bradly observed, being placed in the escutcheon of a diseempered tree, where it can only receive nourishment from the vitiated juices, will become variegated proportionably to the nourishment it draws; and will partake more of the white and yellow juice, than if a branch shall be inarched, the bud having nothing to nourish it but the juices of the plant; it is inoculated on; whereas a cyon inarched is fed by the striped plant, and the healthful one.

As to the natural stripes and variegations, there are some particular circumstances to be observed: 1. That some plants only appear variegated or bloached in the spring and autumn, the stains disapplying as they gather strength: of this kind are rue, thyme, and marjoram. 2. Some plants are continually bloached in the spongy part of their
their leaves, the sap-vessels all the time remaining of a healthful green; which, being strengthened by rich manure, or being inarched in healthful plants, throw off the diltemper. 3. In other plants, the disease is rooted and inveterate, that it is propagated with the feed; such as the arch-angel, water-betony, back-crefs, bor- rage, stripped cellary, and fycamore; the sides of which produce striped plants.

VARIOLE, the small-pox. See Medicine, p. 75.

VARIX, in medicine, the dilatation of a vein, arising from the too great abundance or thickness of the blood.

VARNISH, a thick, viscid, flaming liquor, used by painters, gilders, and various other artificers, to give a glows and lustre to the works; as also to defend them from the weather, dust, &c.

There are several kinds of varnishes in use; as the fictive or dry varnish, of oil of aspin, turpentine, and sandarach melted together. White varnish, called also Venetian varnish, made of oil of turpentine, fine turpentine, and maflic. Spirit of wine varnish, made of sandarach, white amber, gum elemi, and maflic; serving to gild leather, picture-frames, &c. withal.

1. To make the white varnish: take gum sandarach, of the clearest and whiteft fort, eight ounces; gum maflic, of the clearest fort, half an ounce; of farcocolla, the whiteft, three quarters of an ounce; Venice turpentine, an ounce and a half; benzoin, the cleareft, one quarter of an ounce; white rosin, one quarter of an ounce; gum animae, three quarters of an ounce; let all thefe be difolved, and mixed in the manner following:

Put the farcocolla and rofin into a little more spirit, than will cover them to difolve; then add the benzoin, gum animae, and venice-turpentine, into either a glafs or glazed earthen vessel, and pour on as much spirit as will cover them an inch; then put the gum maflic into a glafs or glazed veffel, and pour strong spirit upon it, covering it alfo about an inch thick, to difolve it rightly; then put your gum elemi into a distinct veffel as before, and cover it with spirits to difolve.

For this purpofe, you need only break the rofin a little, and powder the gum animae, farcocolla, and benzoin.

Let all fland three or four days to difolve, shaking the glasses, &c. two or three times a day, and afterwards put them all together into a glazed veffel, stirring them well, and strain the liquor and gums gently, beginning with the gums, through a linen cloth.

Then put it into a bottle, and let it fland a week before you ufe it, and pour off as much of the clear only, as you think sufficient for present ufe.

A hard varnish that will bear the muffle may be thus made: Take of colophony, an ounce; let it over the fire in a well-glazed earthen vessel, till it is melted; then by little and little, flrew in two ounces of powder of amber, keeping it flirring all the while with a flift; and when you perceive it begin to harden or reft the flift, then put in a little turpentine oil, which will thin and soften it immediately; then put in two ounces of gum copal, finely powdered, sprinkling it in as you did the amber, now and then pouring in a little oil of turpentine; and when it is done, flain it as before directed.

This is proper to varnish over gold; and the things done with it must be set into a declining oven, three or four days successively, and then it will refit even the fire itself.

To make a varnish for gold, or metals made in imitation of gold. Take colophony, and, having melted it, put in two ounces of amber finely powdered, and some spirit of turpentine; and, as the amber thickens, keep it well flirring; then put in an ounce of gum elemi, well pulverized, and more spirit of turpentine; contantly flirring the liquor till all is well mixed and incorporated; but take care, however, to use as little turpentine as you can, because the thicker the varnish is made, the harder it will be. Let this be done over a fand-heat, in an open-glafs; then flain it, as is directed for the preceding varnish. This varnish is to be ufed alone, first warming the veffels made of paper paffe; and lay it on with a painting-brush before the fire, but not too near. Left the fire raife it into blifters. After this has been done, har- den it three several times in ovens; first with a fack heat, the next with a warmer, and the third with a very hot one; and the veffels will look like polished gold.

And as for fuch veffels, &c. as shall be made with faw dust and gums, the varnish may be made of the fame ingredients as above-mentioned, except the gum elemi, and this will dry in the fun, or in a gentle warmth.

To make a varnish for any thing covered with leaf-filver. First paint the thing over with fize, and ground chalk or whitening; let them fland till they are thoroughly dry, and then do them over with very good gold-size of a bright colour (for there is much difference in the colour of it, fome being yellow, and others almoft white; the firt is moft proper for gold, and the laft for silver. When this size is fo dry as that it will juft fllick a little to the touch, lay on the leaf-filver, and clofe it well to the fize.

To make a varnish for silver. Melt, in a well-glazed pipkin, fome fine turpentine, and put in three ounces of white amber finely powdered (more or lefs, according to the quantity your work requires;) put it in by little and little, keeping it continually flirring, adding by de- grees some spirit of turpentine, till all the amber is dif- solved; and then add to it an ounce of farcocolla well beaten, and an ounce of gum elemi well levigated, adding now and then a little spirit of turpentine, till all is dif- solved: do this over a gentle fire, and keep it continually flirring.

This varnish will be as white and ftrong as the former; and is to be ufed warm, and hardened by degrees in an oven, as varnished gold, whereby it will look like polished silver.

Laying on of Varnishes. 1. If you varnish wood, let your wood be very smooth, clofe, grained, free from greafe, and rubbed with rufhes. 2. Lay on your colours as smooth as poiffible; and, if the varnish has any blifters in it, take them off by a polifh with rufhes. 3. While you are varnifhing, keep your work warm, but not too hot. 4. In laying on your varnish, begin in the middle, and froke the brufh to the outifide; then to another ex- treme part, and fo on till all be covered: for if you be- gin at the edges, the brufh will leave blots there, and make the work unequal. 5. In fine works ufe the fift tripoli in polifhing: do not polifh it at one time only; but after the firft time, let it dry for two or three days, and polifh it again for the laft time. 6. In the firft polifhing, you muft ufe a good deal of tripoli; but in the next a very little.
little will serve: when you have done, wash off your tri-
poli with a sponge and water: dry the varnish with a dry
linen rag; and clear the work, if a white ground, with
oil and whitew; or, if black, with oil and lamp-black.

Varnish also signifies a sort of shining coat, wherewith
potter's ware, delf ware, china ware, &c. are covered,
giving them a smoothness and lustre. Melted lead is generally used for the first, and sight for the second.

Varnish, among medallists, signifies the colours antique
medals have acquired in the earth.

The beauty which nature alone is able to give to me-
cals, and art has never attained to counterfeit, en-
ances the value of them; that is, the colour, which cer-
tain fails, in which they have a long time lain, tinges the
metal or fpirit: fome of which are blue, almoft as
beautiful as the turquoifie; others with an inimitable ver-
milion colour; others with a certain shining polished
brown, vially finer than brafil figures.

The most usual varnish is a beautiful green, which
hangs to the finest strokes without effacing them, more ac-
curately than the finest enamel does on metals.

No metal but brass is susceptible of this; for the green
ruff that gathers on silver always foils it, and it must be
got off with vinegar or lemon-juice.

Plafters of medals have a fable or modern varnish,
which they use on their counterfeit, to give them the
appearance, or air, of being antique. But this may be
discovered by its softnefs, it being softer than the natu-
ral varnish, which is as hard as the metal itself.

Some deposit their fpiruous metals in the earth for a
considerable time, by which means they contract a fort
of varnish, which may impofe upon the lefs knowing; o-
thers ufe falf armoniac, and others burnt paper.

VASE, a vefsel either for mechanical, chemical, culinary, or
any other ufe. In anatomy, all the parts which con-
vey a fluid are called vefsels, as the veins, arteries, and
lymphatics.

VASCULAR, something confifling of divers vefsels; as
arteries, veins, nerves, &c.

VASCULIFEROUS plants, fuch whose feds are con-
tained in vefsels, which are fometimes divided into cells.

VASE, a term frequently ufed for ancient vefsels dug from
under ground, orotherwise found, and preferred in the
cabinets of the curious.

In architecture, the appellation vafe is alfo given to
certain ornaments placed on corniches, fofticles, or pedes-
tals, representing the vefsels of the ancients, particularly
thofe ufed in facrifice: as incife-pots, flower-pots,

VASSAL, denotes a tenant that holds land in fee of his lord.

VASSAL, in Scots law. See Law, Tit. x. 3.

VASTUS, in anatomy. See Anatomy, p 207.

VATERIA, in botany, a genus of the polyandria mono-
gynia clafs. The corolla confifts of five petals, and the
calix of five fegments; the fapule has three valves, and
one cell containing three feds. There is but one spe-
cies, a native of India.

VATICAN, a magnificent palace of the pope, in Rome,
which is laid to confift of feveral thousand rooms; but
the parts of it molt admired are the grand hair-cafle, the
pope's aj[artment; and especially the library, which is
one of the richest in the world, both in printed books
and manuscripts.

VAUDEMONT, the capital of a county of the fame name
in Lorrain, fifteen miles south-west of Nancy.

VAUDOS, are certain valleys situated north of the mar-
quifate of Saluzzo, in Italy: the chief town is Lucerne.

VAULT, in architecture, an arched roof, fo contrived
that the fones which form it fustain each other.

Vaults are, on many occasions, to be preferred to flats
or flat ceilings, as they give a greater height and ele-
vation, and are besides more firm and durable.

VAUR, a town of Languedoc, in France, eighteen miles
west of Toulouse.

UBEDA, a city of Andalufia, in Spain, forty-five miles
north east of Granada: W. long. 3° 6', N. lat. 38°.

UBERLINGEN, a town of Swabia, in Germany, ten
miles north of Conflance.

UBES, or St. Ubes, a city and port-town of Portugal,
situated on a fine bay, twenty-one miles south of Lisbon.

UBQUITARIANS, in church-hifory, a fedl of heretics
who sprung up in Germany about the year 1590, and
maintained that the body of Jefus Chrift is ubique, every-
where, or in every place, at the fame time. However,
they were not quite agreed among themselves; fome hold-
ing, that the body of Jefus Chrift, even during his mor-
tal life, was every where; and others dating the ubiquity
of his body from the time of his afcenfion only

UBIQUITY, omniprefence: an attribute of the Deity,
whereby he is always intimately prefent to all things.

UDDER, that part in brutes wherein the milk is prepared;
answering to the mamme, or breasts, in women.

VECTOR, in aeronautics, a line fuppofed to be drawn from
any planet moving round a centre, or the focus of an el-
liphs, to that centre or focus.

VEDETTE, in the military art, a sentinel on horseback,
detached from the main body of the army to discover
and give notice of the enemy's deigns.

VEER, a fea term varioufly ufed. Thus veering out a
rope, denotes the letting it go by hand, or letting it run
out of itfelf. It is not ufed for letting out any running
rope except the fheet.

VEER is alfo ufed in reference to the wind; for, when it
changes often, they fay it veers about.

VEGETABLE, a term applied to all plants. confeidered as
capable of growth; i.e. all natural bodies which have
parts organically formed for accretion, but not fenfation.

VEGETATION, the act whereby plants receive nourish-
ment, and grow. See Agriculture, p. 40.

VEGETATIVE SOUL, among philofophers, denotes that
principle in plants, by virtue of which they vegetate, or
receive nourishment and grow.

VEHICLE, in general, denotes any thing that carries or
receives the body of Jefus Chrift is ubique, every-
where, or in every place, at the fame time. However,
they were not quite agreed among themselves; fome hold-
ing, that the body of Jefus Chrift, even during his mor-
tal life, was every where; and others dating the ubiquity
of his body from the time of his afcenfion only

VEIL, a piece of fuff, ferving to cover or hide any thing.

The Veil, in Roman churches, in time of Lent, they have veils or curtains over the altar, crucifix, images of faints, &c.

A veil or crapes is wore on the head by nuns, as a badge
of their profeflion: as incife-pots, flower-pots,

VEIN, in anatomy. See Anatomy, p. 207.

VEIN, among miners, is that space which is bounded with
waghs, and contains ore, spars, canck, clay, chert, stoll,
brownhe.
VENIAL, in the Romifh theology, a term applied to flight faults, and fuch as eafily obtain pardon.

VELEN, in botany, a genus of the diandria monogyia class. The corolla is funnel-shaped, and crooked; the caix is truncated; and it has two or more equal; and the capfule has two eels, and two valves. There are three fpecies, none of them natives of Britain.

VERA cruz, a port-town of Mexico, fituated on the South Sea, wellward of the gulf of Panama.

VERS, in grammar. See Grammar, p 734.

VERBAL Agreement, in Scots law. See Law, Tit. xxi. 1. &c.

VERBASCUM, in botany, a genus of the pantandria monogyia clafs. The corolla is rotated, and somewhat unequal; and the capfule has two cells, and two valves. There are twelve fpecies, four of them natives of Britain, viz. the thapsus, or great white mullein, the leaves of which are emollient; the lychnitis, or hoary mullein; the nigrum, or black mullein; and the blattoria, or yellow moth-mullein.

VERBENA; in botany, a genus of the diandria monogyia clafs. The corolla is funnel-shaped, and crooked; one tooth of the calyx is truncated; and it has two or four...
four naked seeds. There are 16 species, only one of them, viz. the officinalis, or vervain, a native of Britain.

VERBERATION, in physics, a term used to express the cause of sound, which arises from a vibration of the air, when struck in divers manners by the several parts of the resonant body first put into a vibratory motion.

VERBESINA, in botany, a genus of the Syngenesia polygamia superficula class. The receptacle is paleaceous; the pappus is furnished with an awn; the calyx is double; and it has about five floccules in the radius. There are 13 species, none of them natives of Britain.

VERD, or Cape-verd, a promontory of Africa, forty miles north-west of the mouth of the river Gambia: W. long. 18°, N. lat. 15°. There are a number of islands in the Atlantic ocean, called Cape-Verd islands, from their being situated off this cape.

VERDIGREASE, a kind of rust of copper, much used by painters as a green colour.

Verdigrease is properly no other than copper dissolved by a mild acid into the form of an ærugo, or rust.

This rust of copper is rarely used internally; nor ought it, unless in the most desperate cases, where instantaneous vomiting is necessary. Externally it is much used as a detergent or defcriptive: it eats off fungous flesh in ulcers, and, mixed with honey, is used in aphæs and ulcerations of the mouth.

VERDICT, is the answer of the jury given to the court, concerning the matter of fact, in any civil or criminal, committed by the court to their trial and examination.

VERDITER, or Verditer, a kind of mineral substance, sometimes used by the painters, &c. for a blue; but more usually mixed with a yellow for a green colour.

VERDOY, in heraldry, denotes a bordure of a coat of arms, charged with any kinds or parts of flowers, fruits, feeds, plants, &c.

VERGETTE, in heraldry, denotes a pallet, or small pale; and hence, a shield divided by such pallets is termed vergette. See Pale.

VERSION, a translation of some book or writing, out of one language into another.

VERSATION, the art or manner of making verse; also the tune and cadence of verse.

Verfication is properly applied to what the poet does in great esteem among the ancients, under the name of minium. There are two kinds of it, the one natural, the other factitious. The natural is found in some silver mines, in the form of a ruddy sand, which is afterwards prepared and purified by several lotions and coacations. The artificial is made of mineral cinnebar, ground up with aqua-vitae and urine, and afterwards dried.

It is also made of lead burnt and washed, or of a cerufs prepared by fire: but this is not properly called vermillion, but minium, or red-lead.

VERMIN, a collective name including all kinds of little animals, or insects, which are hurtful or troublesome to men, beasts, fruits, &c. as worms, lice, fleas, caterpillars, ants, flies, &c.

VERNAL, something belonging to the spring season.

VERONA, a city of Italy, in the territory of Venice, capital of the Veronesse, situated on the Adige: E. long. 11° 15', N. lat. 45° 20'.

VERNACULAR, is applied to any thing that is peculiar to some one country.

VERSO, in poetry, a line or part of a discourse, consisting of a number of long and short syllables, which run with an agreeable cadence, the like being also reiterated in the course of the piece.

Verse is also used for a part of a chapter, section, or paragraph, subdivided into several little articles.

VERSIFICATION, the art or manner of making verse; also the tune and cadence of verse.

Verification is properly applied to what the poet does more by labour, art, and rule, than by invention.

VERSION, a translation of some book or writing, out of one language into another.

VERT, in heraldry, the term for a green colour. It is called vert in the blazon of the coats of all under the degree of nobles; but in coats of nobility, it is called emerald; and in coats of kings, venus. In engraving, it is expressed by diagonals, or lines drawn athwart from right to left, from the dexter chief corner to the sinister base, as represented in Plate CXLVII. fig. 23.

VERTEBRAL in anatomy. See Anatomy, p. 166.

VERTEX, in anatomy, denotes the crown of the head.

Hence vertex is also used figuratively, for the top of other things; thus, the vertex of a cone, pyramid, &c. is the top of any one of these figures.

Vertex is also used in astronomy, for the point of heaven perpendicularly over our heads, properly called the zenith.

VERMICILLATE PLANTS. See Botany p. 637.

VERTICITY, is that property of the loadstone, whereby it turns, or directs itself to some peculiar point.

VETIGO, in medicine. See Medicine, p. 146.

VERVAIN, in botany. See Verbena.

VESICA,
VESICA, in anatomy. See Anatomy, p. 269.

VESICATORIUM, an external medicine, serving to raise a blister; whence alo it is itself, though improperly, called a blister.

We have vesicatories made of cantharides, euphorbium, fogs, sublimate of mercury, lapis infernalis, mustard, anacardium, iquivs, bronze, vinegar, pepper, leaven, &c.

VESICULA, a diminutive of vesica, signifying a little bladder.

VESPERTILIONUM, an alias, in anatomy. See Anatomy, p. 269.

VESPERTILIO, the bat, in zoology, a genus of quarads belonging to the order of primates. All the three teeth are erect, pointed, near each other, and the first four are equal; the fore-feet have the toes connected by a membrane expanded into a kind of wings, by which the creature is enabled to fly. They fly about in the night, and feed upon moths.

VESPERTILIONUM ALÆ, in anatomy. See Anatomy, p. 275.

VESSEL, denotes in general any thing for holding liquors; such are our domestic cups, pots, &c. as also the retorts, matresses, crucibles, &c. For the theory and construction of chemical vessels, see Chemistry, p. 108.

In anatomy, all the parts which contain or convey a fluid are called vesicles; as the veins, arteries, lymphatics.

VESSEL, in navigation, a general name for all sorts of ships. See Ship.

VESTALIA, in Roman antiquity, a festival celebrated in honour of the goddess Vesta, on the fifth of the ides of June; that is, on the ninth of that month.

VESTALS, among the ancient Romans, were priestesses of the goddess Vesta, and had the perpetual fire committed to their charge: they were at first only four in number, but afterwards increased to six; and it does not appear that their number ever exceeded six, among whom one was superior to the rest, and called veftalis maxima.

The vestals were chosen from six to ten years of age, and obliged to strict continuance for thirty years; the first ten of which were employed in learning the ceremonies of religion, the next ten in the performance of them, and the last ten in teaching them to the younger vestals.

The habit of the vestals consisted of a head-dress, called infula, which fast close to their heads, and from whence hung certain laces called vitæ; a kind of surplice made of white linen, and over it a purple mantle with a long train to it.

VESTIBLE, in architecture, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the stair-case.

VESTIBLE of the car, in anatomy. See Anatomy, p. 297.

VESTRY, a place adjoining to a church, where the vestments of the minister are kept; and also a meeting at such place, confessing of the minister, church-wardens, and chief men of most parishes, who make a parish vestry or meeting.

By custom there are select vestries, being a certain number of persons chosen to have the government of the parish, make rates, and take the accounts of church-wardens, &c.

VESUVIUS, a famous volcano, or burning mountain, situated only six miles east of the city of Naples, in Italy. See Volcano.

ETCH, in botany. See Vicia.

VETERAN, among the ancient Romans, an appellation given to a soldier who was grown old in the service, or had made a certain number of campaigns.

VIALES, in mythology, a name given among the Romans to the gods who had the care and guard of the roads and high-ways.

VIATICUM, in the church of Rome, an appellation given to the eucharist when administered to persons at the point of death.

VIATOR, in Roman antiquity, an appellation given in common to all officers of any of the magistrates; as lifters, ascenfi, scribes, criers, &c.

VIBE, is sometimes used, by physicians, for a black and blue spot in the skin, occasioned by an afflux or extravasation of blood.

VIBRATION, in mechanics, a regular, reciprocal motion of a body, as a pendulum, &c.

VIBURNUM, in botany, a genus of the pentandria tri-gynia class. The calix is above the fruit, and consists of five segments; the corolla has likewise five segments, and the berry contains one seed. There are nine species, two of them natives of Britain, viz. the lanata, or way-faring tree; and the opulus, or waterelder.

VICAR, a person appointed, as deputy to another, to perform his functions in his absence, and under his authority. A vicar in the canon law, denotes a priest of a parish, the preadial tithes whereof are impropriated or appropriated; that is, belong either to a chapter, religious house, &c. or to a layman, who receives them, and only allows the vicar the small tithes, or a convenient salary.

VICE, in ethics, is ordinarily defined an elective habit, deviating, either in excess, or defect, from the just medium wherein virtue is placed.

Vice, in fhipbery, and other arts employed in metals, is a machine, or instrument, serving to hold fast any thing they are at work upon, whether it is to be filed, bent, rivetted, &c.

Vice is also used, in the composition of divers words, to denote the relation of something that comes instead, or in the place, of another; as vice-admiral, vice-chancellor, vice chamberlain, vice-president, &c. are officers who take place in the absence of admirals, &c.

VICE-ROY, a governor of a kingdom, who commands in the name and stead of a king, with full and sovereign authority. See King.

VICIA, in botany, a genus of the diadelphia decandria class. The under side of the stigma is transversely bearded. There are 18 species, six of them natives of Britain, viz. the acacia, or tufted wood-vetch; the feptum, or bush-vetch; the fativa, or common vetch; the lathyroids, or wild-vetch; and the lutea, or yellow vetch.

VICISSITUDE, the regular succession of one thing after another; as the vicissitude of day and night, of the seasons.

VISCOUNT, a degree of nobility next below a count, or earl, and above a baron.

VICTIM, denotes a bloody sacrifice, offered to some deity,
VINCENT, is also a province of Brazil, bounded by the
River Jamiro on the north, by the Atlantic on the east,
by the province of del Rey on the south, and by that
of the Spanish La Plata on the west.
VINDEMATING, the gathering of the grapes, or other
ripe fruits, as apples, pears, cherries, &c.
VINDEMATRUX, or Vindemator, a fixed star of
the third magnitude in the constellation virgo.
VINE See Vitis.
VINEGAR, an acid penetrating liquor, prepared from
wine, cyder, beer, &c. of considerable use both as a
medicine and furnace. See Chemistry, p. 97, 166.
VINEYARD, a plantation of vines.
The best situation of a vineyard is on the declivity of
an hill, lying on the south.
VINOUS, something that relates to wine, or that has the
taste and smell thereof. See Wine.
VINTAGE, a crop of wine, or what is got from the vines
each season.
VINUM, a liquor or drink commonly called wine. See
Wine.
VIOL, a musical instrument of the same form with the
viol, and struck like that with a bow.
VIOLA, in botany, a genus of the syngenesia monogynia
class. It has two erect follicles; the seeds are plumose;
the calyx consists of five leaves, and the corolla of
five irregular petals horned behind; the capsule has
three valves, and one cell. There are 24 species, of
them natives of Britain.
VIOLACEOUS, something that relates to wine, or that has the
sense it stands opposed to spontaneous.
VIOLACEOUS, in botany, a genus of the syngenesia monogynia
class. It has two erect follicles; the seeds are plumose;
the calyx consists of five leaves, and the corolla of
five irregular petals horned behind; the capsule has
three valves, and one cell. There are 24 species, of
them natives of Britain.
VIOLATION, the act of violating, that is, forcing a
woman, or committing a rape upon her.
This term is also used in a moral sense, for a breach or
infringement of a law, ordinance, or the like.
VIOLIN, a musical instrument of the same form with the
viol, and played like that with a bow.
VIOLONCELLO, of the Italians is properly our fifth vi-
olin, which is a double bass-violin, almost twice as big
as the common bass-violin, and its strings just half as thick and half
as long, which renders the sound just an octave higher
than the same.
VIOLONE, in music, a double bass, almost twice as big
as the common bass-violin, and the strings bigger and
longer in proportion, and consequently its sound an octa-
tave lower than that of our bass-violin, which has a no-
table effect in great concerts.
VIPER, in zoology. See Viper.
VIPERINE, a woman of extraordinary stature and courage;
and who, with the female sex, has the man and air of a
man, and performs the actions and exercises of men.
VIÑA de CRUZ, a double bass, almost twice as big
as the common bass-violin, and the strings bigger and
longer in proportion, and consequently its sound an octa-
tave lower than that of our bass-violin, which has a no-
table effect in great concerts.
VIPER, in zoology. See Viper.
VIPERINE, a woman of extraordinary stature and courage;
and who, with the female sex, has the man and air of a
man, and performs the actions and exercises of men.
VIÑA de CRUZ, a double bass, almost twice as big
as the common bass-violin, and the strings bigger and
longer in proportion, and consequently its sound an octa-
tave lower than that of our bass-violin, which has a no-
table effect in great concerts.
VIPER, in zoology. See Viper.
VIPERINE, a woman of extraordinary stature and courage;
and who, with the female sex, has the man and air of a
man, and performs the actions and exercises of men.
VIÑA de CRUZ, a double bass, almost twice as big
as the common bass-violin, and the strings bigger and
longer in proportion, and consequently its sound an octa-
tave lower than that of our bass-violin, which has a no-
table effect in great concerts.
VIPER, in zoology. See Viper.
VIPERINE, a woman of extraordinary stature and courage;
and who, with the female sex, has the man and air of a
man, and performs the actions and exercises of men.
VIRTUAL, or Potential, something that has a power.

VIRILE, something that belongs or is peculiar to a man.

VIRGO, in astronomy, one of the signs or constellations of the zodiac. See Astronomy, p. 487.

VIRILE, something that belongs or is peculiar to a man, or the male sex.

VIRTUAL, or Potential, something that has a power or virtue of acting or doing. The term is chiefly understood in various significations. In the general it denotes power, or perfection of any thing, whether natural or supernatural, animate or inanimate, essential or accidental. But in its more proper or retracted sense, virtue signifies an habit, which improves and perfects the possessor and his actions.

VIRILISTIC, an Italian term, lately introduced into English, signifying a man of curiosity and learning, or one who loves and promotes the arts and sciences: but among us the term seems to be appropriated to those who apply themselves to some curious and quaint, rather than immediately useful, art or study, as antiquaries, collectors of rarities of any kind, microscopical observers, &c.

VIRULENT, a term applied to any thing that yields a virus, that is, a contagious or malignant pus.

VISCERA, in anatomy, a term signifying the same with entrails, including the heart, liver, lungs, spleen, intestines, and other inward parts of the body. See Anatomy, Part VI.

VISCIDITY, or Viscosity, the quality of something that is viscous or vicious, that is, glutinous and sticky, like bird-lime, which the Latins call by the same viscus.

VISCUM, in botany, a genus of the dioecia tetrandria class. The corolla consists of six segments, and the calyx of five teeth; and the berry contains four seeds.

Vissiers, or Vasters, called visiers-azem, that is, grand vizier, is the prime minister of the whole empire. He commands the army in chief, and presides in the divan or great council. Whereof there are two kinds; the first, called by the name viziers; the intermediate ones being shorter, and more than three grains; and the claws are exerted. There are six species, viz. 1. The ichneumon, with the tail tapering towards the point, and the toes distantly from each other.

VISION, in optics, the act of seeing or perceiving external objects, by means of the organ of sight, the eye. See Anatomy, p. 289. and Optics.

VISULA, or Weisel, a large river of Poland, which, taking its rise in the mountains south of Silesia, visits Cracow, Warsaw, &c. and continuing its course north, falls into the Baltic sea below Danzig.

VISUAL, in general, something belonging to vision.

VITAL, in physiology, an appellation given to whatever ministers principally to the constituting or maintaining of life in the bodies of animals: thus, the heart, lungs, and brain are called vital parts; and those operations of these parts, whereby the life of animals is maintained, are called vital functions.

VITEX, in botany, a genus of the didynamia angiosperma class. The corolla consists of six segments, and the calyx of five teeth; and the berry contains four seeds.

VITICUS, in botany, a genus of the dioecia tetrandria class. See Anatomy, p. 289. and Optics.

VITREOUS Humor of the Eye. See Anatomy, p. 289.

VITRIFICATION, in chemistry, is the converting a body into glass, by means of fire.

VITRIOL, a compound body formed of the particles of metals dissolved by the acid of sulphur, and that either by the operations of nature within the earth, or in the chemists laboratory by proper admixtures and affinities, and afterwards, by the help of water, brought into the form of a salt. See Chemistry, p. 81, 152.

VITRIOLATED, among chemists, something that has vitriol infused in it.

VITRIOLIC, an appellation given to whatever abounds with; or partsake of, the nature of vitriol; thus fuch fossil bodies as contain vitriol, are called vitriolic minerals, or ores of vitriol.

VITTA, in anatomy, that part of the amnios which sticks to the order of serre. They have six fore-teeth, the intermediate ones being shorter, and more than three grains; and the claws are exerted. There are six species, viz. 1. The ichneumon, with the tail tapering towards the point, and the toes distantly from each other.

VIVIPAROUS, in natural history, an epithet applied to such animals as bring forth their young alive and perfect, in contradistinction to them that lay eggs, which are called oviparous animals.

VIVAN,
UKRAIN, a province of Muscovy, lying northwards of Little Tartary, so called as being a frontier against Turkey.

ULADISLAW, a city of Great Poland, situated on the river Borisithenes, eighty-miles north-west of Warlaw: E. long. 19°, and N. lat. 53°.

ULCER, in surgery. See Surgery, p. 646.

ULCERATION, in surgery, a little hole in the skin, caused by an ulcer.

ULEX, in botany, a genus of the diadelphus deciduaria class. The calyx consists of two leaves; and the pod is about the length of the calyx. There are two species, one of them, viz. the europeus, or furze, a native of Britain.

ULGINOUS, in agriculture, an appellation given to a moist, marshy, and feney soil.

ULLAGE, in gauging, is so much of a cask or other vessel, as it wants of being full.

ULM, an imperial city of Swabia, in Germany, ninety miles south-west of Ratibon: E. long. 109°, N. lat. 43° 24'.

ULMORIA, in botany. See Filipendula.

ULMUS, in botany, a genus of the pentandria digynia class. The calyx consists of five segments; it has no corolla; and the berry is dry, compressed, and membranaceous. There are three species, two of them natives of Britain, viz. the campesfris, or common elm; and the glabra, or broad-leaved elm.

ULNA, in anatomy. See Anatomy, p. 178.

ULNARIS, in anatomy. See Anatomy, p. 199.

ULSTER, the most northern province of Ireland, the chief town of which is Londonderry.

ULTERIOR, in geography, is applied to some part of a country or province, which, with regard to the rest of that country, is situated on the farther side of the river, mountain, or other boundary, which divides the country into two parts.

ULTIMUS HÆRES, in Scots law. See Law, Tit. xxix.

ULTERIOR, in geography, is applied to some part of a country or province, which, with regard to the rest of that country, is situated on the farther side of the river, mountain, or other boundary, which divides the country into two parts.

UGC NIA, in general, a Latin term denoting the twelfth part of any thing; particularly the twelfth part of a pound, called in English an ounce; or the twelfth part of a foot, called an inch.

UNCTION, the act of anointing or rubbing with oil or other fatty matter.

UNCTION, in matters of religion, is used for the character conferred on sacred things, by anointing them with oil. Anointings were very frequent among the Hebrews. They anointed both their kings and high-priests at the ceremony of their inauguration. They also anointed the sacred vessels of the tabernacle and temple, to sanctify and consecrate them to the service of God. The anointing of kings is supposed to be a ceremony introduced very late among the Christian princes. It is said, that none of the emperors were ever anointed before Justinian, or Justin. The emperors of Germany took the practice from those of the eastern empire: king Pepin of France was the first who received the anointing. In the ancient Christian church, anointment always accompanied the ceremonies of baptism and confirmation. Extreme anointing, or the anointing persons in the article of death, was also practised by the ancient Christians, in compliance with the precept of St James, chap. v. 14. and 15 verses; and this extreme anointment the Romish church has advanced to the dignity of a sacrament. It is administered to none but such as are afflicted with some mortal disease, or are in a decrepit age. It is refused to impenitent persons, as also to criminals. The parts to be anointed are the eyes, the ears, the nostrils, the mouth, the hands, the feet, and the reins. The laity are anointed in the palms of the hands, but priests on the back of it; because the palms of their hands have been already consecrated by ordination. The parts above-mentioned are anointed in the form of a cross. The priest begins anointing the sick person's eyes, saying, ' May God, by his holy anointing, pardon you the sins you have committed by the eyes.' In like manner he proceeds to the other parts, varying the words according to the parts he anoints.

UNDECEMVIR, a magistrate among the ancient Athenians, who had ten other colleagues or associates joined with him in the same commission. The function of the undecemvir at Athens were much the same as those of the prævots de marcscheuffe in France: they took care of the apprehending of criminals, secured them in the hands of justice, and when they were condemned, took them again into custody, that the sentence might be executed on them. They were chosen by the tribes, each tribe naming its own; and as the number of the tribes after Callithenes was but ten, which made ten members, a scribe or notary was added, which made the number eleven.

UNDECEMVIR, a magistrate among the ancient Athenians, who had ten other colleagues or associates joined with him in the same commission. The function of the undecemvir at Athens were much the same as those of the prævots de marcscheuffe in France: they took care of the apprehending of criminals, secured them in the hands of justice, and when they were condemned, took them again into custody, that the sentence might be executed on them. They were chosen by the tribes, each tribe naming its own; and as the number of the tribes after Callithenes was but ten, which made ten members, a scribe or notary was added, which made the number eleven.

UNDER the sea, in the sea-language. A ship is said to be so when she lies still, or waits for some other ships, with her helm luffed, or tied up a lee.

UNDERSTANDING. See Metaphysics, and Logic.

UNDERWALD, a canton of Switzerland, bounded by the Switz and Lucern on the north, by Uri on the east, and by another part of Lucern on the west; being about 25 miles long, and as many broad.

UNDERWOOD, is coppice, or any wood that is not accounted timber.
UNDULATION, in physics, a kind of tremulous motion or vibration observable in a liquid, whereby it alternately rises and falls like the waves of the sea.

This undulatory motion, if the liquid be smooth and at rest, is propagated in concentric circles, as most people have observed upon throwing a stone or other matter upon the surface of a flagrant water, or even upon touching the surface of the water lightly with the finger or the like. The reason of these circular undulations is, that by touching the surface with your finger, there is produced a depression of the water in the place of contact. By this depression the subjacent parts are moved successively out of their place, and the other adjacent parts thrust upwards, which lying successively on the descending liquid, follow it; and thus the parts of the liquid are alternately raised and depressed, and that circularly. When a stone is thrown into the liquid, the reciprocal vibrations are more conspicuous.

Undulatory motion is likewise applied to a motion in the air, whereby its parts are agitated after the like manner as waves in the sea; as is supposed to be the case when the string of a musical instrument is struck. This undulatory motion of the air, is supposed the matter or cause of ultrasound.

UNDULATORY, in medicine and surgery, a topical remedy or composition, chiefly used in the dressing of wounds and ulcers.

UNGUIS, in anatomy. See Anatomy, p. 150.

UNION, a junction, coalition, or assemblage of two or more different things in one.

UNION OF LANDS, in Scots law. See Law, Tit x. 20.

UNION, or the Union, by way of eminence, is more particularly used to express the act whereby the two separate kingdoms of England and Scotland were incorporated into one, under the title of The Kingdom of Great-Britain. This happy union, in vain attempted by king James I. was at length effected in the year 1707, by the general consent of the queen and the élites of each realm. The chief articles of this union are, That the two kingdoms shall be united into one kingdom, by the name of Great-Britain; that they, in consequence thereof, be represented by one parliament, of which sixteen peers and forty-five commoners are to be elected for Scotland, and have the same privileges with those of England; that the subjects of either nation shall have equal freedom of trade, and be liable to the same customs, and the like laws for public government, &c. The kirk or church of Scotland is confirmed; and the courts of justice are to remain the same as they were before the union, yet subject to regulation, &c. A court of exchequer is also erected in Scotland, to be a court of record, revenue, and judicature; for ever; and barons of the said court are appointed, who shall be the judges there.

UNION, or the Union, by way of eminence, is more particularly used to express the act whereby the two separate kingdoms of England and Scotland were incorporated into one, under the title of The Kingdom of Great-Britain. This happy union, in vain attempted by king James I. was at length effected in the year 1707, by the general consent of the queen and the élites of each realm. The chief articles of this union are, That the two kingdoms shall be united into one kingdom, by the name of Great-Britain; that they, in consequence thereof, be represented by one parliament, of which sixteen peers and forty-five commoners are to be elected for Scotland, and have the same privileges with those of England; that the subjects of either nation shall have equal freedom of trade, and be liable to the same customs, and the like laws for public government, &c. The kirk or church of Scotland is confirmed; and the courts of justice are to remain the same as they were before the union, yet subject to regulation, &c. VOCABULARY, in grammar, denotes the collection of the words of a language, with their significations, otherwise called a dictionary, lexicon, or nomenclature. See Dictionary.

A vocabulary is properly a larger kind of dictionary, which does not enter so minutely into the origins and different acceptations of words.

VOCAL, something that relates to the voice or speech: thus vocal music is that set to words, especially verses, and to be performed by the voice; in contradistinction to instrumental music, composed only for instruments, without singing.

VOCATIVE, in grammar, the fifth of nouns. When we name the person we are speaking to, or address ourselves to the thing we are speaking of, as if it were a person, the noun or name requires a new relation, which the Latins and Greeks express by a new termination, called the vocative; as, from dominus, a lord, is formed the vocative domine, O lord.

VOICE, a sound produced in the throat and mouth of an animal, by an apparatus of instruments for that purpose. Voices are either articulate or inarticulate. Articulate voices are those whereof several conpire together to form some syllable or little syllable of sounds; such are the voices expressing the letters of an alphabet, numbers, of which joined together form words. Inarticulate voices are such as are not organized, or assembled into words; such is the barking of dogs, the braying of asses, the hissing of serpents, the singing of birds, &c.

The formation of the human voice, with all the varieties thereof observed in speech, mutter, &c., makes a very curious article of inquiry; and the apparatus and organization of the parts administering thereto, is something exceedingly surprising. Those parts are the trachea or wind-pipe, through which the air passes and repasses into the lungs; the larynx, which is a short cylindrical canal at the head of the trachea; and the glottis, which is a little oval cleft or chink left between two semicircular membranes stretched horizontally within the larynx; which membranes, though capable of joining close together, do generally leave an interval either greater or less between them called the glottis. A particular description of each part may be seen in Anatomy, Part IV.

VOICE, in grammar, a circumstance in verbs, whereby they come to be considered either active or passive; i.e., either expressing an action impressed on another subject, as, I beat; or receiving it from another, as I am beaten. See Grammar, p. 738.

VOICE, in matters of election, denotes a vote or suffrage.

VOLUME, in heraldry, is the fifth flate or cafe of nouns.

When we name the person we are speaking to, or address ourselves to the thing we are speaking of, as if it were a person, the noun or name requires a new relation, which the Latins and Greeks express by a new termination, called the vocative; as, from dominus, a lord, is formed the vocative domine, O lord.

VOLANT, in heraldry, is when a bird in a coat of arms is drawn flying, or having its wings spread out.

VOLATILE, in physics, is commonly used to denote a mixed body whose integral parts are easily diffusible by fire or heat; but is more properly used for bodies whose elements or first component parts are easily separated from each other, and dispersed in air. See Chemistry.

VOLATILIZATION, the act of rendering fixed bodies volatile, or of resolving them by fire into a fine volatile vapour or spirit, which easily diffuses and flies away. All bodies, even the most fixed, as gold, may be volatilized; either of themselves, or with the admixture of some volatile substance, or spirit, by distillation or sublimation.

VOLERY, a great bird-cage, so large that the birds have room to fly up and down in it.

VOLHINIA, or Volonia, a province of Poland, bounded by Poland, on the north; by the lower Volhina, or Ukraine, in the territories of Russia, on the east; by Poland, on the south; and by the province of Red Russia, on the west.

VOLITION, the act of willing. See Metaphysics.

VOLKAMERIA, in botony, a genus of the didynamia class. The calix consists of five segments; and the berry contains two bilocular seeds. There are two species, none of them native of Britain.

VOLLEY, a military salute, made by discharging a great number of fire-arms at the same time.

VOLERO, in Roman antiquity, an appellation given to the slaves, who, during the second Punic war, offered themselves to serve in the army.

VOLI, in the manage, a round or circular tread; and hence by the phrase, to make volis, is understood a gate of two treads, made by a horse going sidewise round a center, in such a manner, that these two treads make parallel tracks, one larger made by the fore-feet, and another smaller made by the hind feet, the group approaching to wards the centre, and the shoulders bearing outwards.

VOLUME, in matters of literature, a book; or writing, of a just bulk to be bound by itself. The name is derived from the Latin volumere, to roll up; the ancient manner of making up books being in rolls of bark or parchment. See Book.

VOLUNTARY, in music, a piece played by a musician extempore, according to his fancy. This is often used before he begins to set himself to play any particular composition, to try the instrument, and to lead him into the key of the piece he intends to perform.

VOLUNTEERS, in the military, perfons who of their own accord, and at their own expense, serve in the army.

VOLUTA, in natural history, a genus of snails belonging to the order of vermes testacese. It is an animal of the snail kind, with an unilocular spiral shell, of which there are 46 species, distinguished by peculiarities in their shells.

VOLUÈ, in architecture, a kind of spiral scroll, used in the
the Ionic and Composite capitals, whereof it makes the principal characteristic and ornament. See Architecture, p. 352.

VOLVULUS, in medicine, a name which some authors give to the ileus passion. See Medicine, p. 114.

VOMIR, in anatomy. See Anatomy, p. 163.

VOMICA, in medicine, is commonly taken for a suppura-
ted impolthume, or an abscess with a suppuration. See Medicine, p. 104.

VOMIT, in pharmacy. See Emetic.

VOMITING, in medicine, a retrograde spasmatic motion

VOORN, one of the islands of Holland, bounded by the

Vortex in the Cartelian philosophy, is a sytem or col-

VORTEX, in meteorology, a whirlwind, or sudden, ra-
pid, and violent motion of the air in gyres, or circles.

VOTE, the suffrage or resolve of each of the members of an assembly, where any affair is to be carried by a majority; but more particularly used for the resolves of the members of either house of parliament.

VOTIVE medals, those on which are expressed the vows of the people for the emperors or empresses. See Medal.

VOW, a solemn and religious promise, or oath. See Oath.

time for accomplishing his vow, he was bound to do it

VOWS, among the Romans, signified sacrifices, offerings,

UPLAND, denotes high ground, or, as some call it, terras

UPPER, in heraldry, is used in respect of shell-fishes,

UPPER, a market-town of Worcestershire, nine miles

UPUPA, in ornithology, a genus belonging to the order of pike. The beak is arcuated, convex, and somewhat

URACHUS, a membranous canal in the fucus of quadru-

URANBURG, or URANiBURG, a castle of Denmark, sit-

URANIGE, a letter which affords a complete

URANUS, one of the planets of the sun. The letters, which, depending on a particular application of

URANUS, a membranous canal in the foetus of quadru-

URANUS, a letter which affords a complete

URANUS, a genera of shells. The letters, which, depending on a particular application of

URANUS, a letter which affords a complete
URANOSCOPEs, in ichthyology, a genus belonging to the order of jugulares. The head is large, rough, and depressed, the upper jaw being shorter than the under one; there are five dentated rays in the membrane of the gills; and the anus is in the middle of the body. There is but one species, found in the Mediterranean sea.

URBINO, a province of Italy, in the pope's territory, bounded by Romania and the gulf of Venice on the north and eait, by the marquisate of Ancona on the south, and by Tuscany on the west, being seventy miles long, and from twenty to fifty broad.

Urbin is also the capital of this province.

UDEs, or UDEs, in heraldry. A crois orde seems to be the same with what we otherwise call chleche, or chleche. See Chleche.

URENA, in botany, a genus of the monadelphia polyanthria class. The calix is double, the exterior one consisting of five segments; the capsule has five cells containing one seed. There are three species, all natives of China.

URETERS, in anatomy. See Anatomy, p. 268.

URETHRA, in anatomy. See Anatomy, p. 272.

URGEL, a town of Spain, in the province of Catalonia, capital of the territory of Urgel, situated on the river Segra, seventy-five miles north of Barcelona.

URI, one of the cantons of Switzerland; bounded by that of Switz, on the north; by Claris and the Grisons, on the east; by Underwald, on the south; and by the Canton of Bern, on the west.

URIM and thummim, among the ancient Hebrews, a certain oracular manner of consulting God, which was done by the high priest, dressed in his robes, and having on his chest or breast-plate.

Various have been the sentiments of commentators concerning the urim and thummim. Josephus, and several others, maintain, that it meant the precious stones used in the high prieft'; and that this was called urim and thummim, because urim signifies some divine virtue and power annexed to the breast-plate of the high priest, by which an oracular answer was obtained from God when he was consulted by him. Spencer believes that the urim and thummim were two little golden figures shut up in the pectoral as in a purse, which gave responses with an articulate voice. In short, there are as many opinions concerning the urim and thummim as there are particular authors that wrote about them. The safest opinion, according to Broughton, seems to be, that the words urim and thummim signify some divine virtue and power annexed to the breast-plate of the high priest, by which an oracular answer was obtained from God when he was consulted by him. And that this was called urim and thummim to express the clearness and perfection which these oracular answers always carried with them; for urim signifies light, and thummim perfection; these answers not being imperfect and ambiguous, like the heathen oracles, but clear and evident. The use made of the urim and thummim was to consult God in difficult cases relating to the whole state of Israel; and sometimes in cases relating to the king, the sanhedrim, the general of the army, or some other great personage.

URINAL, in medicine, a vessel fit to receive and hold urine, and used accordingly for the convenience of sick persons. It is usually of glass, and crooked; and sometimes it is filled with milk, to assuage the pain of the gravel.

URINAL, in chemistry, is an oblong glass vessel, closed for making solutions, and so called from its resemblance to the glasses in which urine is set to settle for the inspection of the physician.

URINE, a serous and saline fluid, of a citron-colour, separated from the blood, and carried by the emulgent arteries to the kidneys, from whence it descends to the bladder by the ureters, and is from time to time emitted thence by the canal of the urethra. See Anatomy, p. 268. For the analysis of urine, see Chemistry, p. 177.

URN, a kind of vase, of a roundish form, but biggest in the middle, like the common pitchers, now seldom used but in the way of ornament over chimney pieces, in buffets, &c. The great use of urns among the ancients, was to preserve the ashes of the dead after they were burnt; for which reason they were called cineraria, and urne cineraria, and were placed sometimes under the tombstone whereon the epitaph was cur; and sometimes in vaults in their own houses. Urns were also used at their sacrifices to put liquid things in.

UROGALLUS, in ornithology. See Tetrao.

URSA, in astronomy. See Astronomy, p. 487.

URSULINES, in church-history, an order of nuns, founded originally by St Angela of Brescia, in the year fifteen hundred thirty seven, and so called from St Ursula, to whom they were dedicated. They observe the rules of St Augustine, and are chiefly noted for taking on them the education and instruction of young maids: their monasteries are a kind of schools where young ladies of the best families receive their education.

URSUS, in zoology, a genus of quadrupeds belonging to the order of fera. There are five forefeet in the upper jaw alternately hollow on the inside, and fix in the under jaw, the two lateral ones being labated; the dog-teeth are solitary and conical; the grinders are five or six; the tongue is smooth; the eyes are furnished with a nictitating membrane; the nose is prominent; and there is a crooked bone in the penis. There are four species, viz. 1. The arctis, or white bear, with an abrupt tail. He is a native of the northern parts of Europe, and feeds upon berries, insects, and the bodies of dead cattle. He is naturally a lazy animal; but when enraged, he becomes agile and furious, standing erect and fighting with his forefeet. When lying, he constantly licks his paws. The female admits the male about the end of October, and the bëbings forth in 112 days. He never attacks a man, unless he be provoked. 2. The meles, has the tail of an uniform colour; the body is ash-coloured above and black below, with a longitudinal black belt across the eyes and ears. He is likewise a native of Europe, and dwells in woods and the cliffs of rocks. He feeds upon eggs, insects, the leaves of the lathynus, &c. In the night he preys upon rabbits, &c and feldom appears in the day. He shuts himself up in a den dug in the earth during the winter, and sucks a pellicle or bladder situated above the anus. 3. The lator, has an annular tail, and a black belt across the eyes. He is found about the sea-shores of America. He feeds upon eggs, fowls, snakes, &c. 4. The laucus, has a long tail; and the body is iron coloured. He is a native of Hudson's bay.

URTICA, in botany, a genus of the monicea tetrandria class. The calix of the male consists of four leaves, and that
that of the female of two valves; neither of them have any corolla; the male has a cup-shaped nectarium, and the female bears one smooth seed. The species are 18, three of them natives of Britain, viz. the pilaster, or Roman nettle; the arum, or lesser nettle; and the drioica, or common mealy.

USUARER, a person charged with a habit or act of usury. See Usury.

USUARIUS CONTRACT, is any bargain or contract whereby by a man is obliged to pay more interest for money than the statute allows.

USURPATION, in law, is an injurious using or enjoyment of a thing for continuation of time, that belongs of right to another.

USURY, in the general, denotes a gain or profit which a person makes of his money, by lending the same; or it is an increase of the principal, exacted for the loan thereof; or the price a borrower gives for the use of a sum credited to him by the lender, called also interest.

The word usury is generally taken in an evil sense, viz. for an unlawful profit which a person makes of his money; in which sense it is, that usury is forbidden by the civil and ecclesiastical, and even by the law of nature. See Law, Tit. xxxiii. 37.

UTERINE, something belonging to the uterus or womb of a woman.

Brother or Sister Uterine, in Scots law. See Law, Tit. xxvii. 3.

UTERUS, in anatomy. See Anatomy, p. 274.

UTILE, a Latin term, signifying profitable or useful; in which sense it is sometimes used by English writers.

UTOXETER, a market-town of Staffordshire, twelve miles south-east of Stafford.

UTRECHT, the capital of a province of the same name, in the united Netherlands, situated twenty-three miles south-east of Amsterdam.

UTRICULARIA, in botany, a genus of the diandria monogynea class. The corolla is ringent and calcareated; the calix consists of two equal leaves; and the capsule of one cell. There are five species, two of them natives of Britain, viz. the vulgaris, or common hooded milfoil; and the minor, or lesser hooded milfoil.

UVA URSI, in botany. See Vaccinium.

UVEA, in anatomy. See Anatomy, p. 289.

VULCANO, or Volcano, in natural history, a burning mountain, or one that vomits forth fire, flame, ashes, cinders, &c.

As to the cause of volcanos, it is found by experience, that there are several inflammable bodies, which, being mixed together in due proportion, will kindle into flame by fermentation alone, without the help of any fiery particles. Thus M. Lemery having covered up in the earth about fifty pounds of a mixture, composed of equal parts of sulphur and filings of iron, tempered with water; after eight or nine hours time, the earth where it lay vomited up flames. From this experiment we see the true cause of the fire of Etna, Vesuvius, and other burning mountains, which probably are made up of sulphur and some other matter proper to ferment with it, and take fire.

VULGATE, a very ancient Latin translation of the Bible, and the only one the church of Rome acknowledges authentic. See Bible.

VULNERARY, in medicine, an epithet given to remedies proper for the cure of wounds and ulcers.

VULPES, the Fox. See Canis.

VULTUR, a genus of birds belonging to the order of accipitres. The head is irrat, and crooked at the point; the head has no feathers, on the forehead being only naked skin; and the tongue is bifid. There are eight species.
WAAG, a river of Hungary, which rises in the Carpathian mountains, on the confines of Poland, and running first from east to west, then turns south, and passing by Leopoldstadt, falls into the Danube, opposite to the island of Schut.

WAAL, a river of the United Netherlands, being one of the branches of the Rhine, which runs from east to west, through the Betu, in the province of Guelderland, passing by Nimoguen, Tiel, Bommel, and Gorcum, and continuing its course easterly, unites its waters with the Maas, and, passing by Dort, falls into the German sea below the Briel.

WADD, or Wadding, is a flopple of paper, hay, straw, or the like, forced into a gun upon the powder, to keep it close in the chamber; or to put up close to the shot, to keep it from rolling out.

WADSET in Scots law. See Law, Tit. xvi., &c.

WAFT. To waft a ship, is to convey her safe, as men of war do merchant ships. To make a waft, is to hang out some coat, sea gown, or the like, on the main shrouds of the ship, as a signal for people to come aboard, and signifying that the ship is in great distress.

WAFERS, or Waffers, are made thus: take very fine flour, mix it with glair of eggs, fift, and a little yeast; mingle the materials; beat them well together; spread the batter, being made thin with gum-water, on even tin plates; and dry them in a stove; then cut them out for use.

You may make them of what colour you please, by tinging the paste with brazil or vermilion for red; indigo or verditer, &c. for blue; saffron, turmeric, or gamboge, &c. for yellow.

WAGGON, a wheel carriage, of which there are various forms, accommodated to the different uses they are intended for. The common waggon consists of the shafts or rads, being the pieces which the hind horse bears upon; the wheels; the flotes, or cross pieces, which hold the shafts together; the bolster, being that part on which the fore wheels and the axle-tree turn in wheeling the waggon across the road; the shell or body of the waggon, having the flaves or rails fixed thereon; the bales, or hoops, which compose the top; the tilt, the place covered with cloth, at the end of the waggon. See Mechanics, p. 50.
WARD, a word of divers significations: thus, a ward in London, is a part of the city committed to the special charge of one of the aldermen of the city. There are twenty-six wards in London, which are as hundreds, and the parishes thereof as towns. A forest is also divided into wards, and so are most of our hospitals.

WARD-HOLDING, in Scots law. See Law, Tit. xi. 1.

WARD-HOOK, or WADD-HOOK, in gunnery, a rod or staff with an iron end turned serpent-wise, or like a screw, to draw the wadding out of a gun when it is to be unloaded. See WADD.

WARDEN, or GUARDIAN, one who has the charge or keeping of any person, or thing, by office. See GUARDIAN.

Such is the warden of the fleet, the keeper of the fleet-prison; who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

Church Wardens. See Church.

WARDHUYS, a port of Norwegian Lapland, 120 miles south-east of the north cape: E. long. 28°; and N. lat. 71°.

WARDMOTHE, in London, is a court so called; which is kept in every ward of the city, answering to the curiata comitia in ancient Rome.

WARDROBE, a closet, or little room adjoining to a bed-chamber, serving to diffuse and keep a person's apparel in; or, for a servant to lodge in, to be at hand to wait, &c.

Market of the wards, in a prince's court, is an apartment where orders of his robbers, wearing apparel, and other necessaries, are preferred under the care and direction of proper officers; as the master of the wardrobe, clerk, &c. of the wardrobe.

WARE, a market-town of Hertfordshire, under the meridian of London, and twenty miles north of that city.

WAREHAM, a borough of Dorsetshire, seventeen miles north-east of Salisbury.

WARN, in law, is to summon a person to appear in a court of justice.

Warming of Tenants, in Scots law. See Law, Tit. xiii. 16.

WARP, in the manufactures, is the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the weaver passes the threads of the woof, to form a cloth, ribband, syltian, or other matter.

WARRANT, in Scots law. See Law, Tit. x. 11.

WARRANT, an act, instrument, or obligation, whereby a person authorizes another to do something which he otherwise had not a right to do.

WARRANTY, a promiss or covenant by deed, made by the bargainer for himself and his heirs, to warrant and secure the bargainee and his heirs against all men for enjoying the thing agreed on between them.

WAREN, a franchise, or place privileged either by prescription or grant from the king, to keep beasts and fow of warren in; as rabbits, hares, partridges, pheasants, &c.

WARRINGTON, a market-town of Lancashire, seventeen miles east of Liverpool.

WARSAW, the capital of Warskia, and of the kingdom of Poland: E. long. 21° 15', and N. lat. 52° 15'.

WARSOVIA, a province of Poland, bounded by Prussia, on the north; by Polachia, on the east; by the province of Little Poland, on the south; and by that of Great Poland, on the west.

WARD, a round knot or knob made with three strands of a rope, so that it cannot fall, by which the tacks, top-sail sheets, and hoppers are made fast, as also some other ropes.

WARD-READED, on board a ship, a name the seamen give to a ship, which, after the comes to her bearing, is built strait up: this way of building, though it does not look well, nor is, as the seamen term it, ship-shape; yet it has this advantage, that a ship is thereby more roomy within board, and becomes thereby a wholesome ship at sea, especially if her bearing be well laid out.

WALL, in architecture, the principal part of a building, as serving both to enclose it, and support the roof, floors, &c. Walls are distinguished into various kinds, from the matter whereof they consist, as of plastered or mud-walls, brick-walls, stone-walls, flint or boulder walls, and boarded-walls. See Architecture.

WALLINGFORD, a borough town of Berkshire, situated on the river Thames, twelve miles north of Reading.

WALLS, the inhabitants of a considerable part of the Spanish Netherlands, viz. those of Artois, Hainault, Namur Luxembourg, and part of Flanders and Brabant.

The Walloon language is said to have been that of the ancient Gauls or Cæls.

WALRUS, in zoology. See Phoca.

WALNUT TREE in botany. See Juglans.

WALSALL, a market-town of Staffordshire, thirteen miles south of St. Ford.

WALSHAM, a market-town of Norfolk, eleven miles north of Norwich.

WALSINGHAM, a market-town of Norfolk, eighteen miles north-west of Norwich.

WALTHAM, a market-town of Leicestershire, sixteen miles north-east of Leicester.

WALTHERIA, in botany, a genus of the monadelphia class.

WAPENTAKE, (from the Saxon) the same with what we call a hundred, and more especially used in the northern counties beyond the river Trent. There have been several conjectures as to the original of the word; one of which is, that anciently makers were made of the armour and weapons of the inhabitants of every hundred; and from these that could not find sufficient pledges of their good abearing, their weapons were taken away, and given to others; whence, it is said, this word is derived.

See Hundred.

WAR, a contest or difference between princes, states, or large bodies of people; which not being determined by the ordinary measures of equity and justice, is referred to the decision of the sword.

WARD, a word of divers significations: thus, a ward in London, is a part of the city committed to the special charge of one of the aldermen of the city. There are twenty-six wards in London, which are as hundreds, and...
A Clock is a machine constructed in such a manner, and regulated by such uniform movements, as to measure time and all its subdivisions with great exactness. The same definition comprehends watches of all kinds; and indeed they are both made upon the same principles. We shall therefore give a view of the construction of both these machines under this article.

**Of the Mechanism of Clocks, and how they measure Time.**

The first figure of Plate CLX is a profile of a clock; P is a weight suspended by a rope that winds about the cylinder or barrel C, which is fixed upon the axis a a; the pivots b b go into holes made in the plates TS, TS, in which they turn freely. These plates are made of brass or iron, and are connected by means of four pillars ZZ; and the whole together is called the frame.

The weight P, if not restrained, would necessarily turn the barrel C with an uniform accelerated motion, in the same manner as if the weight was falling freely from a height. But the barrel is furnished with a ratchet wheel K K, the right side of whose teeth strikes against the click, which is fixed with a screw to the wheel D D, as represented in fig. 2. So that the action of the weight is communicated to the wheel D D, the teeth of which act upon the teeth of the small wheel d which turns upon the pivots e c. This communication of the teeth of one wheel with another is called engrenage or pitching; and a small wheel, like d, is called a pinion.

The wheel E E is fixed upon the axis of the pinion d; and the motion communicated to the wheel D D by the weight is transmitted to the pinion d, consequentally to the wheel E E, as likewise to the pinion e, and wheel F F, which moves the pinion f, upon the axis of which the crown or balance wheel G H is fixed. The pivots of the pinion f play in holes of the plates L M, which are fixed horizontally to the plates T S. In a word, the motion begun by the weight is transmitted from the wheel G H to the palettes I K, which communicates its motion by means of the fork U X riveted on the palettes, to the pendulum A B, which is suspended upon the hook A. The pendulum A B describes, round the point A, an arc of a circle alternately going and returning. If then the pendulum be once put in motion by a pull of the hand, the weight of the pendulum at B will make it return upon itself, and it will continue to go alternately backward and forward till the resistance of the air upon the pendulum, and the friction at the point of suspension at A, destroys the original impressed force. But as, at every vibration of the pendulum, the teeth of the balance wheel G H act upon the palettes I K, (the pivots upon the axis of these palettes play in two holes of the potence r t) that after one tooth H has communicated motion to the palettes K, that tooth escapes; then the opposite tooth G acts upon the palette I, and escapes in the same manner; and thus each tooth of the wheel escapes the palettes I, K, after having communicated their motion to the palettes in such a manner that the pendulum, instead of being flopped, continues to move.

The wheel E E revolves in an hour; the pivot c of this wheel passes through the plate, and is continued to r; upon the pivot is a wheel N N with a long socket fastened in the centre; upon the extremity of this socket r the minute-hand is fixed. The wheel N N acts upon the wheel O; the pinion of which, p, acts upon the wheel g g, fixed upon a socket which turns along with the wheel N. This wheel g g makes its revolution in 12 hours, upon the barrel of which the hour-hand is fixed.

From the above description it is easy to see, 1. That the weight p turns all the wheels, and at the same time continues the motion of the pendulum. 2. That the quickness of the motion of the wheels is determined by that of the pendulum. 3. That the wheels point out the parts of time divided by the uniform motion of the pendulum.

When the cord upon which the weight is suspended is entirely run down from off the barrel, it is wound up again by means of a key, which goes on the square end of the arbor at Q, by turning it in a contrary direction from that in which the weight descends. For this purpose, the inclined side of the teeth of the wheel R (fig. 2) removes the click C, so that the ratchet-wheel R turns while the wheel D is at rest: But as soon as the cord is wound up, the click falls in between the teeth of the wheel D and the right side of the teeth again act upon the end of the click, which obliges the
the wheel D to turn along with the barrel; and the spring A keeps the crank between the teeth of the ratchet-wheel R.

We shall now explain how time is measured by the motion of the pendulum; and how the wheel E, upon the axis of which the minute-hand is fixed, makes but one specific revolution in an hour. The vibrations of a pendulum are performed in a shorter or longer time in proportion to the length of the pendulum itself. A pendulum of 3 feet 9¾ French lines in length, makes 3600 vibrations in an hour; i.e., each vibration is performed in a second of time, and for that reason it is called a second pendulum. But a pendulum of 9 inches 2¾ French lines makes 7200 vibrations in an hour, or two vibrations in a second of time, and is called a half-second pendulum. Hence, in constructing a wheel whose revolution must be performed in a given time, the time of the vibrations of the pendulum which regulates its motion must be considered. Supposing, then, that the pendulum AB makes 7200 vibrations in an hour, let us consider how the wheel E shall take up an hour in making one revolution. This entirely depends on the number of teeth in the wheels and pinions. If the balance-wheel consists of 30 teeth, it will turn once in the time that the pendulum makes 60 vibrations; for at every turn of the wheel, the same tooth acts once on the palette I, and once on the palette K, which occludes two separate vibrations in the pendulum; and the wheel having 20 teeth, it occasions twice 30, or 60 vibrations. Consequently, this wheel must perform 120 revolutions in an hour; because 60 vibrations, which it occasions at every revolution, are contained 120 times in 7200, the number of vibrations performed by the pendulum in an hour. Now in order to determine the number of teeth for the wheels E, F, and their pinions e, f, it must be remarked, that one revolution of the wheel E must turn the pinion e as many times as the number of teeth in the pinion is contained in the number of teeth in the wheel. Thus, if the wheel E contains 72 teeth, and the pinion e 6, the pinion will make twelve revolutions in the time that the wheel makes one; for each tooth of the wheel drives forward a tooth of the pinion, and when the six teeth of the pinion are moved, a complete revolution of the pinion is made. Consequently, the wheel D performs 10 times while the wheel performs one. Now, the wheel E being turned by the pinion e, makes 12 revolutions for one of the wheel E; and the pinion f makes ten revolutions for one of the wheel F; consequently, the pinion f performs 10 times 12 or 120 revolutions in the time the wheel E performs one. But the wheel G, which is turned by the pinion f, occasions 60 vibrations in the pendulum each time it turns round; consequently the wheel G occasions 60 times 120 or 7200 vibrations of the pendulum while the wheel E performs one revolution; but 7200 is the number of vibrations made by the pendulum in an hour, and consequently the wheel E performs but one revolution in an hour; and so of the rest.

From this reasoning, it is easy to discover how a clock may be made to go for any length of time without being wound up: 1. By increasing the number of teeth in the wheels. 2. By diminishing the number of teeth in the pinions. 3. By increasing the length of the cord that suspends the weight; and lastly, by adding to the number of wheels and pinions. But, in proportion as the time is augmented, if the weight continues the same, the force which it communicates to the last wheel GH will be diminished.

It only remains to take notice of the number of teeth in the wheels which turn the hour and minute hands.

The wheel E performs one revolution in an hour; the wheel NN, which is turned by the axis of the wheel E, must likewise make only one revolution in the same time; and the minute-hand is fixed to the barrel of this wheel. The wheel N has 30 teeth, and acts upon the wheel O, which has likewise 30 teeth, and the same diameter; consequently the wheel O takes one hour to a revolution: now the wheel O carries the pinion p, which has six teeth, and which acts upon the wheel q of 72 teeth; consequently the pinion p makes 12 revolutions while the wheel qq makes one, and of course the wheel qq takes 12 hours to one revolution; and upon the barrel of this wheel the hour-hand is fixed. We shall conclude with remarking, that all that has been said here concerning the revolutions of the wheels, &c. is equally applicable to watches as to clocks.

The wheels of a watch, like those of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3. represents the inside of a watch, after the plate (fig. 5.) is taken off. A is the barrel which contains the spring (fig. 6.) which serves in place of a weight, to give motion to the wheels and balance.

The wheels of a watch, like those of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3. represents the inside of a watch, after the plate (fig. 5.) is taken off. A is the barrel which contains the spring (fig. 6.) which serves in place of a weight, to give motion to the wheels and balance.

Watches, as well as clocks, are composed of wheels and pinions, and a regulator to direct the quickness or slowness of the wheels, and of a spring which communicates motion to the whole machine. But the regulator and spring of a watch are vastly inferior to the weight and pendulum of a clock, neither of which can be employed in watches. In place of a pendulum, therefore, we are obliged to use a balance (fig. 4.) to regulate the motion of a watch; and of a spring (fig. 6.) which serves in place of a weight, to give motion to the wheels and balance.

The wheels of a watch, like those of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3. represents the inside of a watch, after the plate (fig. 5.) is taken off. A is the barrel which contains the spring (fig. 6.) which serves in place of a weight, to give motion to the wheels and balance.

Watches, as well as clocks, are composed of wheels and pinions, and a regulator to direct the quickness or slowness of the wheels, and of a spring which communicates motion to the whole machine. But the regulator and spring of a watch are vastly inferior to the weight and pendulum of a clock, neither of which can be employed in watches. In place of a pendulum, therefore, we are obliged to use a balance (fig. 4.) to regulate the motion of a watch; and of a spring (fig. 6.) which serves in place of a weight, to give motion to the wheels and balance.
WATCH and CLOCK WORK.

HII. (fig. 4.) The pivot I, in the end of the verge, enters into the hole c in the potance A (fig. 5.) In this figure the palettes are represented; but the balance is on the other side of the plate, as may be seen in fig. 11. The pivot of the balance enters into a hole of the cock BC, (fig. 10.) A perspective view of which is represented in (fig. 12.) Thus the balance turns between the cock and the potance c, (fig. 5.) as in a kind of cage. The action of the balance-wheel upon the palettes 1, 2, (fig. 4.) is the same with what we have described with regard to the same wheel in the clock; i.e., in a watch the balance wheel obliges the balance to vibrate backwards and forwards like a pendulum. At each vibration of the balance a palette allows a tooth of the balance-wheel to escape, so that the quickness or slowness of the motion of the wheels is entirely determined by the quickness of the vibrations of the balance, and these vibrations of the balance and motion of the wheels are produced by the action of the spring.

But the quickness or slowness of the vibrations of the balance depend not solely upon the action of the great spring, but chiefly upon the action of the spring a, b, c, called the spiral spring, (fig. 14.) Situated under the balance H, and represented in perspective (fig. 11.) The exterior end of the spiral is fixed to the pin a, (fig. 14.) This pin is applied near the plate in a, (fig. 11.) The interior end of the spiral is fixed by a peg to the centre of the balance. Hence if the balance is turned upon itself, the plates remaining immovable, the spring will extend itself, and make the balance perform one revolution. Now, after the spiral is thus extended, if the balance be left to itself, the elasticity of the spiral will bring back the balance, and in this manner the alternate vibrations of the balance are produced.

In fig. 7 all the wheels above described are represented in such a manner, that you may easily perceive at first sight how the motion is communicated from the barrel to the balance.

In fig. 8. are represented, the wheels under the dial-plate by which the hands are moved. The pinion a is adjusted to the force of the prolonged pivot of the wheel D, (fig. 7.) and is called a cannon pinion. This wheel revolves in an hour. The end of the axis of the pinion a, upon which the minute-hand is fixed, is square; the pinion (fig. 8.) is indented into the wheel A, which is carried by the pinion a. Fig. 9. is a wheel fixed upon a barrel, into the cavity of which the pinion (a) enters, and upon which it turns freely. This wheel, (d) revolves in 12 hours, and carries along with it the hour-hand.

WATCHING, in medicine, is produced by too great a determination of the nervous fluid to the organs of the senses; whereby these organs are prepared to receive, readily, any impressions from external objects, which they propagate to the brain, and furnish the soul with divers occasions of thinking. See Medicine, p. 157.

WATER, in physiology, a simple fluid, and liquid body, reputed the third of the four vulgar elements. See Chemistry, p. 67. and Hydrostatics.

Holy Water, a water prepared every Sunday in the Roman church, with divers prayers, exorcisms, &c. used by the people to cross themselves withal at their entrance to and going out of church; and pretended to have the virtue of washing away venial sins, driving away devils, prevailing from thunder, dissolving charms, curing from, or curing diseases, &c. Many of the reformed took the use of holy water to have been borrowed from the lustral water of the ancient Romans.

Water ordeal, or Trial, among our ancestors, was of two kinds, by hot and by cold water. Trial or purgation, by boiling or hot water, was a way of proving crimes, by immerging the body, or the arm, in hot water, with divers religious ceremonies. In the judgment by boiling water, the accused, or he who perjured the accused, was obliged to put his naked arm into a caldron full of boiling water, and to draw out a stone thence placed at a greater or less depth, according to the quality of the crime. This done, the arm was wrapped up, and the judge set his seal on the cloth; and at the end of three days they returned to view it; when if it were found without any scald, the accused was declared innocent. The nobles or great personages purged themselves thus by hot water, and the populace by cold water. The trial, or purgation, by cold water, was thus: After certain prayers and other ceremonies, the accused was swaddled or tied up all in a peloton or lump, and thus cast into a river, lake, or well, of cold water; where if he sunk, he was held criminal; if he floated, innocent.

In the Levitical law, we find mention made of water which proved to prove whether or no a woman was an adulteress; the formula, as it was performed by the priest, may be seen in the fifth chapter of the book of Numbers.

Water, among jewellers, is properly the colour or lustre of diamonds and pearls. The term, though less properly, is sometimes used for the hue or colour of other stones.

Water beetle, in zoology. See Dytiscus.

Water-borne, in the sea-language. A ship is said to be water-borne, when she is where there is no more water than will barely bear her from the ground; or when lying even with the ground, the ruff begins to float or foam.

Water colours, in painting, are such colours as are only diluted and mixed up with gum-water, in contradistinction to oil-colours.

Water-gang, a channel cut to drain a place by carrying off a stream of water.

Water line of a ship, a line which distinguishes that part of her under water from that above, when she is duly laden.

Water-men, are such as row in boats, or ply on the river Thames, in the government of whom the lord-mayor and court of aldermen there, had always the taking more than which makes them liable to a fine of 40l. and half a year's imprisonment.

Water-shoot, a young sprig which springs out of the root or block of a tree.

Water shot, in the sea-language, a fort of riding at anchor, when a ship is moored neither close the tide, nor right up and down, but quartering between both.

Water-table, in architecture, a foot of ledge left in stone.
WATCH and CLOCK WORK.
Water-works, in general, denote all manner of machines

WATERING, in the manufactures, is to give a lustre to

WATLINGTON, a market-town of Oxfordshire, situated

WAVE, in philosophy, a cavity in the surface of water,

water from running down there.

wall begins to abate.

from the ground, from which place the thickness of the

Hone or brick-walls, about eighteen or twenty inches

drifts, may be called water-works. See Hydro-

fluffs, &c. by wetting them lightly with gum-water, and

therwise the folds of the fluffs will stick together: the o-

WAVE-offering, in Jewish antiquity, a sacrifice offered

WAVING, in the sea-language, is the making signs to a
erations of the intellefines; but its great ufe is in the ma-
king ointments and plasters for external fufe, and the greater
part of thofe of the fshops owe their confiffence to it.
The white-wax is alfo an ingredient in fome of the ce-
rates and ointments of the fshops; and is ufed in making
balls, and in many of the nicer arts and manufactures,
where wax is required.

Sealing. Wax is made in the following manner: Take one
pound of bees wax; three ounces of fine turpentine; o-
live-oil, and rosin, finely powdered, of each one ounce:
when they are well melted, and the dros taken off, put
in an ounce and a half of vermilion, or red-lead, finely
ground, and stir them together till they are well incor-
porated: and when this mixture grows a little cool, roll
it into flecks, or in any other form. If you would have
it black, instead of vermilion, or red-lead, put in lamp-
black. The soft, red, and green-wax, ufed in large
feals to fome of our law writings, are thus made: Melt
bees-wax over a gentle heat, with fuch a proportion of
Venice turpentine as, when cold, will give it the due
concifence; this is determined by repeated trials, firft
putting in but little turpentine, and afterwards more and
more, till by dropping a piece upon a marble to cool, it
is found of the true concifence. They then colour it
with red-lead, or vermilion, or with yerditer, or whatever
colours they pleafre, the mixture in this flate re-
cieving any.

Wax work, the representation of the faces, &c. of
persons living or dead; made by applying platter of
Paris in a kind of paste, and thus forming a mould con-
taining the exact representation of the features. Into
this mould melted wax is poured, and thus a kind of
molds are formed; which being painted and fet with
glass eyes, and the figures dreffed in their proper habits,
they bear fhuch a resemblance that it is difficult to diftin-
guish between the copy and the original.

Way, a paffage or road.
The Roman ways are divided into confular, praetorian,
military, and public; and of thofe we have four remark-
able ones in England: the firft, Watling-street, or Wa-
theling-street, leading from Dover to London. Duntlable,
Touefer, Atterton, and the Severn, extending as far
as Anglesea in Wales. The second, called Hikenild, or
Iltenil-street, stretches from Southampton over the river
Ips at Newbridge; thence by Camden and Litcheld;
then paffes the Derwent, near Derby, and ends at Tin-
mouth. The third, called Poftis-way, because in fome
places it was neverperfected, but lies as a large ditch,
leads from Cornwall through Devonshire, by Tewthury,
neai Snow in the Wolds; and from Coventry to Leice-
ter, Newark, and to Lincoln. The fourth, called
Erming, or Erming-street, extends from St. David’s,
in Wales, to Southampton.

Way of a ship, is fometimes the fame as her rafe, or run
forward or backward: but this term is molt commonly
underflood of her failing.

Way-wufe, a title given to the governors of the chief
places in the empire of Muscovy, as also in Poland.

Weave, or Weer, a great flank or dam in a river, fitted
for the taking of fish, or for conveying the stream to a
mill.

New wears are not to be made, or others altered, to
the nuisance of the public, under a certain penalty.

Weasel, in zoology. See Mustela.

Weather, the state or disposition of the atmosphere with
regard to heat, cold, wind, rain, fnow, &c.

As it is in the atmosphere that all plants and animals
live, and as that appears to be the great principle of moft
animal and vegetable productions, alterations, &c. there
does not feem any thing, in all philofophy, of more im-
mediate concernment to us than the state of the weather,
and a knowledge of the great influence it has on our bo-
dies. What vail, but regular, alterations a little turn of
weather makes in a tube filled with mercury, or spirits
of wine, or in a piece of ftring, &c. every body knows,
in the common infance of barometers, thermometers, &c.
and it is owing partly to our inattention, and partly to
our unequal and intemperate courfe of living, that we do
not feel as great and regular ones in the tubes, chords,
and fibres of our own bodies.

Weathercock, a moveable vane in form of a cock, or
other fhape, placed on high, to be turned round accord-
ing to the direftion of the wind, and point out what
quarter the wind blows from.

Weather-glasses. See Barometer, and Thermom-
eter.

Weather-glass. See Barometer, and Thermom-
eter.

Weathering, among sailors, signifies the doubling,
or failing by a head land, or other place.

Weaving, the art of working a web of cloth, filk, or
other stuff, in a loom with a shuttle. For the manner of
performing which, see Cloth.

Web, a fort of fiftue or texture formed of threads inter-
woven with each other; fome whereof are extended in
length, and called the warp; and others drawn acrofs,
and called the woof. See Cloth.

Spider’s Web. See Aranea.

Wedge, one of the mechanical powers. See Mecha-
nics.

Wednesday, the fourth day of the week, so called
from a Saxon idol named Weden, supposed to be Mars,
worshippd on this day.

After Wednesday, the fird day of Lent, fo called from
the cultom obferved in the ancient christian church of
penitents expressing their humiliation at this time, by ap-
ppearing in fackcloth and ashes.

Weed, a common name for all rank and wild herbs, that
grow among. Others, to the detriment of other ufeful herbs
they grow amonng.

Weed, in the miners language, denotes the degeneracy
of a load or vein of fine metal into an ufelefs maraffe.

Week, in chronology, a divifion of time comprifing fe-
ven days. See Astronomy, p. 489.

The origin of this divifion of weeks, or of computing
time by fevens, is greatly controverted. Some will have
it to take its life from the four quarters or intervals
of the moon, between her changes or phases, which, be-
ing about seven days distant, gave occasion to the divifion.
Be this as it v/ill, the divifion is certainly very an-
cient. The Syrians, Egyptians, and molt of the orient-
al nations, appear to have ufed it from all aniquity:
though it did not get footing in the weft till Chriflianity
brought it in: the Romans reckoned their days by seven-
ths, but by ninths, and the ancient Greeks by de-
cads or tenths.

Indeed, the Jews divided their time by weeks, but it
was upon a different principle from the earthen nations.
God himself appointing them to work six days, and to rest the sabbath, in order to keep up the sense and remembrance of the creation; which being effected in six days, he rested the seventh.

Puritton Week, or the Holy Week, is the last week in Lent, wherein the church celebrates the mystery of our Saviour's death and passion.

Week, or Wyck, in geography, a parliament and port-town of Scotland, in the shire of Carnwath: W. long. 2° 45', N. lat. 58° 45'.

WEEVER, in ichthyology. See Trachin us.

Weight, in physics, a quality in natural bodies whereby they tend downwards, towards the centre of the earth. Or, weight may be defined, in a less limited manner, to be a power inherent in all bodies whereby they tend to some common point, called the centre of gravity; and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare. See Mechanics.

Weight, in commerce, denotes a body of known weight, appointed to be put in the balance against other bodies whose weight is required.

Well, or Wel, an imperial city of Germany, in the circle of Swabia, and duchy of Wirtemberg: E. long. 8° 40', N. lat. 48° 40'.

Weimar, a city of Germany, in the circle of Upper Saxony, the capital of the Weimar: E. long. 11° 25', N. lat. 51°.

Weisel, a river of Poland, and the same with the Vistula.

Weismar, a city of Germany, in the duchy of Cleves: E. long. 2° 45', N. lat. 51° 37'.

Westlow, a borough town of Cornwall, twenty-three miles north-west of Salisbury; which sends two members to parliament.

Westmeath, a county of Ireland, in the province of Leinster, bounded by Longford and Cavan on the north; by Eastmeath, on the east; by King's County, on the south; and by the river Shannon, which divides it from Roscommon, on the west.

Westminster, a city which forms the west part of the town which goes by the general name of London; but is under a distinct government; the dean and chapter appointing the high steward, high bailiff, and other officers, who have the government of the city. Here are the king's palaces, and the houses of most of the nobility.
bility, the high court of parliament, and the supreme courts of justice; but there is no bishop of this city. It elects two members of parliament.

WESTMORELAND, an English county, bounded by Cumberland on the north, by Yorkshire on the east, by Lancashire on the south, and by the Irish channel on the west.

WESTPHALIA, the north-west circle of the empire of Germany; bounded by the German ocean, on the north; by the circle of Lower Saxony, on the east; by the Landgraviate of Hesse, the Palatinate of the Rhine, and the electorate of Trier, on the south; and by the Netherlands, on the west: being 200 miles in length, and from 150 to 200 in breadth.

WESTRAML, a market town of Kent, under the meridian of London, 44 miles west of Canterbury.

WETTERAVIA, the southern division of the Landgraviate of Hesse, in Germany, lying along the northern bank of the river Maine, comprehending the counties of Hanau and Nassau.

WETZLAR, an imperial city of Germany, in the circle of the Upper Rhine and territory of Wetteravia situated on the river Lahn, E. long. 8° 15', N. lat. 50° 30'.

WEXFORD, a county of Ireland, in the province of Munster, bounded by the county of Wicklow on the north, by the ocean on the east and south, and by Kilkenney and Waterford on the west.

Wexford, the capital of this county, is situated at the mouth of the river Slaney, sixty five miles south of Dublin.

WEYMOUTH, a port-town of Dorsetshire, situated on a fine bay of the English channel; seven miles south of Dorchester. It sends two members to parliament.

WHALE, in ichthyology. See Baleana and Physeter.

WHARF, a space on the banks of a haven, creek, or hith, provided for the convenient loading and unloading of vessels upon.

WHEAT, in botany. See Triticum. For the culture of wheat, see Agriculture, p. 60.

WHEEL, in mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on an axis. See Mechanics.

HELP, the young of a dog, fox, lion, or any wild beast.

HELP, in a ship, the seaman's term for those brackets which are set up on the capstan close under the bars; they give the sweep to it, and are so contrived that the cable winding about them may not surge so much as it might otherwise do if the body of the capstan were quite round and smooth.

WHETSTONE, a stone which serves for the whetting of knives and other tools upon.

WHEY, the serum, or watery part, of milk. See Whey.

WHIG, a party in Britain, opposed to the Tories, from whom they differ chiefly in their political principles. See Tories.

The names of whig and tory were not known till a bout the middle of the reign of Charles II. when these were given as party distinctions. These parties may be considered either with regard to the state, or to religion. The state tories are either violent, or moderate: the first would have the king to be absolute, and therefore plead for passive obedience, non-resistance, and the hereditary right of the house of Stuart. The moderate tories would not suffer the king to lose any of his prerogative; but then they would not sacrifice those of the people. The state whigs are either strong republicans, or moderate ones. The first, says Rapin, are the remains of the party of the long parliament, who attempted to change monarchy to a commonwealth: but these make so slender a figure, that they only serve to strengthen the party of the other whigs. The tories would persuade the world, that all the whigs are of this kind; and the whigs, would make us believe that all the tories are violent. The moderate state-whigs are much in the same sentiments with the moderate tories and desire that the government may be maintained on the ancient foundation: all the difference is, that the first bear a little more to the parliament and people, and the latter to that of the king. In short, the old whigs were always jealous of the encroachments of the royal prerogative, and watchful over the preservation of the liberties and properties of the people.

WHIP, or whip-staff, in a ship, a piece of timber, in form of a strong staff, fastened into the helm, for the steerman, in small ships, to hold in his hand, in order to move the rudder and direct the ship.

WHIRLPOOL, an eddy, vortex, or gulph, where the water is continually turning round.

These in rivers are very common, from various accidents, and are usually very trifal, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirlpool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among those islands. Wherever it appears, it is very furious; and boats, &c. would inevitably be drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing, in the boat with them; as soon as they perceive the whirlpool, they toss this within its vortex, keeping themselves out of this sub stance, whatever it be. is immediately received into the centre, and carried under water; and as soon as this is done, the surface of the place where the whirlpool was becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place. Usually at about a mile's distance from the first.

WHIRLWIND, a wind that rises suddenly is exceedingly rapid and impetuous when first seen, but is soon spent. See Pneumatics, p. 495.

WHISPERING. See the articles Hearing, Attention, &c.

Whispering places depend upon this principle. If the vibrations of the tremulous body are propagated through a long tube, they will be continually reverberated from the sides of the tube into its axis and by that means prevented from spreading, till they get out of it; whereby they will be exceedingly increased, and the sound rendered much louder than it would otherwise be.

Hence it is that sound is conveyed from one side of a whispering gallery to the opposite side, without being perceived by those who stand in the middle.

WHIST,
WHIST, a well-known game at cards; so called from the silence observed during the play.

WHITBY, a port-town of the north riding of Yorkshire, situated on the German sea, thirty-eight miles north-east of York.

WHITCHURCH, a borough-town of Hampshire, situated ten miles north of Winchester. It sends two members to parliament.

WHITE, one of the colours of natural bodies.

White of the eye, denotes the first tunic or coat of the eye, called albuginea. See Anatomy, p. 289.

WHITE PRIESTS, a name common to several orders of monks, from their being clothed in a white habit.

WHITE-HORSE, in ichthyology. See Balaena.

WHITE-LEAD. See Ceruse.

WHITBY, a port-town of the north riding of Yorkshire, situated on the German sea, thirty-eight miles north-east of York.

WHITE SEA, in geography, a bay of the frozen ocean, in the north of Muscovy, between Russian Lapland and Samoecia.

WHITE WINE, wine of a bright transparent colour, bordering on white, thus called to distinguish it from the red wines. See Wine.

WHITEHAVEN, a port-town of Cumberland, situated on the Irish channel: W. long. 3° 16', N. lat. 53° 30'.

WHITENESS, the quality which denominates a body white.

WHITING, in ichthyology. See Gavius.

WHITE-HORSE, in ichthyology. See Balaena.

WHITSUNDAY, a solemn festival of the Christian church, observed on the fiftieth day after Easter, in memory of the descent of the Holy Ghost upon the apostles in the ancient church, those who were baptized put on white garments, as types of that spiritual purity they received in baptism. As the descent of the Holy Ghost upon the apostles happened upon the day which the Jews called pentecost, this festival retained the name of pentecost among the Christians.

WHITE WINE, wine of a bright transparent colour, bordering on white, thus called to distinguish it from the red wines. See Wine.

WHITEHAVEN, a port-town of Cumberland, situated on the Irish channel: W. long. 3° 16', N. lat. 53° 30'.

WHITENESS, the quality which denominates a body white.

WHITING, in ichthyology. See Gavius.

WHITES, in medicine, the same with flour albus. See Medicine, p. 162.

WHITSUNDAY, a solemn festival of the Christian church, observed on the fiftieth day after Easter, in memory of the descent of the Holy Ghost upon the apostles in the visible appearance of fiery cloven tongues, and of those miraculous powers which were then conferred upon them.

It is called Whitunday, or White Sunday, because being one of the flatted times for baptism in the ancient church, those who were baptized put on white garments, as types of that spiritual purity they received in baptism. As the descent of the Holy Ghost upon the apostles happened upon the day which the Jews called pentecost, this festival retained the name of pentecost among the Christians.

W BURG, the capital of the territory of the same name in Juliana: E. long. 96° 16', N. lat. 56° 20'.

WIBURG, a city and port-town of Russian Finland, situated on the gulf of Finland: E. long. 29° 50', N. lat. 61°.

WICCOMBE CHIPPING, a borough town of Bucks, twelve miles south of Aylesbury. It sends two members to parliament.

WICK DE DUERSTEDE, a town of the United Netherlands, in the province of Utrecht, fifteen miles south-east of the city of Utrecht.

WICKER, a twig of the osier shrub, single or wrought.

WICKET, a small door in the gate of a fortified place, or a hole in a door, through which to view what passes without.

WICKLIFFISTS, or Wickliffites, a religious sect which sprang up in England in the reign of Edward III. and took its name from John Wickliff, doctor and professor of divinity in the university of Oxford, who maintained that the substance of the sacramental bread and wine remained unaltered after consecration; and opposed the doctrine of purgatory, indulgences, auricular confession, the invocation of saints, and the worship of images. He maintained, that the children of the religious may be saved without being baptized; that priests may administer confirmation; that there ought to be only two orders in the church, that of priests, and that of deacons.

He made an English version of the Bible; and composed two volumes, called Aletheia, that is, Truth, from which John Hulla learned most of his doctrines. In short, to this reformer we owe the first hint of the reformation, which was effected about two hundred years after.

WICKLOW, a county of Ireland, in the province of Leinster, bounded by the county of Dublin on the north, by the Irish channel on the east, by Wexford on the south, and by Kildare and Katerlagh on the west.

WICKWARE, a market-town of Gloucestershire, situated twenty miles south of Gloucester.

WIDGEON, in ornithology. See Anas.

WIDOW, a woman who has lost her husband.

WIFE, a married woman, or one joined with, and under the protection of, a husband. See Husband.

WIG IN, a borough-town of Lancashire, twenty nine miles south of Lancaster. It sends two members to parliament.

WIFOL, part of the county of Southampton, and separated from it by a narrow channel, is about twenty miles long, and twelve broad. The chief town is Newport.

WIGTOWN, a borough and port-town of Scotland, in the shire of Galloay, situated on a bay of the Irish channel, ninety miles south-west of Edinburgh.

WILD, or WIL, in law, signifies the declaration of a man's mind and intent relating to the disposition of his lands, goods, or other estate, or of what he would have done after his death.

In the common law, there is a distinction made between a will and a testament; as that is called a will, where lands or tenements are given; and when the disposition concerns goods and chattels alone, it is termed a testament. See Testament.

WILL-WITH-A-WISP, or Jack-with-a-lantern, a meteor chiefly seen in summer-nights, frequenting meadows, marshes, and other moist places. It seems to arise from a vitreous exhalation, which being kindled in the air, reflects a fort of thin flame in the dark, without any sensible heat.

It is often found flying along rivers, hedges, &c. by reason it there meets with a stream of air to direct it. The ignus fatuus, says Sir Isaac Newton, is a vapour shining without heat; and there is the same difference between this vapour and flame, as between rotten wood shining without heat and burning coals of fire.

WILLIAMSBURG, capital of the colony of Virginia, situated in James-county, between James-river and York-river: W. long. 76° 30', N. lat. 39° 20'.

WILLIAM'S FORT, a fort belonging to the English East-India
India company, situated on the western branch of the river Ganges, in the province of Bengal: E. long. 89°, N. lat. 2° 45'.

WILLIAMSTAT, a port-town of Holland, situated on the sea called Hollands-Deep, fourteen miles south of Rotterdam.

WILLOW, in botany. See Salix.

WILNA, a city of Poland, capital of the great duchy of Lithuania, situated on a river of the same name: E. long. 23° 15', N. lat. 55°.

WILTON, a borough-town of Wiltshire, situated on the river Willey, six miles north-west of Salisbury. It sends two members to parliament.

WILTSHIRE, a county of England, bounded by Gloucestershire and Oxfordshire on the north, by Berkshire and Hampshire on the east, by Dorsetshire on the south, and by Somersetshire on the west.

WINCHELESEA, a borough and port-town of Sussex, situated on a bay of the English channel, thirty miles east of Lewes. It sends two members to parliament.

WINCHESTER, the capital city of Hampshire, situated on the river Itching, six miles east of Salisbury. It sends two members to parliament.

WINCHREST, the capital city of Hampshire, situated on the river Itching, sixty-five miles south-west of London.

WIND. See Pneumatics, p. 495.

Wind-mill, a kind of mill, the internal parts of which are much the same with those of a water-mill; from which, however it differs, in being moved by the impulfe of the wind upon its vane, or blade, which are to be considered as a wheel on the axle. See Mechanics.

Wind-flower, in botany. See Anemone.

Wind-galley, a name given by our farriers to a distemper of horses. See Farriery, p. 375.

Wind sails, in a ship, are made of the common sail-cloth, and are usually between twenty-five and thirty feet long, according to the size of the ship, and are of the form of a cone ending obtusely: when they are made use of, they are hoisted by ropes to about two thirds or more of their height, with their bases diffended circularly by hoops, and their apex hanging downwards in the hatch ways of the ship; above each of these, one of the common sails is so difposed, that the greatest part of the air rushing against it, is directed into the wind-sail, and conveyed, as through a funnel, into the upper parts of the body of the ship.

Wind tackle-blocks, in a ship, are the main double blocks which being made fast to the end of a small cable, serve for hoisting of goods into the ship, &c.

To wind, or wind a ship, signifies to bring her head about. How winds or winds the ship? is a question asked by mariners, concerning a ship under sail; signifying as much as, upon what point of the compass does she lie with her head?

Windward, in the sea-language, denotes any thing towards that point from whence the wind blows, in respect of a ship: thus windward-tide, is the tide which runs against the wind.

Wingage of a gun, the difference between the diameter of the bore, and the diameter of the ball.

Windlass, a machine used to raise huge weights withal, as guns, blocks, an hors, &c.

It is very simple, consisting only of an axis, or roller, supported horizontally at the two ends, by two pieces of wood and a pulley: the two pieces of wood meet at top, being placed diagonally so as to prop each other; the axis, or roller, goes through the two pieces, and turns in them. The pulley is fastened at top where the pieces join. Lastly, there are two flaves or handspikes which go through the roller, whereby it is turned, and the rope which comes over the pulley is wound on and off the same.

Windlass, in a ship, is an instrument in small ships, placed upon the deck, just abait the fore mast. It is made of a piece of timber six or eight feet square, in form of an axle-tree, whose length is placed horizontally upon two pieces of wood at the ends thereof, and upon which it is turned about by the help of handspikes put into holes made for that purpose. This instrument serves for weighing anchors, or hoisting of any weight in or out of the ship, and will purchase much more than any capstan, and that without any danger to those that heave; for if in hearing the windlass about, any of the handspikes should happen to break, the windlass would fall of itself.

WINDOW, an aperture or open place in the wall of a house, to let in the wind and light. See Architecture, p. 257.

WINDSOR, a borough-town of Berkshire, twenty miles west of London, most remarkable for the magnificent palace or castle situated there on an eminence, which commands the adjacent country for many miles, the river Thames running at the foot of the hill. The knights of the garter are installed in the royal chapel here. It sends two members to parliament.

WINE, a brim, agreeable, spirituous and cordial liquor, drawn from vegetable bodies, and fermented.

All sorts of vegetables, fruits, seeds, roots, &c. afford wine; as grapes, currants, mulberries, elder-berries, cherries, apples, pulle, beans, pea, turneps, radishes, and even grass itself. Hence under the class of wines, or vinous liquors, come not only wines absolutely so called, but also ale, cider, &c. See Brewing, and Chemistry, p. 95, 161.

Wine in France is distinguished, from the several degrees and steps of its preparation, into, 1. Mere goutte, mother-drop, which is the virgin wine, or that which runs itself out at the top of the vat wherein the grapes are laid, before the vintager enters to tread or stamp the grapes. 2. Muid, furmuil, or flum, which is the wine or liquor in the vat, after the grapes have been trod or flamped. 3. Pressed wine, being that squeezed with a press out of the grapes half bruised by the treading. The hulks left of the grapes are called rope, murk, or mark; the mother-drop, which is the virgin wine, or that which has not yet worked nor fermented. 4. Bouru, cyderkin, and called boisson. 4. Sweet wine, is that which has been prevented working by calling in cold water. 6. Worked wine, that which has been let work on its own account, and which by thorough work has made itself ferment. Strained wine, that made by deeping dry grapes in water, and letting it ferment of itself. Wines are also distinguished with regard to their colour into white wine, red wine, claret wine, pale wine, rofe, or black wine; and with regard to their country, or the soil that produces them, into French wines, Spanish wines, Rhine wines, Hungarian wines, Greek wines, Canary wines, &c. and more particularly...
The inhabitants of Lapland have a wire of a kind. The women do this business, and the way they take is to melt a piece of tin, and place it rounded on all sides but one, where it is flat. They often fell it to strangers, under the notion of its having certain magical virtues.

**WIRKSWORTH** a market-town of Derbyshire, situated six miles north of Darby.

**WISEBEACH** a market-town of the isle of Ely, in Cambridgeshire, situated fifteen miles north of Ely.

**WISDOM** usually denotes a higher and more refined notion of things immediately presented to the mind, as it were, by intuition without the assistance of ratiocination.

**WISTON** a market-town of Pembroke-shire, situated ten miles north of Pembroke.

**WIT** is a quality of certain thoughts and expressions: that talent which some men have of inventing ludicrous thoughts or expressions: we say commonly, a witty man or a man of wit.

The image here is undoubtedly witty. It is ludicrous: and it must occasion surprize; for having no natural foundation, it is altogether unexpected.

The other branch of wit in the thought, is that only which is taken notice of by Addison, following Locke, who defines it "to lie in the assemblage of ideas; and putting those together, with quickness and variety, wherein can be found any resemblance or congruity, thereby to make up pleasant pictures and agreeable visions in the fancy." It may be defined more curiously, and perhaps more accurately, "a junction of things by distant and fanciful relations, which surprize because they are unexpected." The following is a proper example.

Shylock. You knew (none so well, none so well as you) of my daughter’s flight.

Salino. That’s certain: I, for my part, knew the tailor that made the wings she flew withal.

**MERCHANT of Venice, act 3, sc. 1.**

The image here is undoubtedly witty. It is ludicrous: and it must occasion surprize; for having no natural foundation, it is altogether unexpected.

The other branch of wit in the thought, is that only which is taken notice of by Addison, following Locke, who defines it "to lie in the assemblage of ideas; and putting those together, with quickness and variety, wherein can be found any resemblance or congruity, thereby to make up pleasant pictures and agreeable visions in the fancy." It may be defined more curiously, and perhaps more accurately, "a junction of things by distant and fanciful relations, which surprize because they are unexpected." The following is a proper example.

We grant although he had much wit, he was very shy of using it.
WIT (944)

As being loth to wear it out;
And therefore bore it not about,
Unless on holidays, or so,
As men their best apparel do.

Wit is of all the most elegant recreation; the image enters the mind with gaiety, and gives a sudden flash which is extremely pleasant. Wit thereby gently elevates without limiting, raises mirth without dissoluteness, and relaxes while it entertains.

Wit in the expression, commonly called a play of words, being a bithard sort of wit, is referred for the last place. We proceed to examples of wit in the thought; and first of all, being a bithard sort of wit, is referred for the last place.

Falstaff, speaking of his taking Sir John Colevile of the Dale:

Here he is, and here I yield him; and I beseech your Grace, let it be book’d with the rest of this day’s deeds; or, by the Lord, I will have it in a particular ballad elfe, with mine own picture on the top of it, Colevile kibbing my foot: to which cause if I be enforced, if you do not all chew like gilt twopences to me; and I, in the clear sky of fame, o’ershine you as much as the full moon doth the cinders of the element, which flew like pins’ heads to her; believe not the word of the noble. Therefore let me have right, and let defect mount.

Second Part, Henry IV. act 4. sc. 6.

I knew, when seven justices could not take up a quarrel, but when the parties were met themselves, one of them thought but of an if; as, if you had said fo, then I said so: and they shook hands, and swore brothers. Your is the only peace-maker; much virtue is in is.

Shakespeare.

For there is not through all nature another so callous and insensible a member as the world’s posteriors, whether you apply to it the toe or the birch.

Preface to a Tale of a Tub.

The other branch of wit in the thought, viz. ludicrous combinations and oppositions, may be traced through various ramifications. And, first, fanciful cauces are given that have no natural relation to the effects produced:

Lancaster. Fare you well, Falstaff; I, in my condition, Shall better speak of you than you deserve. [Exit.

Falstaff. I would you had but the wit; ’twere better than your dukedom. Good faith, this fame young fober-blooded boy doth not love me; nor a man cannot make him laugh; but that’s no marvel, he drinks no wine. There’s never an of thee demure boys come to any proof; for thin drink doth so overcool their blood, and making many fish-meals, that they fall into a kind of male green-ficknes; and then, when they marry, they get wenches. They are generally fools and cowards; which some of us should be too, but for inflammation. A good sherris-fack hath a twofold operation in it: it ascends me into the brain; dries me there all the foolifh, dull, and crudy vapours which environ it; make it apprehensive, quick, forgetive, full of nimble, fiery, and delectable images; which delivered over to the voice, the tongue, which is the birth, becomes excellent wit. The second property of your excellent therris is, the warming of the blood; which before cold and settled, leat the liver white and pale; which is the badge of pusillanimity and cowardice: but the sherris warms it, and makes it course from the inwards to the parts extreme; it illuminates the face, which, as a beacon, gives warning to all the rest of this little kingdom, man, to arm; and then the vital comoners and inland petty spirits mutter me all to their captain, the heart; who, great, and puff’d up with this retinue, doth any deed of courage; and thence, valour comes of sherris. So that skill in the weapon is nothing without fack, for that fets it a-work; and learning a mere hoard of gold kept by a devil, till sack commences it, and sets it in act and use. Hereof comes it that Prince Harry is valiant; for the cold blood did naturally inherit of his father, he hath, like lean, sterile, and bare land, manured, husbanded, and till’d with excellent endeavour of drinking good and good store of fertile therris, that he is become very hot and valiant. If I had a thousand fans, the first human principle I would teach them, should be to forswear thin potations, and to addict themselves to fack.

Second Part of Henry IV. act 4. sc. 7.

The trenchant blade, toledo truely,
For want of fighting was grown rulry,
And ate into itself, for lack
Of some body to hew and hack.

The peaceful scabbard where it dwelt
The rancour of its edge had felt:
For of the lower end two handful
It had devoured, ’twas so manful;
And so much scorn’d to lurk in cafe,
As if it durst not show its face.

Hudibras, canto 1.

To account for effects by such fantastical causes, being highly ludicrous, is quite improper in any serious composition. Therefore the following passage from Cowley, in his poem on the death of Sir Henry Wooton, is in a bad taste.

He did the utmost bounds of knowledge find,
He found them not so large as was his mind.
But, like the brave Pelian youth, did moan,
Because that art had no more worlds than one.
And when he saw that he through all had past,
He dy’d, left he should idle grow at last.

Fanciful reasoning:

Falstaff. Imbowell’d! — if thou imbowel me to day,
I’ll give you leave to powder me, and eat me to-morrow! S’blood, ’twas time to counterfeit, or that hot temperant Scot had paid me foct and lot too. Counterfeit? I lie, I am no counterfeit: to die is to be a counterfeit; for he is but the counterfeit of a man, who hath not the life of a man; but to counterfeit dying, when a man thereby liveth, is to be no counterfeit, but the true and perfect image of life indeed.

First Part Henry IV. act 1. sc. 10.

Clown. And the more pity that great folk should have contention in this world to drown or hang themselves, more than their even Christians.

Hamlet, act 5. sc. 2.

Pedro. Will you have me, Lady?
Beatrice. No, my Lord, unless I might have another for working days. Your Grace is too costly to wear every day.

Much ado about nothing, Act 2. sc. 5.

Jovina.
**W I T** (955)

*WIT*

Jeff. I shall be saved by my husband; he hath made me a Christian.

Laun. Truly the more to blame he; we were Christians enough before, even as many as could well live by one another: this making of Christians will raise the price of hogs; if we grow all to be pork-eaters, we shall not have a rafter on the coals for money.

*Merchant of Venice, Act 3, sc. 6.*

But Hudibras gave him a twitch,
As quick as lightning, in the breech,
Jilt in the place where honour’s lodg’d,
As wife philosophers have judg’d;
Because a kick in that part, more
Hurst honour, than deep wounds before.

Hudibras, canto 3.

Ludicrous junctures of small things with great, as of equal importance:

This day black omens threat the bright’st fair
That e’er deserv’d a watchful spirit’s care:
Some dire defaster, or by force, or flight:
But what, or where, the fates have wrapt in night:
Whether the nymph shall break Diana’s law;
Or some frail china jar receive a flaw:
Or flain her honour, or her new brocade;
Forget her pray’rs, or miss a masquerade;
Or whether Heav’n has doom’d that Shock must fall.

*Rape of the Lock, canto ii.*

One speaks the glory of the Britifh Queen,
And one describes a charming Indian screen.

*Ibid, canto iii.*

Then flash’d the living lightning from her eyes,
And screams of horror rend th’affrighted skies.
Not louder shrieks to pitying heav’n are cast,
When husbands, or when lapdogs, breathe their last.
Or when rich china vessels fall’n from high,
In glittering dust and painted fragments lie!

*Ibid, canto iii.*

Not youthful kings in battle feiz’d alive,
Not scornful virgins who their charms survive,
Not ardent lovers robb’d of all their bliss,
Not ancient ladies when refus’d a kiss,
Nor tyrants fierce that unrepenting die,
Nor Cynthia when her manteau’s pinn’d awry.
E’er felt fuch rage, refentment, and defpair.

Not ardent lovers robb’d of all their blifs.
Not youthful kings in battle feiz’d alive.
Not scornful virgins who their charms survive.
Not ardent lovers robb’d of all their bliss.
Not ancient ladies when refus’d a kiss.
Nor tyrants fierce that unrepenting die.
Nor Cynthia when her manteau’s pinn’d awry.
E’er felt fuch rage, refentment, and defpair.

As thou, sad virgin! for thy ravish’d hair.

Nor Cynthia when her manteau’s pinn’d awry.
Nor tyrants fierce that unrepenting die.
Not ardent lovers robb’d of all their blifs.
Not youthful kings in battle feiz’d alive.
Not scornful virgins who their charms survive.
Not ardent lovers robb’d of all their bliss.
Not ancient ladies when refus’d a kiss.
Nor tyrants fierce that unrepenting die.
Nor Cynthia when her manteau’s pinn’d awry.
E’er felt fuch rage, refentment, and defpair.

In glittering dust and painced fragments lie!

Or when rich china vefels fall’n from high.
Not louder shrieks to pitying heav’n are cast,
And screams of horror rend th’affnghted skies.
Then flash’d the living lightning from her eyes.

And one describes a charming Indian screen,
One speaks the glory of the Britifh Queen,
Or whether Heav’n has doom’d that Shock must fall.

*Hudibras, part 3, canto 3.*

Here
Here Britain's state men oft the fall foredoom
Of foreign tyrants, and of nymphs at home;
Here thou, great Anna whom three realms obey,
Dost sometimes counsel take—and sometimes tea.

*Rape of the Lock*, canto 3, l. 5.

O'er their quietus where fat judges doze,
And lull their conscience to repose.

*Dispensary*, canto 1.

Speaking of Prince Eugene:
This general is a great taker of snuff as well as of
towns.

*Pope's Key to the Lock*.

Exul menisque donumque.

Metamorphoses, lib. ix. 409.

A seeming opposition from the same cause:
Hic quiescit qui nunquam quievit.

*Waller*.

Program of the Lock, canto 1.

So like the chances are of love and war,
That they alone in this distinguished are;
In love the victors from the vanquish'd fly,
They fly that wound, and they pursue that die.

*Waller*.

What new-found witchcraft was in thee,
With thine own cold to kindle me?
Strange art; like him that should devise
To make a burning glass of ice.

*Cowley*.

Wit of this kind is unsuitable in a serious poem; witness
the following line in Pope's Elegy to the memory of an
unfortunate lady:

Cold is that breast which warm'd the world before.

This sort of writing is finely burlesqued by Swift:

Her hands, the softest ever felt,
Though cold would burn, though dry would melt.

*Strephon and Chloe*.

Taking a word in a different sense from what is meant,
comes under wit, because it occasions some degree of
surprise:

Beatrice. I may sit in a corner, and cry Heigh ho! for
a husband.

Pedro. Lady Beatrice, I will get you one.

Beatrice. I would rather have one of your father's get-
ting. Hath your Grace ne'er a brother like you? Your
father got excellent husbands, if a maid could come by
them.

*Much ado about nothing*, act 2, sc. 5.

Falstaff. My honest lads, I will tell you what I am about.

Pistol. Two yards and more.

Falstaff. No quips now, Pistol: indeed, I am in the
waste; two yards about: but I am now about no waste; I
am about thrift.

*Merry Wives of Windsor*, act 1, sc. 7.

Lo, Sands.—By your leave, sweet ladies,
If I chance to talk a little wild, forgive me:
I had it from my father.

*Anne bullen*. Was he mad, Sir?

Sands. O, very mad, exceeding mad, in love too;
But he would bite none—

*K. Henry VIII*.

An assertion that bears a double meaning, one right, one
wrong, but so connected with other matters as to direct
us to the wrong meaning, is a species of bafard wit which
is distinguished from all others by the name *pun*. For example,

Paris.——Sweet Helen, I must woo you
To help unarm our Hector: his stubborn buckles,
With thee! his white enchanting fingers touch'd,
Shall more obey, than to the edge of steel,
Or force of Greekish fire; thou shalt do more
Than all the island kings, disarm great Hector.

Troilus and Cressida, act 3, sc. 2.

The pun is in the close. The word *disarm* has a double
meaning: it signifies to take off a man's armour, and also
to subdue him in fight. We are directed to the latter tenfe
by the context; but with regard to Helen, the word holds
only true in the former tenfe. We go on with other examples:

Effe nihil dicis quicquid petis, improbe Cinna:
Si nī, Cinna, petis, nī tibi, Cinna, nego.

*Martial*, l. 13, epigr. 61.

Chief Justice. Well! the truth is, Sir John, you live
in great insanity.

Falstaff. He that buckles him in my belt cannot live in
less.

Chief Justice. Your means are very slender, and your
waste is great.

Falstaff. I would it were otherwise: I would my means
were greater, and my waste slenderer.

*Second part Henry IV*, act 1, sc. 5.

Celia. I pray you bear with me, I can go no further.

Clown. For my part, I had rather bear with you than
bear you: yet I should bear no crofs if I did bear you;
for I think you have no money in your purse.

*As you like it*, act 2, sc. 4.

He that imposes an oath makes it,
Not he that for convenience takes it.

Then how can any man be said
To break an oath he never made?

*Hudibras*, part 2, canto 2.

The seventh satire of the first book of Horace is purposely
contrived to introduce at the close a most execrable pun.
Talking of some infamous wretch whose name was *Rex Ru-
pilius*.

Perilius exclamat, Per magnos, Brute, deos te
Oro, qui reges confueris tollere, cur non
Hunc regem jugulas? Operum hoc, mihi crede, tuorum
eft.

Though playing with words is a mark of a mind at ease,
and dispofed to any sort of amusement, we must not thence
conclude that playing with words is always ludicrous.
Words are so intimately connected with thought, that if
the subject be really grave, it will not appear ludicrous even
in this fantastick strain. We are, however, far from recom-
mending it in any serious performance: on the contrary,
the discordance between the thought and expression must
be disagreeable: witness the following specimen.
He hath abandoned his physicians. Madam, under whose practices he hath perfected time with hope; and finds no other advantage in the process, but only the losing of hope by time.

All's well that ends well, all's true.

K. Henry.

My poor kingdom, sick with civil blows!

When that my care could not with-hold thy riots,

What wilt thou do when riot is thy care?

Second part K. Henry IV.

If any one shall observe, that there is a third species of wit, different from those mentioned, consisting in sounds merely, we are willing to give it place. And indeed it must be admitted, that many of Hudibras's double rhymes come under the definition of wit given in the beginning of this article: they are ludicrous, and their singularity occasions some degree of surprize. Swift is not less successful than Butler in this sort of wit; witness the following lines:

A repartee may happen to be witty: but it cannot be considered as a species of wit; because there are many repartees extremely smart, and withal extremely tedious. We give the following example. A certain pugilist Greek, objecting to Anacharsis that he was a Scythian: True, says Anacharsis, my country disgraces me, but you disgrace your country. This fine turn gives surprize; but it is far from being ludicrous.

WITCHCRAFT, a kind of forcery, especially in women, in which it is ridiculously supposed that an old woman, by entering into a contract with the devil, is enabled, in many instances, to change the course of nature; to raise winds; to perform actions that require more than human strength; and to afflict those who offend them with the sharpest pains, &c. In the times of ignorance and superstition, many severe laws were made against witches, by which great numbers of innocent persons, distressed with poverty and age, were brought to a violent death; but these are now happily repealed. See Law, Tit. xxxiii 8.

WITENA MOT. or WITENA-GEMOT, among manufacturers, the threads which the wife men, and was applied to the great council of the nation of latter-days called the parliament.

WITEPSKI, the capital of the palatinate of the same name, in the duchy of Lithuania, in Poland: E. long 20°, N. lat. 53°.

WOLLIN, a town and island of Pomerania, situated in the Baltic sea, at the mouth of the river Oder, subject to the king of Prussia.

WOLODOMIR, the capital of a province of the same name in Russia: E. long. 45° 3', N. lat. 54° 12'.

WOLOGDA, the capital of a province of the same name in Russia, situated on the river Dwina: E. long. 40° 20', N. lat. 59°.

WOLVERHAMPTON, a market-town of Staffordshire, eleven miles south of Stafford.

WOLVES-TEETH, of an horse, are over-grown grinders, the points of which being higher than the rest, prick his tongue and gums in feeding, so as to hinder his chewing. They are seldom met with in any besides young horses; but if they be not daily worn by chewing, they will grow up even to pierce the roof of the mouth.

WOMAN, the female of man. See Homo.

WOMB, See Anatomy, p. 274.

WOOD, a solid substance, wherein the trunks and branches of trees consist. The wood is all that part of a tree included between the bark and the pith. For the structure of the pith, bark, wood, &c. of plants, see Agriculture, p. 40.

WOODBROUGH, a market-town of Suffolk, situated twenty-six miles south-west of Bury.

WOOD COCK, in ornithology. See Scolopax.

WOOD LOUSE, in zoology. See Oniscus.

WOOD-PICKER, in ornithology. See Picus.

WOODSTOCK, a borough-town of Oxfordshire, situated seven miles north of Oxford. It sends two members to parliament.

WO. F., among manufacturers, the threads which the weavers interlace with an instrument called the shuttle. See Cloth.

WOOL, the covering of sheep. See Ovis.

WOOLWICH, a market-town of Kent, situated on the river Thames, six miles east of London.

WORCESTER, the capital city of Worcestershire, situated twenty-seven miles south-west of Wells.
WORKSOP, a market-town of Nottinghamshire, situated twenty-three miles south-east of London. This is the name of a port-town of the United Netherlands, situated on the river Waal, twenty-three miles west of Rotterdam.

WORMS, in geography, an imperial city of Germany, in the circle of Friesland, situated on the Zuyder-see, twenty miles south-west of Utrecht.

WORLD, in language, an articulate sound designed to represent some idea. See Grammar and Language.

WORKSHOP, a market-town of Nottinghamshire, situated twenty miles north of Nottingham.

WORLD, the assemblage of parts which compose the globe of the earth. See Geography, and Astronomy.

WORMS. See Natural History.

WORMS, in medicine. See Medicine, p. 160.

Earth-Worm. See Lumbricus.

Worm, in gunnery, a crew of iron, to be fixed on the end of a rammer, to pull out the wad of a firelock, carbine, or pistol, being the same with the wad-hook, on the one is more proper for small arms, and the other for cannon.

Worm, in chemistry, is a long, winding, pewter pipe, placed in a tub of water, to cool and condense the vapours in the distillation of spirits.

WORMS, in geography, an imperial city of Germany, in the palatinate of the Rhine: E. long. 9° 5', N. lat. 49° 38'.

WORMWOOD, in botany. See Artemisia.

WORSTED, a kind of woolen thread, which, in the spinning, is twisted harder than ordinary. It is chiefly used either woven or knit into stockings, caps, gloves, or the like.

WORSTED, a market-town of Norfolk, situated seven miles north of Norwich.

WOTTON, a market-town of Gloucestershire, situated seventeen miles south of Gloucester.

WOTTON BASSET, a borough-town of Wilts, thirty miles north of Salisbury; which lends two members to parliament.

Wrasse, or Old wife, in ichthyology. See Labrus.

WORD, in language, an articulate sound designed to represent some idea. See Grammar and Language.

Wanstai, a province of China, in Asia, bounded by the provinces of Honan on the west and by the province of Kiang on the north, by the river Hwang, which divides it from the province of Chekiang, on the east.

Wandering Fig: the corolla is funnel-shaped, and divided into five segments; and the receptacle is paleaceous: The calyx of the female consists of two leaves, including two flowers; it has no corolla; the drupa is dry, mucronated, and divided into two segments; and the nucleus has two cells. There are three species, only one of them, viz. the fruticium, or leaff burdock, a native of Britain.

Wanstai, a province of China. See China, p. 643.

WREXHAM, a market-town of Denbighshire, situated twenty-three miles south-east of St. Asaph.

WRINTON, a market-town of Somerfetshire, situated seven miles north of Wells.

WRIST, in anatomy. See Anatomy, p. 179.

WRIT, in law, signifies, in general, the king's precept in writing under seal, issuing from some court, directed to the sheriff, or any other officer, and commanding something to be done in relation to a suit or action, or giving commission to have the same done.

WRITING, the art or act of signifying and conveying our ideas to others, by letters, or characters, visible to the eye. See Composition, Grammar, and Language.

WRONG, in a logical sense. See Error, Falshood, Truth, &c.

WRONG, in a legal sense, the same with injury, or tort.

Wrongous Imprisonment, in Scots law. See Law, Tit. xxxii. 23.

WURTEMBERG, in Germany, is the north part of the circle of Swabia.

WURZBURG, a city of Germany in the circle of Franconia, capital of the bishopric of that name, situated on the river Maine: in E. long. 9° 5', N. lat. 49° 38'.

WY, a river of Wales, which, rising on the confines of Caernarvonshire, and running south-east, divides the counties of Radnor and Brecknock, then crossing Herefordshire it turns south, and falls into the mouth of the Severn at Chepstow.

WYRA (948)
XENSI, a province of China, bounded by the great wall on the north, by the province of Xanfi on the east, by the province of Suchuen on the south, and by Tibet on the west.

XERANTHEMUM, in botany, a genus of the syngeneia polygamia superflua class. The receptacle is paleaceous; the pappus is sectaceous; and the calix is imbricated, and radiated. There are eleven species, none of them natives of Britain.

XEROPHAGIA, in church-history, the eating of dried foods: so the ancient Christians called certain fast-days, on which they eat nothing but bread and salt, and drank only water; sometimes they added pulse, herbs, and fruits. This sort of fasting was observed chiefly in the holy-week, out of devotion, and not by obligation.

XICHU, a city of China, in the province of Huguai: E. long. 112°, N lat. 27°.

XINYAN, a city of Afi, in the province of Laotung: E. long. 120°, N lat. 31°.

XIPHIAS, in ichthyology, a genus belonging to the order of apodes. The upper jaw terminates in a long sword-shaped rostrum; from which it is called the sword-fish; there are no teeth in the mouth; the gill-membrane has eight rays; and the body is somewhat cylindrical. There is but one species, found in the European ocean.

XIPHOIDES, in anatomy. See Anatomy, p. 175.

XYLO.ALOES, or Aloe-wood, in pharmacy. See Aloe.

This drug is distinguished into three sorts, the calambac, the common lignum aloes, and cambourb.

The calambac, or finest aloe-wood, called by authors lignum aloes praestantissimum, and by the Chinese tuk hiang, is the most refined of all the woods we are acquainted with; it is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dinted by the fingers like wax, or moulded about by chewing in the mouth, in the manner of modelling wax. This kind, laid on the fire, melts in great parts like resin, and burns away in a few moments, with a bright flame and perfumed smoke. Its scent, whilst in the mals, is very fragrant and agreeable; and its taste acid and bitterish, but very aromatic and agreeable; it is so variable in its colour, that some have divided it into three kinds, the one variegated with black and purple; the second, with the same black, but with yellowish instead of purple; and the third, yellow alone, like the yolk of an egg; this last is the least esteemed of all, is the same in every respect, except their colour: It is brought from Cochinchina.

The lignum aloes vulgaris is the second in value. This is of a more dense and compact texture, and consequently less refined than the other; there is some of it, however, that is spongy, and has the holes filled up with the right resinous matter; and all of it, when good, has veins of the same resin in it. We meet with it in small fragments, which have been cut and split from larger; these are of a tolerably dense texture in the more solid pieces, and of a dusky brown colour, variegated with resinous black veins. It is in this state very heavy, and less fragrant than in these pieces which shew a multitude of little holes, filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the other, and is not unfrequently purplish, or even blackish. The smell of the common aloe-wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very aromatic. This wood is also brought from Cochinchina, and sometimes from Sumatra.

The cambourb, or, as some write it, camboumb is also called agallochum fylvestre, and lignum aloes mexicanum. It is a light and friable wood, of a dusky and often mottled colour, between a dusky green black, and a deep brown. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as either of the two former. We meet with this very frequent, and in large logs; these sometimes entire, sometimes only the heart of the tree, the cortical part being separated. This is brought from the island of Timor, and is the aloe-wood used by the cabinet-makers and inlayers.

The Indians use the calambac by way of incense, burning small pieces of it in the temples of their gods, and sometimes their great people burn it in their houses, in times of fasting. It is esteemed a cordial, taken inwardly; and they sometimes give it in disorders of the stomach and bowels, and to destroy worms. A very fragrant oil may be procured from it, by distillation; which is recommended in paralytic cases, from five to sixteen drops. It is at present, however, but little used; and would scarce be met with anywhere in the shops, but that it is in ingredient in some of the old compositions.

XYLO.BALSAMUM, a name which naturalists give to the wood of the tree which yields that precious gum known to the Latins by the name of opobalsamum, and to us by the balm of Gilead. See Balsam.

We have branches of this tree brought us from Cairo: they are very soft, brittle, unequal, and full of knots; their bark reddish without, and greenish within. The xylo-balsamum is reputed good to strengthen the brain and stomach, and to expel poison.

XYLOCASIA, in the materia medica, the same with the calamus ligustica. See Casia.

XYLON, the prickly cotton-tree, in botany, a genus of the triandria monogynia class of plants, the corolla whereof consists of a single petal, divided into five oval, hollow, patent segments; the fruit is a large, oblong, turbinate capsule, formed of five woody valves, and containing five cells; the seeds are roundish, and fixed to a columnar pentangular receptacle, and have a quantity of fine down, or coton, adhering to them.

XYNOECIA, in Grecian antiquity, an anniversary feast, observed by the Athenians, in honour of Minerva, upon the sixteenth of Hecatombaenon, in memory that, by the persuasion of Theseus, they left their country seats, in which they lay dispersed here and there in Attica, and united together in one body.

XYRIS, in botany, a genus of the triandria monogynia class. The corolla consists of three equal crested petals; and the gluma consists of two valves. There is but one species, a native of India.

XYSTARCHA, in antiquity, the master or director of the xylus. In the Greek gymnasium, the xystarcha was the
Y

YACHT, or Yatch, a vessel with one deck, carrying from four to twelve guns. See Ship.

YARD, a measure of length used in Britain and Spain, consisting of three feet, chiefly to measure cloth, stuffs, &c.

YARD, in anatomy. See Anatomy, p. 270.

YARDS of a ship are those long pieces of timber which are made a little tapering at each end, and are fitted athwart its proper mast, with the fails made fast to them, so as to be hoisted up, or lowered down, as occasion serves. They have their names from the masts unto which they belong.

YARD-ARM is that half of the yard that is on either side of the mast. When it lies athwart the ship.

YARDS also denote places belonging to the navy, where the ships of war, &c. are laid up in harbour. There are, belonging to his majesty's navy, six great yards, viz. Chatham, Deptford, Woolwich, Portmouth, Sheerness, and Plymouth: these yards are fitted with several docks, wharfs, lanches, and graving places for the building, repairing, and cleaning of his majesty's ships; and therein are lodged great quantities of timber, masts, planks, anchors, and other materials: there are also convenient store-houses in each yard, in which are laid up vast quantities of cables, rigging, sails, blocks, and all other sorts of stores needful for the royal navy.

YARE, among sailors, implies quick or ready: as, to keep his arms yare; that is, to keep them clean and bright.

YARE, a river of Norfolk, which runs from west to east, through that country, passing by Norwich, and falling into the German sea at Yarmouth.

YARMOUTH, a borough and port town of Norfolk, situated on the German sea, at the mouth of the river Yare, twenty miles east of Norwich. It sends two members to parliament.

YARMOUTH is also a borough-town of the Isle of Wight, in Hampshire, situated on the north-west coast of the island, six miles west of Newport. It sends two members to parliament.

YARN, wool or flax spun into thread, of which they weave cloth. See Cloth.

YARUM, a market-town of the north riding of Yorkshire, situated on the river Tees, thirty miles north of York.

YAWNING, an involuntary opening of the mouth, occasioned by a vapour or ventriloquy endeavouring to escape, and generally witnessing an irksome weariness, or an inclination to sleep. Yawning, according to Boerhaave, is performed by expanding at one and the same time all the muscles capable of spontaneous motion; by greatly extending the lungs; by drawing in gradually and slowly a large quantity of air; and gradually and slowly breathing it out, after it has been retained for some time, and ruffled; and then restoring the muscles to their natural state. Hence the effect of yawning is to move, accelerate, and equally distribute all the humoura through all the vessels of the body, and consequently to qualify the muscles and organs of sensation for their various functions.

Sanctorius observes, that a great deal is insensibly discharged, when nature endeavours to get rid of the retained perspirable matter, by yawning and stretching of the limbs. To these a person is most inclined just after sleep, because, a greater quantity going off by the pores of the skin than at other times, whenever a person wakes, the increased contraction that then happens induces a great deal of the perspirable matter in the cutaneous passages, which will continually give such irritations as excite yawning and stretching; and such motions, by shaking the membranes of the whole body, and shifting the contacts of their fibres, and the inclosed matter, by degrees throw it off. Hence we see the reason why healthful strong people are most inclined to such motions, because they perspire most in time of sleep, and therefore have more of the perspirable matter to lodge in the pores, and greater irritations thereunto.

YAWS, in the sea language. A ship is said to make yaws, when she does not steer steady, but goes in and out when there is a stiff gale.

YAWS, a distemper endemical to Guinea and the hotter climates of Africa. See Medicine, p. 137.

YEAR. See Astronomy, p. 489.

Year and Day in Scots law. See Law, Tit. vi. 21, 22.

YELLOW, one of the original colours of light.

YELLOWS, a disease in a horse, much the same with that called the jaundice in man. See Fæbiery, p. 561.

YELLOWHAMMER, in ornithology. See Fringilla.

YEOMAN, the first or highest degree among the plebeians of England, next in order to the gentry.

The Yeomen are properly freeholders, who having land of their own, live on good husbandry.

Yeoman is also a title of office in the king's house, ld, of a middle place or rank between an usher and a groom.

YEOMAN
Yeomen of the guard were anciently two hundred and fifty men of the belt rank under gentry, and of larger stature than ordinary, each being required to be six feet high.

At present there are but one hundred yeomen in constant duty, and seventy more not in duty; and as any of the hundred dies, his place is supplied out of the seventy.

They go dressed after the manner of king Henry VIII’s time. They formerly had diet as well as wages when in waiting, but this was taken off in the reign of queen Anne.

YEOVIL, a market-town of Somersetshire, situated eighteen miles south of Wells.

YEST, a head or scum rising upon beer or ale, while working or fermenting in the vat. See Brewing.

It is used for a leaven or ferment in the baking of bread, serving to swell or puff it up very considerably in a little time, and to make it much lighter, softer, and more delicate.

YEW, in botany. See Taxus.

YLA, one of the western islands of Scotland, situated in the Irish sea, west of Cantire.

YNCA, an appellation anciently given to the kings of Peru, and the princes of their blood; the word literally signifying lord, king, emperor, and royal blood.

YOAK, or Yoke in agriculture, a frame of wood, fitted over the necks of oxen, whereby they are coupled together, and harnessed to the plough.

Yoak of land in our ancient customs, was the space which a yoke of oxen, that is, two oxen, may plow in one day.

Sea Yoak. When the sea is so rough that the helm cannot be governed by the hands, the seamen make a yoak to steer by; that is, they fix two blocks to the end of the helm, and receiving two small ropes through them, which they call falls, by having some men at each tackle, they govern the helm by direction. They have another way of making a sea yoak, by taking a double turn about the end of the helm with a single rope, the ends being laid to the ship’s sides, by means whereof they guide the helm.

YOANGFU, a city of China, in the province of Huguam, situated on the river Kiai E. long. 114°, N. lat. 30° x 0°.

YOLK, the yellow part in the middle of an egg. See Egg.

YONNE, a river in France, which rising in Burgundy, and running north through Nivernois and Champagne, falls into the Seine at Montereau fur Yonne.

YORK, the capital city of Yorkshire, situated on the river Ouse, 180 miles north of London: W. long. 50°, N. lat. 54°. It is a large city, and has some good buildings in it, particularly the cathedral, which is a Gothic pile, equal to any thing of the kind in England. It is the see of an archbishop, and sends two members to parliament.

New York, one of the British colonies in North America, which comprehending the Jerseys, that frequently have the same governor, is situated between 72° and 74° of W. long. and between 41° and 44° of N. lat. bounded by Canada on the north, New England on the east, the American Sea on the south, and Pennsylvania and the country of the Iroquois on the west.

New York, the capital city of this province, is situated on an island in the mouth of Hudson’s river, in W. lon. 72° 30′, N. lat. 41°.

Yucca, a genus of the hexandria monogyina class. The corolla is open and bell-shaped; it has no stigmas; and the capsule has three cells. There are four species, all natives of America.

A kind of bread is made from the dried root of this plant by the Indians, which much resembles that made from the root of the calandra or scutellaria of Linnaeus.

Zaman

ZAARA, one of the divisions of Africa, situated under the tropic of cancer, is bounded by Bildulgerid on the north, by the unknown parts of Africa on the east, by Nigritia or Negroland on the south, and by the Atlantic ocean on the west. This is a barren desert, and so destitute of water, that the camels which pass over it from Morocco to traffic with Negroland, are half loaded with water and provisions.

ZAFFER, or Zafrs, in chemistry, the name of a blue substance, of the hardness and form of a stone; and generally suppos’d to be a native sapphire.

It is in reality, however, a preparation of cobalt; the calx of that mineral being mixed with powdered flints and wetted with water to bring it into this form.

ZAMORA, a city of Spain, in the province of Leon, situated on the river Douro, thirty-two miles north of Salamanca: W. long. 6°, N. lat. 41° 30′.

Vol. III. No. 100.
ZANTE, an island in the Mediterranean sea, situated E. long. 21° 30', N. lat. 37° 50', being about twenty four miles long, and twelve broad. The chief town is Zante, and is situated on the east side of the island, being well fortified and defended by a castle.

ZAPATA, a kind of feast or ceremony held in Italy, in the courts of certain princes, on St Nicholas's day; wherein people hide presents in the shoes or flippers of thefe who would do honour to, in such a manner as may surprife them on the morrow when they come to dress; being done in imitation of the practice of St Nicholas, who used in the night-time to throw purses of money into the windows, to marry poor maids withal.

ZARA, a city of Dalmatia, situated on the gulf of Venice: E. long. 17°, N. lat. 44°.

ZARNAW, a city of Poland, in the province of Little Poland and palatinate of Sandomir, situated E. long. 20°, N lat. 51° 30'.

ZEA, INDIAN CORN, in botany, a genus of the monoecia triandria clas. The calyx of the male is a double flowered glume, without any awn; the corolla is likewise a glume, without any awn; the calyx and corolla of the male consists each of two valves; the stylus is filiform, and pendulous; and the seeds are oblong, being sunk in an oblong receptacle. There is but one species, a native of America.

ZEAL, the exercise of a warm animated affection, or passion, for anything.

ZELAND, the chief of the Danish islands, is situated at the entrance of the Baltic sea, bounded by the Schagger-rac-eea. on the north, by the Sound, which separates it from Schonen, on the east; by the Baltic sea, on the south; and by the Strait called the Great Belt, which separates it from the island of Funen, on the west; being of a round figure, near two hundred miles in circumference; the chief town is Copenhagen.

ZELAND, is also a province of the United Netherlands, consisting of eight islands, which lie in the mouth of the river Scheld, bounded by the province of Holland, from which they are separated by a narrow channel, on the north; by Brabant, on the east; by Flanders, from which they are separated by one of the branches of the Scheld, on the south; and by the German ocean, on the west.

ZEALOTS, an ancient sect of the Jews, so called from their pretended zeal for God's law, and the honour of religion.

ZEBRA, in zoology. See Equus.

ZECHARIAH, a canonical book of the Old Testament, containing the predictions of Zechariah, the son of Barachia, and grandson of Ileod. He is the eleventh of the twelve lesser prophets. Zechariah entered upon the prophetic office at the same time with Haggai, and was sent to the Jews upon the same message, to reprove them for their backwardness in erecting the temple, and restoring divine worship; but especially for the disorder of their lives and manners, which could not but derive a curse upon them. By several notable visions and types, he endeavours to confirm their faith, and establish their assurances concerning God's providence with them, and care over them; and as a proof and demonstration of this, he interposes the most comfortable promises of the coming of the kingdom, the temple, the priesthood, the victory, the glory of Christ the Branch. Nor does he for-get to assure them of the ruin of Babylon, their most implacable enemy. This prophet is the longest and most obscure of all the lesser prophets, his style being interrupted and without connexion.

ZEDOARY, in the materia medica, a root, the several pieces of which differ so much from one another in shape, that they have been divided into two kinds, as if two different things, under the names of the long and round zedoary, being only the several parts of the same root.

Zedoary is to be chosen fresh, round, and hard, in large pieces; it matters not as to shape, whether long or round; of a smooth surface, and of a sort of fatty appearance within, too hard to be bitten by the teeth, and of the briskeft smell that may be; such as is friable, dulky, and worm eaten, is to be rejected.

Zedoary, both of the long and round kind, is brought us from China; and we find by the Arabs, that they also had it from the same place. The round tubers are less frequent than the long, and some of them have therefore supposed them the produce of a different and more rare plant; but this is not so probable as that the general form of the root is long, and the round tubers are only lafos nature, and less frequent in it.

Zedoary, distilled with common water, affords a thick and dense effential oil, which soon concretes of itself into a kind of camphor, and on this oil Its virtues principally depend. It is a sudorific, and is much recommended by some in fevers, especially of the malignant kinds. It is also given with success as an expectorant in all disorders of the breast, arising from a tough phlegm, which it powerfully incides and attenuates; it is also good against flatulences, and in the cholick; it strengthens the thorax, and afflicts digestion; and, finally, is given with success in nervous cases of all kinds.

ZELL, a city of Germany, in the circle of Lower Saxony, capital of the duchies of Zell and Lunenburg, situated at the confluence of the rivers Aller and Fulhe, thirty miles north of Hanover, and forty south of Lunenburg: E. long. 10°, N. lat 52° 52'.

ZEND, or ZENDAVESTA, a book containing the religion of the Magians, or worshippers of fire, who were disciples of the famous Zoroaster. See Magi.

This book was composed by Zoroaster during his retirement in a cave, and contained all the pretended revelations of that impostor. The first part contains the liturgy of the magi, which is used among them in all their oratories and fire-temples to this day; they reverence it as the Chriftians do the Bible, and the Mahometans the Koran. There are found many things in the zend taken out of the scriptures of the Old Testament, which Dr. Prideaux thinks is an argument that Zoroaster was originally a Jew. Great part of the Psalms of David are infected: he makes Adam and Eve to have been the first parents of mankind, and gives the fame history of the creation and deluge as Moses does, and commands the same observances about clean and unclean beasts, the same law of paying tythes to the sacerdotal order, with many other institutions of Jewish extraction. The rest of its contents are an historical account of the life, actions, and prophecies of its author, with rules and exhortations to moral living. The Mahometans have a feast which they call Zendikites, who are said to be the Sadducees of Mahometanism, denying providence and the resurrection, believing
ZEPHANIAH, a canonical book of the Old Testament, containing the prophecies of Zephaniah the son of Cushi, and grandson of Gedaliah; being the ninth of the twelve minor prophets. He prophesied in the time of king Josiah, a little after the captivity of the ten tribes, and before that of Judah; so that he was co-temporary with Jeremiah. He freely publishes to the Jews, that what increased the divine wrath against them, was their contempt of God's service, their apostasy, their treachery, their idolatry, their violence and rapine, and other enormities: such high provocations as these rendered their destruction terrible, universal, and unavoidable: and then, as most of the prophets do, he minglest extortions with repentance, as the only expedient in these circumstances.

ZEPHYR, the west wind, or that which blows from the west.

ZEST, the woody thick skin, quartering the kernel of a walnut; prescribed by some physicians, when dried and taken with white-wine, as a remedy against the gravel.

ZETETIC method, in mathematics, the method made use of to investigate or solve a problem.

ZEUGMA, a figure in grammar, whereby an adjective or verb which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

ZEUS, in ichthyology, a genus belonging to the family of the salmonid. The male has no calyx; the corolla consists of a double-valved glume without any awn. The female has no calyx; the corolla consists of a single-valved gama with an awn; the filus is bifid; and there is but one seed. The species are two, none of them natives of Britain.

ZEBRETICUS, in zoology. See Castor.

ZINGIBER, in botany. See Amomum.

ZINK. See Chemistry, p. 80, 106, 143.

ZINZIBER, or Zingiber, Ginger, in botany, the naked flaked oval spitted amomum. See Amomum, and Ginger.

ZIRANIA, in botany a genus of the monocca hexanaria class. The male has no calyx; the corolla consists of a double-valved glume without any awn. The female has no calyx; the corolla consists of a single-valved gama with an awn; the filus is bifid; and there is but one seed. The species are two, none of them natives of Britain.

ZIZIPHORA, in botany, a genus of the diandria monogymina class. The corolla consists of five leaves; and the corolla of five petals; the nectarium consists of ten leaves, covering the germen, and the capsule has five cells. There are 8 species, none of them natives of Britain.

ZODIAC, in astronomy, a fascia or broad circle, whose middle is the ecliptic, and its extremes two circles parallel thereto; at such a distance from it as to blend or comprehend the excursions of the sun and planets. See Astronomy.
### CORRIGENDA.

Page 132. col. 1. l. 25, 26. Instead of from the salivary glands, from smoking, &c. read, as to the salivary glands from smoking, &c.

P. 510. col. 2. l. 1. For (ibid. no 2.) read (Plate CXLVII. fig. 1. n° 1.)

### NOTA N D A.

1. In the Table of Errata at the end of Vol. I. it was said, "That Plate XLVII. represented a different Orrery from the one described." This was a mistake the Printer was somehow led into: for the Orrery there represented is the right one, and corresponds with the description.

2. In FLAX-DRressing, plans of two machines relating to that article were referred to, but which several circumstances now render it difficult for the Editors to give. It is therefore hoped these will be dispensed with, as they are not of the most general importance, and the article is sufficiently explained and illustrated without them; and especially as ten plates more than the proposed number, and 16 pages of letter-press, are given gratis.

### DIRECTIONS to the BINDER.

1. Be careful in cutting the book, not to pare too much off the margin; as it was necessary, in several places, particularly in BOOK-KEEPING, to enlarge the page beyond the measure of the rest of the book.

2. Title-pages for the Three Volumes are printed. Place them respectively at the beginning of the Volume; and after the title in Vol. I. insert the Preface.

3. In BOOK-KEEPING, Vol. I. cancel pages 585, 586; and in their place insert the leaves marked with an asterisk and enclosed with parentheses, viz. (*585) (*586), (*A) (*A), (*B) (*B), (*C) (*C), (*D) (*D), (*E) (*E).

4. Insert the Plates as directed below.
