ENCYCLOPÆDIA BRITANNICA.

VOLUME the THIRD.
Encyclopædia Britannica;

OR, A

DICTIONARY

OF

ARTS and SCIENCES,

COMPILED UPON A NEW PLAN.

IN WHICH

The different SCIENCES and ARTS are digested into
distinct Treatises or Systems;

AND

The various TECHNICAL TERMS, &c. are explained as they occur
in the order of the Alphabet.

ILLUSTRATED WITH ONE HUNDRED AND SIXTY COPPERPLATES.

By a SOCIETY of GENTLEMEN in SCOTLAND.

IN THREE VOLUMES.

VOL. III.

EDINBURGH:

Printed for A. BELL and C. MACFARQUHAR;
And sold by COLIN MACFARQUHAR, at his Printing-office, Nicolson-street.

M. DCC. LXXI.
Macao, an island of China, in the province of Canton, fifty miles south of Canton. Macao, in ornithology. See Psittacus. Maccabees, two apocryphal books of scripture; so called from Judas Mattathias, surnamed Maccabeus. The first book of the Maccabees is an excellent history, and comes nearest to the style and manner of the sacred historians of any extant. It contains the history of forty years, from the reign of Antiochus Epiphanes to the death of Simon the high priest; that is, from the year of the world 3829 to the year 3869, 131 before Christ. The second book of the Maccabees begins with two epistles sent from the Jews of Jerusalem to the Jews of Egypt and Alexandria, to exhort them to observe the feast of the dedication of the new altar erected by Judas on his purifying the temple. After these epistles follows the preface of the author to his history, which is an abridgment of a larger work, composed by one Jason, a Jew of Cyrene, who wrote the history of Judas Maccabees and his brethren, and the wars against Antiochus Epiphanes and Eupator his son. This second book does not, by any means, equal the accuracy and excellency of the first. It contains a history of about fifteen years, from the execution of Hellenicus’s commission, who was sent by Seleucus to fetch away the treasures of the temple, to the victory obtained by Judas Maccabees over Nicanor; that is, from the year of the world 3828, to the year 3843, 147 years before Christ.

Macclesfield, a market-town of Cheshire, thirty-five miles east of Chester, from whence the noble family of Parker take the title of earl.

Mace, the second coat or covering of the kernel of the nutmeg, is a thin and membranaceous substance, of an oleaginous nature and a yellowish colour; being met with in flakes of an inch and more in length, which are divided into a multitude of ramifications. It is of an extremely fragrant, aromatic and agreeable flavour, and of a pleasant, but acrid and oleaginous taste. Mace is carminative, flatulentic, and astrigent; and possesses all the virtues of nutmeg, but is less astrigent.

Macedonia, a province of European Turkey, bounded by Servia and Romania, on the north and east; by the gulfs of Salonichi, Contra, and Thessaly, on the south; and by Albania and Epirus, on the west.

Maceration, is an infusion of, or soaking ingredients in water or any other fluid, in order either to soften them, or draw out their virtues.

Machine, in general, whatever hath force sufficient to raise or drop the motion of a heavy body. See Mechanics.

Machinery, in epic and dramatic poetry, is when the poet introduces the use of machines, or brings some supernatural being upon the stage, in order to solve some difficulty, or to perform some exploit out of the reach of human power. See Composition.

Mackeran, or Makan, the capital of a province in Persia of the same name; situated in E. long. 66°, and N. lat. 26°.

Mackerel, in ichthyology. See Scomber.
MACRÓCERCI, a name given to that class of animal-cules, with tails longer than their bodies.

MACRÓPYRENIUM, in natural history, a genus of fossils, consisting of crinoid cephalopods, with a long nucleus standing out at each end of the masts.

MACRÓTELÔSTYLA, in natural history, a name of a genus of crustaceans, which are composed of two pyramids, joined to the end of a column; both the pyramids, as also the column, being hexagonal, and the whole body consequently composed of eighteen planes.

MACULE, in astronomy, dark spots appearing on the luminous faces of the sun, moon, and even some of the planets. See Astronomy.

These spots are most numerous and easily observed in the sun. It is not uncommon to see them in various forms, magnitudes, and numbers, moving over the sun's disk. They were first of all discovered by the lynean astronomer Galileo, in the year 1610, soon after he had finished his new-invented telescope.

MAD APPLE. See RUßIA.

MADAGASCAR, or St. Laurence, an island of Africa, situated between 43° and 51° of east longitude, and between 12° and 26° south latitude, three hundred miles south-east of the continent of Africa. It is about a thousand miles in length from north to south, and generally between two and three hundred miles broad. The country is divided among a great number of petty sovereigns.

MADDER. See RUßIA.

MADÉRAS, a river which arises in Burgundy, and runs through Lorraine and Champagne into the Netherlands, and at last, after passing by many considerable towns, discharges itself into the German sea, a little below the Briel.

MAESTRÌCHT, a town in the province of Brabant, situated on the river Meuse, thirteen miles north of Liege: E. long. 5° 40', and N. lat. 50° 55'.

MAGADOXÁ, the capital of the territory of the same name, at the mouth of the river Magadoxa, on the coast of Anian, in Africa: E. lon. 41°, and N. lat. 2°.

MAGÁNOXÁ, a place in which stores are kept, of arms, ammunition, provisions, &c. Every fortified town ought to be furnished with a large magazine, which should contain stores of all kinds, sufficient to enable the garrison and inhabitants to hold out a long siege, and in which smiths, carpenters, wheelwrights, &c. may be employed, in making every thing belonging to the artillery, as carriages, wagons, &c.

MAGÁLEN, or NÁMI OF ST. MAGÁLEN, an order of religious in the Roman church, dedicated to St. Mary Magdalene, and sometimes called Magdalenes. These chiefly consist of courtesans, who, quitting their profession, devote the rest of their lives to repentance and mortification.

MAGDEBURG, the capital of the duchy of the same name, situated on the river Elbe, seventy miles west of Berlin: E. long. 12°, and N. lat. 52° 15'.

MAGDELENE, a large river of South America, which, rising near the equator, runs north through Terra Firma, and, uniting its waters with the river Cance, obtains the name of the river Grande, and falls into the north sea, below the town of Madre de Popa.

MAGELLÁN, or STREIGHTS, or rather STREIGHTS OF MAGELLÁN, These straits are about three hundred miles in length from the Atlantic to the Pacific ocean, but of a very unequal breadth; and were at first discovered and passed by Ferdinand Magellan, from whom they had their name: they are situated between the island Terra del Fuego and the most southern part of the continent of America, between 76° and 84° of W. long. and between 52° and 54° of south lat.

MAGI, or MAGIANs, an ancient religious sect in Persia and other eastern countries, who maintained, that there were two principles, the one the cause of all good, the other the cause of all evil; and, abominating the adoration of images, worshipped God only by fire, which they looked upon as the brightest and most glorious symbol of Oromades, or the good God; as darkness is the truest symbol of Aryanus, or the evil god. This religion was reformed by Zoroaster, who maintained that there was one supreme independent being; and under him two principles or angels, one the angel...
of goodness and light, and the other of evil and darkness: that there is a perpetual struggle between them, which shall last to the end of the world; that then the angels of darkness and his disciples shall go into a world of their own, where they shall be punished in everlasting darkness; and the angel of light and his disciples shall also go into a world of their own, where they shall be rewarded in everlasting light.

The priests of the magi were the most skilful mathematicians and philosophers of the ages in which they lived, insomuch that a learned man and a magician became equivalent terms. The vulgar looked on their knowledge as more than natural, and imagined them inspired by some supernatural power; and hence those who practised wicked and mischievous arts, taking upon themselves the name of magians, drew on it that ill signification which the word magician now bears among us.

This fact still subsists in Persia, under the denomination of gars, where they watch the sacred fire with the greatest care, and never suffer it to be extinguished.

MAGIC, originally signified only the knowledge of the more sublime parts of philosophy; but as the magi likewise professed alchemy, divination and forcery, the term magi became odious, being used to signify an unlawful diabolical kind of science, acquired by the affiduous work of the devil and departed souls.

Magic lantern, in optics. See Optics.

MAGISTERY, in chemistry, a very fine powder made by solution and precipitation.

Magistry of Bifmuth. See Chemistry, p. 90.

MAGISTRATE, any public officer to whom the executive power of the law is committed, either wholly or in part.

Magna assisa eligenda, is a writ anciently directed to the sheriff for summoning four lawful knights before the justices of assize, in order to choose twelve knights of the neighbourhood, &c. to pass upon the great assize between such a person plaintiff, and such a one defendant.

Magna charta, the great charter of the liberties of Britain, and the basis of our laws and privileges.

This charter may be said to derive its origin from king Edward the Confessor, who granted several privileges to the church and state by charter: these liberties and privileges were also granted and confirmed by king Henry I. by a celebrated great charter now lost; but which was confirmed or re-enacted by king Henry II. and king John. Henry III. the successor of this just prince, after having caused twelve men to make inquiry into the liberties of England in the reign of Henry I. granted a new charter, which was the same as the present magna charta: this he several times confirmed, and as often broke; till, in thirty-seventh year of his reign, he went to Westminster-hall, and there, in the presence of the nobility and bishops, who held lighted candles in their hands, magna charta was read, the king all the while holding his hand to his breast, and at last solemnly swearing faithfully and inviolably to observe all the things therein contained, &c. then the bishops extinguishing the candles, and throwing them on the ground, they all cried out, "Thus let him be extinguished, and flack in hell, who violates this charter." It is observed, that notwithstanding the solemnity of this confirmation, king Henry, the very next year, again invaded the rights of his people, till the barons entered into a war against him, when, after various successes, he confirmed this charter, and the charter of the forei, in the fifty second year of his reign. This excellent charter, so equitable and beneficial to the subject, is the ancient charter written in the kingdom: by the 25 Edw. I. it is ordained that it shall be taken as the common law; and by the 43 Edward III. all statutes made against it are declared to be void.

MAGNESIA. See Chemistry, p. 119.

Magnet, or Loadstone, in natural history, a very rich iron ore, found in large detached masses, of a dusky iron-grey, often tinged with brownish or reddish, and when broken appearing something like the common emery, but less sparkling. It is very heavy, considerably hard, of a perfectly irregular and uneven surface, and of a firm structure, but usually with some porous irregularities within. It is found in Britain, and all other places where there are iron mines. See Mechanics.

Magnifying, the making of objects appear larger than they would otherwise do; whence convex lenses, which have the power of doing this, are called magnifying glasses. See Optics.

MAGNITUDE, whatever is made up of parts locally extended, or that hath several dimensions; as a line, surface, solid, &c.

Magnolia, in botany, a genus of the polyandria class. The calix consists of three leaves, and the corolla of nine petals; the capsules are imbricated, and have two valves; and the seed is a pendulous berry. There are four species, all natives of America.

Magpy, in ornithology. See Corvus.

Mahometans, those who believe in the religion and divine million of Mahomet, or Mohammed.

It will not be improper here to give a general account of this extraordinary person, and the religion which he had the address to propagate over most of the eastern nations.

Mohammed was born in the reign of Anushirwan the Jutt, emperor of Persia, about the end of the 6th century of the Christian era. He came into the world under some disadvantages. His father Abd'allah was a younger son of Abd'almotalleb, and, dying very young; and in his father's life time, left his widow and infant son in very mean circumstances, his whole substance consisting but of five camels and one Ethiopian slave. Abd'alma'tleb was therefore obliged to take care of his grandchild Mohammed, which he not only did during his life, but at his death enjoined his eldest son Abu Taleb, who was brother to Abd'allah by the same mother, to provide for him for the future; which he very affectionately did, and instructed him in the business of a merchant which he followed; and to that end he took him into Syria when he was but thirteen, and
and afterwards recommended him to Khadijah, a noble and rich widow, for her factor; in whose service he behaved himself so well, that by making him her husband the soon raised him to an equality with the richest in Mecca.

After he began by this advantageous match to live at his ease, it was that he formed the scheme of establishing a new religion, or, as he expressed it, of replanting the only true and ancient one, professed by Adam, Noah, Abraham, Moses, Jesus, and all the prophets, by destroying the gross idolatry into which the generality of his countrymen had fallen, and weeding out the corruptions and superstitions which the latter Jews and Christians had, as he thought, introduced into their religion, and reducing it to its original purity, which confided chiefly in the worship of one only God.

Before he made any attempt abroad, he rightly judged that it was necessary for him to begin with the conversion of his own household. Having therefore retired with his family, as he had done several times before, to a cave in mountain Hara, he there opened the secret of his mission to his wife Khadijah; and acquainted her that the angel Gabriel had just before appeared to him, and told him that he was appointed the apostle of God; and also repeated to her a passage which he pretended had been revealed to him by the minister of the angel, with those other circumstances of this first appearance, which are related by the Mohammedan writers. Khadijah received the news with great joy; flattering by his whole hands her soul was, that she trusted he would be the prophet of his nation; and immediately communicated what she had heard to her cousin Warakah Ebn Nawfal, who, being a Christian, could write in the Hebrew character, and was tolerably well versed in the scriptures; and he as readily came into her opinion, affuring her that the same angel who had formerly appeared unto Moses was now sent to Mohammed. The first overture the prophet made in the month of Ramadan, in the fortieth year of his age, which is therefore usually called the year of his mission.

Encouraged by so good a beginning, he resolved to proceed, and try for some time what he could do by private persuasion, not daring to hazard the whole affair by exposing it too suddenly to the public. He soon made profelytes of those under his own roof, viz. his wife Khadijah, his servant Zeid Ebn Harethah (to whom he gave his freedom on that occasion, which afterwards became a rule to his followers) and his cousin and pupil Ali, the son of Abu Taleb, though then very young: but this laft, making no account of the other two, used to style himself the first of believers. The next person Mohammed applied to was Abd’allah Ebn Abi Kohafa, surnamed Abu Beer, a man of great authority among the Koreith, and one whose interest he well knew would be of great service to him; as it soon appeared: for Abu Beer, being gained over, prevailed also on Othman Ebn Affan, Abd’ alrahm Ebn Awf, Saad Ebn Abi Wakkas, al Zobeir Ebn al Awam, and Telha Ebn Obeid’dallah, all principal men of Mecca, to follow his example. These men were the six chief companions, who, with a few more, were converted in the space of three years; at the end of which, Mohammed having, as he hoped, a sufficient interest to support him, made his mission no longer a secret, but gave out that God had commanded him to admonish his near relations, and, in order to do it with more convenience and prospect of success, he directed Ali to prepare an entertainment, and invite the sons and descendants of Abd’almutalleb, intending then to open his mind to them: this was done, and about forty of them came; but Abu Laheb, one of his uncles, making the company break up before Mohammed had an opportunity of speaking, obliged him to give them a second invitation the next day; and when they were come, he made them the following speech: "I know no man in all Arabia who can offer his kindred a more excellent thing than I now do you: I offer you happiness both in this life, and in that which is to come; God Almighty hath commanded me to call you unto him; Who therefore among you will be assistant to me herein, and become my brother and my vicegerent? All of them he tapering, and declining the matter, Ali at length rose up, and declared that he would be his assistant; and vehemently threatened those who should oppose him. Mohammed upon this embraced Ali with great demonstrations of affection, and desired all who were present to hearken to and obey him, as his deputy; at which the company broke out into a great laughter, telling Abu Taleb that he must now pay obedience to his son.

This repulse however was so far from discouraging Mohammed, that he began to preach in public to the people, who heard him with some patience, till he came to upbraid them with the idolatry, obstinacy, and perseverance of themselves and their fathers; which so highly provoked them, that they declared themselves his enemies, and would soon have procured his ruin, had he not been protected by Abu Taleb. The chief of the Koreith warmly solicited this perilon to defy his nephew, making frequent remonstrances against the innovations he was attempting; which proving ineffectual, they at length threatened him with an open rupture, if he did not prevail on Mohammed to desist. At this Abu Taleb was so far moved, that he earnestly dissuaded his nephew from pursuing the affair any farther, representing the great danger he and his friends must otherwise run. But Mohammed was not to be intimidated, telling his uncle plainly, that if they set the sun against him on his right hand, and the moon on his left, he would not leave his enterprise: and Abu Taleb, seeing him so firmly resolved to proceed, used no further arguments, but promised to stand by him against all his enemies.

The Koreith, finding they could prevail neither by fair words nor menaces, tried what they could do by force and ill treatment; using Mohammed’s followers so very injuriously, that it was not safe for them to continue at Mecca any longer; whereupon Mohammed gave leave to such of them as had not friends to protect them to seek for refuge elsewhere. And accordingly, in the fifth year of the prophet’s mission, sixteen of them, four of whom were women, fled into Ethiopia; and among them Othman Ebn Affan and his wife Rakiath, Mohammed’s daughter. This was the first flight; but afterwards several others followed them, retiring one after another, to the number of eighty-three men and eighteen women, besides
besides 'children. These refugees were kindly received by the Najafhi, or king of Ethiopia, who refused to deli-
ver them up to those whom the Koréih sent to demand them, and, as the Arab writers unanimously attest, even professed the Mohammedan religion.

In the sixth year of his million Mohammed had the pleasure of seeing his party strengthened by the conver-
sion of his uncle Hamza, a man of great valour and merit, and of Omar Ebn al Khattab, a person highly esti-
mated, and once a violent opponent of the prophet. As persecution generally advances rather than obstructs the spreading of a religion, Ilamamit made so great a progress among the Arab tribes, that the Koréih, to suppress it effectually, if possible, in the seventh year of Mohammed's million, made a solemn league or covenant against the Ha-

themites and the family of Abd'almotalleb, engaging them to contract no marriages with any of them, and to have no communication with them; and, to give it the greater sanction, reduced it into writing, and laid it up in the Caaba. Upon this the tribe became divided into two factions; and the family of Hashem all repaired to Abu Taleb, as their head; except only Abd'al Uzza, surnamed Abu Beih, who, out of his inveterate hatred to his nephew and his doctrine, went over to the opposite party, whose chief was Abu Sofian Ebn Harb, of the family of Ommeya.

The families continued thus at variance for three years; but, in the tenth year of his mission, Mohammed told his uncle Abu Taleb, that God had manifestly shewed his disapprobation of the league which the Koréih had made against them, by sending a worm to eat out every word of the instrument, except the name of God. Of this accident Mohammed had probably some private notice; for Abu Taleb went immediately to the Koréih and acquainted them with it; offering, if it proved false, to deliver his nephew up to them; but, in case it were true, he insinuated that they ought to lay aside their animo-
sity, and annul the league they had made against the Hashemites. To this they acquiesced, and, going to in-
spect the writing, to their great astonishment found it to be as Abu Taleb had said; and the league was thereupon declared void.

In the same year Abu Taleb died, at the age of above fourscore; and it is the general opinion that he died an infulder; though others say, that when he was at the point of death he embraced Mohammedism, and produce some paffages out of his poetical compositions to confirm their assertion. About a month, or, as some write, three days after the death of this great benefactor and patron, Moh-

ammed had the additional mortification to lose his wife Khadijah, who had so generously made his fortune. For which reason this year is called the year of mourning.

On the death of these two persons the Koréih began to be more troublesome than ever to their prophet, and especially some who had formerly been his intimate friends; insomuch that he found himself obliged to seek shelter elsewhere, and first pitched upon Tayef, about sixty miles east from Mecca, for the place for his retreat. Thither therefore he went, accompanied by his servant Zied, and applied himself to two of the chief of the tribe of Thakif who were the inhabitants of that place; but they received them very coldly. However, he stayed there a month; and fome of the more confiderate and better fort of men treated him with a little respect; but the slaves and inferior people at length rose against him, and, bringing him to the wall of the city, obliged him to depart, and return to Mecca; where he put himself under the protection of al Motaam Ebn Adi.

This repulse greatly discouraged his followers; ho-
ever, Mohammed was not wanting to himself, but boldly continued to preach to the public assemblies at the pilgrim-

age, and gained several profelytes, and among them fix of the inhabitants of Yathreb of the Jewish tribe of Khazraj, who, on their return home, failed not to speak much in commendation of their new religion, and ex-

horted their fellow-citizens to embrace the fame.

In the twelfth year of his mission it was that Moham-
ed gave out that he had made his night journey from Mecca to Jerusalem and thence to heaven, so much spoken of by all that write of him. Dr Prideaux thinks he invented it, either to anwer the expectations of thofe who demanded some miracle as a proof of his mission; or else, by pretending to have conversed with God, to effa-

hish the authority of whatever he should think fit to leave behind by way of oral tradition, and make his fayings to serve the fame purpofe as the oral law of the Jews. But it does not appear that Mohammed himself ever expected to fave a great regard should be paid to his fayings, as his followers have fince done; and feing he all along dif-

claimed any power of performing miracles, it feems ra-
ther to have been a fearch of policy to raife his reputation, by pretending to have actually converfed with God in heaven, as Moses had heretofore done in the mount, and to have received fome institutions immediately from him, whereas before he contented himself with persuading them that he had all by the miniftiy of Gabriel.

However, this fery appeared fo abfurd and incredible, that several of his followers left him upon it; and had prob-
ably ruined the whole design, had not Abu Beer vouched for his veracity, and declared that, if Mohammed af-

firmed it to be true, he verily believed the whole. Which happy accident not only retrieved the prophet's credit, but increased it to such a degree, that he was fecure of being able to make his disciples fwallow whatever he pleased to impose on them for the future. And this fcorion, notwithstanding its extravagance, was one of the moft artful contrivances Mohammed ever put in practice, and what chiefly contributed to the rafing of his reputation to that great height to which it afterwards arrived.

In this year, called by the Mohammedans the accepted year, twelve men of Yathreb or Medina, of whom ten were of the tribe of Khazraj, and the other two of that of Aws, came to Mecca, and took an oath of fidelity to Mohammed at al Akaba, a hill on the north of that city. This oath was called the women's oath; not that any wo-
men were present at this time, but because a man was not thereby obliged to take up arms in defence of Moh-

ammed or his religion; it being the fame oath that was afterwards exacted of the women, the form of which we have in the Koran, and is to this effect; viz. That they should renounce all idolatry; and they should not steal, nor commit fornication, nor kill their children (as the
Pagan Arabs used to do when they apprehended they should not be able to maintain them,) nor forge calumnies; and that they should obey the prophet in all things that were reasonable. When they hadsolemly engaged to all this, Mohammed sent one of his disciples, named Masab, to Medina, to inform them more fully of what they should do. 

When Masab arrived at Medina, by the assent and assistance of those who had been formerly converted, gained several profeffors of the new religion, particularly Osaid Ebn Hodeira, a chief man of the city, and Saad Ebn Moahd, prince of the tribe of Aws; Mohammedism spreading so fast, that there was scarce a house wherein there were not some who had embraced it.

The next year, being the thirteenth of Mohammed's mission, Masab returned to Mecca, accompanied by seventy-three men and two women of Medina who had professed Islamism, besides some other people who were as yet unbelievers. On their arrival, they immediately forewarned Mohammed, and offered him their assistance, of which he was now in great need; for his adherents were by this time grown so powerful in Mecca, that he could not stay there much longer without imminent danger. Wherefore he accepted their proposal, and met them one night, by appointment at al Akaba above-mentioned, attended by his uncle al Abbas, who, though he was not then a believer, wished his nephew well, and made a speech to those of Medina, wherein he told them, that as Mohammed was obliged to quit his native city, and seek an asylum elsewhere, and they had offered him their protection, they would do well not to deceive him; that if they were not firmly resolved to defend, and not betray him, they had better declare their minds, and let him provide for his safety in some other manner. Upon their professing their sincerity, Mohammed swore to be faithful to them, on condition that they should protect him against all insults; as heartily as they would their own wives and families. They then asked him how they were to compensate them, if they should happen to be killed in his quarrel; he answered, paradise. Whereupon they pledged their faith to him, and so returned home; after Mohammed had chosen twelve out of their number, who were to have the same authority among them as the twelve apostles of Christ had among his disciples.

Hitherto Mohammed had propagated his religion by fair means, so that the whole fuccefs of his enterprise, before his flight to Medina, must be attributed to persuasion only, and not to compulsion. For before this second oath of fealty or inauguration at al Akaba, he had no permission to use any force at all; and in several places of the Koran, which he pretended were revealed during his stay at Mecca, he declares his business was only to preach and admonish; that he had no authority to compel any person to embrace his religion; and that, whether people believe or not, was none of his concern, but belonged soley unto God. And he was so far from allowing his followers to use force, that he exhorted them to bear patiently those injuries which were offered them on account of their faith; and, when persecuted himself, chose rather to quit the place of his birth and retire to Medina, than to make any refistance. But this great passiveness and moderation seem entirely owing to his want of power, and the great superiority of his opponents; for the first twelve years of his mission; for no sooner was he enabled, by the assent of those of Medina, to make head against his enemies, than he gave out, that God had allowed him and his followers to defend themselves against the infidels; and at length, as his forces increased, he pretended to have the divine leave even to attack them; and to destroy idolatry, and set up the true faith by the sword; finding, by experience, that his designs would otherwise proceed very slowly, if they were not utterly overthrown; and knowing, on the other hand, that innovators, when they depend solely on their own strength, and can compel, seldom run any risk; from whence, says Machiavel, it follows, that all the armed prophets have succeded, and the unarmed ones have failed. Moses, Cyrus, Theseus, and Romulus, would not have been able to establish the observance of their institutions for any length of time, had they not been armed. The first passage of the Koran which gave Mohammed the permission of defending himself by arms, is said to have been that in the twenty-second chapter; after which a great number to the same purpose were revealed.

That Mohammed had a right to take up arms for his own defence against his unjust persecutors, may, perhaps, be allowed; but whether he ought afterwards to have made use of that means for the establishing of his religion, is not so easy to determine. How far the secular power may or ought to interfere in affairs of this nature, mankind are not agreed. The method of converting by the sword gives no very favourable idea of the faith which is so propagated, and is disapproved by every body in those of another religion, though the same persons are willing to admit of it for the advancement of their own; supposing that, though a false religion ought not to be established by authority, yet a true one may; and accordingly force is almost as constantly employed in these cases by those who have the power in their hands, as it is constantly complained of by those who suffer the violence.

It is certainly one of the most convincing proofs that Mohammedism was no other than a human invention, that it owed its progress and establishment almost entirely to the sword; and it is one of the strongest demonstrations of the divine original of Christendom, that it prevailed against all the force and powers of the world by its mere dint of its own truth, after having stood the assaults of all manner of persecutions, as well as other oppositions, for three hundred years together, and at length made the Roman emperors themselves submit thereto; after which time, indeed, this proof seems to fail, Christendom being then established, and Paganism abolished, by public authority, which has had great influence in the propagation of the one and destruction of the other ever since. But to return:

Mohammed, having provided for the security of his companions as well as his own, by the league offensive and defensive which he had now concluded with those of Medina, directed them to repair thither, which they accordingly did; but himself with Abu Beer and Ali stayed behind, having not yet received the divine permission, as

...
he pretended, to leave Mecca. The Korish, fearing the consequence of this new alliance, began to think it absolutely necessary to prevent Mohammed's escape to Medina; and having held a council thereon, after several milder expedients had been rejected, they came to a resolution that he should be killed; and agreed that a man should be chosen out of every tribe for the execution of this design; and that each man should have a blow at him with his sword, that the guilt of his blood might fall equally on all the tribes, to whose united power the

This conspiracy was scarce formed, when, by some means or other, it came to Mohammed's knowledge; and he gave out that it was revealed to him by the angel Gabriel, who had now ordered him to retire to Medina. Whereupon, to amuse his enemies, he directed Ali to lie down in his place, and wrap himself up in his green cloak, which he did; and Mohammed escaped miraculously, as they pretend, to Abu Beer's house, unperceived by the conspirators, who had already assembled at the prophet's door. They, in the mean time, looking through the crevice, and seeing Ali, whom they took to be Mohammed himself, asleep, continued watching there till morning, when Ali arose, and they found themselves deceived.

From Abu Beer's house Mohammed and he went to a cave in mount Thur, to the south-east of Mecca, accompanied only by Amer Ebn Foheirah, Abu Beer's servant, and Abd'Allah Ebn Oreitah, an idolater whom they had hired for a guide. In this cave they lay hid three days, to avoid the search of their enemies; which they very narrowly escaped, and not without the assistance of more miracles than one; for some say that the Korish were struck with blindness, so that they could not find the cave; others, that after Mohammed and his companions were got in, two pigeons laid their eggs at the entrance, and a spider covered the mouth of the cave with her web, which made them look no farther. Abu Beer, seeing the prophet in such imminent danger, became very forrowful; whereupon Mohammed comforted him with these words, recorded in the Koran, *Bk not grieved, for God is with us.* Their enemies being retired, they left the cave, and set out for Medina, by a by road; and having fortunately, or, as the Mohammedans tell us, miraculously escaped some who were sent to pursue them, arrived safely at that city; when Ali folio ved them in three days, after he had settled some affairs at Mecca.

The first thing Mohammed did after his arrival at Medina, was to build a temple for his religious worship, and a house for himself, which he did on a parcel of ground which had before served to put camels in, or, as others tell us, for a burying-ground and belonged to Sahal and Sohal, the sons of Amr, who were orphans. This action Dr Prideaux explains against, representing it as a flagrant instance of injustice; for that, says he, he violently deftroyed these poor orphans, the sons of an inferior artificer (whom the author he quotes calls a carpenter) of this ground, and so founded the first fabric of his worship with the like wickedness as he did his religion. But, to fav nothing of the improbability that Mohammed should act in so impolitic a manner at his first coming, the Moham-

medan writers set this affair in a quite different light: one tells us that he treated with the lads about the price of the ground, but they feared he would accept it as a present: however, as historians of good credit assure us, he actually bought it; and the money was paid by Abu Beer. Besides, had Mohammed accepted it as a present, the orphans were in circumstances sufficient to have afforded it; for they were of a very good family, of the tribe of Najjar, one of the most illustrious among the Arabs, and not the sons of a carpenter. As Dr Prideaux's author writes, who took the word Najjar, which signifies a carpenter, for an appellative, whereas it is a proper name.

Mohammed, being securely settled at Medina, and able not only to defend himself against the insults of his enemies, but to attack them, began to send out small parties to make reprisals on the Korish; the first party consisting of no more than nine men, who intercepted and plundered a caravan belonging to that tribe, and in the action took two prisoners. But what established his affairs very much, was the foundation on which he built all his succeeding greatness, was the gaining of the battle of Bedr, which was fought in the second year of the Hejra, and is so famous in the Mohammedan history. Some reckon no less than twenty-seven expeditions wherein Mohammed was personally present, in nine of which he gave battle, besides several other expeditions in which he was not present. His forces he maintained partly by the contributions of his followers for this purpose, which he called by the name of *zacat* or alms, and the paying of which he very artfully made one main article of his religion; and partly by ordering a fifth part of the plunder to be brought into the public treasury for that purpose, in which matter he likewise pretended to act by the divine direction.

In a few years by the success of his arms (notwithstanding he sometimes came off by the worst) he considerably raised his credit and power. In the fifth year of the Hejra he set out with 1400 men to visit the temple of Mecca, not with any intent of committing hostilities, but in a peaceable manner. However, when he came to al Hodeibiya, which is situate partly within and partly without the sacred territory, the Korish went to let him know that they would not permit him to enter Mecca, unless he forced his way; whereupon he called his troops about him, and they all took a solemn oath of fealty or homage to him, and he resolved to attack the city; but those of Mecca sending Arwa Ebn Mafud, prince of the tribe of Thakif, as their ambassador, to defign peace, a truce was concluded between them for ten years, by which any person was allowed to enter into league either with Mohammed, or with the Koreish, as he thought fit. It may not be improper to shew the inconceivable veneration and respect the Mohammedans by this time had for their prophet, to mention the account which the above-mentioned ambassador gave the Koreish, at his return of their behaviour. He said he had been at the courts both of the Roman emperor and of the king of Persia, and never saw any prince so highly respected by his subjects as Mohammed was by his companions; for, whenever he made the ablution, in order to say his prayers, they ran and caught the water that he had used; and, whenever he spit, they immediately licked it up, and gathered it in a skin, as a mark of respect.
ed up every hair that fell from him with great superfluition. In the eleventh year of the Hejra, Mohammed began to think of propagating his religion beyond the bounds of Arabia, and sent messengers to the neighbouring princes, with letters to invite them to Mohammedism. Nor was this project without some success. Khofru Parviz, then king of Persia, received his letter with great disfain, and tore it in a passion, fending away the messenger very abruptly; which when Mohammed heard, he said, God shall tear his kingdom. And soon after a messenger came to Mohammed from Badhan king of Yaman, who was a dependent on the Persians, to acquaint him that he had received orders to send him to Khofru. Mohammed put off his answer till the next morning, and then-told the messenger it had been revealed to him that night that Khofru was slain by his son Shiryeh; adding, that he was well assured his new religion and empire should rise to as great a height as that of Khofru; and therefore bid him advise his master to embrace Mohammedism. The messenger being returned, Badhan in a few days received a letter from Shiryeh, informing him of his father's death, and ordering him to give the prophet no further disturbance. Whereupon Badhan and the Persians with him turned Mohammedans.

The emperor Heraclius, as the Arabian historians assure us, received Mohammed's letter with great respect, laying it on his pillow, and diffimmed the bearer honourably. And some pretend that he would have professed this new faith, had he not been afraid of losing his crown. Mohammed wrote to the fame effect to the king of Ethiopia, though he had been converted before, according to the Arab writers; and to Mokawkas, governor of Egypt, who gave the messenger a very favourable reception, and sent several valuable presents to Mohammed, and among the rest two girls, one of which, named Mary, became a great favourite with him. He also sent letters of the like purport to several Arab princes; particularly one to al Hareth Ebn Abi Shamer king of Ghaffan, who returning for answer that he would go to Mohammed himself, the prophet said, May his kingdom perish; another to Hawdha Ebn Ali, king of Yamama, who was a Chriftian, and, having some time before professed Islamifm, had lately returned to his former faith; this prince sent back a very rough answer, upon which Mohammed cursing him, he died soon after; and a third to al Mondar Ebn Sawa, king of Bahrin, who embraced Mohammedism, and all the Arabs of that country followed his example.

The eighth year of the Hejra was a very fortunate year to Mohammed. In the beginning of it, Khaled Ebn al Walid and Anuru Ebn al As, both excellent fouldiers, the firit of whom afterwards conquered Syria and other countries, and the latter Egypt, became profeffors of Mohammedifm. And soon after the prophet sent 3000 men against the Grecian forces, to revenge the death of one of his ambafladors, who being fent to the governor of Bohra on the fame errand as thofe who went to the above-mentioned princes, were slain by an Arab, of the tribe of Ghaffan, at Muta, a town in the territory of Balka in Syria, about three days journeycaftward from Jerufalem, near which town they encountered. The Grecians being wafily superior in number (for, including the auxiliary
In the tenth year Ali was sent into Yaman to propagate the Mohammedan faith there, and, as it is said, converted the whole tribe of Hamdan in one day. Their example was quickly followed by all the inhabitants of that province, except only those of Najran, who, being Christians, chose rather to pay tribute.

Thus was Mohammedism established, and idolatry rooted out, even in Mohammed's life-time (for he died the next year) throughout all Arabia, except only Yama-

ma, where Mosfeisana, who set up also for a prophet as Mohammed's competitor, had a great party, and was not reduced till the Khalifat of Abu Beer: and the Arabians, being then united in one faith and under one prince, found themselves in a condition of making those conquests, which extended the Mohammedan faith over so great a part of the world.

Of the Koran. The word Koran, derived from the verb karaa, to read, signifies properly, in Arabic, the reading, or, rather, that which ought to be read; by which name the Mohammedans denote not only the entire book or volume of the Koran, but also any particular chapter or section of it; just as the Jews call either the whole scripture, or any part of it, by the name of Karah, or Mikra, words of the same origin and import. See Al-

CORAN.

Besides this peculiar name, the Koran is also honoured with several appellations, common to other books of scripture: as, al Farkan, from the verb foraka, to di-

wide or distinguish; not, as the Mohammedan doctors say, because those books are divided into chapters or sections, or distinguishing between good and evil; but in the same notion that the Jews use the word Perek, or Pirkah, from the same root, to denote a section or portion of scripture. It is also called al Mohaf, the volume, and all Kitab, the book, by way of eminence, which answers to the Biblia of the Greeks; and al Dhikr, the admio-
nition, which name is also given to the Pentateuch and Gospel.

The Koran is divided into 114 larger portions of very unequal length, which we call chapters, but the Arabians Sowar, in the singular Sura, a word rarely used on any other occasion, and properly signifying a row, order, or a regular series; as a course of bricks in building, or a rank of soldiers in an army; and is the name in use and import with the Sura, or Tora of the Jews, who also call the fifty three sections of the Pentateuch Sedarin, a word of the same signification.

These chapters are not in the manuscript copies distinguished by their numerical order, but by particular titles, which are taken sometimes from a particular matter treated of, or person mentioned therein; but usually from the first word of note, exactly in the same manner as the Jews have named their Sedarin; though the word from which some chapters are denominated be very far distant, towards the middle, or perhaps the end of the chapter; which seems ridiculous. But the occasion of this seems to have been, that the verse or passage wherein such word occurs, was, in point of time, revealed and committed to writing before the other verses of the same chapter which preceded it in order; and the title being given to the chapter before it was completed, or the passages re-

duced to their present order, the verse from whence such title was taken did not always happen to begin the chap-
ter. Some chapters have two or more titles, occasioned by the difference of the copies

Some of the chapters having been revealed at Mecca, and others at Medina, the noting this difference makes a part of the title: but the reader will observe that several of the chapters are said to have been revealed partly at Mecca, and partly at Medina; and, as to others, it is yet a dispute among the commentators to which place of the two they belong.

Every chapter is subdivided into smaller portions, of very unequal length also, which we commonly call verses; but the Arabic word is Ayat, the name with the Hebrew Osob, and signifies signs, or wonders; such as are the secrets of God, his attributef, works, judgments, and ordinances, delivered in those verses; many of which have their particular titles also, imposed in the same manner as those of the chapters.

Besides these unequal divisions of chapter and verse, the Mohammedans have also divided their Koran into sixty equal portions, which they call Abzab, in the singu-

lar Hizb, each subdivided into four equal parts; which is also an imitation of the Jews, who have an ancient di-

vision of their Mithma into sixty portions called Mafic-
toth: but the Koran is more usually divided into thirty sections only, named Ajza, from the singular Joz, each of twice the length of the former, and in the like manner subdivided into four parts. These divisions are for the ufe of the readers of the Koran in the royal temples, or in the adjoining chapels where the emperors and great men are interred. There are thirty of these readers belonging to every chapel, and each reads his section every day, so that the whole Koran is read over once a-day.

Next after the title, at the head of every chapter, except only the ninth, is prefixed the following solemn form, by the Mohammedans called the Bifmallah, In the name of the Most Merciful God; which form they constantly place at the beginning of all their books and writings in general, as a peculiar mark or distinguishing character of their religion, it being counted a sort of impiety to omit it. The Jews, for the same purpose, make use of the form, In the name of the Lord, or, In the name of the great God: and the eastern Christians that of, In the name of the Father, and of the Son, and of the Holy Ghost. But Mohammed probably took this form, as he did many other things, from the Persian Magi, who used to begin their books in these words, Benam Yazdan bakhshisgher dadar; that is, In the name of the most merciful just God.

There are twenty-nine chapters of the Koran, which have this peculiarity, that they begin with certain letters of the alphabet, some with a single one, others with more. These letters the Mohammedans believe to be the peculiar marks of the Koran, and to conceal several profound mysteries, the certain understanding of which, the more intelligent confess, has not been communicated to any mortal, their prophet only excepted. Notwithstanding which, some will take the liberty of guessing at their meaning by that species of Cabala called by the Jews Notari-

kon, and suppose the letters to stand for as many words, expelling
ordinances, and decrees; and therefore these mysterious letters, as well as the verses themselves, seem in the Koran to be called signs. Others explain the intent of these letters from their nature or organ, or else from their value in numbers, according to another species of the Jewish Cabala called Gematria; the uncertainty of which conjectures sufficiently appears from their disagreement. Thus, for example, five chapters, one of which is the second, begin with these letters, A L M. which some imagine to stand for, Allah latif magid; God is gracious and to be glorified; or, Ana li minni, to me and from me, viz. belongs all perfection, and proceeds all good; or else for Ana Allah alam, I am the most wise God, taking the first letter to mark the beginning of the first word, the second the middle of the second word, and the third the last of the third word; or for Allah, Gabriel, Mohammed, the author, revealer, and preacher of the Koran. Others say, that as the letter A belongs to the lower part of the throat, the first of the organs of speech; L to the palate, the middle organ; and M to the lips, which are the last organ; so these letters signify that God is the beginning, middle, and end, or ought to be praised in the beginning, middle, and end, of all our words and actions: or, as the total value of these three letters, in numbers, is seventy-one, they signify, that, in the space of so many years, the religion preached in the Koran should be fully established. The conjecture of a learned Christian is at least as certain as any of the former, who supposes these letters were set there by the amenunshis, for Amar li Mohammed, i.e. As the command of Mohammed, as the five letters prefixed to the nineteenth chapter seem to be there written by a Jewish scribe, for Cob yar, i.e. Thus be commanded.

The Koran is universally allowed to be written with the utmost elegance and purity of language, in the dialect of the tribe of Koreifh, the most noble and polite of all the Arabians, but with some mixture, though very rarely, of other dialects. It is confessedly the standard of the Arabic tongue, and, as the more orthodox believe, and are taught by the book itself, inimitable by any human pen, (though some sceptics have been of another opinion) and therefore infilled on as a permanent miracle, greater than that of raising the dead, and alone sufficient to convince the world of its divine original.

And to this miracle did Mohammed himself chiefly appeal for the confirmation of his mission, publicly challenging the most eloquent men in Arabia, which was at that time stocked with thoufands, whose sole study and ambition it was to excel in elegance of style and composition, to produce even a single chapter that might be compared with it.

The general design of the Koran seems to be this: to unite the professors of the three different religions then followed in the populous country of Arabia, who, for the most part, lived promiscuously, and wandered without guides, the far greater number being idolaters, and the rest Jews and Christians mostly of erroneous and heretick belief, in the knowledge and worship of one eternal, invisible God, by whose power all things were made, and those which are not may be; the supreme Governor, Judge, and absolute Lord of the creation; established under the sanction of certain laws, and the outward signs of certain ceremonies, partly of ancient, and partly of novel invention, and enforced by setting before them rewards and punishments, both temporal and eternal: and to bring them all to the obedience of Mohammed, as the prophet and ambassador of God, who, after the repeated admonitions, promises and threats of former ages, was at last to establish and propagate God's religion on earth by force of arms, and to be acknowledged chief pontiff in spiritual matters, as well as supreme prince in temporal.

The great doctrine then of the Koran is the unity of God; to restore which point Mohammed pretended was the chief end of his mission; it being laid down by him, as a fundamental truth, that there never was, nor ever can be, more than one true orthodox religion. For, though the particular laws or ceremonies are only temporary, and subject to alteration, according to the divine direction; yet, the substance of it, being eternal truth, is not liable to change, but continues immutable to the fame. And he taught, that, whenever this religion became neglected, or corrupted in essentials, God had the goodness to re-inform and re-admonish mankind thereof, by several prophets, of whom Moses and Jesus were the most distinguished, till the appearance of Mohammed, who is their heir, no other being to be expected after him. And the more effectually to engage people to hearken to him, the great part of the Koran is employed in relating examples of dreadful punishments formerly inflicted by God on those who rejected and abused his messengers; several of which stories, or some circumstances of them, are taken from the Old and New Testament, but many more from the apocryphal books and traditions of the Jews and Christians of those ages, set up in the Koran as truths in opposition to the scriptures, which the Jews and Christians are charged with having altered; and indeed few or none of the relations or circumstances in the Koran were invented by Mohammed, as is generally suppos'd, being easy to trace the greatest part of them much higher, as the rest might be, were more of those books extant, and it was worth while to make the inquiry.

The other part of the Koran is taken up in giving necessary laws and directions, in frequent admonitions to moral and divine virtues, and, above all, to the worshiping and reverencing of the only true God, and renunciation to his will; among which are many excellent things intermixed, not unworthy even a Christian's perusal.

But besides these, there are a great number of passages which are occasional, and relate to particular emergencies. For whenever any thing happened which perplexed and gravelled Mohammed, and which he could not otherwise get over, he had constant recourse to a new revelation, as an infallible expedient in all nice cases; and he found the success of this method answer his expectation. It was certainly an admirable and polite contrivance of his to bring down the whole Koran at once to the lowest heaven only, and not to the earth as a bungling prophet would probably have done; for if the whole had been published at once, innumerable objections might have been made, which it would have been very hard, if not impossible,
impossible, for him to solve: but as he pretended to have
received it by parcels, as God saw proper that they should
be published for the conversion and instruction of the people,
he had a sure way to answer all emergencies, and to
extricate himself with honour from any difficulty which
might occur.

That Mohammed was really the author and chief con-
troller of the Koran, is beyond dispute; though it be
highly probable that he had no small assistance in his de-
sign from others, as his countrymen failed not to object
to him; however, they differed so much in their conjectures
as to the particular persons who gave him such assistance,
that they were not able, it seems, to prove the charge;
Mohammed, it is to be presumed, having taken his mea-
sures too well to be discovered. Dr. Prideaux has given
the most probable account of this matter, though chiefly
from Christian writers, who generally mix such ridiculous
fables with what they deliver, that they deserve not
much credit.

However it be, the Mohammedans absolutely deny the
Koran was composed by their prophet himself, or any o-
ther for him; it being their general and orthodox belief
that it is of divine original, nay, that it is eternal and
unchanged, remaining, as some express it, in the very
effence of God: that the first transcript has been from
everlasting by God's throne, written on a tablet of va-
fonte, called the preserved table, in which are also re-
corded the divine decrees past and future: that a copy
from this table, in one volume on paper, was by the mi-
nistry of the angel Gabriel sent down to the lowest heaven,
in the month of Ramadan, on the night of power: from
whence Gabriel revealed it to Mohammed by parcels,
some at Mecca, and some at Medina, at different times,
during the space of twenty-three years, as the exigency
of affairs required: giving him, however, the confolu-
tion to shew him the whole (which they tell us was bound
in silk, and adorned with gold and precious stones of pa-
radise) once a year; but in the last year of his life he
had the favour to see it twice. They say that few chap-
ters were delivered entire, the most part being revealed
piece-meal, and written down from time to time by the
prophet's amanuenses in such or such a part of such or
such a chapter, till they were completed according to
the directions of the angel. The first parcel that was
revealed is generally agreed to have been the first five
verses of the ninety-first chapter.

After the new revealed passages had been from the
prophet's mouth taken down in writing by his scribe,
they were published to his followers, several of whom
took copies for their private use, but the far greater
number got them by heart. The originals, when re-
turned, were put promiscuously into a chest, observing
no order of time, for which reason it is uncertain when
many passages were revealed.

When Mohammed died, he left his revelations in the
same disorder, and not digested into the method, such as
it is which we now find them in. This was the work
of his successor Abu Beer, who, considering that a great
number of passages were committed to the memory of
Mohammed's followers, many of whom were slain in
their wars, ordered the whole to be collected, not only
from the palm-leaves and skins on which they had been
written, and which were kept between two boards or
covers, but also from the mouths of such as had gotten
them by heart. And this transcript, when completed,
he committed to the custody of Hafsa the daughter of
Omar, one of the prophet's widows.

From this relation it is generally imagined that Abu
Beer was really the compiler of the Koran; though, for
ought appears to the contrary, Mohammed left the chap-
ters complete as we now have them, excepting such pas-
sages as his successor might add or correct from those
who had gotten them by heart; what Abu Beer did else
being, perhaps, no more than to range the chapters in
their present order, which he seems to have done with
out any regard to time, having generally placed the long-
east first.

However, in the thirty-first year of the Hejra, Othman
being then Khalif, and observing the great disagreement
in the copies of the Koran in the several provinces of
the empire, those of Irak, for example, following the
reading of Abu Mufa al Afhari, and the Syrians that of
Madad Ebn Afsaw, he, by advice of the companions,
ordered a great number of copies to be transcribed from
that of Abu Beer, in Hafsa's care, under the inspection
of Zeid Ebn Thabet, Abd'allah Ebn Zobair, Said Ebn
al As, and Abd'rahman Ebn al Hareth the Mahkumite;
whom he directed, that, where-ever they disagreed about
any word, they should write it in the dialect of the Koreifi,
in which it was at first delivered. These copies, when
made, were dispersed in the several provinces of the em-
pire, and the old ones burnt and supplanted. Though
many things in Hafsa's copy were corrected by the above-
mentioned supervisors, yet some few various readings still
occur.

The fundamental position, on which Mohammed e-
rected the superstructure of his religion, was, That, from
the beginning to the end of the world, there has been,
and for ever will be, but one true orthodox belief; con-
stituting, as to matter of faith, in the acknowledging of
the only true God, and the believing in and obeying such
messengers or prophets as he should from time to time
send, with proper credentials, to reveal his will to man-
kind; and, as to matter of practice, in the observance
of the immutable and eternal laws of right and wrong,
together with such other precepts and ceremonies as God
should think fit to order for the time being, according to
the different dispensations in different ages of the world:
for these last, he allowed, were things indifferent in their
own nature; and became obligatory by God's positive
precept only; and were therefore temporary, and subject

to alteration, according to his will and pleasure. And
to this religion he gives the name of Islam, which word
signifies resignation, or submission to the service and
commands of God; and is used as the proper name of
the Mohammedan religion, which they will also have to be the
name at bottom with that of all the prophets from Adam.

Under pretext that this eternal religion was in his time
 corrupted, and professed in its purity by no one left of
men, Mohammed pretended to be a prophet sent by God,
to reform those abuses which had crept into it, and to
reduce it to its primitive simplicity; with the addition
however
however of peculiar laws and ceremonies, some of which had been used in former times, and others were now first instituted. And he comprehended the whole substance of his doctrine under these two propositions, or articles of faith, viz. that there is but one God, and that himself was the apostle of God; in consequence of which latter article, all such ordinances and institutions as he thought fit to establish must be received as obligatory and of divine authority.

The Mohammedans divide their religion, which they call Islam, into two distinct parts; Iman, i.e. faith, or theory; and Din, i.e. religion, or practice; and teach that it is built on five fundamental points, one belonging to faith, and the other four to practice.

The first is, that there is no god but the true God; and that Mohammed is his apostle. Under which they comprehend six distinct branches, viz. 1. Belief in God; 2. In his angels; 3. In his scriptures; 4. In his prophets; 5. In the resurrection and day of judgment; and, 6. In God’s absolute decree and predetermination both of good and evil.

The four points relating to practice are, 1. Prayer, under which are comprehended those washings or purifications which are necessary preparations required before prayer; 2. Alms; 3. Fasting; and, 4. The pilgrimage to Mecca.

That both Mohammed, and those among his followers who are reckoned orthodox, had and continue to have under which are comprehended those washings or purifications which are necessary preparations required before prayer; 2. Alms; 3. Fasting; and, 4. The pilgrimage to Mecca.

That both Mohammed, and those among his followers who are reckoned orthodox, had and continue to have under which are comprehended those washings or purifications which are necessary preparations required before prayer; 2. Alms; 3. Fasting; and, 4. The pilgrimage to Mecca.

That both Mohammed, and those among his followers who are reckoned orthodox, had and continue to have under which are comprehended those washings or purifications which are necessary preparations required before prayer; 2. Alms; 3. Fasting; and, 4. The pilgrimage to Mecca.

That both Mohammed, and those among his followers who are reckoned orthodox, had and continue to have under which are comprehended those washings or purifications which are necessary preparations required before prayer; 2. Alms; 3. Fasting; and, 4. The pilgrimage to Mecca.

That both Mohammed, and those among his followers who are reckoned orthodox, had and continue to have under which are comprehended those washings or purifications which are necessary preparations required before prayer; 2. Alms; 3. Fasting; and, 4. The pilgrimage to Mecca.

That both Mohammed, and those among his followers who are reckoned orthodox, had and continue to have under which are comprehended those washings or purifications which are necessary preparations required before prayer; 2. Alms; 3. Fasting; and, 4. The pilgrimage to Mecca.

That both Mohammed, and those among his followers who are reckoned orthodox, had and continue to have under which are comprehended those washings or purifications which are necessary preparations required before prayer; 2. Alms; 3. Fasting; and, 4. The pilgrimage to Mecca.

time to time sent by God into the world, amounts to no less than 224,000, according to one Mohammedan tradition, or to 124,000, according to another: among whom 318 were apostles, sent with special commissions to reclaim mankind from infidelity and superstitious; and fix of them brought new laws or dispensations, which successively abrogated the preceding: these were Adam, Noah, Abraham, Moses, Jesus, and Mohammed. All the prophets in general, the Mohammedans believe to have been free from great sins and errors of consequence, and professors of one and the same religion, that is, Islam, notwithstanding the different laws and institutions which they observed. They allow of degrees among them, and hold some of them to be more excellent and honourable than others. The first place they give to the revealers and establifhers of new dispensations, and the next to the apostles.

In this great number of prophets, they not only reckon divers patriarchs and persons named in scripture, but not recorded to have been prophets, (wherein the Jewish and Christian writers have sometimes led the way,) as Adam, Seth, Lot, Isaac, Nun, Joshua, &c. and introduce some of them under different names, as Enoch, Heber, and Jethro, who are called, in the Koran, Edris, Hud, and Shoaib; but several others whose very names do not appear in scripture (though they endeavour to find some persons there to fix them on) as, Saleh, Khedr, Dhul'keff, &c.

The next article of faith required by the Koran is the belief of a general resurrection and a future judgment.

When a corpse is laid in the grave, they say he is received by an angel, who gives him notice of the coming of the two Examiners; which are two black livid angels, received by an angel, who gives him notice of the coming of the two Examiners; which are two black livid angels, named Monker and Nakir. These order the dead person to fit upright, and examine him concerning his faith, as to the unity of God, and the Messiah of Mohammed: if he answer rightly, they suffer the body to rest in peace, and it is refrefhed by the air of paradise; but, if not, they beat him on the temples with iron maces, till he roars out for anguish so loud that he is heard by all from east to west, except men and genii. Then they prepare the earth for the corpse, which is gnawed and flung till the resurrection by ninety-nine dragons, with seven heads each; or, as others say, their fins will become venomous beasts, the grievous ones flinging like dragons, the smaller like serpents; circumstances which some understand in a figurative sense.

As to the soul, they hold, that, when it is separated from the body by the angel of death, who performs his office with care and gentleness towards the good, and with violence towards the wicked, it enters into that state which they call Al Berzakh, or the interval between death and the resurrection. If the departed person was a believer, they say two angels meet him, who convey it to heaven, that its place there may be assigned, according to its merit and degree. For they distinguish the souls of the faithful into three classes; the first of prophets, whose souls are admitted into paradise immediately; the second of martyrs, whose spirits, according to a tradition of Mohammed, rest in the crops of green birds, which eat of the fruits and drink of the rivers of paradise; and the third of other believers, concerning the fate of whose souls before the resurrection there are various opinions.

Though some among the Mohammedans have thought that the resurrection will be merely spiritual, and no more than the returning of the soul to the place whence it first came (an opinion defended by Ebn Sina, and called by some the opinion of the philosophers); and others, who allow man to confit of body only, that it will be merely corporeal; the received opinion is, that both body and soul will be raised; and their doctors argue strenuously for the possibility of the resurrection of the body, and dispute with great subtlety concerning the manner of it. But Mohammed has taken care to preserve one part of the body, whatever becomes of the rest, to serve for a basis of the future edifice, or rather a heaven for the mass which is to be joined to it. For he taught, that a man's body was entirely consumed by the earth, except only the bone called al Ajj, which we name the os coccygis, or rump bone; and that, as it was the first formed in the human body, it will also remain uncorrupted till the last day, as a seed from whence the whole is to be renewed: and this, he said, would be effected by a forty days rain, which God should send, and which would cover the earth to the height of twelve cubits, and cause the bodies to sprout forth like plants. Herein also, is Mohammed beholden to the Jews; who say the same things of the bone Luz, excepting that what he attributes to a great rain, will be effected, according to them, by a dew, impregnating the dust of the earth.

The time of the resurrection the Mohammedans allow to be a perfect secret to all but God alone; the angel Gabriel himself acknowledging his ignorance in this point, when Mohammed asked him about it. However, they say, the approach of that day may be known from certain signs which are to precede it. These signs they distinguish into two sorts, the lesser, and the greater.

The lesser signs are, 1. The decay of faith among men. 2. The advancing of the meanest persons to eminent dignity. 3. That a maid-servant shall become the mother of her mistress (or master;) by which is meant, either that towards the end of the world men shall be much given to sensuality, or that the Mohammedans shall then take many captives. 4. Rumors and seditions. 5. A war with the Turks. 6. Great disturbances in the world, so that a man when he paces by another's grave, shall say, Would to God I were in his place. 7. That the provinces of Irak and Syria shall refuse to pay their tribute. And, 8. That the buildings of Medina shall reach to Ahab, or Yahab.

The greater signs are,

1. The sun's rising in the west; which some have imagined it originally did.

2. The appearance of the beaft, which shall rise out of the earth, in the temple of Mecca, or on mount Safa, or in the territory of Tayef, or some other place. This beaft, they say, is to be sixty cubits high; though others, not satisfied with so small a size, will have her reach to the clouds and to heaven, when her head only is out; and that she will appear for three days, but shew only a third part of her body. They describe this monster, as
to her form, to be a compound of various species; having the head of a bull, the eyes of a hog, the ears of an elephant, the horns of a flag, the neck of an ostrich, the breast of a lion, the colour of a tiger, the back of a cat, the tail of a ram, the legs of a camel, and the voice of an ass. Some say this beast is to appear three times in several places, and that she will bring with her the rod of Moses and the seal of Solomon; and, being so swift that none can overtake or escape her, will with the first strike all the believers on the face, and mark them with the word mummum i.e. believer; and with the latter will mark the unbelievers on the face likewise, with the word Cather, i.e. infidel, that every person may be known for what he really is. They add that the same beast is to demonstrate the vanity of all religions except Islam, and to speak Arabic. All this stuff seems to be the result of a confused idea of the beast in the Revelations.

3. War with the Greeks, and the taking Constanti- nople by 70,000 of the pallerity of Isaac, who shall not win that city by force of arms, but the walls shall fall down while they cry out, There is no God but God: God is most great! As they are dividing the spoils, news will come to them of the appearance of Antichrist; whereupon they shall leave all and return back.

4. The coming of Antichrist, whom the Mohammedans call Masb al Daajal, i.e. the false or lying Christ, and simply al Daajal. He is to be one-eyed, and marked on the forehead with the letters C. F. R. signifying Caesar or infidel. They say that the Jews give him the name of Messiah Ben David, and pretend he is to come in the last days, and to be lord both of land and sea, and that he will reform the kingdom to them.

5. The descent of Jesus on earth. They pretend that he is to descend near the white tower to the east of Damascus, when the people are returned from the taking of Constantinople; that he is to embrace the Mohammedan religion, marry a wife, get children, kill Antichrist, and at length die after forty years, or, according to others, twenty four years continuance on earth. Under him, they say, there will be great security, and plenty in the world, all hatred and malice being laid aside; when lions and camels, bears and sheep, shall live in peace, and a child shall play with serpents unurt.

6. War with the Jews; of whom the Mohammedans are to make a prodigious slaughter. The very trees and stones discovering each of them as hide themselves, except only the tree called Gharkad, which is the tree of the Jews.

7. The eruption of Gog and Magog, or, as they are called in the east, Yajaj and Majaj; of whom many things are related in the Koran and the traditions of Mohammed. These barbarians, they tell us, having passed the lake of Tiberias, which the vanguard of their vast army will drink dry, will come to Jerusalem, and there greatly distress Jesus and his companions; till, at his request, God will destroy them, and fill the earth with their carcasses, which, after some time, God will send birds to carry away, at the prayers of Jesus and his followers. Their bows, arrows, and quivers, the Moslems will burn for seven years together; and, at last, God will send a rain to cleanse the earth, and to make it fertile.

8. A snowe, which shall fill the whole earth.

9. An eclipse of the moon. Mohammed is reported to have said, that there would be three eclipses before the last hour; one to be seen in the east, another in the west, and the third in Arabia.

10. The returning of the Arabs to the worship of Allat and al Uzza, and the rest of their ancient idols, after the decease of every one in whole heart there was faith equal to a grain of mustard seed, none but the very word of men being left alive. For God, they say, will send a cold odouriferous wind, blowing from Syria Damascus, which shall sweep away the souls of all the faithful, and the Koran itself, so that men will remain in the grossest ignorance for an hundred years.

11. The discovery of a vast heap of gold and silver by the retreating of the Ephrates, which will be the destruction of many.

12. The demolition of the Caaba, or temple of Mecca, by the Ethiopians.

13. The speaking of beasts and inanimate things.

14. The breaking out of fire in the province of Hejaz; or, according to others, in Yemen.

15. The appearance of a man of the descendants of Kahtan, who shall drive men before him with his staff.

16. The coming of the Muhdi, or director; concerning whom Mohammed prophesied, that the world should not have an end till one of his own family should govern the Arabsians, whose name should be the same with his own name, and whose father's name should also be the same with his father's name; and who should fill the earth with righteousness. This person the Shites believe to be now alive, and concealed in some secret place, till the time of his manifestation; for they suppose him no other than the last of the twelve Imams, named Mohammed Abul'Kafem, as their prophet was; and the son of Hasson al Askeri, the eleventh of that succession. He was born at German in the 255th year of the Hijra. From this tradition, it is to be presumed, an opinion pretty current among the Christians, took its rife, that the Mohammedans are in expectation of their prophet's return.

17. A wind which shall sweep away the souls of all who have but a grain of faith in their hearts, as has been mentioned under the tenth sign.

These are the greater signs, which, according to their doctrine, are to precede the resurrection, but still leave the hour of it uncertain; for the immediate sign of its being come will be the first blast of the trumpet; which they believe will be founded three times. The first they call the blast of confirmation: at the hearing of which all creatures in heaven and earth shall be struck with terror, except those whom God shall please to exempt from it. The effects attributed to this first sound of the trumpet are very wonderful; for they say, the earth will be shaken, and not only all buildings, but the very mountains levelled; that the heavens shall melt, the sun be darkened, the stars fall, on the death of the angels, who, as some imagine, hold them suspended between heaven and earth; and the sea shall be troubled and dried up, or, according to others, turned into flames, the sun, moon, and stars being thrown into it: the Koran, to express the greatness of the terror of that day, adds, that women who
give fock shall abandon the care of their infants, and even the fhe camels which have gone ten months with young (a moft valuable part of the fubftance of that nation) fhall be utterly neglefted. A farther effect of this blast will be that concourse of heafs mentioned in the Koran, though some doubt whether it be to precede the resurrection or not. They who fuppofe it will precede, think that all kinds of animals, forgetting their repective natural hierarchies and timidity, will run together into one place, being terrified by the found of the trumpet and the fudden shock of nature.

The Mohammedans believe that this firft blast will be followed by a fecond, which they call the blast of examination; when all creatures both in heaven and earth shall die or be affiode, except thofe which God fhall please to exempt from the common fate; and this, they fay, fhall happen in the twinkling of an eye, nay in an instant; nothing furviving except God alone, with paradise and hell, and the inhabitants of those two places, and the throne of glory. The laft who fhall die will be the angel of death.

Fifty years after this will be heard the blast of resurrection, when the trumpet fhall be sounded the third time by Ifrafil, who, together with Grabiel and Michael, will be previously reftored to life, and, standing on the rock of the temple of Jerusalem, fhall, at God's command, call together all the dry and rotten bones, and other difperfed parts of the bodies; and the very hairs, to judgment. This angel, having, by the divine order, fet the trumpet to his mouth, and called together all the fouls from all parts, will throw them into his trumpet, from whence, on his giving the laft sound, at the command of God, they will fly forth like bees, and fill the whole space between heaven and earth, and then repair to their repective bodies, which the opening earth willuffer to arife; and the firft who fhall fo arife, according to a tradition of Mohammed, will be himself. For this birth the earth will be prepared by the rain above mentioned, which is to fall continually for forty years and will reftemb the feed of a man, and be fuppiled from the water under the throne of God, which is called living water: by the efficacy and virtue of which the dead bodies fhall spring forth from their graves, as they did in their mother's womb, or as corn fprouts forfh by common rain, till they become perfect, after which breath will be breathed into them, and they will fleep in their sepulchres till they are raifed to life at the laft trump.

When thofe who have rifen fhall have waited the limited time, the Mohammedans believe God will at length appear to judge them; Mohammed undertaking the office of intercedor after it fhall have been declined by Adam, Noah, Abraham, and Jesus, who fhall beg deliverance only for their own fouls. They fay, that on this folemn occasion God will come in the clouds surrounded by angels, and will produce the books wherein the actions of every perfon are recorded by their guardian angels, and will command the prophets to bear witness againft thofe to whom they have been repectively fent. Then every one will be examined concerning all his words and actions, uttered and done by him in this life; not as if God needed any information in these repects, but to oblige the per-
perfon's good works fo much as equalleth the weight of the contrary, his good works be exhausted, and thereunto him, that he may be admitted into paradife; but if, an ant, God will, of his mercy, cause it to be doubled ven to every cne his due, and there remaineth of this suffered it. Which being done, if the angels (by whose away a proportional part of the good works of him who will be fent to hell laden with both. This will be the manner of giving this satisfadion will be by taking for the injuries which they have suffered. And, fince words and actions, being mere accidents, are not caable of being themselves weighed. They say that the books wherein they are written will be thrown into the scales, and according as those wherein the good or evil actions are recorded shall preponderate, sentence will be given; those whose balances laden with good works shall be heavy, will be faved; but those whose balances are light, will be condemned. Nor will any one have caufe to complain that God suffers any good action to pafs unrewarded, because the wicked for the good they do have their reward in this life, and therefore can expect no faour in the next.

This examination being pafs, and every one's works weighed in a just balance, that mutual retaliation will follow, according to which every creature will take vengeance one of another, or have satisfadion made them for the injuries which they have suffered. And, fince there will then be no other way of returning like for like, the manner of giving this satisfadion will be by taking away a proportional part of the good works of him who offered the injury, and adding it to thofe of him who fuffered it. Which being done, if the angels (by whose miniftry this is to be performed) fay, Lord, we have given to every one his due, and there remaineth of this person's good works so much as equalleth the weight of an ant, God will, of his mercy, caufe it to be doubled unto him, that he may be admitted into paradife; but if, on the contrary, his good works be exhausted, and there remain evil works only, and there be any who have not yet received satisfadion from him, God will order that an equal weight of their fins be added unto his, that he may be punifhed for them in their ftead, and he will be fent to hell laden with both. This will be the method of God's dealing with mankind. As to brutes, af ter they shall have likewise taken vengeance of one another, he will command them to be changed into duft; wicked men being referred to more grievous punishment, fo that they shall cry out, on hearing this sentence paffed on the brutes, Would to God that we were dust alfo. As to the genii, many Mohammedans are of opinion, that fuch of them as are true believers, will undergo the fame fate as the irrational animals, and have no other reward than the favour of being converted into duft; and for this they quote the authority of their prophet.

The trials being over, and the assemby difolved, the Mohammedans hold, that thofe who are to be admitted into paradife will take the right hand way, and thofe who are defined to hell fire will take the left; but both of them must firft pafs the bridge called in Arabic al Sirat, which they fay is laid over the midft of hell, and describe to be firmer than a hair, and sharper than the edge of a fword; fo that it feems very difficult to conceive how any one fhall be able to fland upon it: for which reafon, moft of the fect of the Motaz dites rejedt it as a fable; though the orthodox think it a fufficient proof of the truth of this article, that it was ferially afirmed by him who never afferted a fallaehood, meaning their prophet; who, to add to the difficulty of the paffage, has likewife declared, that this bridge is befet on each fide with briers and hooked thorns; which will however be no impediment to the good, for they fhall pafs with wonderful ease and f'=wiftnefs, like lightning, or the wind, Mohammed and his Mohifmens leading the way; whereas the wicked, what with the flipperinefs and extreme narrownefs of the path, the inte-
collection of Mohammed and the blessed; wherein those who shall have been dead, will be restored to life, as has been said; and those whose bodies shall have contracted any footnotes or filth from the flames and smoke of hell, will be immersed in one of the rivers of paradise, called the river of life, which will wash them whiter than pearls.

The righteous, as the Mohammedans are taught to believe, having surmounted the difficulties, and passed the sharp bridge above mentioned, before they enter paradise, will be refreshed by drinking at the pond of their prophet, who describes it to be an exact square of a month's journey in compass; its water, which is supplied by two pipes from al Cawthar, one of the rivers of paradise, being whiter than milk or silver, and more odoriferous than musk, with as many cups set around it as there are stars in the firmament; of which water whoever drinks will thirst no more for ever. This is the first taste which the blessed will have of their future and now near approaching felicity.

Though paradise be so very frequently mentioned in the Koran, yet it is a dispute among the Mohammedans whether it be already created, or be to be created hereafter; the Muzlamites and some other sectaries affirming that there is not at present any such place in nature, and that the paradise which the righteous will inhabit in the next life will be different from that from which Adam was expelled. However, the orthodox profess the contrary, maintaining that it was created even before the world, and describe it, from their prophet's traditions, in the following manner.

They say it is situate above the seventh heavens (or in the seventh heaven) and next under the throne of God; and, to express the amenity of the place, tell us, that the earth of it is of the finest wheat flour, or of the purest musk, or, as others will have it, of saffron: that its stones are pearls and jacinths, the walls of its buildings enriched with gold and silver, and that the trunks of all its trees are of gold: among which the most remarkable is the tree called Tuba, or the tree of happiness. Concerning this tree, they fable, that it stands in the palace of Mohammed, though a branch of it will reach to the house of every true believer; that it will be laden with pomegranates, grapes, dates, and other fruit, of surprising biggess, and of tastes unknown to mortals. So that, if a man desire to eat of any particular kind of fruit, it will immediately be presented him; or, if he chuse flesh, birds ready dressed will be set before him, according to his wish. They add, that the boughs of this tree will spontaneously bend down to the hand of the person who would gather of its fruits, and that it will supply the blessed not only with food, but also with fine garments, and beards to ride on ready saddled and bridled, and adorned with rich trappings, which will burst forth from its fruits; and that this tree is so large, that a person, mounted on the fleetest horse, would not be able to gallop from one end of its shade to the other in a hundred years.

As plenty of water is one of the greatest additions to the pleasures of any place, the Koran often speaks of the rivers of paradise as a principal ornament thereof: some of these rivers, they say, flow with water, some with milk, some with wine, and others with honey; all taking their rise from the root of the tree Tuba.

But all these glories will be eclipsed by the resplendent and ravishing girls of paradise, called, from their large black eyes, Hur al aman, the enjoyment of whole company will be a principal felicity of the faithful. These, they say, are created, not of clay, as mortal women are, but of pure musk; being, as their prophet often affirms in his Koran, tree from all natural impurities, defects, and inconveniences incident to the sex, of the strictest modesty, and secluded from public view in pavilions of hollow pearls, so large, that, as some traditions have it, one of them will be no less than four paragangs (or, as others say, sixty miles) long, and as many broad.

The name which the Mohammedans usually give to this happy mansion, is al Jannat, or the garden; and sometimes they call it, with an addition, Jannat al Ferdows, the garden of paradise; Jannat Eden, the garden of Eden, (though they generally interpret the word Eden, not according to its accent in Hebrew, but according to its meaning in their own tongue, where-in it signifies a settled or perpetual habitation:) Jannat al Mawwa, the garden of abode; Jannat al Naim, the garden of pleasures; and the like: by which several appellations, some understand so many different gardens, or at least places of different degrees of felicity, (for they reckon no less than an hundred such in all,) the very meanest whereof will afford its inhabitants so many pleasures and delights, that one would conclude they must even fink under them, had not Mohammed declared, that, in order to qualify the blessed for a full enjoyment of them, God will give to every one the abilities of an hundred men.

The sixth great point of faith, which the Mohammedans are taught by the Koran to believe, is God's absolute decree and predetermination both of good and evil. For the orthodox doctrine is, that whatever hath or shall come to pass in this world, whether it be good, or whether it be bad, proceedeth entirely from the divine will, and is irreconcilable fixed and recorded from all eternity in the preferved table; God having secretly predetermined not only the adverse and prosperous fortune of every person in this world, in the most minute particulars, but also his faith or infidelity, his obedience or disobedience, and consequently his everlasting happiness or misery after death; which fate or predetermination it is not possible, by any forethought or wisdom, to avoid.

Of this doctrine Mohammed makes great use in his Koran for the advancement of his designs; encouraging his followers to fight without fear, and even desperately, for the propagation of their faith, by representing to them that all their caution could not avert their inevitable destiny, or prolong their lives for a moment; and deterring them from disobeying or rejecting him as an impotent, by letting before them the danger they might thereby incur of being, by the just judgment of God, abandoned to destruction, hardships of heart, and a reprovable mind, as a punishment for their obstinacy.

Of the four fundamental points of religious practice required by the Koran, the first is prayer, under which are also comprehended those legal washings or purifications which are necessary preparations thereto.
Of these purifications there are two degrees, one called Ghofl, being a total immersion or bathing of the body in water; and the other called Wudu, (by the Persians, Abdej,) which is the washing of their faces, hands, and feet, after a certain manner. The Ghofl is required in some extraordinary cases only, as after having lain with a woman, or been polluted by emission of seed, or by approaching a dead body; women also being obliged to it after their courses or childbirth. The latter is the ordinary ablution in common cases, and before prayer, and must necessarily be used by every person before he can enter upon that duty. It is performed with certain formal ceremonies, which have been described by some writers, but much easier apprehended by seeing them done, than by the best description.

That his followers might be more punctual in this duty, Mohammed is said to have declared, that the practice of religion is founded on cleanliness, which is the one half of the faith, and the key of prayer, without which it will not be heard by God. That these expressions may be the better understood, Al Ghazali reckons four degrees of purification; of which the first is the cleaning of the body from all pollution, filth, and excrements; the second, the cleaning of the members of the body from all wickedness and unrighteous actions; the third, the cleaning the heart from all blameable inclinations and obnoxious vices; and the fourth, the purging a man's secret thoughts from all affections which may divert their attention on God: adding, that the body is but as the outward shell, in respect to the heart, which is as the kernel.

Circumcision, though it be not so much as once mentioned in the Koran, is yet held, by the Mohammedans, to be an ancient divine institution, confirmed by the religion of Islam; and, though not so absolutely necessary but that it may be dispensed with in some cases, yet highly proper and expedient. The Arabs used this rite for many ages before Mohammed, having probably learned it from the Hymarites and other tribes practiced the same. The Hymarites, we are told, used to circumcise their children, not on the eighth day, as is the custom of the Jews, but when about twelve or thirteen years old, at which age their father underwent that operation; and the Mohammedans imitate them so far as not to circumcise children before they be able at least distinctly to pronounce that profession of their faith. There is no God but God, Mohammed is the apostle of God; but pitch on what age they please for the purpose, between six or sixteen, or thereabouts.

Prayer was, by Mohammed, thought so necessary a duty, that he used to call it the pillar of religion, and the key of paradise; and when the Thakifites, who dwelt at Tayef, sending, in the ninth year of the Hejra, to make their submission to that prophet, after the keeping of their favourite idol had been denied them, begged, at last, that they might be dispensed with as to their paying of their appointed prayers, he answered, There is no God but God, Mohammed is the apostle of God; but pitch on what age they please for the purpose, between six or sixteen, or thereabouts.

That so important a duty, therefore, might not be neglected, Mohammed obliged his followers to pray five times every twenty-four hours, at certain fixed times; viz. 1. In the morning, before sun-rise: 2. When noon is past, and the sun begins to decline from the meridian: 3. In the afternoon, before sun-set: 4. In the evening, after sun-set, and before day be shut in: and, 5. After the day is shut in, and before the first watch of the night. For this institution he pretended to have received the divine command from the throne of God himself, when he took his night-journey to heaven; and the observance of the stated times of prayer is frequently insisted on in the Koran, though they be not particularly prescribed therein. Accordingly, at the aforesaid times, of which public notice is given by the Muedhdins, or Criers, from the steeple of their Mosques, (for they use no bells,) every conscientious Mohammetan prepares himself for prayer, which he performs either in the Mosque or any other place, provided it be clean, after a prescribed form, and with a certain number of praises or ejaculations, (which the more scrupulous count by a string of beads and using certain postures of worship;) all which have been particularly laid down and described, though with some few mistakes, by other writers, and ought not to be abridged, unless in some special cases, as on a journey, or preparing for battle, &c.

For the regular performance of the duty of prayer among the Mohammedans, besides the particulars above-mentioned, it is also requisite that they turn their faces, while they pray, towards the temple of Mecca; the quarter where the same is situate being, for that reason, pointed out within their mosques by a niche, which they call al Mehrab; and without, by the situation of the doors opening into the galleries of the steeple, there are also tables calculated for the ready finding out their Keblah, or direction.

The next point of the Mohammedan religion is the giving of alms; which are of two sorts, legal and voluntary. The legal alms are of indispensablenecessary, being commanded by the law, which directs and determines both the portion which is to be given, and of what things it ought to be given; but the voluntary alms are left to every one's liberty, to give more or less, as he shall see fit. The former kind of alms some think to be properly called Zacat, and the latter Sadakat; though this name be also frequently given to the legal alms. They are called Zecat, either because they increase a man's store by drawing down a blessing thereon, and produce in his soul the virtue of liberality; or because they purify the remaining part of one's sustenance from pollution, and the soul from the filth of avarice; and Sadakat, because they are a proof of a man's sincerity in the worship of God. Some writers have called the legal alms sithen, but improperly, since in some cases they fall short, and in others exceed that proportion.

The third point of religious practice is fasting; a duty of so great moment, that Mohammed used to say it was the gate of religion, and that the odour of the mouth of him who fasteth is more grateful to God than that of mufk; and al Ghazali reckons fasting one fourth part of the faith. According to the Mohammedan divines, there are three degrees of fasting: 1. The refraining the belly and other parts of the body from satisfying their lusts; 2. The refraining the ears, eyes, tongue, hands, feet, and other
ther, members from sin; and 3. The falling of the heart
from worldly cares, and restraining the thoughts from
very thing besides God.

The Mohammedans are obliged, by the express com-
mand of the Koran, to fast the whole month of Ramadan,
from the time the new moon first appears, till the ap-
pearance of the next new moon; during which time they
must abstain from eating, drinking, and women, from day-
break till night or sun-set. And this injunction they
observe so strictly, that, while they fast, they suffer no-
thing to enter their mouths, or other parts of their bo-
dy, esteeming the fast broken and null, if they smell per-
fumes, take a clyster or injection, bathe, or even pur-
ficipally swallow their spittle: some being so cautious,
that they will not open their mouths to speak, lest they should
breathe the air too freely; the fast is also deemed void,
if a man kisses or touches a woman, or if he vomit deigned-
ly. But after sun-set they are allowed to refresh them-
seflves, and to eat and drink, and enjoy the company of
their wives till day-break; though the more rigid begin
the fast again at midnight. This fast is extremely rigor-
ous and mortifying when the month of Ramadan happens
to fall in summer, (or, the Arabian year being lunar,
each month runs through all the different seasons in the
course of thirty-three years) the length and heat of the
days making the observance of it much more difficult and
uneasy than in winter.

The reason given why the month of Ramadan was pitch-
ed on for this purpose is, that on that month the Koran
was sent down from heaven. Some pretend that Abra-
ham, Moses, and Jesus, received their respective revelations
in the same month.

The pilgrimage to Mecca is so necessary a point of
practise, that, according to a tradition of Mohamned,
whose death without performing it may as well die a
Jew or a Christian; and the same is expressly command-
ed in the Koran.

The temple of Mecca stands in the midst of the city,
and is honoured with the title of Masjid al Haram, i.e.,
the sacred or inviolable temple. What is principally re-
verenced in this place, and gives sanctity to the whole,
is a square stone building, called the Caaba, as some fancy,
from its height, which surpasses that of the other build-
ings in Mecca; but more probably from its quadrangular
form, and Beit Allah, i.e. the house of God, being pe-
culiarly hallowed and set apart for his worship. The
length of this edifice, from north to south, is twenty-four
cubits, its breadth from east to west twenty-three cubits,
and its height twenty-seven cubits: the door, which is
on the east side, stands about four cubits from the ground;
the floor being level with the bottom of the door. In
the corner next this door is the black stone. On the
north side of the Caaba, within a semicircular inclosure
fifty cubits long, lies the white stone, said to be the fe-
pulchre of Ḫumāil, which receives the rain water that
falls off the Caaba by a spout, formerly of wood, but
now of gold. The Caaba has a double roof, supported
within by three octagonal pillars of aloes wood; between
which, on a bar of iron, hang some silver lamps. The
outside is covered with rich black damask, adorned with
an embrodered band of gold, which is changed every
year, and was formerly sent by the Khalifs, afterwards
by the Sultans of Egypt, and is now provided by the
Turkifh emperors. At a small distance from the Caaba,
on the east side, is the station or place of Abraham, where
is another stone much respected by the Mohammedans,
of which something will be said hereafter.

The Caaba, at some distance, is surrounded, but not
entirely, by a circular inclosure of pillars joined towards
the bottom by a low balustrade, and towards the top by
bars of silver. Juit without this inner inclosure, on the
south, north, and west sides of the Caaba, are three
buildings, which are the oratories or places where three
of the orthodox fefts assemble to perform their devotions,
(the fourth seat, viz. that of al Shafei, making use of
the station of Abraham for that purpose;) and, towards
the south-east, stands the edifice which covers the well
Zemzem, the treasury, and the cupola of al Abbas.

All these buildings are inclosed, at a considerable dis-
tance, by a magnificent piazza, or square colonnade, like
that of the Royal Exchange in London, but much larger,
covered with small domes or cupolas; from the four cor-
ners whereof rise as many minarets or spires, with
two galleries, and adorned with gilded spires and cre-
cents, as are the cupolas which cover the piazza and the
other buildings. Between the pillars of both inclosures
hang a great number of lamps, which are constantly light-
ed at night.

This is properly all that is called the temple; but, the
whole territory of Mecca being also Haram or sacred,
there is a third inclosure distinguished at certain distances
by small turrets, some five, some seven, and others ten
miles distant from the city. Within this compass of
ground it is not lawful to attack an enemy, or even to
hunt or fow, or cut a branch from a tree.

The temple of Mecca was a place of worship, and in
singular veneration with the Arabs, from great antiquity,
and many centuries before Mohammed. Though it was
most probably dedicated at first to an idolatrous use, yet
the Mohammedans are generally persuaded that the Caaba
is almost coeval with the world.

After this edifice had undergone several repafrations,
it was a few years after the birth of Mohammed rebuilt
by the Koreifs on the old foundation, and afterwards re-
paired by Abdallâh Ebn Zobeir, the Khalif of Mecca;
and at length again rebuilt by Yufufl, surnamed al Heja,
in the seventy-fourth year of the Hejra, with some alter-
ations, in the form wherein it now remains. Some
years after, however, the Khalif Harun al Râhid (or,
as others write, his father al Mohdi, or his grandfather
al Manfûr) intended again to change what had been al-
terred by al Heja, and to reduce the Caaba to the old
form in which it was left by Abd-âllâh; but was diff-
ued from meddling with it, let so holy a place should
become the sport of princes, and, being new-modelled af-
after every one’s fancy, should lose that reverence which
was justly paid it. But, notwithstanding the antiquity
and holiness of this building, they have a prophecy, by
tradition from Mohammed, that in the last times the
Ethiopians shall come and utterly demolish it; after
which it will not be rebuilt again for ever.

Before we leave the temple of Mecca, two or three
particulars deserve further notice. One is the celebrated *black stone*, which is set in silver, and fixed in the southwest corner of the Caaba, being that which looks toward Baira, about two cubits and one third, or, which is the same thing, seven spans from the ground. This stone is exceedingly respected by the Mohammedans, and is kissed by the pilgrims with great devotion, being called by some the *right hand of God on earth*. They believe that it is one of the precious stones of paradise, and fell down to the earth with Adam, and, being taken up again, or otherwise preferred at the deluge, the angel Gabriel afterwards brought it back to Abraham, when he was building the Caaba. It was at first whiter than milk, but afterwards black and shiny, by the touch of a menstruous woman, or, as others tell us, by the fins of mankind, or rather by the tongues and kisses of so many people; the surfaces only being black, and the inside still remaining white.

To this temple every Mohammedan, who has health and means sufficient, ought once, at least, in his life to go on pilgrimage; nor are women excused from the performance of this duty. The pilgrims meet at different places near Mecca, according to the different parts from whence they come, during the months of Shawal and Dhu'lkaada; being obliged to be there by the beginning of Dhu'lhajja; which month, as its name imports, is peculiarly set apart for the celebration of this solemnity.

At the place above-mentioned the pilgrims properly commence such; when the men put on the Ihram or sacred habit, which consists only of two woollen wrappers, one wrapped about their middle to cover their privities, and the other thrown over their shoulders, having their heads bare, and a kind of flippers which cover neither the heel nor the instep, and so enter the sacred territory in a slow and laborious manner, in imitation of Abraham, who, meeting the devil in that place, and being by him disturbed in his devotions, or tempted to disobedience, when he was going to sacrifice his son, was commanded by God to drive him away by throwing stones at him; though others pretend this rite is to be as old as Adam, who also put the devil to flight in the same place and by the same means.

This ceremony being over, on the same day, the tenth of Dhu'lhajja, the pilgrims slay their victims in the said valley of Mina; of which they and their friends eat part, and the rest is given to the poor. These victims must be either sheep, goats, kine, or camels; males, if of either of the two former kinds; and females, if of either of the latter; and of a fit age. The sacrifices being over, they shave their heads and cut their nails, burying them in the same place; after which the pilgrimage is looked upon as completed; though they again visit the Caaba, to take their leave of that sacred building.

**MAIDEN**, an instrument used in Scotland for beheading criminals.

This is a broad piece of iron, about a foot square, very sharp on the lower part, and loaded above with a very heavy weight of lead. At the time of execution it is pulled up to the top of a narrow wooden frame, about ten feet high, and as broad as the engine, with mouldings on each side for the maiden to stand on. A convenience is made about four feet from the ground, for the prisoner to lay his neck; and there is a kind of bar so fastened as to keep him from turning. The prisoner being thus secured, and the sign given, the maiden is let loose, which in a moment separates his head from his body.

**MAIDSTONE**, the county-town of Kent, situated on the Medway, twenty-two miles west of Canterbury; E. long. 57°, N. lat. 51° 36'. It sends two members to parliament.
MAJESTY, a title given to kings, which frequently serves as a term of distinction.

Thus the emperor is called Sacred Majesty, Imperial Majesty, and Caesarian Majesty; the king of France is called his Most Christian Majesty, and when he treats with the emperor, the word Sacred is added; and the king of Spain is termed his Most Catholic Majesty: with respect to other kings, the name of the kingdom is added, as his Britannic Majesty, his Polish Majesty, &c. Formerly princes were more sparing in giving titles, and more modest in claiming them: before the reign of Charles V. the kings of Spain had only the title of Highness; and before that of Henry VIII. the kings of England were only addressed under the title of Grace and Highness.

MAIL, or coat of Mail, a piece of defensive armour for the body, made of small iron rings, interwoven in the manner of a net.

Action of Mails and Duties, in Scots law. See Law, Tit. xxx. 20.

MAINE, a river of Germany, which rises on the east side of the circle of Franconia and running from east to west, discharges itself into the Rhine at Mentz.

MAINPRISE, in law, is the receiving a person into friendly custody, who might otherwise be committed to prison, on security given that he shall be forthcoming at a certain time and place appointed.

MAJOR, in the art of war, the name of several officers of very different ranks and functions; as 1. Major-general, the next officer to the lieutenant-general: his chief business is to receive the orders from the general, or in his absence from the lieutenant-general of the day: he is to distribute to the brigade-majors, with whom he is to regulate the guards, convoys, and detachments. When there are two attacks at a siege, he commands that one be approached. He ought to be well acquainted with the strength of each brigade: of each regiment in particular, and to have a list of all the field officers. In short, he is in the army what a major is in a regiment. He is allowed an aide-de-camp, and has a serjeant and fifteen men for his guard. 2. Major of a brigade, the officer who receives the orders from the major-general, and afterwards delivers them to the adjutants of the regiments at the head of the brigade: where he takes and marches the detachments, &c. to the general rendezvous. He ought to be an expert captain, to know the state and condition of the brigade, and keep a roll of the colonels, lieutenants-colonels, majors, and adjutants. 3. Major of a regiment; the next officer to the lieutenant-colonel, generally promoted from the oldest captain. He is to take care that the regiment be well exercised, to see it march in good order, and to rally it in case of its being broke. He is the only officer among the foot that is allowed to be on horseback in time of action, that he may the more readily execute the colonel's orders, either in advancing or drawing off the regiment. 4. Major of a regiment of horse, is the first captain, who commands in the absence of the colonel. 5. Town-major, the third officer in a garrison, being next to the deputy-governor. He ought to understand fortification, and hath charge of the guards, rounds, patrols, &c. His business is also to take care that the soldiers arms are in good order; he likewise orders the gates to be opened and shut, and gives the governor an account of all that passes within the place.

There are also aids major, drums major, &c. so called from their preeminence above others of the same denomination.

MAJOR, in logic, the first proposition of a syllogism. See Logic.

MAJORANA in botany See Origanum.

MAJORCA, the capital of a Spanish island of the same name: E. long. 2º 30', N. lat. 36º 30'.

This island is in the Mediterranean sea, about sixty miles long, and forty-five broad, situated about eighty miles south of the coast of Catalonia, and an hundred miles east of Valencia.

MAIRE or fireights of Le Maire, is a passage to Cape Horn, situated between Terra del Fuego in South America, and Staten island; which being discovered by Le Maire, obtained his name.

MAIZ. See Zea.

MALA, the cheek, in anatomy. See Anatomy, p. 160.

MALABAR, the south west coast of the peninsula of hither India, about 400 miles long, and 100 broad, bounded by Vizagapatam on the north, by the mountains of Baligate, on the east; and by the Indian ocean on the west and south.

MALACCA, the most southerly part of the further peninsula of India, about 600 miles long, and generally about 200 miles broad: bounded by Siam, on the north; by the bay of Siam and the Indian ocean, on the east; and by the fireights of Malacca, on the south-west. The capital of this country, which is also commonly called Malacca, is situated in 100º of E. long. and 2º 30' N. lat.

MALACHI, or the prophecy of Malachi, a canonical book of the old Testament, and the last of the twelve lesser prophets. Malachi prophesied about three hundred years before Christ, reproving the Jews for their wickedness after their return from Babylon, charging them with rebellion, sacrilege, adultery, prophaneness, and infidelity, and condemning the priests for being scandalously careless in their ministrations: at the same time not forgetting to encourage the pious few, who, in that corrupt age, maintained their integrity. This prophet distinctly points at the Messiah, who was suddenly to come to his temple, and to be introduced by Elijah the prophet that is, by John the Baptist, who came in the spirit and power of Elias or Elijah.

MALACIA, in medicine, is a languishing disorder incident to pregnant women, in which they long sometimes for one kind of food, and sometimes for another, and eat it with an extraordinary greediness.

MALACOPTERYGIOUS, among ichthyologists, an appellation given to such fishes as have the rays of their fins bony, but not pointed or sharp at the extremities, like those of acanthopterygious fishes.

MALACOSTOMOUS fishes, those destitute of teeth in the jaws, called in English leather-mouthed; as the tench, carp, bream, &c.
MALAGA, a city and port of Spain, in the province of Granada, situated in the Mediterranean, sixty-six miles north-east of Gibraltar; W. long. 4° 45', N. lat. 36° 40'.

MALAGMA, a cataplasm. See Cataplasm.

MALAMOCCA, a small island and port-town in the lagunes of Venice, situated five miles south of that city.

MALDIVA-ISLANDS, are about a thousand small islands in the Indian ocean, 500 miles south-west of the continent of the hither India, extending from the second degree of south latitude, to the seventh degree of north latitude.

MALDON, a port-town of Essex, ten miles east of Chelmsford. It sends two members to parliament.

MALE, among zoologists, that sex of animals which has the parts of generation without the body.

MALIGNANT, among physicians, a term applied to diseases of a very dangerous nature, and generally infectious: such are the dysentery, hospital-fever, &c. in their worst forms.

MALL, or Sea-mall, in ornithology. See Larus.

MALLEABLE, a property of metals, whereby they are capable of being extended under the hammer.

MALLEUS, in anatomy. See Anatomy, p. 297.

MALPO, or Saint Malo, a city and port-town of France, in the province of Britany, situated on a rock, in the English channel, but joined to the continent by a caufeway: W. long. 2°, N. lat. 48° 40'.

MALPO, in botany, a genus of the monadelphia polyandria class. The calix is double, the exterior one having three leaves; and the capsule contains but one seed. There is only one species, a native of Mauritania.

MALPIGIA, in botany, a genus of the decandria class. The calyx consists of five leaves, and the corolla of five roundish petals; and the berry has one cell and three seeds. There are nine species, none of them natives of Britain.

MALPLAQUET, a village in the Austrian Netherlands, in the province of Hainault, about seven miles from Mons.

MALT. See Brewing.

MALTA, the capital of a small island of the same name in the Mediterranean, is situated in E. long. 15°, N. lat. 35° 15'; consisting of three towns, separated by channels, which form so many peninsulas of solid rock, rising a great height above the sea.

Knights of Malta, otherwise called Hospitallers of St. John of Jerusalem, a religious military order, whose residence is in the island of Malta. The order consists of three classes, the knights, chaplains, and servants at arms; there are also priests who officiate in the churches; friar-fervants, who assist at the offices; and donnes, or clerics; but these are not reckoned constituent parts of the body. The government of the order is mixed, being partly monarchical, and partly aristocratical: the grand master is sovereign. The knights formerly consisted of eight different languages, but now only seven, the English having withdrawn themselves. None are admitted into this order but such as are of noble birth: the knights are of two sorts, those who have a right to be candidates for the dignity of grand master, called grand croissants, and those who are only knights assistants: they never marry, yet have continued from 1090 to the present time. The knights are received into this order, either by undergoing the trials prescribed by statutes, or by dispensation.

MALTON, a borough of Yorkshire, situated on the river Derwent, twenty miles north-east of York. It sends two members to parliament.

MALVA, in botany, a genus of the monadelphia polyandria class. The calix is double, the exterior one consisting of three leaves; and there are many capsules, containing each one seed. There are 22 species, five of them natives of Britain, viz. the sylvestris, or common mallow; the rotundifolia, or dwarf mallow; the parviflora, or small flowered mallow; the alcea, or vervain mallow; and the mosehata, or jagged-leaved vervain mallow. The leaves of the mallow are emollient.

MALUS, in botany. See Pyrus.

MAMALUKES, the name of a dynasty that reigned in Egypt.

The Mamalukes were originally Turkish and Circassian slaves, bought of the Tartars by Melicfaleh, to the number of a thousand, whom he bred up to arms, and raised some to the principal offices of the empire. They killed sultan Moodam, to whom they succeeded.

Others say, that the mamalukes were ordinarily chosen from among the Christian slaves, and that they were the same thing in a great measure with the Janissaries among the Turks. They never married. They first are said to have been brought from Circassia, and some have supposed that they began to reign about the year 869.

MAMMAE, in anatomy. See Anatomy, p. 277.

MAMMEA, in botany, a genus of the polyandria gynia class. The corolla consists of four petals, and the calyx of two leaves; and the berry is large, and contains four seeds. There are two species, none of them natives of Britain.

MAN, in zoology. See Homo.

MANCHESER, a large town of Lancashire, forty miles south-east of Lancaster.

MANDAMUS, in law, a writ that issues out of the court of king's bench, sent to a corporation, commanding them to admit or restore a person to his office.

MANDARINS, a name given to the magistrates and governors of provinces in China, who are chosen out of the most learned men, and whose government is always at a great distance from the place of their birth. Mandarin is also a name given by the Chinese to the learned language of the country; for besides the language peculiar to every province, there is one common to all the learned in the empire, which is in China what Latin is in Europe; this is called the mandarin tongue, or the language of the court.

MANDATE, in law, a judicial commandment to do something. See Mandamus.

MANDATE, in Scots law. See Law, Tit. xxii. 9.

MAN-
MANDERSCHEIT, a city of Germany, in the electorate of Trier, and the capital of the county of Manderheite: E. long. 6° 32', N. lat. 40° 20'.
MANDRAGORA, in botany. See ATropa.
MANE, the hair hanging down from a horse's neck; which should be long, thin, and fine; and if frizzled, so much the better.
MANEGE, or Manage, the exercise of riding the great horse, or the ground set apart for that purpose; which is sometimes covered, for continuing the exercise in bad weather; and sometimes open, in order to give more liberty and freedom both to the horseman and horse. See Horsemanship.
MANES, in the pagan system of theology, a general name of the deceased in matters of importance: this was called Necromancy. See Necromancy.
MANIFESTO, a public declaration made by a prince in writing, shewing his intentions to begin a war, or other enterprize, with the motives that induce him to it, and the reasons on which he founds his rights and pretensions.
MANILLE, in commerce, a large brass-ring in the form of a bracelet, either plain or engraved, flat or round. Manilles are the principal commodities which the Europeans carry to the coast of Africa, and exchange with the natives for slaves. Th ese people wear them as ornaments on the small of the leg, and on the thick part of the arm above the elbow. The great men wear manilles of gold and silver, but these are made in the country by the natives themselves.
MANIPULUS, in Roman antiquity, a body of infantry, consisting of two hundred men, and constituting the third part of a cohort.
MANIS, the scaly lizard, in zoology, a genus of quadrupeds, belonging to the order of Bruta, the characters of which are these: They have no fore-teeth either in the upper or under jaw; the tongue is long and cylindrical; the snout is long and narrow; and the body is covered with hard scales. There are two species, viz.
1. The pentadactyla, or scaly lizard with five toes on each foot. The head is smaller than the neck; the eyes are very small; the length of the body, including the tail, is from six to eight feet. The whole body is covered with hard scales, excepting the under part of the head and neck, the breast, the belly, and the internal side of each leg. Betwixt the scales of this animal, there are some hard hairs like the bristles of a hog, brownish at the points. The scales are of a reddish colour, very hard, convex above, and concave below. All the parts which want scales are naked. The scales are unconnected, and the animal can raise or lower them at pleasure like the quills of the porcupine. When irritated, he erects his scales, and rolls himself up like a hedge-hog. In this situation, neither the tiger, the lion, nor any other animal, is able to hurt him. This creature has nothing forbidding about him but his figure. He is mild and inoffensive, feeding on nothing but worms and other insects. His motion is slow; and he has no other method of escaping the pursuit of man, but by concealing himself in crannies of rocks, and in holes which they dig in the ground, where they likewise bring forth their young. This animal is a native of the East Indies; and are so few in number, that they are seldom to be met with.
2. The tetradactyla, or scaly lizard with four toes on each foot. This species is very similar to the former; only the tail is much longer in proportion to the body, and each part as want scales, instead of being naked, are covered with a soft hair. It is likewise found in the East Indies. See Plate CIV. fig. 4.
MANNA, in the materia medica, the concreted juice of some vegetable, naturally exuding from it, soluble in water, and not inflammable. It is a honey-like juice, brought to us from Calabria and
MANTLE, or Mantle tree, in architecture, the manufacturer, one who works up a natural product into an artificial commodity.

MANTLE, in heraldry, that appearance which is laid across the jamb, and surrounds the lower part of the chimney, or that piece of timber or military habit, worn by the ancient cavaliers over their armour to preserve it from rust; or, as others supposed originally to be the representation of a mantle, which is laid across the jamb, and surrounds the lower part of the chimney piece.

MANOR, an ancient royalty or lordship, formerly called a barony, confiding of demesnes, services, and a court-baron; and comprehending in it meffuages, lands, meadow, pithure, wood, rents, an advowfon, &c. It may contain one or more villages or hamlets, or only a great part of a village. &c.

MANS, the capital of the territory of Maine, in the province of Orleanois in France: E. long. 5°, N. lat. 48° 6'.

MANSFIELD, a city of Germany, the capital of a county of the same name, in the circle of Upper Saxony: E. long. 11° 45', N. lat. 51° 36'.

MANSION, in law, is the chief dwelling house of a lord within his fee, or the capital meffuage or manor-houle.

MANSLAUGHTER, generally termed homicide, is killing a person without premeditated malice.

MANTELETS, in the art of war, a kind of moveable forts, some with red veins, others with white, black, or brown veins. 14. The gray spotted marbles are variegated, some are veined with blue, and others with black, and others with green spots. 14. The red variegated marble is the brocatello of the Italians, with white and gold veins.

MAP, a plain figure, representing the surface of the earth, or a part thereof, according to the laws of perspective. See Geography.

MAPLE, in botany. See Acer.

MAPPARIUS, in Roman antiquity, the officer who received from the emperor or other magistrate.

MARANFA, in botany, a genus of the monandria monogynia class. The corolla is ringent, and consists of five segments. There are two species, none of them natives of Britain.

MARASMUS, among physicians, denotes an atrophy or consumption, in its last and most deplorable stage.

MARBLE, in natural history, a genus of shells; being bright and beautiful stones composed of small separate concretions, moderately hard, not giving fire with steel, fermenting with and soluble in acid muriatra, and calcining in a light fire.

The colours of marbles being a very obvious and striking character, they are arranged according to them in the following divisions. 1. Of the white plain marbles there are two sorts; the Parian marble of the ancients, and flatuary marble of the moderns, an extremely bright and elegant marble; and the Carara marble, a very fine marble, more compact and close than the former, but less bright. 2. Of the plain yellowish marbles there is only one sort, which is a hard, pale yellow, and glossy marble, found in many parts of Italy. 3. Of the bluish and black marbles there are a great many species, as the Chinese marble, basiliths, &c. 4. Of the light green marbles there is only one kind the Lacedemonian marble of the ancients. 5. The pale coloured or whitish brown, commonly called Derby-marble. 6. The green marbles with shells. 7. The black coralloide marble, with and without shells. 8. Of the white variegated marbles there are a great many species, variegated with purple, brown, red, blue, &c. 9. Of the brown variegated marbles there are likewise several sorts, some with red veins, others with white, black, or brown veins. 10. Of the yellow-veined and variegated marbles, some are veined with purple, and others with blue. 11. Of the black variegated marbles, some are veined with white, and others with blue, yellow, red &c. 12. The green variegated marbles are likewise distinguished by the colour of their veins. 13. The gray spotted marbles are variegated, some with black, and others with green spots. 14. The red variegated marble is the brocatello of the Italians, with white and gold veins.

Colouring of Marble. The colouring of marbles is a nice art; and in order to succeed in it, the pieces of marble on which the experiments are tried must be well polished, and clear from the leaf spot or vein. The harder the marble is, the better it will bear the heat necessary in the operation; therefore alabaster,
and the common soft white marble, are very improper to perform these operations upon.

Heat is always necessary for the opening the pores of the marble, so as to render it fit to receive the colours: but it must never be made red hot; for then the texture of the marble itself is injured, and the colours are burnt, and lose their beauty. Too small a degree of heat is as bad as too great; for, in this case, tho' the marble receive the colour, it will not be fixed in it, nor strike deep enough. Some colours will strike, even cold; but they are never so well funk in as when a just degree of heat is used. The proper degree is that which, without making the marble red, will make the liquor boil upon its surface. The menuliurns used to strike in the colours must be varied according to the nature of the colour to be used. A lixivium made with horse's or dog's urine, with four parts quick lime, and one part potato, is excellent for some colours; common lye of wood-ashes does very well for others: for some, spirit of wine is best; and finally, for others, oily liquors, or common white wine.

The colours which have been found to succeed best with the peculiar menuliurns, are these: stone blue dissolved in six times the quantity of spirit of wine, or of the urinous lixivium; and that colour which the painters call Prunus, dissolved in common lye of wood-ashes. An extract of saffron, and that colour made of wood-ashes, are burnt, and lose their beauty. Too small a degree of heat is as bad as too great; for, in this case, the marble is not struck deeply enough. Some colours will strike, even cold; but they are never so well sunk in as when a just degree of heat is used. The proper degree is that which, without making the marble red, will make the liquor boil upon its surface. The menuliurns used to strike in the colours must be varied according to the nature of the colour to be used. A lixivium made with horse's or dog's urine, with four parts quick lime, and one part potato, is excellent for some colours; common lye of wood-ashes does very well for others: for some, spirit of wine is best; and finally, for others, oily liquors, or common white wine.

The proper degree is that which, without making the marble red, will make the liquor boil upon its surface. The menuliurns used to strike in the colours must be varied according to the nature of the colour to be used. A lixivium made with horse's or dog's urine, with four parts quick lime, and one part potato, is excellent for some colours; common lye of wood-ashes does very well for others: for some, spirit of wine is best; and finally, for others, oily liquors, or common white wine.
per, by dipping it on the flat, as also linen cloth, &c.

Marbling a book on the covers is performed by forming clouds with aqua fortis, or spirit of vitriol mixed with ink, and afterwards glazing the covers.

**MARCASITES**, in natural history, are defined to be compound inflammable metallic bodies, of a hard and solid substance, of an obscurely and irregularly foliaceous structure, of a bright glittering appearance, naturally constituting whole strata, though sometimes found in detached masses; very freely giving fire with steel; not fermenting with acid menstruums; and when put into the fire, yielding a blue sulphureous flame, and afterwards calcining into a purple powder. There are only three known species of this genus: 1. The silver-coloured marcasite, found in vast abundance in lead and tin mines. 2. The gold coloured marcasite. 3. The heavy pale-white marcasite.

Marcasites were at first supposed to be almost all pure gold or silver, according to their colour; but experience has shown, that if they contain any metal at all, no method has hitherto been found of working them to advantage. In Germany, indeed, they extract sulphur and vitriol from the silver marcasite, which two substances are always contained in it; and besides these, it has usually a quantity of arsenic. It has been recommended as a flyptic, after being calcined: but as the arsenic may not be all carried off by that operation, its use as a medicine seems extremely dangerous.

**MARCGRAVE**, or Magrave, a degree of honour in Germany answering to our marquis.

**MARCGRAVIA**, in botany, a genus of the polyandria class. The corolla consists of one petal, and the calyx consists of six imbricated leaves; and the berry has one cell, containing many seeds. There is but one species, a native of America.

**MARCH**, in chronology, the third month of the year, consisting of thirty-one days.

**MARCHANTIA**, in botany, a genus of the cryptogamia class. The corolla consists of one petal, and the calyx consists of six imbricated leaves; and the berry has one cell, containing many seeds. There are eight species, four of them natives of Britain, viz. the polymorpha, or common marchantia; the cruciata, or cross-headed marchantia; the hemispharica, or marib marchantia; and the conica, or wart marchantia.

**MARCHE**, a territory of Lyonois, in France, having Berry on the north, Burbonois and Auvergne on the east, Limousin on the south, and Poitou on the west.

**MARCHBURG**, a town of Germany, in the circle of Austria and duchy of Storia: W. long. 15° 50', N. lat. 47°.

**MARCIONITES**, Christian heretics in the IIth century, thus denominated from their leader Marcion, who maintained, that there were two principles or gods, a good and a bad one.

**MARCOSIANS**, a sect of Christian heretics in the IIth century, so called from their leader Marcus, who represented the supreme God as consisting not of a trini-
those who have done signal service to the commonwealth.

MARK, or MAR, also denotes a weight used in several states of Europe, and for several commodities, especially gold and silver. In France, the mark is divided into 8 ounces, or 64 drachms, or 192 dimes, or 240 mauls, or 620 felins, or 4628 grains. In Holland, the mark-weight is also called roge weight, and is equal to that of France. When gold and silver are sold by the mark, it is divided into 25 carats.

MARK is also used among us for a money of account, and in some other countries for a coin.

The English mark is two thirds of a poundsterling, or 12 st. 4d. and the Scotch mark is of equal value in Scotch money of account.

MARKET, a public place in a city or town, in which live cattle, provisions, or other goods, are set to sale; and also a privilege, either by grant or prescription, by which a town is enabled to keep a market.

MARLBRO', or MARLBOROUGH, a borough town of Wiltshire, eighteen miles north of Salisbury. It sends two members to parliament.

MARLBOROUGH-FOXT, an English factory on the west coast of the island of Sumatra, three miles east of Bencoolen: E. long. 101°, and S. lat. 4° 15'.

MARLE. See Agriculture, p. 48.

MARLOW, a borough town of Buckinghamshire, fifteen miles south of Aylesbury. It sends two members to parliament.

MARMALADE, a confedtion of plumbs, apricots, quinces, &c. boiled with sugar to a consistence.

MARMATE. See Marble.

MARMAR. See Marble.

MARMORA, a little island of Turkey, situated in the sea of Marmora, to which it gives name, lying sixty miles south-west of Constantinople.

MAROTTE, in zoology. See Mus.

MARSCH, or MARRIAGE, a great river, which, rising in the Carpathian mountains, runs through Transylvania and Hungary, and falls into the river Teyse at Segedin.

MARPOURG, a city of Germany, forty miles north of Frankfurt: E. long. 8° 40', and N. lat. 50° 40'.

MARQUE, or letters of MARQUE, in military affairs, are letters of reprisal, granting the subjects of one prince or state liberty to make reprisals on those of another.

Letters of marque among us are extraordinary commissions granted by authority for repossession, taken and disposed of by strangers at sea; and reprisals is only the retaking, or taking of one thing for another.

MARQUETRY, or INLAID-WORK, is a curious work composed of several fine hard pieces of wood, of various colours, fastened in thin slices on a ground, and sometimes enriched with other matters, as silver, bras, tortoise-shell, and ivory: with these affinities the art is now capable of imitating any thing; whence it is by some called the art of painting in wood.

MARQUIS, a title of honour, next in dignity to that of duke, first given to those who commanded the marches, that is, the borders and frontiers of countries.

MARR, that part of Aberdeenshire situated between the rivers Dee and Don.

MARRIAGE, a contract both civil and religious, between a man and a woman, by which they engage to live together in mutual love and friendship, for the ends of procreation, &c. See Law, Tit. vi.

The Romans, as well as the Greeks, disallowed of polygamy. A Roman might not marry any woman who was not a Roman. It was thought dishonourable for a woman to marry twice.

We find but few laws in the books of Moses concerning the institution of marriage: he restrained the Israelites from marrying within certain degrees of consanguinity; but we find, that polygamy, though not expressly allowed, is, however tacitly implied in the laws of Moses: there is a particular law that obliged a man, whose brother died without issue, to marry his widow, and raise up children to his brother. The Hebrews purchased their wives, by paying down a competent dowry for them; and a man was at liberty to marry, not only in any of the twelve tribes, but even out of them, provided it was with such nations as used circumcision.

The ancient Christian church laid several restraints upon her members in relation to marriage: such was the rule forbidding Christians to marry with infidels and heathens: another restraint related to the consanguinity and affinity prohibited in Scripture: a third was, that children under age should not marry without the consent of their parents, guardians, or next relations: and another was, that there should be some parity of condition between the contracting parties. They not only condemned polygamy, but even reckoned it unlawful to marry after a divorce. The Romish church requires of the clergy perpetual abstinence from marriage; and has advanced this institution to the dignity of a sacrament.

MARROW, in anatomy, a soft oelaginous substance contained in the cavity of the bones. See Anatomy, p. 147.

MARRUBIUM, in botany, a genus of the didynamia gymnosperma class. The calyx is rigid, with ten stamens; and the upper lip of the corolla is bifid, linear, and erect. There are nine species, only one of them, viz. the vulgare, or white horehound, is a native of Britain.

MARS, in astronomy. See Astronomy, p. 441.

MARS, among chemists, denotes iron, as being supposed to be under the influence of that planet. See Chemistry, p. 82 and 133.

MARSEILLES, a city and port of Provence, situated on a fine bay of the Mediterranean, twenty-five miles north-west of Toulon: E. long. 5° 20', N. lat. 43° 15'.

MARSIAL, in its primary significations, means an officer who has the command or care of horses; but it is now applied to officers who have various different employments, as earl marshal, knight marshal, or marshal of the king's horse, &c.

MARSIAL of the king's bench, an officer who has the custody of the king's-bench-prison in Southwark. This officer is obliged to give his attendance, and to take
take into his custody all persons committed by that court.

**Marshal of the exchequer**, an officer to whom that court commits the king's debts.

**Marshal of the king's hall**, an officer who has the care of placing the household servants and strangers at table, according to their quality.

**Marshal, or Mareschal**, of France, an officer of the greatest dignity in the French armies. When two or more marshals are in the army, the eldest commands.

**Marshall's coat**, in heraldry, is the disposition of several coats of arms belonging to distinct families, in one and the same escutcheon or shield, together with their ornaments, parts, and appurtenances.

**Marshfield**, a market-town of Wiltshire, thirty miles north-west of Salisbury.

**Marshmallow**, in botany. See *Althaea*.

**Marsilea**, in botany, a genus of the cryptogamia class. The antherae are four, and placed on an obtuse conic body: the fruit is of a roundish figure, consisting of four cells, in each of which are contained several roundish seeds. There are two species, none of them natives of Britain.

**St Martha**, a city and port-town of Terra Firma, in South America, and the capital of the province of St Martha: W. long. 74° 30', N. lat. 11° 45'.

**Martial law**, is the law of war, which entirely depends on the arbitrary power of the prince, or of those to whom he has delegated it. For though the king can make no laws in time of peace without the consent of parliament, yet in time of war he uses an absolute power over the army.

**Martin**, in zoology. See *Mustela*.

**Cape Martin**, a promontory of Valencia, in Spain, on the Mediterranean; it is under the meridian of London: N. lat. 28° 50'.

**Martingale**, in the manege, a thong of leather, fastened to one end of the girths under the belly of a horse, and at the other end to the muis roll, to keep him from rearing.

**Martinico**, the chief of the French Caribbee-islands, situated in 61° of west long. and between 14° and 5° N lat. It is sixty miles long, but is scarce twenty broad in any part.

**Martylets**, in heraldry, little birds represented without feet, and used as a difference or mark of distinction for younger brothers, to put them in mind that they are to truant to the wings of virtue and merit, in order to raise themselves, and not their feet, they having little land to set their foot on. See Plate CX fig. 2.

**Martynia**, in botany, a genus of the didynamia angiopermia class. The calyx consists of five segments; the corolla is ringent; and the capsule is woody, with a hooked beak, two valves, and three cells. There are two species, both natives of America.

**Martyr**, is one who lays down his life for the sake of his religion.

**Martyrology**, is a catalogue or list of martyrs, including the history of their lives and sufferings for the sake of religion.

The martyrologies draw their materials from the calendars of particular churches, in which the several festivals dedicated to them are marked; and which seem to be derived from the practice of the ancient Romans, who inscribed the names of heroes and great men in their faith, or public registers.

The martyrologies are very numerous, and contain many ridiculous and even contradictory narratives; which is easily accounted for, if we consider how many forged and spurious accounts of the lives of saints and martyrs appeared in the first ages of the church, which the legendary writers afterwards adopted without examining into the truth of them. However, some good critics, of late years, have gone a great way towards clearing the lives of the saints and martyrs from the monstrous heap of fiction they laboured under.

**Marvel of Peru**, in botany. See *Mirabilis*.

**Marygold**, See *Caltha*.

**Corn Marygold**, See *Chrysanthemum*.

**French Marygold**, in botany. See *Tagetes*.

**Maryland**, one of the British plantations in North America, situated between 74° and 78° W long. and between 38° and 40° N lat.

**Masculine**, or *Masculine gender*. Among grammarians, that belonging to the male. See *Grammar*.

**Masham**, a market town of Yorkshire, situated twenty-four miles north-west of the city of York.

**Mask**. See *Masque*.

**Mason**, a person employed, under the direction of an architect, in raising of a stone-building.

**Free and accepted Masons**, a very ancient society or body of men, so called, either from some extraordinary knowledge of masonry or building, which they are supposed to be masters of, or because the first founders of the society were persons of that profession. These are now very considerable, both for number and character, being found in every country in Europe, and consisting principally of persons of merit and consideration. As to antiquity, they lay claim to a standing of some thousand years. What the end of their institution is, seems still in some measure a secret; and they are said to be admitted into the fraternity by being put in possession of a great number of secrets, called the mason's word, which have been religiously kept from age to age. Being never divulged.

**Masonry**, in general, a branch of architecture, consisting in the art of hewing or squaring stones, and cutting them level or perpendicular, for the uses of building: but, in a more limited sense, masonry is the art of assembling and joining stones together with mortar. See *Architecture*.

**Mass**, in the church of Rome, the office or prayers used at the celebration of the eucharist; or, in other words, consecrating the bread and wine into the body and blood of Christ, and offering them, to transubstantiate, as an expiatory sacrifice for the quick and the dead. As the mass is in general believed to be a representation of the passion of our blessed Saviour, so every
every action of the priest, and every particular part of the service, is supposed to allude to the particular circumstances of his passion and death.

The general division of masses consists in high and low. The first is that sung by the choristers, and celebrated with the assistance of a deacon and sub-deacon: low masses are those in which the prayers are barely rehearsed without singing.

There are a great number of different or occasional masses in the Romish church, many of which have nothing peculiar but the name: such are the masses of the saints; that of St Mary of the Snow, celebrated on the fifth of August; that of St Margaret, patronesses of lying-in women; that of the feast of St John the Baptist, at which are said three masses; that of the Innocents, at which the glory in excelsis and the hallelujah are omitted, and it being a day of mourning the altar is of a violet colour. As to ordinary masses, some are said for the dead, and, it is supposed, contribute to fetch the soul out of purgatory. At these masses the altar is put in mourning, and the only decorations are a cross in the midst of six yellow wax-lights: the dresses of the celebrant and the very mass-book are black: many parts of the office are omitted, and the people are dismissed without the benediction.

If the masses be said for a person distinguished by his rank or virtues, it is followed with a funeral oration: they erect a chapel ardente, that is, a representation of the deceased, with branches and tapers of yellow wax, either in the middle of the church, or near the deceased’s tomb, where the priest pronounces a solemn abdication of the deceased. There are likewise private masses, said for stolen or strayed goods or cattle; for health; for travellers, &c. which go under the name of votive masses. There is still a further distinction of masses denominated from the countries in which they were used: thus the Gothic mass, or misa mofarabum, is that used among the Goths when they were masters of Spain, and which is still kept up at Toledo and Salamanca; the Ambrosian mass is that composed by St Ambrose, and used only at Milan, of which city he was bishop; the Gallic masses, used by the ancient Gauls; and the Roman masses, used by almost all the churches in the Romish communion.

MASSA, the capital of the duchy of Massa Carrara, in Italy, situated between the territories of Lucca and Genoa: E. long. 10° 40', N. lat 43° 55'.

MASSACHUSET-colony, the principal sub-division of New-England, is bounded by New Hampshire, on the north; by the Atlantic ocean, on the east and south; and by Connecticut and New York, on the west. It is about 100 miles long, and 40 broad.

MASSALIANS, a set of enthusiasts who sprang up about the year 361, in the reign of the emperor Constantius, who maintained that men have two souls, a celestial and a diabolical, and that the latter is driven out by prayer.

MASSETER, in anatomy. See Anatomy, p. 221.

MASSORA, in matters of literature, a critical work, containing remarks on the verses, words, letters, and vowel-points of the Hebrew text of the bible; a work more laborious than useful.

MASS, in naval architecture, a large timber in a ship, for sustaining the yards, sails, &c.

In large vessels there are four masts, viz. the main-mast, fore-mast, mizen-mast, and bowsprit. See Ship-building.

MASTER, in general, is a title of authority; as, the grand master of Malta, the master of St Lazarus, &c. The Romans had a great many officers thus denominated; as, the master of the people, or dictator; the master of the cavalry, foot, centur, &c. Master of arts, is the first degree taken up in universities. Masters in chancery, in ordinary, of which there are twelve, the master of the rolls being chief, are usually chosen out of the barristers of the common law, and sit in chancery, or at the rolls, as assistants to the lord chancellor and master of the rolls.

Master of the horse, a great officer of the crown, who orders all matters relating to the king’s stables, races, breed of horses; and commands the equestrians and all the other officers and tradesmen employed in the king’s stables. His coaches, horses, and attendants are the king’s, and bear the king’s arms and livery.

Master of the revels, an officer who orders all things relating to the performance of plays, masques, balls, &c. at court.

Master of the rolls, a patent officer for life, who has the custody of the rolls of parliament and patents which pass the great-seal, and of the records of chancery, as also commissions, deeds, recognizances, which, being made of rolls of parchment, gave rise to the name.

In absence of the chancellor, he sits as judge in the court of chancery: at other times, he hears causes in the rolls chapel, and makes orders; but all hearings before him are appealable to the chancellor.

Master of the wardrobe, an officer under the lord chamberlain, who has the care of the royal robes, as well as the wearing apparel, collar, George, and garter, &c. He has also the charge of all former kings and queens robes remaining in the Tower, all hangings, bedding, &c. for the king’s house, the charge and delivery of velvet and scarlet allowed for livery.

He has under him a clerk of the robes, wardrobe-keeper, a yeoman, &c.

Master-wort, in botany. See Imperator.

Mastication, the action of chewing, or of agitating the solid parts of our food between the teeth, by means of the motion of the jaws, the tongue, and the lips, whereby it is broken into small pieces, impregnated with saliva, and so fitted for deglutition and a more easy digestion.

Mastic, in the materia medica, a solid resin, of a pale, yellow, white colour, brought to us principally from the island of Chios, in drops or tears as it naturally forms itself in exudating from the tree, about the bigness and much in the form of a pea. It is to be chosen clear, pellucid, and of a pale yellowish colour, well scented, and brittle. We meet with a kind of cement sometimes kept in the shops under the name of mastic. It is composed of mastic, and several other ingredients, and is formed into cakes for use. This is intended for the service of the lapidaries, to fill up cracks in stones, and for other such purposes: but
MAT (30) MAT

but is by no means to be used as mastich for any of the medicinal purposes.

Mastich is detergent, astringent, and stomachic; it is greatly recommended in invertebrate coughs and against spitting of blood. It strengthens the stomach, affords digestion, and stops vomiting.

Mastigadour, or slabbering-bit, in the Maddeil kingdom.

Matapan, a country in the fourth part of Africa, learning; but, at present, denotes that science which furnishes us with the most general and scrupulous a manner as we possibly could; since we cannot but remark, that it is too frequent in writers which ought to be about half a foot high.

Matapan, a city and port town of the hither India: E. long. 81°, and N. lat. 16° 18'.

Matamane, a country in the fourth part of Africa, bounded by Benguelo, on the north; by Manomotapa, on the east, by Capetria, on the south; and by the Atlantic ocean, on the west.

Matapan Cape, in the Morea, the fourteenth promontory of Europe, situated in E. long. 22°, N. lat. 76°.

Match, a kind of rope slightly twisted, and prepared to retain fire for the uses of artillery, mines, fire-works, &c.

It is made of hempen tow, spun on the wheel like cord, but very slack; and is composed of three twists, which are afterwards again covered with tow, so that the twists do not appear at all, it is boiled in the lettuce of old wines. This, when once lighted at the end, burns on gradually and regularly, without ever going out, till the whole be consumed: the hardest and driest match is generally the best.

Matching, in the wine trade, the preparing vessels to preserve wines and other liquors, without their growing sour or vapid. The method of doing it, is as follows: melt brimstone in an iron ladle, and when thoroughly melted, dip it into flaps of coarse linen-cloth; take these out, and let them cool: this the wine cooper calls a matching; take one of these matches, set one end of it on fire, and put it into the bung-hole of a cask; let it burn nearly out: then drive in the bung tightly, and set the cask aside for an hour or two. At the end of this time examine the cask, and you will find that the sulphur has communicated a violent purgant and suffocating scent to the cask, with a considerable degree of acidity, which is the gas and acid spirit of the sulphur. The cask may after this be filled with a small wine, which has scarce done its fermentation; and bunging it down tight, it will be kept good, and will soon clarify: this is a common and very useful method; for many poor wines could scarce be kept potable even a few months without it.

Dura Mater. See Anatomy, p. 284.

Pia Mater. See Anatomy, p. 285.

Materan, the capital of a kingdom of the same name, situated on the south coast of the island of Java. This city is said to lie in E. long. 110°, S. lat 7° 45'.

Materia Sutitis, denotes a fine subtile matter, which the Carthusians use to preserve and penetrate freely the pores of all bodies, to fill up all their pores so as not to leave the least vacancy or interstice between them: they had recourse to this machine to support the doctrine of an absolute plenum, and to make it consist with the phenomena of motion, &c.

Materia medica, comprehends all the substances either used in medicine in their natural state, or which afford preparations that are fo; these belong partly to the animal, partly to the vegetable, and partly to the mineral kingdom.

The preparations and virtues of all which are delivered under their respective articles, but in as concise and scrupulous a manner as we possibly could; since we cannot but remark, that it is too frequent in writers on the materia medica, to give us rather encomiums than impartial accounts of the simples they treat of.

Mathematics, originally signified any discipline or learning; but, at present, denotes that science which teaches, or contemplates, whatever is capable of being numbered or measured, in so far as comparable or measurable; and accordingly is subdivided into Arithmetic, which has numbers for its object, and Geometry, which treats of magnitude. See Arithmetic and Geometry.

Mathematics are commonly distinguished into pure and speculative, which consider quantity abstractedly; and mixed, which treat of magnitude as subsisting in material bodies, and consequently are interwoven every where with physical considerations.

Mixed mathematics are very comprehensive; since to them many may be referred Astronomy, Optics, Geography, Hydraulics, Mechanics, Fortification, Navigation, &c. See the articles Astronomy, Optics, &c.

Pure mathematics have one peculiar advantage, that they occasion no disputes among wrangling disputants, as in other branches of knowledge; and the reason is, because the definitions of the terms are premised, and every body that reads a proposition has the same idea of every part of it. Hence it is easy to put an end to all mathematical controversies, by shewing either that our adversary has not stuck to his definitions, or has not laid down true premises, or else that he has drawn false conclusions from true principles; and in case we are able to do neither of these, we must acknowledge the truth of what he has proved.

It is true, that in mixed mathematics, where we reason mathematically upon physical subjects, we cannot give such just definitions as the geometers: we must therefore rest content with descriptions; and they will be of the same use as definitions, provided we are consistent with ourselves, and always mean the same thing by those terms we have once explained.

Dr. Barrow gives a most elegant description of the excellence and usefulness of mathematical knowledge, in his inaugural oration, upon being appointed professor of mathematics at Cambridge.

The mathematics, he observes, effectually exercise, not vainly delude, nor vexationally torment, flaudous minds with obscure abstractions; but plainly demonstrate everything within their reach, draw certain conclusions, instruct by profitable rules, and unfold pleasant questions. These disciplines likewise enure and corroborate the mind to a constant diligence in study; they wholly deliver us from a credulous simplicity, most strongly fortify us against the vanity of scepticism, ef- fectual
MAT (31)

factually restrain us from a rash presumption, most easily incline us to a due affect, perfectly subject us to the government of right reason. While the mind is abstracted and elevated from sensible matter, distinctly views pure forms, conceives the beauty of ideas, and investigates the harmony of proportions; the manners themselves are distinctly corrected and improved, the affections composed and rectified, the fancy calmed and settled, and the understanding raised and excited to more divine contemplations.

MATRICARI, in botany, a genus of the family Matricaria, aregillerkept of the admission of officers and persons entered into any body or society, whereto a lift is made.

MATRIX, in anatomy. See Anatomy, p. 274.

MATRONALIA, a festival of the ancient Roman matrons, from whom it had its name. It was celebrated on the kalends of March in honour of the god Mars; and was to the Roman ladies what the festival of the Saturnalia was to their husbands; for at this time they served their women slaves at tables, and received presents from their husbands. See Saturnalia.

MATER, whatever is extended and capable of making resistance: hence, because all bodies, whether solid or fluid, are extended, and do resist, we conclude that they are material, or made up of matter. See Mechanics.

St. Matthew wrote his gospel in Judea, at the request of some he had converted; and it is thought he began it in the year 41, eight years after Christ's resurrection. It was written, according to the testimony of all the ancients, in the Hebrew or Syrian language, which was then common in Judea, but the Greek version of it, which now passes for the original, it as old as the apothegms.

St. Matthew's day, a festival of the Christian church, observed on September 21.

St. Matthew, in geography, a small island on the coast of Guinea, planted by the Portuguese, but deserted: W. long. 9°, S. lat. 2° 30'.

St. MATTHIAS's day, a festival of the Christian church, observed on the 24th of February.

MATTINS, the first canonical hour, or the first part of the daily service, in the Roman church.

MATTURANTS, in pharmacy, medicines which promote the suppuration of tumours.

MAUNDY Thursday, is the Thursday in Passion-week, which was called Maunday or Mandate-thursday, from the command which our Saviour gave his apostles which he gave them to love one another, after he had washed their feet as a token of his love to them.

St. MAUR, an island of the Mediterranean, situated between the provinces of Epirus, and the island of Cephalonia; subject to Venice: E. long. 21°, N. lat. 38° 30'.

MAURICE, or Moritius, an island in the Indian ocean, subject to the Dutch: E. long. 55°, S. lat. 20°.

MAURIENNE, St. John, the capital of the territory of Maurienne, in Savoy: E. long. 6° 10', N. lat. 45° 18'.

MAURITANIA, the ancient name of the coast of Barbary, from the city of Tangier to that of Algiers: the west part of it, in which Tangier stands, was called Mauritania Tingitana; and that farther east, Mauritania Caesarienfis.

MAUSOLEUM, a magnificent tomb, or funeral monument. The word is derived from Mausolus, king of Caria, to whom Artemisia, his wife, erected a lofty, flatly ornamented monument, esteemed one of the wonders of the world, and called it, from his name, Mausoleum.

St. MAWES, a port and borough town of Cornwall; situated twenty miles north of the Lizard. It sends two members to parliament.

MAXILLA, the jaws, or those parts of an animal in which the teeth are set.

MAXIM, an established proposition or principle; in which loose it denotes much the same with axiom.

MAXIMUM, in mathematics, denotes the greatest quantity attainable in any given case.

It is a quantity conceived to be generated by motion, increases, or decreases, till it arrives at a certain magnitude or position, and then on the contrary grows lesser or greater, and it be required to determine the said magnitude or position, the question is called a problem de maximis et minimis.

MAY, the fifth month of the year, consisting of thirty-one days.

MAY, is also the name of a little island, in the mouth of the frith of Forth, in Scotland.

MAYENNE, a city of France, in the province of Orleans: W. long. 45°, and N. lat. 48° 20'.

MAYO, one of the Cape Verde islands: W. long. 23° 30', N. lat. 15°.

Mayo, is also a county of Ireland, in the province of Connaught, having Sligo on the north, and Roscommon on the south.

MAYOR,
MAYOR, the chief magistrate of a city or town, chosen annually out of the aldermen.

MAZARA, the capital of the province of the same name in Sicily, situated on the south-west coast; E. long. 12° 30', N. lat. 37° 42'.

MEAD, an agreeable liquor, made of honey and water. There are many receipts for making mead, of which the following is one of the best. Take four gallons of water, and as much honey as will make it bear an egg; add to this, the rind of three lemons; boil it, and scum it as it rifes. Then take it off the fire, and add the three lemons cut in pieces; pour it into a clean tub or open vessel, and let it work for three days: then scum it well, and pour off the clear part into a cask, and let it stand open till it ceases to make a hissing noise; then stop it up close, and in three months time it will be fine and fit for bottling.

If you would give it a finer flavour, take cloves, mace, and nutmeg, of each four drams; beat them small, tie the powder in a piece of cloth, and put it into the cask.

MEADOW, in its general signification, means pature or grazed-land, annually mown for hay; but it is more particularly applied to lands that are so low as to be too moist for cattle to graze upon them in winter without spoiling the sward.

MEAN, in general, denotes the middle between two extremes: thus we say, mean distance, mean proportion, &c.

MEASLES, in medicine, a cutaneous disease, attended with a fever, in which there is an appearance of eruption, frequently attended with a suppuration. They are more frequent in children than in adults, and more common among females than males. The principal symptoms are a rise of temperature, a swelling of the lymphatic glands in the neck, and the appearance of small red papules on the face, neck, and body.

MEASUREMENT, in geometry, denotes any quantity assumed as one, or unity, to which the ratio of other homogenous or similar quantities is expressed.

MEASURE, in a legal and commercial sense, denotes a certain quantity or proportion of anything bought, sold, valued, or the like. Measures are then various, according to the various kinds and dimensions of the things measured. Hence arise linear or longitudinal measures, for lines or lengths; square measures, for areas or surfaces; and solid or cubic measures, for bodies and their capacities. All which again are very different in different countries, and in different ages, and even many of them for different commodities. Whence arise other divisions of ancient and modern measures, domestic and foreign ones, dry measures, liquid measures, &c. For the different kinds of measures, see Arithmetic, Geometry, and the particular names of measures, as they occur in the alphabetical order.

MEASURES is also used to signify the cadence and time observed in poetry, dancing, and music, to render them regular and agreeable.

MEASURE, in music, the interval or space of time which the person who beats time takes between the rising and falling of his hand, in order to conduct the movement sometimes quicker and sometimes slower, according to the music or subject that is to be sung or played.

MEAT. See Food, Diet, Drink, &c.

MEATH, the name of two counties in Ireland, in the province of Leinster, distinguished by the epithets East and West.

MEATUS AUDITORIUS, in anatomy. See Anatomy, p. 296.

MEAUX, a city in France, twenty-four miles north-east of Paris.

MECCA, the capital of Arabia, and place of Mohammed's nativity: E. long 43° 30', N. lat. 21° 20'. It is a large well-built city, in the middle of which stands the caaba, or temple.

M E C H A N I C S.

This term, in the common acceptance, implies no more than the nature of what is called the mechanical powers, together with the combination of these powers in the construction of machines. But as the general properties of matter and central forces are necessary in order to a thorough knowledge of mechanics, we have joined all these subjects together under the general name of Mechanics.

Of Matter, and its Properties.

By the word matter is here meant every thing that has length, breadth, and thickmess, and resists the touch. The inherent properties of matter are solidity, inactivity, mobility, and divisibility. The solidity of matter arises from its having length, breadth, thickmess; and hence it is that all bodies are comprehended under some shape or other, and that every particular body hinders all others from occupying the same part of space which it poiffesses. Thus, if a piece of wood or metal be squeezed ever so hard between two plates, they cannot be brought into contact. And even water or air has this property; for if a small quantity of it be fixed between any other bodies, they cannot be brought to touch one another.

A second property of matter is inactivity, or pafliveness; by which it always endeavour to continue in the state that it is in, whether of rest or motion. And therefore, if one body contains twice or thrice as much matter as another body does, it will have twice or thrice as much inactivity; that is, it will require twice or thrice as much force to give it an equal degree of motion, or to stop it after it hath been put into such a motion.

That matter can never put itself into a motion is allowed by all men. For a stone, lying on the plain surface of the earth, never removes itself from that place, nor does any one imagine it ever can. But most people are apt to believe, that all matter has a propensity to fall from a state of motion into a state of rest; because they see, that if a stone
frob or a cannon-ball be put into ever fo violent a motion, it soon stops; not considering that this stoppage is caused, 1. By the gravity or weight of the body, which links it to the ground in spite of the impulse; and, 2. By the resist-ance of the air through which it moves, and by which its velocity is retarded every moment till it falls.

A bowl moves but a short way upon a bowling-green; because the roughness and unevenness of the grassy surface soon creates friction enough to stop it. But if the ground were perfectly level, and smooth, and the bowl were perfectly hard, round, and smooth, it would go a great way further; as it would have nothing but the air to resist it: if then the air were taken away, the bowl would go on without any friction, and consequently without any diminution of the velocity it had at setting out: and therefore, if the green were extended quite around the earth, the bowl would go on round and round the earth, for ever.

If the bowl were carried several miles above the earth, and there projected in a horizontal direction, with such a velocity as would make it move more than a semidiameter of the earth, in the time it would take to fall to the earth by gravity: in that case, and if there were no refilling medium in the way, the bowl would not fall to the earth at all; but would continue to circulate round it, keeping always in the same tract, and returning to the same point from which it was projected, with the same velocity as at first. In this manner the moon moves round the earth, although it be as inactive and dead as any stone upon it.

The third property of matter is mobility; for we find that all matter is capable of being moved, if a sufficient degree of force be applied to overcome its inactivity or resistance.

The fourth property of matter is divisibility, of which there can be no end. For since matters can never be annihilated by cutting or breaking, we can never imagine it to be cut into small particles, but that if one of them be laid on a table, the uppermost side of it will be further from the table than the undermost side.

Plate CV. fig. 1. That matter is infinitely divisible in a mathematical sense, is easy to be demonstrated. For, let AB be the length of a particle to be divided; and let it be touched at opposite ends by the parallel lines CD and EF, which suppose to be infinitely extended beyond D and F. Set off the equal divisions GH, HI, &c. on the line EF, towards the right hand from B; and take a point, as at R, any where towards the left hand from A, in the line CD: Then, from this point draw the right lines RG, RH, RI, &c. each of which will cut off a part from the particle AB. But after any finite number of such lines are drawn, there will still remain a part, as AP, at the top of the particle, which can never be cut off; because the lines DR and EF being parallel, no line can ever be drawn from the point R to any point of the line EF that will coincide with the line RD. Therefore the particle AB contains more than any finite number of parts.

A fifth property of matter is attraction, which seems rather to be infused than inherent. Of this there are four kinds, viz. cohesion, gravitation, magnetism, and electricity.

The attraction of cohesion is that by which the small parts of matter are made to stick and cohere together. Of this we have several instances, some of which follow.

1. If a small glass tube, open at both ends, be dipped in water, the water will rise up in the tube to a considerable height above its level in the basin; which must be owing to the attraction of a ring of particles of the glass all around in the tube, immediately above those to which the water at any instant rises. And when it has risen so high, that the weight of the column balances the attraction of the tube, it rises no higher. This can be no ways owing to the preffure of the air upon the water in the basin; for, as the tube is open at top, it is full of air above the water, which will press as much upon the water in the tube as the neighbouring air does upon any column of an equal diameter in the basin. Besides, if the same experiment be made in an exhausted receiver of the air-pump, there will be found no difference.

2. A piece of loaf-sugar will draw up a fluid, and a sponge will suck in water; and on the same principle sap ascends in trees.

3. If two drops of quicksilver be placed near each other, they will run together, and become one large drop.

4. If two pieces of lead be scraped clean, and pressed together with a twist, they will attract each other so strongly, as to require a force much greater than their own weight to separate them. And this cannot be owing to the preffure of the air, for the same thing will hold in an exhausted receiver.

5. If two polished plates of marble or brass be put together, with a little oil between them to fill up the pores in their surfaces, and prevent the lodgement of any air; they will cohere so strongly, even if suspended in an exhausted receiver, that the weight of the lower plate will not be able to separate it from the upper one. In putting these plates together, the one should be rubbed upon the other, as a joiner does two pieces of wood when he glues them.

6. If two pieces of cork, equal in weight, be put near each other in a basin of water, they will move equally fast toward each other, with an accelerated motion, until they meet: and then, if either of them be moved, it will draw the other after it. If two corks of unequal weights be placed near each other, they will approach with accelerated velocities inversely proportionate to their weights: that is, the lighter cork will move as much faster than the heavier, as the heavier exceeds the lighter in weight. This shews that the attraction of each cork is in direct proportion to its weight or quantity of matter.

This kind of attraction reaches but to a very small distance; for, if two drops of quicksilver be rolled in dust, they will not run together, because the particles of dust keeps them out of the sphere of each other's attraction.

Where the sphere of attraction ends, a repulsive force begins; thus, water repels most bodies till they are wet; and hence it is, that a small needle, if dry, swims upon water; and flies walk upon it without wetting their feet.

The repelling force of the particles of a fluid is but small; and therefore, if a fluid be divided, it easily unites again. But if glass, or any other hard substance, be broke
broke into small parts, they cannot be made to flick together again without being first wetted; the repulsion being too great to admit of a re-union.

The repelling force between water and oil is so great, that we find it almost impossible to mix them so that they cannot ever be brought near together by condenstation as to make them flick or cohere. Hence it is, that when the weight of the incumbent atmosphere is taken off from any small quantity of air, that quantity will diffuse itself so as to occupy (in comparison) an infinitely greater portion of space than it did before.

Attraction of gravitation is that power by which distant bodies tend towards one another. Of this we have daily instances in the falling of bodies to the earth. By this power in the earth it is, that bodies, on whatever side, fall in lines perpendicular to its surface; and consequently, on opposite sides, they fall in opposite directions; all towards the centre, where the force of gravity is as it were accumulated; and by this power it is, that bodies on the earth's surface are kept to it on all sides, so that they cannot fall from it. And as it acts upon all bodies in proportion to their respective quantities of matter, without any regard to their bulks or figures, it accordingly constitutes their weight. Hence,

If two bodies which contain equal quantities of matter, were placed at ever so great a distance from one another, and then left at liberty in free space; if there were no other bodies in the univerfe to affect them, they would fall equally swift towards one another by the power of gravity, with velocities accelerated as they approached each other; and would meet in a point which was half way between them at first. Or, if two bodies containing unequal quantities of matter, were placed at any distance, and left in the same manner at liberty, they would fall towards one another with velocities which would be in an inverse proportion to their respective quantities of matter; and moving faster and faster in their mutual approach, would at last meet in a point as much nearer to the place from which the heavier body began to fall, than to the place from which the lighter body began to fall, as the quantity of matter in the former exceeded that in the latter.

All bodies that we know of have gravity or weight. For, that there is no such thing as positive levity, even in smoke, vapours, and fumes, is demonstrable by experiments on the air-pump; which shews, that although the smoke of a candle ascends to the top of a tall receiver, when full of air; yet upon the air's being exhausted out of the receiver, the smoke falls down to the bottom of it. So, if a piece of wood be immersed in a jar of water, the wood will rise to the top of the water, because it has a less degree of weight than its bulk of water has; but if the jar be emptied of water, the wood falls to the bottom.

As every particle of matter has its proper gravity, the effect of the whole must be in proportion to the number of the attracting particles; that is, as the quantity of matter in the whole body. This is demonstrable by experiments on pendulums; for if they are of equal lengths, whatever their weights be, they vibrate in equal times. Now it is plain, that if one be double or triple the weight of another, it must require a double or triple power of gravity to make it move with the same celerity; just as it would require a double or triple force to project a bullet of twenty or thirty pound weight with the same degree of swiftness that a bullet of ten pounds would require.

Hence, it is evident, that the power or force of gravity is always proportional to the quantity of matter in bodies, whatever their bulks or figures are.

Gravity also, like all other virtues or emanations which proceed or issue from a centre, decreases as the distance multiplied by itself increases: that is, a body at twice the distance of another attracts with only a fourth part of the force; at thrice the distance, with a ninth part; at four times the distance, with a fourteenth part; and so on. This too is confirmed by comparing the distance which the moon falls in a minute from a right line touching her orbit, with the distance through which heavy bodies near the earth fall in that time; and also by comparing the forces which retain Jupiter's moons in their orbits, with their respective distances from Jupiter. These forces will be explained afterwards.

The velocity which bodies near the earth acquire in descending freely by the force of gravity, is proportional to the times of their descent. For, as the power of gravity does not consist in a single impulse, but is always operating in a constant and uniform manner, it must produce equal effects in equal times; and consequently in a double or triple time, a double or triple effect; and so, by acting uniformly on the body, must accelerate its motion proportionably to the time of its descent.

To be a little more particular on this subject, let us suppose that a body begins to move with a celerity constantly and gradually increasing, in such a manner, as would carry it through a mile in a minute; at the end of this space it will have acquired such a degree of celerity, as is sufficient to carry it two miles the next minute, thro' it should then receive no new impulse from the cause by which its motion had been accelerated; but if the same accelerating cause continues, it will carry the body a mile farther; on which account, it will have run through four miles at the end of two minutes; and then it will have acquired such a degree of celerity, as is sufficient to carry it through a double space in as much more time, or eight miles in two minutes, even though the accelerating force should act upon it no more. But this force still continuing to operate in an uniform manner, will again, in an equal time, produce an equal effect; and so, by carrying it a mile further, cause it to move through five miles the third minute; for, the celerity already acquired, and the celerity still acquiring, will each have its complete effect. Hence we learn, that if the body should move one mile the first minute, it would move three the second, five the third, seven the fourth, nine the fifth, and so on in proportion.

And thus it appears, that the spaces described in successive equal parts of time, by an uniformly accelerated motion, are always as the odd numbers 1, 3, 5, 7, 9, &c.
and consequently, the whole spaces are as the squares of the times, or of the last acquired velocities. For, the continued addition of the odd numbers yields the squares of all numbers from unity upwards. Thus, 1, is the first odd number, and the square of 1 is 1; 3 is the second odd number, and this added to 1 makes 4, the square of 2; 5 is the third odd number, which added to 4 makes 9, the square of 3; and so on forever. Since, therefore, the times and velocities proceed evenly and constantly as 1, 2, 3, 4, &c. but the spaces described in each equal time are as 1, 3, 5, 7, &c. it is evident that the space described,

In 1 minute will be - - 1 = square of 1
In 2 minutes - - 1+3= 4 = square of 2
In 3 minutes - 1+3+5 = 9 = square of 3
In 4 minutes 1+3+5+7=16 = square of 4 &c.

As heavy bodies are uniformly accelerated by the power of gravity in their descent, it is plain that they must be uniformly retarded by the same power in their ascent. Therefore, the velocity which a body acquires by falling, is sufficient to carry it up again to the same height from whence it fell; allowance being made for the resistance of the air, or other medium in which the body is moved. Thus, the body D (fig. 2.) in rolling down the inclined plane AB, will acquire such a velocity by the time it arrives at B, as will carry it up to the inclined plane BC, almost to C; and would carry it quite up to C, if the body and plane were perfectly smooth, and the air gave no resistance. —So, if a pendulum were put into motion in a space quite void of air and all other resistance, and had no friction on the point of suspension, it would move for ever; for the velocity it had acquired in falling through the descending part of the arc, would be still sufficient to carry it equally high in the ascending part thereof.

The centre of gravity is that point of a body in which the whole force of its gravity or weight is united. Therefore, whatever supports that point bears the weight of the whole body; and whilst it is supported, the body cannot fall, because all its parts are in a perfect equilibrium about that point.

An imaginary line drawn from the centre of gravity of any body towards the centre of the earth, is called the line of direction. In this line all heavy bodies descend, if not obstructed.

Since the whole weight of a body is united in its centre of gravity, as that centre ascends or descends we must look upon the whole body to do so too. But as it is contrary to the nature of heavy bodies to ascend of their own accord, or not to descend when they are permitted; we may be sure that, unless the centre of gravity be supported, the whole body will tumble or fall. Hence it is, that bodies stand upon their bases when the line of direction falls within the base; for in this case the body cannot be made to fall without first raising the centre of gravity higher than it was before. Thus, the inclining body ABCD, (fig. 3.) whose centre of gravity is E, stands firmly on its base CDIK, because the line of direction EF falls within the base. But if a weight, as ABGH, be laid upon the top of the body, the centre of gravity of the whole body and weight together is raised up to I; and and then, as the line of direction ID falls without the base at D, the centre of gravity I is not supported; and the whole body and weight tumble down together.

The broader the base is, and the nearer the line of direction is to the middle or centre of it, the more firmly does the body stand. On the contrary, the narrower the base, and the nearer the line of direction is to the side of it, the more easily may the body be overthrown: a less change of position being sufficient to remove the line of direction out of the base in the latter case than in the former. And hence it is, that a sphere is so easily rolled upon a horizontal plane; and that it is so difficult, if not impossible, to make things which are sharp pointed to stand upright on the point. From what hath been said, it plainly appears, that if the plane be inclined on which the heavy body is placed, the body will slide down upon the plane whilst the line of direction falls within the base; but it will tumble or roll down when that line falls without the base. Thus, the body D (fig. 4.) will only slide down the inclined plane CD, whilst the body B rolls down upon it.

When the line of direction falls within the base of our feet, we stand; and most firmly, when it is in the middle; but when it is out of that base, we immediately fall. And it is not only pleasing, but even surprising, to reflect upon the various and unthought of methods and processes which we use, to retain this position, or to recover it when it is lost. For this purpose, we bend our body forward when we rise from a chair, or when we go upstairs; and for this purpose a man leans forward when he carries a burden on his back, and backward when he carries it on his breast, and to the right or left side as he carries it on the opposite side.

The quantity of matter in all bodies is in exact proportion to their weights, bulk for bulk. Therefore, heavy bodies are as much more dense or compact than light bodies of the same bulk, as they exceed them in weight. All bodies are full of pores, or spaces void of matter; and in gold, which is the heaviest of all known bodies, there is perhaps a greater quantity of space than of matter. For the particles of heat and magnetism find an easy passageway through the pores of gold; and even water itself has been forced through them. Besides, if we consider how easily the rays of light pass through so solid a body as glass, in all manner of directions, we shall find reason to believe that bodies are exceedingly porous.

All bodies are some way or other affected by heat; and all metallic bodies are expanded in length, breadth, and thickness thereby. —The proportion of the expansion of several metals, according to the best experiments, is nearly thus. Iron and glass as 3, steel 4, copper 4 and one eighth, brass 5; tin 6, lead 6 and one eighth. An iron rod 3 feet long is about one 70th part of an inch longer in summer than in winter.

The expansion of metals by heat, is demonstrated by the following machine, called a pyrometer AA (fig. 5.) A flat piece of mahogany, in which are fixed four brass flutes B,C,D,L; and two pins, one at F, and the other at H. On the pin F turns the crooked index EI, and upon the pin H the straight index GK; against which a piece of watch-spring R bears gently, and so presses it towards
MECHANICS.

towards the beginning of the scale MN, over which the point of that index moves. This scale is divided into inches and tenth parts of an inch: the first inch is marked 1000, the second 2000, and so on. A bar of metal O is laid into notches in the top of the fluds C and D; one end of the bar bearing against the adjusting screw P, and the other end against the crooked index E1, at a 20th part of its length from its centre of motion F. Now it is plain, that however much the bar O lengthens, it will move that part of the index E1 against which it bears just as far: but the crooked end of the same index, near H, being 20 times as far from the centre of motion F as the point is against which the bar bears, it will move 20 times as far as the bar lengthens. And as this crooked end bears against the index GK at only a 20th part of its whole length GS from its centre of motion H, the point S will move through 20 times the space that the point of bearing near H does. Hence, as 20 multiplied by 20 produces 400, it is evident, that if the bar lengthens but a 400th part of an inch, the point S will move a whole inch on the scale; and as every inch is divided into 10 equal parts, if the bar lengths but the 10th part of the 400th part of an inch, which is only the 4000th part of an inch, the point S will move the tenth part of an inch, which is very perceptible.

To find how much a bar lengthens by heat, first lay it cold into the notches of the fluds, and turn the adjusting screw P until the spring R brings the point S of the index GK to the beginning of the divisions of the scale at M; then, without altering the screw any farther, take off the bar, and rub it with a dry woollen cloth till it feels warm: and then, laying it on where it was, observe how far it pushes the point S upon the scale by means of the crooked index E1; and the point S will shew exactly how much the bar has lengthened by the heat of rubbing. As the bar cools, the spring R bearing against the index KG, will cause its point S to move gradually back towards M in the scale: and when the bar is quite cold, the index will rest at M, where it was before the bar was made warm by rubbing. The indexes have small rollers under them at I and K; which, by turning round on the smooth wood as the indexes move, make their motions the easier, by taking off a great part of the friction, which would otherwise be on the pins F and H, and of the points of the indexes themselves on the wood.

Besides the universal properties above mentioned, there are bodies which have properties peculiar to themselves: such as the loadstone, in which the most remarkable are these, 1. It attracts iron and steel only. 2. It constantly turns one of its sides to the north and another to the south, when suspended by a thread that does not twist. 3. It communicates all its properties to a piece of steel when rubbed upon it, without losing any itself. According to Dr Helliham's experiments, the attraction of the loadstone decreases as the square of the distance increases. Thus, if a loadstone be suspended at one end of a balance, and counterpoised by weights at the other end, and a flat piece of iron be placed beneath it, at the distance of four tenths of an inch, the stone will immediately deflect and adhere to the iron. But if the stone be again removed to the same distance, and as many grains be put into the scale at the other end as will exactly counterbalance the attraction, then, if the iron be brought twice as near the stone as before, that is, only two tenths of an inch from it, there must be four times as many grains put into the scale as before, in order to be a just counterbalance to the attractive force, or to hinder the stone from deflecting and adhering to the iron. So if four grains will do in the former case, there must be sixteen in the latter. But from some later experiments, made with the greatest accuracy, it is found that the force of magnetism decreases in a ratio between the reciprocal of the square and the reciprocal of the cube of the distance; approaching to the one or the other, as the magnitudes of the attracting bodies are varied.

Several bodies, particularly amber, glafs, jet, sealing-wax, agate, and almost all precious stones, have a peculiar property of attracting and repelling light bodies when heated by rubbing. This is called electrical attraction; for the properties of which, see ELECTRICITY.

Of Central Forces.

We have already mentioned it as a necessary consequence arising from the deadness or inactivity of matter, that all bodies endeavour to continue in the state they are in, whether of rest or motion. If the body A (fig. 6.) were placed in any part of free space, where nothing either draws or impels it in any way, it would for ever remain in that part of space, because it could have no tendency of itself to remove any way from thence. If it receives a single impulse any way, as suppos from A towards B, it will go on in that direction; for, of itself it could never swerve from a right line, nor flop its course. When it has gone through the space AB, and met with no resistance, its velocity will be the same at B as it was at A; and this velocity, in as much more time, will carry it through as much more space, from B to C; and so on for ever. Therefore, when we see a body in motion; we conclude that some other substance must have given it that motion; and when we see a body fall from motion to rest, we conclude that some other body or cause stopped it.

As all motion is naturally rectilinear, it appears, that a bullet projected by the hand, or shot from a cannon, would for ever continue to move in the same direction it received at first, if no other power diverted its course. Therefore, when we see a body move in a curve of any kind whatever, we conclude it must be acted upon by two powers at least; one putting it in motion, and another drawing it off from the rectilinear course it would otherwise have continued to move in: and whenever that power, which bent the motion of the body from a straight line into a curve, ceases to act, the body will again move on in a straight line, touching that point of the curve in which it was when the action of that power ceased. For example, a pebble moved round in a sling ever so long a time, will fly off the moment it is let at liberty by slipping one end of the sling cord; and will go on in a line touching the circle it described before; which line would actually be a straight one, if the earth's attraction did not affect the pebble, and bring it down to the ground. This shews, that the natural tendency of the pebble, when put
put into motion, is to continue moving in a straight line, although by the force that moves the fling it is made to revolve in a circle.

The change of motion produced is in proportion to the force impressed: for the effects of natural causes are always proportional to the force or power of those causes. By these laws it is easy to prove that a body will describe the diagonal of a square or parallelogram, by two forces conjoin'd, in the same time that it would describe either of the sides by one force singly. Thus, suppose the body A (fig. 7.) to represent a ship at sea; and that it is drove by the wind, in the right line AB, with such a force as would carry it uniformly from A to B in a minute: then, suppose a stream or current of water running in the direction AD, with such a force as would carry the ship through an equal space from A to D in a minute. By these two forces, acting together at right angles to each other, the ship will describe the line AEC in a minute: which line (because the forces are equal and perpendicular to each other,) will be the diagonal of an exact square. To confirm this law by an experiment, let there be a wooden square ABCD (fig. 8.) so contriv'd, as to have the part BEFC made to draw out or push into the square at pleasure. To this part let the pulley H be joined, so as to turn freely on an axis, which will be at H when the piece is pushed in, and at k when it is drawn out. To this part let the ends of a straight wire k be fixed, so as to move along with it, under the pulley: and let the ball G be made to slide easily on the wire. A thread m is fixed to this ball, and goes over the pulley to I; by this thread the ball may be drawn up on the wire, parallel to the side AD, when the part BEFC is pushed as far as it will go into the square. But, if this part be drawn out, it will carry the ball along with it, parallel to the bottom of the square DC. By this means, the ball G may either be drawn perpendicularly upward by pulling the thread m, or moved horizontally along by pulling out the part BEFC, in equal times, and through equal spaces; each power acting equally and separately upon it. But if, when the ball is at G, the upper end of the thread be tied to the pin I, in the corner A of the fixed square, and the movable part BEEB be drawn out, the ball will then be acted upon by both the powers together: for it will be drawn up by the thread towards the top of the square, and at the same time carried with its wire k towards the right hand BC, moving all the while in the diagonal line L; and will be found at g when the sliding part is drawn out as far as it was before, which then will have caused the thread to draw up the ball to the top of the side of the square, just as high as it was before, when drawn up singly by the thread without moving the sliding part.

If the acting forces are equal, but at oblique angles to each other, so will the sides of the parallelogram be: and the diagonal run through by the moving body will be longer or shorter, according as the obliquity is greater or smaller. Thus, if two equal forces act conjointly upon the body A, (fig. 9.) one having a tendency to move it through the space AB in the same time that the other has a tendency to move it through an equal space AD; it will describe the diagonal AEC in the same time that either of the single forces would have caused it to describe either of the sides. If one of the forces be greater than the other, then one side of the parallelogram will be so much longer than the other. For if one force singly would carry the body through the space AE, in the same time that the other would have carried the space AD, the joint action of both will carry it in the same time through the space AHF, which is the diagonal of the oblique parallelogram ADEF.

If both forces act upon the body in such a manner, as to move it uniformly, the diagonal described will be a straight line; but if one of the forces acts in such a manner as to make the body move faster and faster as it goes forward, then the line described will be a curve. And this is the case of all bodies which are projected in rectilinear directions, and at the same time acted upon by the power of gravity, which has a constant tendency to accelerate their motions in the direction wherein it acts.

Laws of the Planetary motions.

From the uniform projectile motion of bodies in straight lines, and the universal power of gravity or attraction, arises the curvilinear motion of all the heavenly bodies. If the body A (fig. 10.) be projected along the straight line AFH in open space, where it meets with no resistance, and is not drawn aside by any power, it will go on forever with the same velocity, and in the same direction. But if, at the same moment the projectile force is given it at A, the body S begins to attract it with a force duly adjusted*, and perpendicular to its motion at A, it will then be drawn from the straight line AFH, and forced to revolve about S in the circle ATW; in the same manner, and by the same law, that a pebble is moved round in a circle. And if, when the body is in any part of its orbit (as suppose at K) a smaller body as L, within the sphere of attraction of the body K, be projected in the right line LM, with a force duly adjusted, and perpendicular to the line of attraction LK, then, the small body L will revolve about the large body K in the orbit NO, and accompany it in its whole course round the yet larger body S. But then, the body K will no longer move in the circle ATW; for that circle will now be described by the common centre of gravity between K and L. Nay, even the great body S will not keep in the centre; for it will be the common centre of gravity between all the three bodies S, K, and L, that will remain immovable there. So, if we suppose S and K connected by a wire P that has no weight, and K and L connected by a wire q that has no weight, the common centre of gravity of all these three bodies will be a point in the wire P near S; which point being supported, the bodies will be all in equilibrio as they move round it. Though indeed, strictly speaking, the common centre of gravity of all the three bodies will not be in the wire K, P.

* To make the projectile force a just balance to the gravitating power, so as to keep the planet moving in a circle, it must give such a velocity as the planet would acquire by gravity when it had fallen through half the semidiameter of that circle.
P but when these bodies are all in a right line. Here, S
may represent the sun, K the earth, and L the moon.

In order to form an idea of the curves described by two
bodies revolving about their common centre of gravity,
whilst they themselves with a third body are in motion
round the common centre of gravity of all the three; let
us first suppose E (Plate CVI. fig. 1.) to be the fun, and
e the earth going round him with any moon; and their
moving forces regulated as above. In this case, whilst
the earth goes round the sun in the dotted circle RTUWX,
&e, the fun will go round the circle ABD, whose centre
C is the common centre of gravity between the sun and
earth: the right line £ representing the mutual attrac-
tion between them, by which they are as firmly con-
ected as if they were fixed at the two ends of an iron bar
strong enough to hold them. So, when the earth is at
e, the sun will be at E; when the earth is at T, the sun
will be at F; and when the earth is at g, the sun will be
at G, &c.

Next, let us take in the moon g (at the top of the fi-
gure,) and suppose the earth to have no progressive motion
about the sun; in which case, whilst the moon revolves
about the earth in her orbit ABCD, the earth will re-
volv e in the circle S 15, whose centre R is the common
centre of gravity of the earth and moon; they being con-
 nected by the mutual attraction between them in the same
manner as the earth and fun are.

But the truth is, that whilst the moon revolves about
the earth, the earth is in motion about the sun; and now,
the moon will cause the earth to describe an irregular curve,
and not a true circle, round the sun; it being the common
centre of gravity of the earth and moon and that will then
describe the same circle which the earth would have moved
in, if it had not been attended by a moon. For, suppos-
ing the moon to describe a quarter of her progressive or-
bit about the earth in the time that the earth moves from
e to f, it is plain that when the earth comes to f, the
moon will be found at r; in which time, their common
centre of gravity will have described the dotted arc RrT,
the earth the curve Rrf, and the moon the curve q 14r.
In the time that the moon describes another quarter of
her orbit, the centre of gravity of the earth and moon
will describe the dotted arc T 2 U, the earth the curve
f 6g, and the moon the curve r 15; and so on.—And
thus, whilst the moon goes once round the earth in her
progressive orbit, their common centre of gravity describes
the regular portion of a circle R 1 T 2 U 3 V 4 W, the earth
the irregular curve R 1 f 6 g 7 b 8 i, and the moon the
yet more irregular curve q 14 r 1 5 r 1 6 b 1 7 y; and
then, the same kind of tracks over again.

The centre of gravity of the earth and moon is 6000
miles from the earth's centre towards the moon; there-
fore the circle S 13 which the earth describes round that
centre of gravity (in every course of the moon round her
orbit) is 12000 miles in diameter. Consequently, the
earth is 12000 miles nearer the sun at the time of full
moon than at the time of new. [See the earth at f and
at h.]

To avoid confusion in so small a figure, we have sup-
pused the moon to go only twice and a half round the earth,
in the time that the earth goes once round the sun: it
being impossible to take in all the revolutions which she
makes in a year, and to give a true figure of her path,
unless we should make the semidiameter of the earth's or-
it at least 84 inches; and then, the proportional semidi-
diameter of the moon's orbit would be only a quarter of
an inch.

If the moon made any complete number of revolutions
about the earth in the time that the earth makes one re-
volution about the sun, the paths of the sun and moon
would return into themselves at the end of every year; and
so be the fame all over again: but they return not into
themselves in less than 19 years nearly; in which time,
the earth makes nearly 19 revolutions about the sun, and
the moon 233 about the earth.

If the planet A (Plate CV. fig. io.) be attracted to-
wars the sun, with such a force as would make it fall
from A to B, in the time that the projectile impulse would
have carried it from A to F, it will describe the arc AG
by the combined action of these forces, in the same time
that the former would have caused it to fall from A to B,
or the latter have carried it from A to F. But, if the
projectile force had been twice as great, that is, such as
would have carried the planet from A to H, in the same
time that now, by the supposition, it carries it only from
A to F; the sun's attraction must then have been four
times as strong as formerly, to have kept the planet in the
circle ATW; that is, it must have been such as would
have caused the planet to fall from A to E, which is four
times the distance of A from B, in the time that the pro-
jectile force singly would have carried it from A to H,
which is only twice the distance of A from F. Thus, a
double projectile force will balance a quadruple power
of gravity in the same circle; as appears plain by the figure,
and shall soon be confirmed by an experiment.

Plate CVI. fig. 2. The whirling-table is a machine
contrived for shewing experiments of this nature. AA is
a strong frame of wood, B a winch or handle fixed on the
axis C of the wheel D, round which is the cast-iron string
F, which also goes round the small wheels G and K,
crossing between them and the great wheel D. On the
upper end of the axis of the wheel G, above the frame,
is fixed the round board d, to which the bearer MSX
may be fastened occasionally, and removed when it is not
wanted. On the axis of the wheel H is fixed the bearer
NTZ: and it is easy to see, that when the winch B is
turned, the wheels and bearers are put into a whirling mo-
tion.

Each bearer has two wires, W, X, and Y, Z, fixed and
screwed tight into them at the ends by nuts on the out-
side. And when these nuts are unscrewed, the wires may
draw in order to change the balls U and V, which
slide upon the wires by means of bras loops fixed into
the balls, which keep the balls up from touching the
wood below them. A strong silk line goes through each
ball, and is fixed to it at any length from the centre of the
bearer to its end, as occasion requires, by a nut-screw
at the top of the ball; the flank of the screw going into
the centre of the ball and preffing the line against the un-
der side of the hole that it goes through.—The line goes
from the ball, and under a small pulley fixt in the middle
of the bearer; then up through a socket in the round
plate.
plate (see S and T) in the middle of each bearer; then through a slit in the middle of the square top (O and P) of each tower, and, going over a small pulley on the top, comes down again the same way, and is at last fastened to the upper end of the socket fixed in the middle of the above-mentioned round plate. These plates S and T have each four round holes near their edges for letting them slide up and down upon the wires which make the corner of each tower. The balls and plates being thus connected each by its particular line, it is plain, that if the balls be drawn outward, or towards the ends M and N of their respective bearers, the round plates S and T will be drawn up to the top of their respective towers O and P.

There are several brass weights, some of two ounces, some of three, and some of four, to be occasionally put within the towers O and P, upon the round plates S and T: each weight having a round hole in the middle of it, for going upon the sockets or axes of the plates, and is slit from the edge to the hole, for allowing it to be slipped over the forefaid line which comes from each ball to its respective plate.

The experiments to be made by this machine are,

1. Take away the bearer MX, and take the ivory ball a, to which the line or silk cord b is fastened at one end; and having made a loop on the other end of the cord, put the loop over a pin fixed in the centre of the board d. Then, turning the winch B to give the board a whirling motion, you will see that the ball does not immediately begin to move with the board; but, on account of its inactivity, it endeavour to continue in the state of rest which it was in before.—Continue turning, until the board communicates an equal degree of motion with its own to the ball; and then turning on, you will perceive that the ball will remain upon one part of the board, keeping the same velocity with it, and having no relative motion upon it, as is the case with every thing that lies upon the plane surface of the earth, which having the motion of the earth communicated to it, never endeavour to remove from that place. But flop the board suddenly by hand, and the ball will go on, and continue to revolve upon the board, until the friction thereof stops its motion: which shews, that matter being once put into motion, would continue to move for ever, if it met with no resistence. In like manner, if a person stands upright in a boat before it begins to move, he can stand firm; but the moment the boat sets off, he is in danger of falling towards that place which the boat departs from: because, as matter, he has no natural propensity to move. But when he acquires the motion of the boat, let it be ever so swift, if it be smooth and uniform, he will stand as upright and firm as if he was on the plain shore; and if the boat strike against any obstacle, he will fall towards that obstacle; on account of the propensity he has, as matter, to keep the motion which the boat has put him into.

2. Take away this ball, and put a longer cord to it, which may be put down through the hollow axis of the bearer MX, and wheel G, and fix a weight to the end of the cord below the machine; which weight, if left at liberty, will draw the ball from the edge of the whirling-board to its centre.

Draw off the ball a little from the centre, and turn the winch; then the ball will go round and round with the board, and will gradually fly off farther and farther from the centre, and raise up the weight below the machine; which shews that all bodies revolving in circles have a tendency to fly off from these circles, and must have some power acting upon them from the centre of motion, to keep them from flying off. Stop the machine, and the ball will continue to revolve for some time upon the board; but as the friction gradually stops its motion, the weight acting upon it will bring it nearer and nearer to the centre in every revolution, until it brings it quite thither. This shews, that if the planets met with any resistence in going round the sun, its attractive power would bring them nearer and nearer to it in every revolution, until they fell into it.

3. Take hold of the cord below the machine with one hand, and with the other throw the ball upon the round board as it was at right angles to the cord, by which means it will go round and round upon the board. Then, observing with what velocity it moves, pull the cord below the machine, which will bring the ball nearer to the centre of the board, and you will see that the nearer the ball is drawn to the centre, the faster it will revolve; as those planets which are nearest the sun revolve faster than those which are more remote; and not only go round sooner, because they describe smaller circles, but even move faster in every part of their respective circles.

Take away this ball, and apply the bearer MX, whose centre of motion is in its middle at w, directly over the centre of the whirling-board d. Then put two balls (V and U) of equal weights upon their bearing wires; and having fixed them at equal distances from their respective centres of motion w and x upon their silk cords, by the screw nuts, put equal weights in the towers O and P. Lastly, put the catgut strings E and F upon the grooves G and H of the small wheels; which being of equal diameters, will give equal velocities to the bearers above, when the winch B is turned; and the balls U and V will fly off towards M and N, and will raise the weights in the towers at the same instant. This shews, that when bodies of equal quantities of matter revolve in equal circles with equal velocities, their centrifugal forces are equal.

5. Take away these equal balls, and, instead of them, put a ball of fix ounces into the bearer MX, at a fixth part of the distance wu from the centre, and put a ball of one ounce into the opposite bearer, at the whole distance xy, which is equal to uw from the centre of the bearer; and fix the ball at these distances on their cords, by the screw nuts; at top; then the ball U, which is six times as heavy as the ball V, will be at only a fixth part of the distance from its centre of motion; and conseqently will revolve in a circle of only a fixth part of the circumference of the circle in which V revolves. Now, let any equal weights be put into the towers; and the machine be turned by the winch; which (as the catgut string is on equal wheels below) will cause the balls to revolve in equal times; but V will move six times as fast as U, because it revolves in a circle of six times its radius; and both the weights in the towers will rise at once. This shews, that the centrifugal forces of revolving bodies (or their
their tendencies to fly off from the circles they describe) are in direct proportion to their quantities of matter multiplied into their respective velocities, or into their distances from the centres of their respective circles. For, supposing $U$, which weighs 6 ounces, to be two inches from its centre of motion $w$, the weight multiplied by the distance is 12; and supposing $V$, which weighs only one ounce, to be 12 inches distant from its centre of motion $x$; the weight 1 ounce multiplied by the distance 12 inches is 12. And as they revolve in equal times, their velocities are as their distances from the centre, namely, as 1 to 6.

If these two balls be fixed at equal distances from their respective centres of motion, they will move with equal velocities; and if the tower $O$ has 6 times as much weight put into it as the tower $P$ has, the balls will raise their weight at the same moment. This shews, that the ball $U$, being six times as heavy as the ball $V$, has six times as much centrifugal force, in describing an equal circle with an equal velocity.

6. If bodies of equal weights revolve in equal circles with unequal velocities, their centrifugal forces are as the squares of the velocities. To prove this law by an experiment, let two balls $U$ and $V$ of equal weights be fixed on their cords at equal distances from their respective centres of motion $w$ and $x$; and then let the catgut string $E$ be put round the wheel $K$ (whose circumference is only one half of the circumference of the wheel $H$ or $G$) and over the pulleys $t$ to keep it tight; and let four times as much weight be put in the tower $P$ as in the tower $O$. Then turn the winch $B$, and the ball $V$ will revolve twice as fast as the ball $U$ in a circle of the same diameter, because they are equidistant from the centres of the circles in which they revolve; and the weights in the towers will both rise at the same instant; which shews, that a double velocity in the same circle will exactly balance a quadruple power of attraction in the centre of the circle. For the weights in the towers may be considered as the attractive forces in the centres, acting upon the revolving balls; which, moving in equal circles, is the same thing as if they both moved in one and the same circle.

7. If bodies of equal weights revolve in unequal circles, in such a manner that the squares of the times of their going round are as the cubes of their distances from the centres of the circles they describe; their centrifugal forces are inversely as the squares of their distances from those centres. For, the catgut string remaining as in the last experiment, let the distance of the ball $V$ from the centre $x$ be made equal to two of the cross divisions on its bearer, and the distance of the ball $U$ from the centre $w$ be three and a sixth part; the balls themselves being of equal weights, and $V$ making two revolutions by turning the winch in the time that $U$ makes one; so that if we suppose the ball $V$ to revolve in one moment, the ball $U$ will revolve in two moments, the squares of which are one and four: for the square of 1 is only 1, and the square of 2 is 4; therefore the square of the period or revolution of the ball $V$ is contained 4 times in the square of the ball $U$. But the distance of $V$ is 2, the cube of which is 8; and the distance of $U$ is $3^2$, the cube of which is 27 very nearly; in which 8 is contained four times; and therefore, the squares of the periods of $V$ and $U$ are to one another as the cubes of their distances from $x$ and $w$, which are the centres of their respective circles. And if the weight in the tower $O$ be four ounces, equal to the square of 2, the distance of $V$ from the centre $x$; and the weight in the tower $P$ be 10 ounces, nearly equal to the square of 3, the distance of $U$ from $w$; it will be found, upon turning the machine by the winch, that the balls $U$ and $V$ will rise their respective weights at very nearly the same instant of time. Which confirms that famous proposition of Kepler, viz. That the squares of the periodical times of the planets round the sun are in proportion to the cubes of their distances from him; and that the sun's attraction is inversely as the square of the distance from its centre: that is, 12, twice the distance, his attraction is four times less; and thrice the distance, nine times less; at four times the distance, sixteen times less; and so on, to the remotest part of the system.

8. Take off the catgut string $E$ from the great wheel $D$ and the small wheel $H$, and let the string $F$ remain upon the wheels $D$ and $G$. Take away also the bearer $MX$ from the whirling-board $d$, and instead thereof put the machine $AB$ (fig. 4.) upon it, fixing this machine to the centre of the board by the pins $c$ and $d$, in such a manner, that the end $e^\prime$ may rise above the board to an angle of 30 or 40 degrees. In the upper side of this machine there are two glass tubes $a$ and $b$, close stop at both ends; and each tube is about three quarters full of water. In the tube $a$ is a little quicksilver, which naturally falls down to the end $a$ in the water, because it is heavier than its bulk of water; and on the tube $b$ is a small cork which floats upon the top of the water at $e$, because it is lighter; and it is small enough to have liberty to rise or fall in the tube. While the board $b$ with this machine upon it continues at rest, the quicksilver lies at the bottom of the tube $a$, and the cork floats on the water near the top of the tube $b$. But, upon turning the winch, and putting the machine in motion, the contents of each tube will fly off towards the uppermost ends (which are farther from the centre of motion) the heaviest with the greatest force. Therefore, the quicksilver in the tube $a$ will fly off quite to the end $a$, and occupy its bulk of space there, excluding the water from that place, because it is lighter than quicksilver; but the water in the tube $b$ flying off to its higher end $e$, will exclude the cork from that place, and cause the cork to descend towards the lowermost end of the tube, where it will remain upon the lowest end of the tube near $b$; for the heavier body having the greater centrifugal force, will therefore possess the uppermost part of the tube; and the lighter body will keep between the heavier and the lowermost part.

This demonstrates the absurdity of the Cartesian doctrine of the planets moving round the sun in vortexes: for, if the planet be more dense or heavy than the bulk of the vortex, it will fly off therein, farther and farther from the sun; if less dense, it will come down to the lowest part of the vortex, at the sun: and the whole vortex itself must be surrounded with something like a great wall, otherwise it would fly off, planets and all together.
But while gravity exists, there is no occasion for such vortexes; and when it ceases to exist, a stone thrown upwards will never return to the earth again.

9. If a body be so placed upon the whirling board of the machine (fig. 1) that the centre of gravity of the body be directly over the centre of the board, and the board be put into ever so rapid a motion by the winch, the body will turn round with the board, but will not remove from the middle of it: for, as all parts of the body are in equilibrium round its centre of gravity, and the centre of gravity is at rest in the centre of motion, the centrifugal force of all parts of the body will be equal at equal distances from its centre of motion; and therefore the body will remain in its place. But if the centre of gravity be placed ever so little out of the centre of motion, and the machine be turned swiftly round, the body will fly off towards that side of the board on which its centre of gravity lies. Thus, if the wire C (fig. 5.) with its little ball B be taken away from the demi-globe A, and the flat side of this demi-globe be laid upon the whirling-board of the machine, so as their centres may coincide; if then the board be turned ever so quick by the winch, the demi-globe will remain where it was placed. But if the wire C be screwed in the demi-globe at d, the whole becomes one body, whose centre of gravity is now at or near d. Let the pin c be fixed in the centre of the whirling-board, and the deep groove b cut in the flat side of the demi-globe be put upon the pin, so as the pin may be in the centre of A [See fig. 6, where this groove is represented at e] and let the whirling board be turned by the winch, which will carry the little ball B (fig. 5.) with its wire C, and the demi-globe A, all round the centre-pin c; and then the centrifugal force of the little ball B, which weighs only one ounce, will be so great, as to draw off the demi-globe A, which weighs two pounds, until the end of the groove at e strikes against the pin c, and so prevents the demi-globe A from going any farther; otherwise, the centrifugal force of B would have been great enough to have carried A quite off the whirling-board. Which shews, that if the sun were placed in the very centre of the orbits of the planets, it could not possibly remain there; for the centrifugal forces of the planets would carry them quite off, and the sun with them; especially when several of them happened to be in any one quarter of the heavens. For the sun and planets are as much connected by the mutual attraction that subsists between them, as the bodies A and B are by the wire C which is fixed to them both. And even if there were but one single planet in the whole heavens to go round ever so large a sun in the centre of its orbit, its centrifugal force would soon carry off both itself and the sun. For, the greatest body placed in any part of free space could be easily moved; because if there were no other body to attract it, it could have no weight or gravity of itself; and consequently, though it could have no tendency of itself to remove from that part of space; yet it might be very easily by any other substance. And perhaps it was this consideration which made the celebrated Archimedes say, that if he had a proper place at some distance from the earth wherein to fix his machinery, he could move the whole earth.

Vol. III. No 70. 2

10. As the centrifugal force of the light body B will not allow the heavy body A to remain in the centre of motion, even though it be 24 times as heavy as B; let us now take the ball A (fig. 7.) which weighs 6 ounces, and connect it by the wire C with the ball B, which weighs only one ounce; and let the fork E be fixed into the centre of the whirling-board; then, hang the balls upon the fork by the wire C in such a manner that they may exactly balance each other; which will be when the centre of gravity between them, in the wire at d, is supported by the fork. And this centre of gravity is as much nearer to the centre of the ball A, than to the centre of the ball B, as A is heavier than B, allowing for the weight of the wire on each side of the fork. This done, let the machine be put into motion by the winch; and the balls A and B will go round their common centre of gravity d, keeping their balance, because either will not allow the other to fly off with it. For, supposing the ball B to be only one ounce in weight, and the ball A to be fix ounces; then, if the wire C were equally heavy on each side of the fork, the centre of gravity d would be fix times as far from the centre of the ball B as from the centre of the ball A, and consequently B will revolve with a velocity six times as great as A does; which will give B six times as much centrifugal force as any single ounce of A has; but then, as B is only one ounce, and A six ounces, the whole centrifugal force of A will exactly balance the whole centrifugal force of B; and therefore, each body will retain the other so as to make it keep in its circle. This shews that the sun and planets must all move round the common centre of gravity of the whole system, in order to preserve that just balance which takes place among them. For, the planets being as inactive and dead as the above balls, they could no more have put themselves into motion than these balls can; nor have kept in their orbits, without being balanced at first with the greatest degree of exactness upon their common centre of gravity by the Almighty Hand that made them and put them in motion.

Perhaps it may be here asked, that since the centre of gravity between these balls must be supported by the fork E in this experiment, what prop it is that supports the centre of gravity of the solar system, and consequently bears the weight of all the bodies in it; and by what is the prop itself supported? The answer is easy and plain; for the centre of gravity of our balls must be supported, because they gravitate towards the earth, and would therefore fall to it: but as the sun and planets gravitate only towards one another, they have nothing else to fall to; and therefore have no occasion for any thing to support their common centre of gravity; and if they did not move round that centre, and consequently acquire a tendency to fly off from it by their motions, their mutual attractions would soon bring them together; and so the whole would become one mass in the sun: which would also be the case if their velocities round the sun were not quick enough to create a centrifugal force equal to the sun's attraction.

But after all this nice adjustment, it appears evident, that the Deity cannot withdraw his regulating hand from his works, and leave them to be solely governed by the
laws which he has impressed upon them at first. For if he should once leave them so, their order would in time come to an end; because the planets must necessarily disturb one another's motions by their mutual attractions, when several of them are in the same quarter of the heavens; as is often the case; and then, as they attract the sun more towards that quarter than when they are in a manner dispersed equally around him, if he was not at that time made to describe a portion of a larger circle round the common centre of gravity, the balance would then be immediately destroyed; and as it could never restore itself again, the whole system would begin to fall together, and would in time unite in a mass at the sun.

Of this disturbance we have a very remarkable instance in the comet which appeared lately; and which, in going laft up before from the sun, went near to Jupiter, and was so affected by his attraction, as to have the figure of its orbit much changed; and not only so, but to have its period altered, and its course to be different in the heavens from what it was laft before.

11. Take away the fork and balls from the whirling-board, and place the trough AB (fig. 8.) thereon, fixing its centre to the centre of the whirling-board by the pin H. In this trough are two balls D and E, of unequal weights, connected by a wire f, and made to slide easily upon the wire c stretched from end to end of the trough, and made fast by nut-screws on the outside of the ends. Let these balls be so placed upon the wire c, that their common centre of gravity g may be directly over the centre of the whirling board. Then, turn the machine by the winch ever so swiftly, and the trough and balls will go round their centre of gravity so as neither of them will fly off; because, on account of the equilibrium, each ball detains the other with an equal force acting against it. But if the ball E be drawn a little more towards the end of the trough at A, it will remove the centre of gravity towards that end from the centre of motion; and then, upon turning the machine, the little ball E will fly off, and strike with a considerable force against the end A, and draw the great ball B into the middle of the trough. Or, if the great ball D be drawn towards the end B of the trough, so that the centre of gravity may be a little towards that end from the centre of motion, and the machine be turned by the winch, the great ball D will fly off, and strike violently against the end B of the trough, and will bring the little ball E into the middle of it. If the trough be not made very strong, the ball D will break through it.

12. The reason why the tides rise at the same absolute time on opposite sides of the earth, and consequently in opposite directions, is made abundantly plain by a new experiment on the whirling table. The cause of their rising on the side next the moon every one understands to be owing to the moon's attraction: but why they should rise on the opposite side at the same time, where there is no moon to attract them, is perhaps not so generally understood.

For it would seem that the moon would rather draw the waters (as it were) closer to that side, than raise them upon it, directly contrary to her attractive force. Let the circle abed (fig. 9.) represent the earth, with its side e turned toward the moon, which will then attract the waters so as to raise them from c to g. But the question is, why should they rise as high at that very time on the opposite side, from a to f? In order to explain this, let there be a plate AB (fig. 10.) fixed upon one end of the flat bar DC; with such a circle drawn upon it as abed (fig. 9.) to represent the round figure of the earth and sea, and such an ellipse as egfb to represent the swelling of the tide at e and g, occasioned by the influence of the moon. Over this plate AB let the three ivory balls egfb be hung by the silk lines h, i, k, fastened to the tops of the crooked wires H, I, K, in such a manner, that the ball at e may hang freely over the side of the circle e, which is farthest from the moon M (at the other end of the bar); the ball at f may hang freely over the centre, and the ball g hang over the side of the circle g, which is nearest the moon. The ball f may represent the centre of the earth, the ball g some water on the side next the moon, and the ball e some water on the opposite side. On the back of the moon M is fixt the short bar N parallel to the horizon, and there are three holes in it above the little weights p, q, r. A silk thread o is tied to the line k above the ball g, and, passing by one side of the moon M, goes through a hole in the bar N, and has the weight p hung to it. Such another thread n is tied to the line i, close above the ball f; and, passing through the centre of the moon M and middle of the bar N, has the weight q hung to it, which is lighter than the weight p. A third thread m is tied to the line h, close above the ball e, and passing by the other side of the moon M, through the bar N, has the weight r hung to it, which is lighter than the weight g.

The use of these three unequal weights is to represent the moon's unequal attraction at different distances from her. With whatever force she attracts the centre of the earth, she attracts the side next her with a greater degree of force, and the side farthest from her with a less. So, if the weights are left at liberty, they will draw all the three balls towards the moon with different degrees of force, and cause them to make the appearance shown in (fig. 11.) by which means they are evidently farther from each other than they would be if they hung at liberty by the lines h, i, k; because the lines would then hang perpendicularly. This shews, that as the moon's attraction the side of the earth, which is nearest her with a greater degree of force than the does the centre of the earth, she will draw the water on the side more than she draws the centre, and so causes it to rise on that side: and as she draws the centre more than she draws the opposite side, the centre will recede farther from the surface of the water than the opposite side, and so leave it as high there as she raised it on the side next to her. For, as the centre will be in the middle between the tops of the opposite elevations, they must of course be equally high on both sides at the same time.

But upon this supposition the earth and moon would soon come together; and to be sure they would, if they had not a motion round their common centre of gravity, to create a degree of centrifugal force sufficient to balance their mutual attraction. This motion they have; for as the moon goes round her orbit every month, at
the distance of 240000 miles from the earth's centre, and
of 234000 miles from the centre of gravity of the earth
and moon, so does the earth go round the same centre of
gravity every month at the distance of 6000 miles from
it; that is, from it to the centre of the earth. Now as
the earth is (in round numbers) 8000 miles in diameter,
the distance of its side next the moon is 2000 miles.
Therefore the centrifugal forces of these parts are as
2000, 6000, and 10000; that is, the centrifugal force of
any side of the earth, when it is turned from the moon,
is five times as great as when it is turned towards the moon.
And as the moon's attraction (express'd by the number 6000) at
the earth's centre keeps the earth from flying out of this
monthly circle, it must be greater than the centrifugal
force of the waters on the side next her; and consequently,
her greater degree of attraction on that side is suffi-
cient to raise them; but as her attraction on the opposite
side is less than the centrifugal force of the water there,
the excess of this force is sufficient to raise the water juft as high on the opposite side.—To prove this ex-
perimentally, let the bar DC (fig. 10.) with its fur-
ture be fixed upon the whirling-board of the ma-
cine (fig. 2.) by pulling the pin P into the centre of
the board; which pin is in the centre of gravity of the
whole bar with its three balls e, f, and moon M.
Now, if the whirling-board and bar be turned slowly
round by the winch, until the ball f hangs over the
centre of the circle, as in fig. 11, the ball g will be kept
towards the moon by the heaviest weight p (fig. 9.)
and the ball e, on account of its greater centrifugal force,
and the lefser weight r, will fly off as far to the other side
as in fig. 12. And fo, whilst the machine is kept turn-
ing, the balls e and g will hang over the ends of the el-
lipsis t, r. So that the centrifugal force of the ball e will
exceed the moon's attraction j uft as much as her attrac-
tion exceeds the centrifugal force of the ball g, whilst
her attraction just balances the centrifugal force of the
ball f, and makes it keep in its circle. And hence it is
evident that the tides must rise to equal heights at the
fame time on opposite sides of the earth. This experi-
ment, to the belief of my knowledge, is entirely new.

From the principles thus established, it is evident that
the earth moves round the fun, and not the fun round the
earth: for the centrifugal law will never allow a great
body to move round a small one in any orbit whatever;
especially when we find, that if a small body moves round
a great one, the great one must also move round the
common centre of gravity between them two. And it is well
known, that the quantity of matter in the fun is 227000
times as great as the quantity of matter in the earth.
Now, as the fun's distance from the earth is at lea-
st 81,000,000 of miles, if we divide that distance by
227000, we shall have only 357 for the number of miles
that the centre of gravity between the sun and earth is
distant from the sun's centre. And as the fun's semidia-
meter is 4 of a degree, which, at so great a distance as
that of the sun, must be no lefs than 341500 miles, if
this be divided by 357, the quotient will be 10680,
which shews that the common centre of gravity is within
the body of the fun, and is only the 10680 part of his
semidiameter from his centre towards his surface.

All globular bodies, whose parts can yield, and which
do not turn on their axes, must be perfect spheres, be-
cause all parts of their surfaces are equally attracted to-
toward their centres. But all such globes which do turn
on their axes, will be oblate spheroids; that is, their
surfaces will be higher, or farther from the centre, in
the equatorial than in the polar regions. For, as the equa-
torial parts move quicker, they must have the great-
eſt centrifugal force; and will therefore recede farthest
from the axis of motion. Thus, if two circular hoops
AB and CD, (Plate CVII. fig. 1.) made thin and flex-
ible, and croffing one another at right angles, be turned
round their axis EF by means of the winch N, the wheel
n, and pinion n, and the axis be loose in the pole or in-
terference e, the middle parts A, B, C, D will fly the far
to strike against the fides of the frame at F and G, if
the pole e, in linking to the pin E, be not ftopt by it from
finking farther: fo that the whole will appear of an oval fi-
gure, the equatorial diameter being considerably longer than
the polar. That our earth is of this figure, is demon-
strable from actual measurement of some degrees on its
surface, which are found to be longer in the frigid zones
than in the torrid: and the difference is found to be
such as prove the earth's equatorial diameter to be 35
miles longer than its axis.—Since then, the earth is high-
er at the equator than at the poles, the sea, which like
all other fluids naturally runs downward (or towards the
places which are nearest the earth's centre) would run
towards the polar regions, and leave the equatorial parts
dry, if the centrifugal force of the water, which carries
it to those parts, and so raised them, did not detain and
keep it from running back again towards the poles of the
earth.

Of the Mechanical Powers.

If we confider bodies in motion, and compare them
together, we may do this either with respect to the quan-
tities of matter they contain, or the velocities with which
they are moved. The heavier any body is, the greater
is the power required either to move it or to flop its mo-
tion: and again, the fwtier it moves, the greater is its
force. So that the whole momentum or quantity of force
of a moving body is the refult of its quantity of matter
multiplied by the velocity with which it is moved. And
when the products arising from the multiplication of the
particular quantities of matter in any two bodies by their
respective velocities are equal, the momenta or entire
forces are fo too. Thus, fuppofe a body, which we fhall
call A, to weigh 40 pounds, and to move at the rate of
two miles in a minute; and another body, which we fhall
call B, to weigh only four pounds, and to move 20 miles
in a minute; the entire forces with which thefe two
bodies would strike against any obstacle would be equal
to each other, and therefore it would require equal powers
to ftop them. For 40 multiplied by 2 gives 80, the force
of the body A; and 20 multiplied by 4 gives 80, the
force of the body B.

Upon this cally principle depends the whole of me-
chanics...
M E C H A N I C S.

Mechanics: and it holds universally true, that when two bodies are suspended by any machine, so as to act contrary to each other; if the machine be put into motion, and the perpendicular ascent of one body multiplied into its weight, be equal to the perpendicular descent of the other body multiplied into its weight, these bodies, how unequal soever in their weights, will balance one another in all situations: for, as the whole ascent of one is performed in the same time with the whole descent of the other, their respective velocities must be directly as the spaces they move through; and the excess of weight in one body is compensated by the excess of velocity in the other.—Upon this principle it is easy to compute the power of any mechanical engine, whether simple or compound; for it is but only inquiring how much swifter the power moves than the weight does (i. e. how much farther in the same time,) and just so much is the power increased by the help of the engine.

In the theory of this science, we suppose all planes perfectly even, all bodies perfectly smooth, levers to have no weight, cords to be extremely pliable, machines to have no friction; and in short, all imperfections must be set aside until the theory be established, and then proper allowances are to be made.

The simple machines, usually called mechanical powers, are fix in number, viz. the lever, the wheel and axle, the pulley, the inclined plane, the wedge, and the screw. They are called mechanical powers, because they help us to raise weights, move heavy bodies, and overcome resistances, which we could not effect without them.

A lever is a bar of iron or wood, one part of which being supported by a prop, all the other parts turn upon that prop as their centre of motion: and the velocity of every part or point is directly as its distance from the prop. Therefore, when the weight to be raised at one end is to the power applied at the other to raise it, as the distance of the power from the prop is to the distance of the weight from the prop, the power and weight will exactly balance each other; and a little addition to the power will raise the weight. Thus, in the present instance, the weight \( W \) is 12 ounces, and its distance from the prop is 1 inch; and 12 multiplied by 1 is 12; the power \( P \) is equal to 1 ounce, and its distance from the prop is 1 inch; and 12 multiplied by 1 is 12; the power and weight will exactly balance each other; and a little addition to the power will raise the weight.

There are four kinds of levers. 1. The common fort, where the prop is placed between the weight and the power; but much nearer to the weight than to the power. 2. When the prop is at one end of the lever, the power at the other, and the weight between them. 3. When the prop is at one end, the weight at the other, and the power applied between them. 4. The bended lever, which differs only in form from the first sort, but not in property. Tho' of the first and second kind are often tided in mechanical engines; but there are few instances in which the third sort is used.

A common balance is a lever of the first kind; but as both its ends are at equal distances from its centre of motion, they move with equal velocities; and therefore, as it gives no mechanical advantage, it cannot properly be reckoned among the mechanical powers.

A lever of the first kind is represented by the bar ABC, (Plate CVII. fig. 2.) supported by the prop D. Its principal use is to loosen large stones in the ground, or raise great weights to small heights, in order to have ropes put under them for raising them higher by other machines. The parts AB and BC, on different sides of the prop D, are called the arms of the lever: the end A of the shorter arm AB being applied to the weight intended to be raised, or to the resistance to be overcome; and the power applied to the end C of the longer arm BC.

In making experiments with this machine, the shorter arm AB must be as much thicker than the longer arm BC, as will be sufficient to balance it on the prop. This supposed, let \( P \) represent a power whose intensity is equal to one ounce, and \( W \) a weight whose intensity is equal to 12 ounces. Then, if the power be 12 times as far from the prop as the weight is, they will exactly counterpoise; and a small addition to the power \( P \) will cause it to descend, and raise the weight \( W \); and the velocity with which the power descends will be to the velocity with which the weight rises, as 12 to 1; that is, directly as their distances from the prop; and consequently, as the spaces through which they move.

Hence it is plain, that a man who by his natural strength, without the help of any machine, could support an hundred weight, will by the help of this lever be enabled to support twelve hundred. If the weight be less, or the power greater, the prop may be placed so much the farther from the weight; and then it can be raised to a proportionably greater height. For universally, if the intensity of the weight multiplied into its distance from the prop be equal to the intensity of the power multiplied into its distance from the prop, the power and weight will exactly balance each other; and a little addition to the power will raise the weight. Thus, in the present instance, the weight \( W \) is 12 ounces, and its distance from the prop is 1 inch; and 12 multiplied by 1 is 12; the power \( P \) is equal to 1 ounce, and its distance from the prop is 12 inches, which multiplied by one is 12 again; and therefore there is an equilibrium between them. So, if a power equal to 2 ounces be applied at the distance of 6 inches from the prop, it will just balance the weight \( W \); for 6 multiplied by 2 is 12, as before. And a power equal to 3 ounces placed at 4 inches distance from the prop would do the same; for 3 times 4 is 12; and so on, in proportion.

The flatera, or Roman steadyard, is a lever of this kind, contrived for finding the weights of different bodies by one single weight placed at different distances from the prop or centre of motion \( D \). For, if a scale hangs at \( A \), the extremity of the shorter arm \( AB \), and is of such a weight as will exactly counterpoise the longer arm \( BC \); if this arm be divided into as many equal parts as it will contain, each equal to \( AB \), the single weight \( P \) (which we may suppose to be 1 pound) will serve for weighing any thing as heavy as itself, or as many times heavier as there are divisions in the arm \( BC \), or any quantity between its own weight and that quantity. As for example, if \( P \) be 1 pound, and placed at the first division 1 in the arm \( BC \), it will balance 1 pound in the scale at \( A \); if it be removed to the second division at 2, it will balance 2 pounds in the scale; if to the third, 3 pounds: and so on to the end of the arm \( BC \). If each of these integral divisions be subdivided into as many equal parts as a pound contains ounces, and the weight
To this kind of lever may be reduced several sorts of instruments, such as scissors, pinchers, snuffers; which are made of two levers acting contrary to one another; their prop or centre of motion being the pin which keeps them together.

In common practice, the longer arm of this lever greatly exceeds the weight of the shorter; which gains great advantage, because it adds so much to the power.

A lever of the second kind has the weight between the prop and the power. In this, as well as the former, the advantage gained is as the distance of the power from the prop to the distance of the weight from the prop: for the respective velocities of the power and weight are in that proportion; and they will balance each other when the intensity of the power multiplied by its distance from the prop is equal to the intensity of the weight multiplied by its distance from the prop. Thus, if AB (fig. 2.) be a lever on which the weight W of 6 ounces hangs at the distance of 1 inch from the prop G, and a power P equal to the weight of one ounce hangs at the end B, 6 inches from the prop, by the cord CD going over the fixed pulley E, the power will just support the weight; and a small addition to the power will raise the weight 1 inch for every 6 inches that the power defends.

This lever shews the reason why two men carrying a burden upon a neck between them, bear unequal shares of the burden in the inverse proportion of their distances from it. For it is well known, that the nearer any of them is to the burden, the greater share he bears of it; and if he goes directly under it, he bears the whole. So, if one man be at G, and the other at P, having the pole or neck AB resting on their shoulders; if the burden or weight W be placed five times as near the man at G, as it is to the man at P, the former will bear five times as much weight as the latter. This is likewise applicable to the case of two horses of unequal strength, to be fodder, as each horse may draw a part proportional to his strength; which is done by dividing the beam so, that the point of traction may be as much nearer to the stronger horse than to the weaker, as the strength of the former exceeds that of the latter.

To this kind of lever may be reduced oars, rudders of ships, doors turning upon hinges, cutting knives which are fixed at the point of the blade, and the like.

If in this lever we suppose the power and weight to change places, so that the power may be between the weight and the prop, it will become a lever of the third kind; in which, there may be a balance between the power and the weight, the intensity of the power must exceed the intensity of the weight, just as much as the distance of the weight from the prop exceeds the distance of the power from it. Thus, let E (fig. 4.) be the prop of the lever AB, and W a weight of 1 pound, placed 3 times as far from the prop, as the power P acts at F, by the cord DE going over the fixed pulley D; in this case, the power must be equal to three pounds, in order to support the weight.

To this sort of lever are generally referred the bones of a man's arm: for when we lift a weight by the hand, the muscle that exerts its force to raise that weight, is fixed to the bone about one tenth part as far below the elbow as the hand is. And the elbow being the centre round which the lower part of the arm turns, the muscle must therefore exert a force ten times as great as the weight that is raised.

As this kind of lever is a disadvantage to the moving power, it is never used but in cases of necessity; such as that of a ladder, which, being fixed at one end, is by the power of a man's arms reared against a wall; and in clock-work, where all the wheels may be reckoned levers of this kind, because the power that moves every wheel, except the first, acts upon it near the centre of motion by means of a small pinion, and the resistance it has to overcome acts against the teeth round its circumference.

The fourth kind of lever differs nothing from the first, but in being bended for the sake of convenience. ACB (fig. 5.) is a lever of this sort, bended at C, which is its prop, or centre of motion. P is a power acting upon the longer arm AC at F, by means of the cord DE going over the pulley G; and W is a weight or resistance acting upon the end B of the shorter arm BC. If the power be to the weight as BC is to CF, they are in equilibrium. Thus, suppose W to be 5 pounds acting at the distance of one foot from the centre of motion C, and P to be 1 pound acting at F, five feet from the centre C, the power and weight will just balance each other. A hammer drawing a nail is a lever of this sort.

2. The second mechanical power is the wheel and axle, in which the power is applied to the circumference of the wheel, and the weight is raised by a rope which coils about the axle as the wheel is turned round. Here it is plain, that the velocity of the power must be to the velocity of the weight, as the circumference of the wheel is to the circumference of the axle; and consequently, the power and weight will balance each other, when the intensity of the power is to the intensity of the weight as the circumference of the axe is to the circumference of the wheel. Let AB (fig. 6.) be a wheel, CD its axle, and suppose the circumference of the wheel to be 8 times as great as the circumference of the axle; then a power P equal to 1 pound hanging by the cord I, which goes round the wheel, will balance a weight W of 8 pounds hanging by the rope K which goes round the axle. And as the friction on the pivots or gudgeons of the axle is but small, a small addition to the power will cause it to descend, and raise the weight: but the weight will rise with only an eighth part of the velocity wherewith the power descends, and consequently through no more than an eighth part of an equal space, in the same time. If the wheel be pulled round by the handles S, S, the power will be increased in proportion to their length. And by this means, any weight may be raised as high as the operator pleases.

To this sort of engine belong all cranes for raising great weights; and in this case, the wheel may have cogs all around it instead of handles, and a small lantern or trundle may be made to work in the cogs, and be turned by
by a winch; which will make the power of the engine to exceed the power of the man who works it, as much as the number of revolutions of the winch exceed those of the axle D, when multiplied by the excess of the length of the winch above the length of the semidiameter of the axle, added to the semidiameter or half-thickness of the rope K, by which the weight is drawn up. Thus, suppose the diameter of the rope and axle taken together to be 12 inches, and consequently half their diameters to be 6 inches; so that the weight W will hang at 6 inches perpendicular distance from below the centre of the axle. Now, let us suppose the wheel AB, which is fixt on the axle, to have 80 cogs, and to be turned by means of a winch fix inches long, fixt on the axis of a trundle of 8 fixe or rounds, working in the cogs of the wheel. Here it is plain, that the winch and trundle would make 10 revolutions for one of the wheel AB, and its axis D, on which the rope K winds in raising the weight W; and the winch being no longer than the sum of the semi-diameters of the great axle and rope, the trundle could have no more power on the wheel, than a man could have by pulling it round by the edge, because the winch would have no greater velocity than the edge of the wheel has, which we here suppose to be ten times as great as the velocity of the rising weight; so that, in this case, the power gained would be as 10 to 1. But if the length of the winch be 12 inches, the power gained will be as 20 to 1: if 18 inches (which is long enough for any man to work by) the power gained would be as 30 to 1; that is, a man could raise 30 times as much by such an engine, as he could do by his natural strength without it, because the velocity of the handle of the winch would be 30 times as great as the velocity of the rising weight; the absolute force of any engine being in proportion of the velocity of the power to the velocity of the weight raised by it. But then, just as much power or advantage as is gained by the engine, so much time is lost in working it. In this sort of machines it is requisite to have a ratchet-wheel G on one end of the axle, with a catch H to fall into its teeth; which will at any time support the weight, and keep it from descending, if the workman should, through inadvertency or carelessness, quit his hold whilst the weight is raising. And by this means, the danger is prevented which might otherwise happen by the running down of the weight when left at liberty.

3. The third mechanical power or engine consists either of one moveable pulley, or a system of pulleys; some in a block or case which is fixed, and others in a block which is moveable, and rises with the weight. For the single pulley, that only turns on its axis, and rises not with the weight, may serve to change the direction of the power, yet it can give no mechanical advantage thereto; but is only as the beam of a balance, whose arms are of equal length and weight. Thus, if the equal weights W and P (fig. 7) hang by the cord BB upon the pulley A, whose block b is fixed to the beam HI, they will counterpoise each other, just in the same manner as if the cord were cut in the middle, and its two ends hung upon the hooks fixt in the pulley at A and A, equally distant from its centre.

But if a weight W hangs at the lower end of the moveable block p of the pulley D, and the cord GF goes under the pulley, it is plain that the half G of the cord bears one half of the weight W, and the half F the other; for they bear the whole between them. Therefore, whatever holds the upper end of either rope, sustains one half of the weight; and if the cord at P be drawn up so as to raise the pulley D to C, the cord will then be extended to its whole length, all but that part which goes under the pulley; and consequently, the power that draws the cord will have moved twice as far as the pulley D with its weight W rises: on which account, a power whose intensity is equal to one half of the weight will be able to support it, because if the power moves (by means of a small addition) its velocity will be double the velocity of the weight; as may be seen by putting the cord over the fixt pulley C (which only changes the direction of the power, without giving any advantage to it) and hanging on the weight P, which is equal only to one half of the weight W; in which case there will be an equilibrium, and a little addition to P will cause it to descend, and raise W through a space equal to one half of that through which P descends. Hence, the advantage gained will be always equal to twice the number of pulleys in the moveable or undermove block. So that, when the upper or fixt block u contains two pulleys, which only turn on their axes, and the lower or moveable block U contains two pulleys, which not only turn upon their axes, but also rise with the block and weight; the advantage gained by this is as 4 to the working power. Thus, if one end of the rope KMOQ be fixed to a hook at I, and the rope passes over the pulleys N and R, and under the pulleys L and P, and has a weight T, of one pound, hung to its other end at T, this weight will balance and support a weight W of four pounds hanging by a hook at the moveable block U, allowing the said block as a part of the weight. And if as much more power be added as is sufficient to overcome the friction of the pulleys, the power will descend with four times as much velocity as the weight rises, and consequently through four times as much space.

The two pulleys in the fixed block X, and the two in the moveable block Y, are in the same case with those last mentioned; and those in the lower block give the same advantage to the power.

As a system of pulleys has not great weight and lies in a small compass, it is easily carried about; and can be applied, in a great many cafes, for raising weights, where other engines cannot. But they have a great deal of exactitude, on three accounts: 1. Because the diameters of their axes bear a very considerable proportion to their own diameters; 2. Because in working they are apt to rub against one another, or against the sides of the block; 3. Because of the stiffness of the rope that goes over and under them.

4. The fourth mechanical power is the inclined plane; and the advantage gained by it is as great as its length exceeds its perpendicular height. Let AB (fig. 8.) be a plane parallel to the horizon, and CD a plane inclined to it; and suppose the whole length CD to be three times as great as the perpendicular height C/F: in this case, the cylinder E will be supported upon the plane CD, and kept...
M E C H A N I C S.

47

kept from rolling down upon it, by a power equal to a third part of the weight of the cylinder. Therefore, a weight may be rolled up this inclined plane with a third part of the power which would be sufficient to draw it up by the side of an upright wall. If the plane was four times as long as high, a fourth part of the power would be sufficient; and so on, in proportion. Or, if a pillar was to be raised from a floor to the height GF, by means of the engine ABDC, (which would then act as a half wedge, where the resistance gives way only on one side) the engine and pillar would be in *equilibrio*; and if the power applied at GF was to the weight of the pillar as GF to GD; and if the power be increased, so as to overcome the friction of the engine against the floor and pillar, the engine will be driven, and the pillar raised: and when the engine has moved its whole length upon the floor, the pillar will be raised to the whole height of the engine, from G to F.

The force wherewith a rolling body descends upon an inclined plane, is to the force of its absolute gravity, by which it would descend perpendicularly in a free space, as the height of the plane is to its length. For, suppose the plane AB (fig. 9.) to be parallel to the horizon, the cylinder C will keep at rest upon any part of the plane where it is laid. If the plane be so elevated, that its perpendicular height D (fig. 10.) is equal to half its length AB, the cylinder will roll down upon the plane with a force equal to half its weight; for it would require a power (acting on the direction of AB) equal to half its weight, to keep it from rolling. If the plane AB (fig. 11.) be elevated, so as to be perpendicular to the horizon, the cylinder C will descend with its whole force of gravity, because the plane contributes nothing to its support or hindrance; and therefore, it would require a power equal to its whole weight to keep it from descending.

Let the cylinder C (fig. 12.) be made to turn upon slender pivots in the frame D, in which there is a hook e, with a line G tied to it: let this line go over the fixed pulley H, and have its other end tied to a hook in the weight I. If the weight of the body I, be to the weight of the cylinder C, added to that of its frame D, as the perpendicular height of the plane LM is to its length AB, the weight will just support the cylinder upon the plane, and a small touch of a finger will either cancel it to ascend or descend with equal ease; then, if a little addition be made to the weight I, it will descend, and draw the cylinder up the plane. In the time that the cylinder moves from A to B, it will rise through the whole height of the plane ML; and the weight will descend from H to K, through a space equal to the whole length of the plane AB.

If the plane be made to move upon rollers or friction-wheels, and the cylinder be supported upon it; the same power will draw the plane under the cylinder, which before drew the cylinder up the plane, provided the pivots of the axes of the friction-wheels be small, and the wheels themselves be pretty large. For, let the machine ABC (fig. 13.) (equal in length and height to ABM, fig. 12.) be provided with four wheels, whereof two appear at D and E, and the third under C, whilst the fourth is hid from sight by the horizontal board a. Let the cylinder F be laid upon the lower end of the inclined plane CB, and the line G be extended from the frame of the cylinder, about six feet parallel to the plane CB; and, in that direction, fixed to a hook in the wall; which will support the cylinder, and keep it from rolling off the plane. Let one end of the line H be tied to a hook at C in the machine, and the other end to a weight K, the same as drew the cylinder up the plane before. If this line be put over the fixed pulley I, the weight K will draw the machine along the horizontal plane L, and under the cylinder F; and when the machine has been drawn the whole length CB, the cylinder will be raised to d, equal to the perpendicular height AB above the horizontal part a.

To the inclined plane may be reduced all hatchets, chisels, and other edge tools which are chamfered only on one side.

5. The fifth mechanical power or engine is the *wedge*, which may be considered as two equally inclined planes DEF and CEF, joined together at their bases e EF: then DC (Plate CVIII. fig. 1.) is the whole thickness of the wedge at its back ABCD, where the power is applied; EF is the depth or height of the wedge; DF the length of one of its sides, equal to CF the length of the other side; and OF is its sharp edge, which is entered into the wood intended to be split by the force of a hammer or mallet striking perpendicularly on its back. Thus, AB (fig. 2.) is a wedge driven into the cleft CDE of the wood FG.

When the wood does not cleave at any distance before the wedge, there will be an equilibrium between the power impelling the wedge downward, and the resistance of the wood acting against the two sides of the wedge; if the power be to the resistance, as half the thickness of the wedge at its back is to the length of either of its sides; or, as Aa to A6, or Ba to B6 (fig. 2.) And if the power be increased, so as to overcome the friction of the wedge and the resistance arising from the cohesion or stickage of the wood, the wedge will be driven in, and the wood split asunder.

But, when the wood cleaves at any distance before the wedge (as it generally does) the power impelling the wedge will not be to the resistance of the wood, as half the thickness of the wedge is to the length of one of its sides; but as half its thickness is to the length of either side of the cleft, estimated from the top or acting part of the wedge. For, if we suppose the wedge to be lengthened down from a to the bottom of the cleft at E, the fame proportion will hold; namely, that the power will be to the resistance, as half the thickness of the wedge is to the length of either of its sides: or, which amounts to the same thing, as the whole thickness of the wedge is to the length of both its sides.

In order to prove what is here advanced concerning the wedge, let us suppose the wedge to be divided lengthwise into two equal parts; and then it will become two equally inclined planes; one of which, as abc, (Plate CVII. fig. 14.) may be made use of as a half wedge for separating the moulding cd from the wainscot AB. It is evident, that when this half-wedge has been driven its whole length ac between the wainscot and moulding, its side ac will be at ed; and the moulding will be separated.
Some writers have advanced, that the power of the wedge is to the resistance to be overcome, as the thickness of the back of the wedge is to the length onl of one of its sides; which seems very strange: for, if we suppose AB (Plate CVIII. fig. 3.) to be a strong inflexible bar of wood or iron fixed into the ground at CB, and D and E to be two blocks of marble lying on the ground on opposite sides of the bar, it is evident that the block D may be separated from the bar to the distance $d$, equal to $ab$, by driving the inclined plane or half wedge $afo$ down between them; and the block E may be separated to an equal distance on the other side, in like manner, by the half wedge $edo$. But the power impelling each half wedge will be to the resistance of the block against its side, as the thickness of that half wedge is to the length of its acting side. Therefore the power to drive both the half wedges is to both the resistances, as both the half backs is to the length of both the acting sides, or as half the thickness of the whole back is to the length of either side. And, if the bar be taken away, the blocks put close together, and the two half wedges joined to make one; it will require as much force to drive it down between the blocks, as is equal to the sum of the separate powers acting upon the half wedges when the bar was between them.

To confirm this by an experiment, let two cylinders, as AB (fig. 4.) and CD, be drawn towards one another by lines running over fixed pulleys, and a weight of 40 ounces hanging at the lines belonging to each cylinder: and let a wedge of 40 ounces weight, having its back jut as thick as either of its sides is long, be put between the cylinders, which will then act against each side with a resistance equal to 40 ounces, whilst its own weight endeavours to bring it down and separate them. And here, the power of the wedge's gravity impelling it downward, will be to the resistance of both the cylinders against the wedge, as the thickness of the wedge is to the length of both its sides; for there will then be an equilibrium between the weight of the wedge and the resistance of the cylinders against it, and it will remain at any height between them; requiring just as much power to pull it upward as to pull it downward. —If another wedge of equal weight and depth with this, and only half as thick, be put between the cylinders, it will require twice as much weight to be hung at the ends of the lines which draw them together, to keep the wedge from going down between them. That is, a wedge of 40 ounces, whose back is only equal to half the length of one of its sides, will require 80 ounces to each cylinder, to keep it in an equilibrium between them: and twice 80 is 160, equal to four times 40. So that the power will be always to the resistance, as the thickness of the back of the wedge is to the length (not of its one side, but) of both its sides.

The best way, though perhaps not the neatest, for making a wedge with its appurtenances for such experiments, is as follows. Let IKLM (fig. 4.) and LMNO be two flat pieces of wood, each about fifteen inches long and three or four in breadth, joined together by a hinge at LM; and let P be a graduated arch of brass, on which the said pieces of wood may be opened to any angle not more than 60 degrees, and then fixed at the given angle by means of the two screws $a$ and $b$. Then, IKNO will represent the back of the wedge, LM its sharp edge which enters the wood, and the outsides of the pieces IKLM and LMNO the two sides of the wedge against which the wood acts in cleaving. By means of the said arch, the wedge may be opened so as to adjust the thicknesses of its back in any proportion to the length of either of its sides, but not to exceed that length: and any weight, as $p$, may be hung to the wedge upon the hook M, which weight, together with the weight of the wedge itself, may be considered as the impelling power; which is all the same in experiment, whether it be laid upon the back of the wedge to pulh it down, or hung to its edge to pull it down.

—Let AB and CD be two wooden cylinders, each about two inches thick, where they touch the outsides of the wedge; and let their ends be made like two round flat plates, to keep the wedge from slipping off endwise between them. Let a small cord with a loop on one end of it go over a pivot in the end of each cylinder, and the cords S and T belonging to the cylinder AB go over the first pulleys W and X, and be fastened at their other ends to the bar $wx$, on which any weight, as $Z$, may be hung at pleasure. In like manner, let the cords Q and R belonging to the cylinder BC go over the first pulleys U and V to the bar $uy$, on which a weight $Y$ equal to $Z$ may be hung. These weights, by drawing the cylinders towards one another, may be considered as the resistance of the wood acting equally against opposite sides of the wedge; the cylinders themselves being supported in parallel to each other, by their pivots in loops on the lines E,F,G,H; which lines may be fixed to hooks in the ceiling of the room. The longer these lines are, the better; and they should never be less than four feet each. The further also the pulleys $W,V$ and $W,X$ are from the cylinders, the truer will the experiments be; and they may turn upon pins fixed into the wall.

In this machine, the weights $Y$ and $Z$, and the weight $p$, may be varied at pleasure, so as to be adjusted in proportion...
portion of the length of the wedge's side to the thickness of its back; and when they are so adjusted, the wedge will be in equilibribo with the refittance of the cylinders.

The wedge is a very great mechanical power, since not only wood but even rocks can be split by it; which would be impossible to effect by the lever, wheel and axle, or pulley: for the force of the blow, or strokes, shakes the cohering parts, and thereby makes them separate the more easily.

6. The sixth and last mechanical power is the screw; which cannot properly be called a simple machine, because it is never used without the application of a lever or winch to assist in turning it: and then it becomes a compound engine of a very great force either in pressing the parts of bodies close together, or in raising great weights. It may be conceived to be made by cutting a piece of paper ABC (fig. 5.) into the form of an inclined plane or half wedge, and then coiling it round a cylinder AB (fig. 6.) And here it is evident, that the winch E must turn the cylinder once round before the weight or resistance D can be moved from one spiral winding to another, as from d to e: therefore, as much as the circumference of a circle described by the handle of the winch is greater than the interval or distance between the spirals, so much is the force of the screw. Thus, supposing the distance between the spirals to be half an inch, and the length of the winch to be twelve inches: the circle described by the handle of the winch where the power acts will be 76 inches nearly, or about 152 half inches, and consequently 152 times as great as the distance between the spirals: and therefore, a power at the handle, whose intensity is equal to no more than a single pound, will balance 152 pounds acting against the screw; and as much additional force, as is sufficient to overcome the friction, will raise the 152 pounds; and the velocity of the power will be to the velocity of the weight, as 152 to 1. Hence it appears, that the longer the winch be made, and the nearer the spirals are to one another, so much the greater is the force of the screw.

A machine for shewing the force or power of the screw may be contrived in the following manner. Let the wheel C (fig. 7.) have a screw ab on its axis, working in the teeth of the wheel D, which suppose to be 48 in number. It is plain, that for every time the wheel C and screw ab are turned round by the winch A, the wheel D will be moved one tooth by the screw; and therefore, in 48 revolutions of the winch, the wheel D will be turned once round. Then, if the circumference of a circle described by the handle of the winch be equal to the circumference of a groove e round the wheel D, the velocity of the handle will be 48 times as great as the velocity of any given point in the groove. Consequentially, if a line G (above number 48) goes round the groove e, and has a weight of 48 pounds hung to it below the pedestal EF, a power equal to one pound at the handle will balance and support the weight. To prove this by experiment, let the circumferences of the grooves of the wheels C and D be equal to one another; and then if a weight H of one pound be suspended by a line going round the groove of the wheel C, it will balance a weight of 48 pounds hanging by the line G; and a small addition to the weight H will cause it to descend, and so raise up the other weight.

If the line G, instead of going round the groove e of the wheel D, goes round its axle I; the power of the machine will be as much increased, as the circumference of the groove e exceeds the circumference of the axle: which, supposing it to be six times, then one pound at H will balance 6 times 48, or 288 pounds hung to the line on the axle: and hence the power or advantage of this machine will be as 288 to 1. That is to say, a man, who by his natural strength could lift a hundred weight, will be able to raise 288 hundred, or 14 2/3 ton weight by this engine.

But the following engine is still more powerful, on account of its having the addition of four pulleys: and in it we may look upon all the mechanical powers combined together, even if we take in the balance. For as the axis D (fig. 8.) of the bar AB is in its middle at C, it is plain that if equal weights are suspended upon any two pins equidistant from the axis C, they will counterpoise each other.—It becomes a lever by hanging a small weight P upon the pin n, and a weight as much heavier upon either of the pins b, c, d, e, or f, as is in proportion to the pins being so much nearer the axis. The wheel and axle FG is evident; so is the screw E, which takes in the inclined plane, and with it the half wedge. Part of a cord goes round the axle, the rest under the lower pulleys K, m, over the upper pulleys L, n, and then it is tied to a hook at m in the lower or moveable block, on which hangs the weight W.

In this machine, if the wheel F has 30 teeth, it will be turned once round in thirty revolutions of the bar AB, which is fixed on the axis D of the screw E: if the length of the bar is equal to twice the diameter of the wheel, the pins a and n at the ends of the bar will move 60 times as fast as the teeth of the wheel do: and consequently, one ounce at P will balance 60 ounces hung upon a tooth at q in the horizontal diameter of the wheel. Then, if the diameter of the wheel F is 10 times as great as the diameter of the axle G, the wheel will have 10 times the velocity of the axle; and therefore one ounce P at the end of the lever AC will balance 10 times 60 or 6000 ounces hung to the rope H which goes round the axle. Lastly, if four pulleys be added, they will make the velocity of the lower block K, and weight W, four times less than the velocity of the axle: and this being the last power in the machine, which is four times as great as that gained by the axle, it makes the whole power of the machine 4 times 600, or 2400. So that a man who could lift one hundred weight in his arms, by his natural strength, would be able to raise 2400 hundred weight by this engine.—But it is here as in all other mechanical cases; for the time lost is always as much as the power gained, because the velocity with which the power moves will ever exceed the velocity with which the weight rises, as much as the intensity of the weight exceeds the intensity of the power.

The friction of the screw itself is very considerable; and there are few compound engines, but what, upon account of the friction of the parts against one another,
Mechanics.

will require a third part of more power to work them when loaded, than what is sufficient to constitute a balance between the weight and the power.

Of Mills, Cranes, Wheel carriages, and the Engine for driving Piers.

As these machines are so universally useful, it would be ridiculous to make any apology for describing them.

In a common breast-mill, where the fall of water may be about ten feet, AA (Plate CVIII. fig. 9.) is the great wheel, which is generally about 17 or 18 feet in diameter, reckoned from the outermost edge of any float-board at a to that of its opposite float at b. To this wheel the water is conveyed through a channel; and so, falling upon the wheel, turns it round.

On the axis BB of this wheel, and within the millhouse, is a wheel D, about 8 or 9 feet diameter, having 61 cogs, which turn a trundle E containing ten upright flaves or rounds; and when these are the number of cogs and rounds, the trundle will make 6 3/12 revolutions for one revolution of the wheel.

The trundle is fixed upon a strong iron axis called the spindle, the lower end of which turns in a brass foot, fixt at F, in the horizontal beam ST called the bridge-tree; and the upper part of the spindle turns in a wooden bush fixt into the nether millstone which lies upon beams in the floor YY. The top part of the spindle above the bush is square, and goes into a square hole in a strong iron cross abed (see fig. 3.) called the rynd; under which, and close to the bush, is a round piece of thick leather upon the spindle, which it turns round at the same time as it does the rynd.

The rynd is let into grooves in the under surface of the running millstone G (fig. 2.) and so turns it round in the same time that the spindle E is turned round by the cog-wheel D. This millstone has a large hole quite through its middle, called the eye of the millstone. The upper millstone may be set as close to the under one, or nearer the millstones are to one another, the finer they grind the corn; and the more remote from one another, the coarser.

The upper millstone G is inclosed in a round box H, which does not touch it anywhere; and is about an inch distant from its edge all around. On the top of this box stands a frame for holding the hopper KK, to which is hung the shoe I by two lines fastened to the hind-part of it, fixed upon hooks in the hopper, and by one end of the crook Lffring K fastened to the fore-part of it at J; the other end being twisted round the pin L. As the pin is turned one way, the string draws up the shoe closer to the hopper, and so lessens the aperture between them; and as the pin is turned the other way, it lets down the shoe, and enlarges the aperture.

If the shoe be drawn up quite to the hopper, no corn can fall from the hopper into the mill; if it be let a little down, some will fall; and the quantity will be more or less, according as the shoe is more or less let down. For the hopper is open at bottom, and there is a hole in the bottom of the shoe, not directly under the bottom of the hopper, but forward towards the end i, over the middle of the eye of the millstone.

There is a square hole in the top of the spindle, in which is put the feeder e (fig. 10.) This feeder (as the spindle turns round) jogs the shoe three times in each revolution, and so causes the corn to run constantly down from the hopper, through the shoe, into the eye of the millstone, where it falls upon the top of the rynd, and is, by the motion of the rynd and the leather under it, thrown below the upper shoe, and ground between the upper and lower one. The violent motion of the stone creates a centrifugal force in the corn going round with it, by which means it gets farther and farther from the centre, as in a spiral, in every revolution, until it be thrown quite out; and, being then ground, it falls through a spout M, called the mill eye, into the trough N.

When the mill is fed too fast, the corn bears up the stone, and is ground too coarse; and besides, it clogs the mill so as to make it go too slow. When the mill is too slowly fed, it goes too fast, and the stones by their attrition are apt to strike fire against one another. Both which inconveniences are avoided by turning the pin L backwards or forwards, which draws up or lets down the shoe; and so regulates the feeding, as the miller sees convenient.

The heavier the running millstone is, and the greater the quantity of water that falls upon the wheel, so much the faster will the mill bear to be fed; and consequently so much the more it will grind. And on the contrary, the lighter the stone, and the less the quantity of water, so much slower must the feeding be. But when the stone is considerably worn, and become light, the mill must be fed slowly at any rate; otherwise the stone will be too much borne up by the corn under it, which will make the meal coarse.

The quantity of power required to turn a heavy millstone is but a very little more than what is sufficient to turn a light one: for as it is supported upon the spindle by the bridge-tree ST, and the end of the spindle that turns in the brass foot therein being but small, the odds arising from the weight is but very inconsiderable in its action against the power or force of the water. And besides, a heavy stone has the same advantage as a heavy fly; namely, that it regulates the motion much better than a light one.

In order to cut and grind the corn, both the upper and under millstones have channels or furrows cut into them, proceeding obliquely from the centre towards the circumference. And these furrows are each cut perpendicularly on one side and obliquely on the other into the stone, which
which gives each furrow a sharp edge, and in the two
stones they come, as it were, against one another like the
edges of a pair of scissors: and so cut the corn, to make
it grind the easier when it falls upon the places between
the furrows. These are cut the same way in both stones
when they lie upon their backs, which makes them run
cross ways to each other when the upper stone is inverted
by turning its furrowed surface towards that of the lower.
For, if the furrows of both stones lay the same way, a
great deal of the corn would be driven onward in the
lower furrows, and so come out from between the stones
without ever being cut.

When the furrows became blunt and shallow by wear-
ing, the running stone must be taken up, and both stones
new dress with a chisel and hammer. And every time
the stone is taken up, there must be some tallow put
round the spindle upon the bush, which will soon be melt-
ed by the heat that the spindle acquires from its turning
and rubbing against the bush, and so will get in betwixt
them: otherwise the bush would take fire in a very little
time.

The bush must embrace the spindle quite close, to pre-
vent any shake in the motion; which would make some
parts of the stones grate and fire against each other; whilst
other parts of them would be too far asunder, and by that
means spoil the meal in grinding.

Whenever the spindle wears the bush so as to begin to
shake in it, the stone must be taken up, and a chisel drove
into several parts of the bush; and when it is taken out,
wooden wedges must be driven into the holes; by which
means the bush will be made to embrace the spindle close
all around it again. In doing this, great care must be
taken to drive equal wedges into the bush on opposite sides
of the spindle; otherwise it will be thrown out of the per-
pendicular, and so hinder the upper stone from being set
parallel under the under one, which is absolutely nece-
ssary for making good work. When any accident of this kind
happens, the perpendicular position of the spindle must be
restored by adjusting the bridge-tree ST by proper wedges
put between it and the brayer QR.

It often happens, that the rynd is a little wrinkled in
laying down the upper stone upon it; or is made to sink
a little lower upon one side of the spindle than on the oth-
er; and this will cause one edge of the upper stone to
drag all around upon the other, whilst the opposite
guide will not touch. But this is easily set to rights,
by raising the stone a little with a lever, and putting bits
of paper, cards, or thin chips, betwixt the rynd and the
stone.

The diameter of the upper stone is generally about six
feet, the lower stone about an inch more: and the upper
stone when new contains about 24½ cubic feet, which
weighs somewhat more than 1900 pounds. A stone of
this diameter ought never to go more than 60 times
round in a minute; for if it turns faster, it will heat the
meal.

The grinding surface of the under stone is a little con-
 vex from the edge to the centre, and that of the upper
stone a little more concave; so that they are farther
from one another in the middle, and come gradually
nearer towards the edges. By this means, the corn at
its first entrance between the stones is only bruised: but
as it goes farther on towards the circumference or edge,
it is cut smaller and smaller; and at last finely ground
just before it comes out from between them.

The water-wheel must not be too large, for if it be,
its motion will be too slow; nor too little, for then it
will want power. And for a mill to be in perfection, the
floats of the wheel ought to move with a third part of the
velocity of the water, and the stone to turn round once in
a second of time.

Such a mill as this, with a fall of water about 7½ feet,
will require about 32 hogheads every minute to turn the
wheel with a third part of the velocity with which the
water falls, and to overcome the resistance arising from
the friction of the gears and attrition of the stones in grind-
ing the corn.

The greater fall the water has, the less quantity of it
will serve to turn the mill. The water is kept up in the
mill-dam, and let out by a sluice called the penstock,
when the mill is to go. When the penstock is drawn up
by means of a lever, it opens a passage through which the
water flows to the wheel: and when the mill is to be flopped,
the penstock is let down, which stops the water from fall-
ing upon the wheel.

A less quantity of water will turn an overflown-mill
(where the wheel has buckets instead of float boards)
than a breast-mill where the fall of the water seldom ex-
ceeds half the height AB of the wheel. So that, where
there is but a small quantity of water, and a fall great en-
ough for the wheel to lie under it, the bucket (or over-
flown) wheel is always used. But where there is a large
body of water, with a little fall, the breast or float-board
wheel must take place. Where the water runs only upon
a little declivity, it can act but slowly upon the under
part of the wheel at A: in which case the motion of the
wheel will be very slow: and therefore, the floats ought
to be very long, though not high, that a large body of
water may act upon them: so that what is wanting in ve-
locity may be made up in power; and then the cog-wheel
may have a greater number of cogs in proportion to the
rounds in the trundle, in order to give the millstone a suf-
cient degree of velocity.

They who have read what is said in the first section,
concerning the acceleration of bodies falling freely by the
power of gravity acting constantly and uniformly upon
them, may perhaps ask, Why should the motion of the
wheel be equable, and not accelerated, since the water
acts constantly and uniformly upon it? The plain an-
swer is, That the velocity of the wheel can never be so great
as the velocity of the water that turns it; for, if it should
become so great, the power of the water would be quite
loft upon the wheel, and then there would be no proper
force to overcome the friction of the gears and attrition of
the stones. Therefore, the velocity with which the wheel
begins to move, will increase no longer than till its momen-
tum or force is balanced by the resistance of the machine;
and then the wheel will go on with an equable motion.

[If the cog-wheel D be made about 18 inches diameter,
with 30 cogs, the trundle as small in proportion with 10
flaves, and the millstones each about two feet in diameter,
and the whole work be put into a strong frame of wood,
as represented in the figure, the engine will be a hand-mill for grinding corn or malt in private families. And then, it may be turned by a winch, instead of the wheel AA; the millstone making three revolutions for every one of the winch. If a heavy fly be put upon the axle B, near the winch, it will help to regulate the motion.

If the cogs of the wheel and rounds of the trundle could be put in as exactly as the teeth are cut in the wheels and pinions of a clock, then the trundle might divide the wheel exactly; that is to say, the trundle might make a given number of revolutions for one of the wheel, without a fraction. But as any exact number is not necessary in mill-work, and the cogs and rounds cannot be set so truly as to make all the intervals between them equal; a skilful millwright will always give the wheel what he calls a hunting cog; that is, one more than what will answer to an exact division of the wheel by the trundle. And then, as every cog comes to the trundle, it will take the next fluff or round behind the one which it took in the former revolution: and by that means, will wear all the parts of the cogs and rounds which work upon one another equally, and to equal distances from one another in a little time; and so make a true uniform motion throughout the whole work. Thus, in the above water-mill, the trundle has 10 flaves, and the wheel 61 cogs.

Sometimes, where there is a sufficient quantity of water, the cog-wheel AA (Plate CIX. fig. 1.) turns a large trundle BB, on whose axis C is fixed the horizontal wheel D, with cogs all round its edge, turning two trundles E and F at the same time; whose axes or spindles G and H turn two millstones I and K, upon the fixed flones L and M. And when there is not work for them both, either may be made to lie quiet, by taking out one of the flaves of its trundle, and turning the vacant place towards the cog-wheel D. And there may be a wheel fixt on the upper end of the great upright axle C for turning a couple of bolting-mills, and other work for drawing up the sacks, cleaning the corn, sharpening of tools, &c.

If, instead of the cog-wheel AA and trundle BB, horizontal levers be fixed into the axle C, below the wheel D; then, horses may be put to these levers for turning the mill; which is often done where water cannot be had for that purpose.

The working parts of a wind-mill differ very little from those of a water mill; only the former is turned by the action of the wind upon four fails, every one of which ought (as is generally believed) to make an angle of $\frac{54}{3}$ degrees with a plane perpendicular to the axis on which the arms are fixt for carrying them; it being demonstrable, that when the falls are set to such an angle, and the axis turned end-ways toward the wind, the wind has the greatest power upon the falls. But this angle answers only to the cafe of a vane or sail just beginning to move; for, when the vane has a certain degree of motion, it yields to the wind; and then that angle must be increased to give the wind its full effect.

Again, the increase of this angle should be different, according to the different velocities from the axis to the extremity of the vane. At the axis it should be $\frac{54}{3}$ degrees, and thence continually increase, giving the vane a twist, and so causing all the ribs of the vane to lie in different planes.

Lastly, these ribs ought to decrease in length from the axis to the extremity, giving the vane a curvilinear form; so that no part of the force of any one rib be spent upon the rest, but all move on independent of each other. All this is required to give the falls of a wind-mill their true form: and we see both the twist and the diminution of the ribs exemplified in the wings of birds.

It is almost incredible to think with what velocity the tips of the falls move when acted upon by a moderate gale of wind. We have several times counted the number of revolutions made by the falls in ten or fifteen minutes; and from the length of the arms from tip to tip, have computed, that if a hoop of that diameter was to run upon the ground with the same velocity that it would move if put upon the fall-arms, it would go upwards of 30 miles in an hour.

As the ends of the falls nearest the axis cannot move with the same velocity that the tips or farthest ends do, although the winds act equally strong upon them; perhaps a better position than that of stretching them along the arms directly from the centre of motion, might be to have them set perpendicularly across the farther ends of the arms, and there adjusted lengthwise to the proper angle. For, in that case, both ends of the falls would move with the same velocity; and being farther from the centre of motion, they would have so much the more power: and then, there would be no occasion for having them so large as they are generally made, which would render them lighter, and consequently there would be so much the less friction on the thick neck of the axle where it turns in the wall.

A crane is an engine by which great weights are raised to certain heights, or let down to certain depths. It consists of wheels, axles, pulleys, ropes, and a gib or gibbet. When the rope H (fig. 2.) is hooked to the weight K, a man turns the winch A, on the axis whereof is the trundle B, which turns the wheel C, on whose axis D is the trundle E, which turns the wheel F with its upright axis G, on which the great rope HH winds as the wheel turns; and going over a pulley I at the end of the arm d of the gib code, it draws up the heavy burden K, which being raised to a proper height, as from a ship to the quay, is then brought over the quay by pulling the wheel Z round by the handles z,z, which turns the gib by means of the half wheel b fixt on the gib-post cc, and the strong pinion a fixt on the axis of the wheel Z. This wheel gives the man that turns it an absolute command over the gib, so as to prevent it from taking any unlucky swing, such as often happens when it is only guided by a rope tied to its arm d; and people are frequently hurt, sometimes killed, by such accidents.

The great rope goes between two upright upright rollers i and k, which turn upon gudgeons in the fixed beams f and g: and as the gib is turned towards either side, the rope bends upon the roller next that side. Were it not for these rollers, the gib would be quite unmanageable; for the moment it was turned ever so little towards any side, the weight K would begin to descend, because the rope would be shortened between the pulley
I and axis $G$; and so the gib would be pulled violently to that side, and either be broken to pieces, or break every thing that came in its way. These rollers must be placed so, that the sides of them, round which the rope bends, may keep the middle of the bended part directly even with the centre of the hole in which the upper gudgeon of the gib turns in the beam $f$. The truer these rollers are placed, the easier the gib is managed, and the less apt to swing either way by the force of the weight $K$.

A ratchet-wheel $Q$ is fixed upon the axis $D$, near the trundle $E$; and unto this wheel falls the catch or click $R$. This hinders the machine from running back by the thickness of the rope $H$; the power of the crane would be as $24$ to $1$: but the radius of the wheel being double the above length, it doubles the said power, and so makes it as $48$ to $1$: in which case a man may raise $48$ times as much weight by this engine as he could do by his natural strength without it, making proper allowance for the friction of the working parts. — Two men may work at once, by having another winch on the opposite end of the axis of the trundle under $B$; and so make the power still double.

If this power be thought greater than what may be generally wanted, the wheels may be made with fewer cogs in proportion to the flaves in the trundles: and so the power may be of whatever degree is judged to be requisite. But if the weight be so great as will require yet more power to raise it (supposing a double quantity) then the rope $H$ may be put under a moveable pulley, as $F$, and the end of it tied to a hook in the gib at $a$; which will give a double power to the machine, and so raise a double weight hooked to the block of the moveable pulley.

When only small burdens are to be raised, this may be quickly done by men pushing the axle $G$ round by the hand-spokes $y, y, y$; having first disengaged the trundle $B$ from the wheel $C$: and then, this wheel will only act as a fly upon the wheel $F$; and the catch $R$ will prevent its running back, if the men should inadvertently leave off pushing before the burden be unhooked from $B$.

Lastly, when very heavy burdens are to be raised, which might endanger the breaking of the cogs in the wheel $F$; their force against these cogs may be much abated by men pushing round the hand-spokes $y, y, y$, whilst the man at $A$ turns the winch.

We have only shewn the working parts of this crane, without the whole of the beams which support them; knowing that these are easily suppos'd, and that if they had been drawn, they would have hid a great deal of the working parts from sight, and also confumed the figure.

Another very good crane is made in the following manner. $A$ (fig. 3.) is a great wheel turned by men walking within it at $H$. On the part $C$, of its axle $B$, the great rope $D$ is wound as the wheel turns; and this rope...
rope draws up goods in the same way as the rope HH does in the above-mentioned crane, the gib-work here being supposed to be of the same sort. But these cranes are very dangerous to the men in the wheel; for, if any of the men should chance to fall, the burden will make the wheel run back and throw them all about within it; which often breaks their limbs, and sometimes kills them. The late ingenious Mr Padmore of Bristol, whose contrivance the forementioned crane is, observing this dangerous construction, contrived a method for remedying it, by putting cogs all around the outside of the wheel, and applying a trundle E to turn it; which increases the power as much as the number of cogs in the wheel is greater than the number of flaves in the trundle: and by putting a ratchet-wheel F on the axis of the trundle, (as in the above-mentioned crane, with a catch to fall into it, the great wheel is swept from running back by the force of the weight, even if all the men in it should leave off walking. And by one man working at the winch I, or two men at the opposite winches when needful, the men in the wheel are much assisted, and much greater weights are raised, and could be by men only within the wheel. Mr. Padmore put also a grip-wheel G upon the axis of the trundle, which being pinched in the same manner as described in the former crane, heavy burdens may be let down without the leaf danger. And before this contrivance, the lowering of goods was always attended with the utmost danger to the men in the wheel; as every one must be sensible of, who has seen such engines at work.

And it is surprising that the makers of wharfs and cranes should be so regardless of the limbs, or even lives of their workmen, that, excepting the late Sir James Creed of Greenwich, and some gentlemen at Bristol, there is scarce an instance of any who has used this safe contrivance.

The structure of wheel-carriages is generally so well known, that it would be needless to describe them. And therefore, we shall only point out some inconveniences attending the common method of placing the wheels, and loading the waggon.

In coaches, and all other four-wheeled carriages, the fore wheels are made of a less size than the hind ones, both on account of turning short, and to avoid cutting the braces: otherwise, the carriage would go much easier if the fore-wheels were as high as the hind ones; and the higher the better, because their motion would be so much the flower on their axles, and consequently the friction proportionably taken off. But carriers and coachmen give another reason for making the fore-wheels much lower than the hind-wheels; namely, that when they are so, the hind-wheels help to push on the fore ones: which is too unphilosophical and absurd to deserve a refutation; and yet for their satisfaction, we shall shew by experiment that it has no existence but in their own imaginations.

It is plain, that the small wheels must turn as much oftener round than the great ones, as their circumferences are less. And therefore, when the carriage is loaded equally heavy on both axes, the fore-axle must endure as much more friction, and consequently wear out as much sooner, than the hind-axle, as the fore-wheels are less than the hind ones. But the great misfortune is, that all the carriers to a man do obstinately pull, against the clearest reason and demonstration, in putting the heavier part of the load upon the fore-axle of the waggon; which not only makes the friction greatest where it ought to be least, but also presteth the fore-wheels deeper into the ground than the hind wheels, notwithstanding the fore-wheels, being less than the hind ones, are with so much the greater difficulty drawn out of a hole or over an obdacle, even supposing the weights on their axles were equal. For the difficulty, with equal weights, will be as the depth of the hole or height of the obdacle is to the semidiameter of the wheel. Thus, if we suppose the small wheel D (fig. 4.) of the waggon AB to fall into a hole of the depth EF, which is equal to the semidiameter of the wheel, and the waggon to be drawn horizontally along; it is evident, that the point E of the small wheel will be drawn directly against the top of the hole; and therefore, all the power of horses and men will not be able to draw it out, unless the ground gives way before it. Whereas, if the hind wheel C falls into such a hole, it sinks not nearly so deep in proportion to its semidiameter; and therefore, the point G of the large wheel will not be drawn directly, but obliquely, against the top of the hole; and so will be easily got out of it. Add to this, that since a small wheel will often sink to the bottom of a hole, in which a great wheel will go but a very little way, the small wheels ought in all reason to be loaded with less weight than the great ones; and then the heavier part of the load would be less jolted and then the heavier part of the load would be thrown upon the hind-axle than upon the fore one, as the ground rises from a level below the carriage. But as this seldom happens, and when it does, a small temporary weight laid upon the pole between the horfes would overbalance the danger; and this weight might be thrown into the waggon when it comes to level ground; it is strange that an advantage so plain and so obvious would arise from loading the hind-wheels heaviest, should not be laid hold of; by complying with this method.

To confirm these reasonings by experiment, let a small model of a waggon be made, with its fore wheels 2½ inches in diameter, and its hind-wheels 4½; the whole model weighing about 20 ounces. Let this little carriage be loaded any how with weights, and have a small cord tied to each of its ends, equally high from the ground it relies upon; and let it be drawn along a horizontal board, first by a weight in a scale hung to the cord at the fore part; the cord going over a pulley at the end of the board to facilitate the draught, and the weight just sufficient to draw it along. Then, turn the carriage, and hang the scale and weight to the hind cord, and it will be
be found to move along with the same velocity as at first: which shews, that the power required to draw the carriage is all the same, whether the great or small wheels are foremost; and therefore the great wheels do not help in the least to push on the small wheels in the road.

Hang the scale to the fore cord, and place the forewheels (which are the small ones) in two holes, cut three eighth-pieces of an inch deep into the board; then put a weight of 32 ounces into the carriage, over the fore-axle, and an equal weight over the hind one: this done, put 44 ounces into the scale, which will be just sufficient to draw out the fore-wheels; but if this weight be taken out of the scale, and one of 16 ounces put into its place, if the hind-wheels are placed in the holes, the 16 ounces weight will draw them out; which is little more than a third part of what was necessary to draw out the fore-wheels. This shews, that the larger the wheels are, the less power will draw the carriage, especially on rough ground.

Put 64 ounces over the axle of the hind-wheels, and 32 over the axle of the fore ones, in the carriage; and place the fore wheels in the holes: then, put 38 ounces into the scale, which will just draw out the fore wheels; and when the hind ones come to the hole, they will find but very little resistance, because they sink but a little way in it.

But shift the weights in the carriage, by putting the 32 ounces upon the hind axle, and the 64 ounces upon the fore one; and place the fore wheels in the holes: then, if 76 ounces be put into the scale, it will be found no more than sufficient to draw out these wheels; which is double the power required to draw them out, when the lighter part of the load was put upon them: which is a plain demonstration of the absurdity of putting the heaviest part of the load in the fore part of the waggon.

Every one knows what an outcry was made by the generality, if not the whole body, of the carriers, against the broad-wheel act; and how hard it was to persuade them to comply with it, even though the government allowed them to draw with more horses, and carry greater loads, than usual. Their principal objection was, that as a broad wheel must touch the ground in a great many more points than a narrow wheel, the friction must of course be just so much the greater; and consequently, there must be so many more horses than usual, to draw the waggon. It is believed that the majority of people were of the same opinion, not considering, that if the whole weight of the waggon and load in it bears upon a great many points, the friction must be just so much the greater; and consequently, there must be so many more horses than usual, to draw the waggon. It is believed that the majority of people were of the same opinion, not considering, that if the whole weight of the waggon and load in it bears upon a great many points, each sustains a proportionately less degree of weight and friction, than when it bears only upon a few points; so that what is wanting in one, is made up in the other; and therefore will be just equal under equal degrees of weight, as may be shewn by the following plain and easy experiment.

Let one end of a piece of packthread be fastened to a brick, and the other end to a common scale for holding weights: then, having laid the brick edge-wise on a table, and let the scale hang under the edge of the table, put as much weight into the scale as will just draw the brick along the table. Then taking back the brick to its former place, lay it flat on the table, and leave it to be acted upon by the same weight in the scale as before, which will draw it along with the same ease as when it lay upon its edge. In the former case, the brick may be considered as a narrow wheel on the ground; and in the latter, as a broad wheel. And since the brick is drawn along with equal ease, whether its broad side or narrow edge touches the table, it shews that a broad wheel might be drawn along the ground with the same ease as a narrow one (supposing them equally heavy) even though they should drag, and not roll, as they go along.

As narrow wheels are always sinking into the ground, especially when the heaviest part of the load lies upon them, they must be considered as going constantly up hill, even on level ground; and their edges must sustain a great deal of friction by rubbing against the sides of the ruts made by them. But both these inconveniences are avoided by broad wheels; which, instead of cutting and ploughing up the roads, roll them smooth, and harden them; as experience testifies in places where they have been used, especially either on wet or sandy ground: though after all it must be confessed, that they will not do as well on clayey cross-roads; because they would soon gather up as much clay as would be almost equal to the weight of an ordinary load.

If the wheels were always to go upon smooth and level ground, the best way would be to make the spokes perpendicular to the naves; that is, to stand at right angles to the axes; because they would then bear the weight of the load perpendicularly, which is the strongest way for wood. But because the ground is generally uneven, one wheel often falls into a cavity or rut when the other does not; and then it bears much more of the weight than the other does: in which case, concave or dissolving wheels are best; because when one falls into a rut, and the other keeps upon high ground, the spokes become perpendicular in the rut, and therefore have the greatest strength when the obliquity of the load throws most of its weight upon them; whilst those on the high ground have less weight to bear, and therefore need not be at their full strength. So that the usual way of making the wheels concave is by much the better.

The axes of the wheels ought to be perfectly straight, that the rims of the wheels may be parallel to each other; for then they will move easiest, because they will be at liberty to go on straight forwards. But in the usual way of practice, the axes are bent downward at their ends, which brings the sides of the wheels next the ground nearer to one another than their opposite or higher sides are; and this not only makes the wheels to drag sidewise as they go along, and gives the load a much greater power of crushing them than when they are parallel to each other, but also endangers the overturning of the carriage when any wheel falls into a hole or rut; or when the carriage goes in a road which has one side lower than the other, as along the side of a hill. Thus (in the hind view of a waggon or cart) let AB and BF (fig. 5.) be the great wheels parallel to each other, on their straight axle K, and HCI the carriage loaded with heavy goods from C to G. Then, as the carriage goes on in the oblique road A-B, the centre of gravity of the whole machine and load will be at C (see p. 35. col. 1.) and the line
line of direction C/D falling within the wheel BF, the carriage will not overfet. But if the wheels be inclined to each other at the ground, as AE and BF (fig. 6) are, and the machine be loaded as before, from C to G, the line of direction C/D falls without the wheel BF, and the whole machine tumbles over. When it is loaded with heavy goods (such as lead or iron) which lie low, it may travel safely upon an oblique road fo long as the centre of gravity is at C, and the line of direction Cd (fig. 5) falls within the wheels; but if it be loaded high with lighter goods (such as woolpacks) from C to L, (fig. 7) the centre of gravity is raised from C to K, which throws the line of direction K/d without the lowest edge of the wheel BF, and then the load overfets the waggon.

If there be some advantage from small fore-wheels, on account of the carriage turning more easily and short than it can be made to do when they are large; there is at least as great a disadvantage attending them, which is, that as their axle is below the level of the horfes breasts, the horfes not only have the loaded carriage to draw along, but also part of its weight to bear; which tires them sooner, and makes them grow much fuffer in their hams; than they would be if they drew on a level with the fore axle; and for this reason, we find coach-horfit eons become unfit for riding. So that on all accounts it is plain, that the fore-wheels of all carriages ought to be fo high, as to have their axles even with the breasts of the horfes; which would not only give the horfes a fair draught, but likewise cause the machine to be drawn by a lefs degree of power.

MECHLIN, a large well built and fortified city of Brabant, twelve miles north east of Brufelss.

MECHOLACAN, a province of Mexico, bounded by Panama, on the north; by Mexico Proper, on the east; by the Pacific ocean, on the south; and by Guadalajara, or New Galicia, on the west.

MECKLENBURG DUCHY, a province of Germany, in the province of Lower Saxony, about 100 miles long, and 60 broad; bounded by the Baltic sea, on the north; by Pomerania, on the east; by Brandenburg, on the south; and by the duchies of Holstein, Lauenburg, and Lawenburg, on the west.

MECON, a great river, which rifes in the north of further India, and, running south through the kingdoms of Laos and Cambodia, falls into the Indian ocean.

MECONIUM, in medicine, a black thick fces gather'd in the intestines of infants, and brought with them into the world at the time of their birth.

MECONIUM, in pharmacy, the extract of English poppies.

Meconium has all the virtues of the foreign opium, but in a somewhat lower degree. See Opium.

MEDAL, a piece of metal in the form of coin, intending to convey to posterity the portrait of some great perfon, or the memory of some illustrious action. The parts of a medal are the two sides, one of which is called the face or head, and the other the reverse. On each side is the area, or field, which makes the middle of the medal; the rim, or border; and the exergue: and one of the two sides are distinguished the type or the figure represented, and the legend or inscription.

As to the antiquity of medals, the Greek are certainly the most ancient; for long before the building of Rome the Greeks had beautiful money in gold, silver, and copper. This plainly appears from several genuine medals of Macedon, older than Philip and Alexander; from Greek medals with the names of several magistrates prior to the Macedonian empire; to which we may add some Sicilian coins of still greater antiquity. As the Greek medals are the most beautiful, they have a design, accuracy, force, and delicacy, that expreses even the muscles and veins, and are struck with such exquisite art, as the Romans could never come up to. Those struck when Rome was governed by consuls, are the most ancient among the Romans; but the copper and silver medals do not go beyond the 48th year of Rome, nor the gold beyond the year 546. Among the imperial medals, we distinguish between the upper and lower empire: the first commenced under Julius Caesar, and ended A.D. about 260; the lower empire includes near 1200 years, and ends at the taking of Constantinople. It is the custom, however, to account all the imperial medals till the time of the Paleologi, among the antique; though we have none of any considerable beauty later than the time of Heraclius, who died in 641. The Gothic medals make part of the imperial ones. Modern medals are those struck within these 300 years. There are no true Hebrew medals, except a few shekels of copper and silver, but none of gold; though there is mention made of one in the king of Denmark's cabinet.

There was formerly no difference between money and medals. An old Roman had his purse full of the same pieces that we now preserve in cabinets. As soon as an emperor had done any thing remarkable, as gaining a victorv, giving up a tax, or the like, it was immediately stamped on a coin, and became current thro' his whole dominions. This was a pretty device to spread abroad the virtues of an emperor, and make his actions circulate; and thus a fresh coin was a kind of gazette, that published the latest news of the empire.

Several of our modern coins have the legend round the edges: but the ancients were too wise to register their exploits on so nice a surface. As to the figures upon medals, the Romans always appear in the proper drags of their country, so that we may observe the little variations of the mode in the drapery of the medal: they would have thought it ridiculous to have drawn an emperor of Rome in a Grecian cloak or a Phyrgian mitre. On the contrary, we often see a king of England or France dressed up like a Julius Caesar, as if they had a mind to pass themselves upon posterity for Roman
of Roman emperors. Nothing is more usual than to see allusions to Roman customs and ceremonies on the medals of our own nation; nay, they very often carry the figure of an heathen god. If posterity take its notions of us from our medals, they must fancy that one of our kings paid a great devotion to Minerva, another to Apollo, &c. or, at least, that our whole religion was a mixture of paganism and Christianity. Had the old Romans been guilty of the same extravagance, there would have been no great confusion in their antiquities, that their coins would not have had half the use we now find in them.

The use of medals is very considerable: they give a very great light into history, in confirming such passages as are true in old authors, in reconciling such as are told in different manners, and in recording such as have been omitted. In this case a cabinet of medals is a body of history. It was, indeed, the best way in the world to perpetuate the memory of great actions, thus to coin out the life of an emperor, and to put every exploit into the mint. It was a kind of printing before the art was invented; and they have this advantage over books, that they tell their story quicker, and sum up a whole volume in twenty or thirty reverses: thus Mr Vaillant, out of a small collection of medals, has given us a chronicle of the kings of Syria. They are indeed the best epitomes in the world, and let us see, with one cast of the eye, the substance of above an hundred pages. Another use of medals is, that they not only shew the actions of an emperor, but at the same time mark out the year in which they were performed; for as every exploit has its date set to it, a series of an emperor's coins is his whole life digested into annals. A medallist, upon the first naming of an emperor, will immediately tell his age, family, and life. To remember where he enters in the succession, he only considers in what part of the cabinet he lies; and by running over in his thoughts such a particular drawer, will give an account of all the remarkable parts of his reign. Nor are medals of less use in architecture, painting, poetry, &c. A cabinet of medals is a collection of pictures in miniature, and by them the plans of many of the most considerable buildings of antiquity are preferred.

Impreffions of Medals. A very easy and elegant way of taking the impressions of medals and coins, not generally known, is thus directed by Dr Shaw: Melt a little flingglasa-glue made with brandy, and pour it thinly over the medals, so as to cover its whole surface: let it remain on for a day or two, till it is thoroughly dry and hardened; and then taking it off, it will be fine, clear, and hard, as a piece of Moscovy glass, and will have a very elegant impression of the coin.

Another easy method is as follows: Take a perfect and sharp impression, in the finest black sealing-wax, of the coin or medal you desire. Cut away the wax round the edges of the impression; then with a preparation of gum-water, of the colour you would have the picture, spread the paint upon the wax-impression with a small hair pencil, observing to work it into all the sinking or hollow places, these being the rising parts of the medal; and the colour must be carefully taken from the other parts with a wet finger. Then take a piece of very thin poll-paper, a little larger than the medal, and moisten it quite through. Place it on the wax impression; and on the back of the paper lay three or four pieces of thick woolen cloth or flannel, of about the same size. The impression, with its coverings, should be placed between two smooth iron plates, about two inches square, and one tenth of an inch thick. These must be carefully put into a small press, made of two plates of iron, about five inches and a half long, one inch and a half wide, and half an inch in thickness, having a couple of long male-screws running through them, with a turning female-screw on each, to force the plates together. These being brought together, by means of the screws, will take off a true and fair picture of the medal; which, if any deficiencies should appear, may easily be repaired with a hair pencil, or pen, dipped in the colour made use of.

If a relievo only be desired, nothing is necessary, but to take a piece of card, or white paste-board, well soaked in water; then placing it on the wax-mould, without any colouring, and letting it remain in the press for a few minutes, a good figure will be obtained.

This method of taking off medals, &c. is convenient, and seems much more so than the several inventions usually practised in sulphur, plaster of Paris, paper, &c. wherein a mould must be formed, either of clay, horn, plaster, or other materials, which requires a good deal of time and trouble.

Medallion, or Medalion, a medal of an extraordinary size, supposed to be anciently struck by the emperors for their friends, and for foreign princes and embassadors; but that the smallness of their number might not endanger the loss of the devices they bore, the Romans generally took care to stamp the subject of them upon their ordinary coins.

Medallions, in respect of the other coins, were the same as modern medals in respect of modern money; they were exempted from all commerce, and had no other value but what was set upon them by the fancy of the owner. Medallions are so scarce that there cannot be any set made of them, even though the metals and fizes should be joined promiscuously.

Medelpadia, a small province of Sweden lying northward of Helsingia.

Medeola, in botany, a genus of the hexandria figyza clafs. It has no calix: the corolla consists of six revoluted segments; and the berry contains three seeds. There are two species, none of them natives of Britain.

Media, in geography, the ancient name of Gilan. See Gilan.

Mediastinum, in anatomy. See Anatomy, p. 278.

Mediate, or Intermediate, something that stands between and connects two or more terms, considered...
as extremes; in which sense it is opposed to immediate.
MEDICAGO, in botany, a genus of the diadelphia de-
candria class. The pod is compressed; and the cari-
na of the corolla declines from the vexillum. There
are nine species, four of them natives of Britain, viz.
The falcata, or yellow medic; the fativa, or lucern; the
Ipulina, or melilot trefoil; and the arabica, or heart-
trefoil.

MEDICINE.

MEDICINE is generally defined to be, The art of
preserving health when present, and of restoring it
when lost.

Men would never think of any particular regimen or
mode of living in order to preserve health, before they
felt the pains which accompany the want it. The first
painful sensation must necessarily have produced a desire
for relief. But in a period when physicians and medici-
ners were equally unknown, how was that relief to be
obtained? or what system of conduct would man in this
situation naturally follow? Whoever can answer these
questions, will unfold the genuine principles of the medi-
cal art, and give an infallible standard for judging what
progress has been made in the improvement of it, what
particular circumstances have contributed to obstruct or
forward the knowledge and cure of diseases.

Medicine being thus founded on a powerful instinct in
human nature, its existence in some form must have been
to the first disease that appeared among mankind.
Most arts require the experience of ages before they can
arrive at a high degree of perfection. Medicine is un-
questionably one of the most ancient; and consequently,
the improvement of it might be expected to bear some
proportion to its antiquity. But, whilst philosophy, in
all its branches, has been cultivated and improved to a
great extent; medicine, notwithstanding the collateral ad-
vantages it has of late derived from anatomy and other
sciences, still continues to be buried in rubbish and obscu-

Many causes have contributed to retard our progres in
the knowledge of the causes and cure of diseases. In the
early ages, prescriptions were either the result of tradition
founded upon uncertain facts, or mere random trials
without any rational view of success: Accordingly, when
any uncommon cafe occurred, the patients were placed in
cross-ways, and other public places, to receive the advice
of passengers who might chance to know the disease or an
efficacious remedy. In this way valuable medicines might
be accidentally discovered. But memory, and, in remark-
able cures, engravings on pillars or the walls of temples,
were poor instruments for recording the symptoms of dif-
causes, and the ingredients of prescriptions.

After the knowledge of medicine began to be studied
and practised as a liberal profession, a jealousy of reputa-
tion, joined to a thirst for money and ignorance of phi-

osophy, laid a solid foundation for medical disputa-
tion. One party of physicians, known by the name of Em-

pyreics, excluded all reasoning, and trusted solely to expe-
tience. Another party, called Dogmatists, maintained, that

no man ought to prescribe, without being able to give a

theory both of the disease and of the nature and action of
the medicine. This dispute continued for ages, and, like
other disputes of a similar nature, remains still in some
measure undecided. The principles of both these parties
are unquestionably good. But the physician who excludes
either of them, will make but little progress in the knowl-
edge of his profession. A judicious mixture of the two
is indispensably necessary. Indeed it is difficult to deter-
mine whether too great an attachment to empiricism or
dogmatism has contributed most to obstruct the improve-
ment of physic.

But there is one cause which has operated more power-
fully in preventing the improvement of medicine than ev-
even a combination of all the other causes. Most branches
of philosophy are principally cultivated by people who ex-
pect their reward in reputation, not in money. The prac-
tice of physic is become as literally a trade as any branch
of business whatever. Young men are taught physic with
no other view than that of gaining their bread. Whener-
ever a physician gets into extensive practice, he may
bully and make a noise; but, even supposing his abilities
to be great, he can never find leisure to think, or digest
his observations.

Another cause of the imperfect state of medicine arises
from the varieties in constitutions, and the complex na-
ture of diseases. It is even extremely difficult, after a
disease has been cured, to determine with certainty, whe-
ther the cure was performed by the operation of nature,
or by any particular virtue in the medicine. This diffi-
culty is greatly increased by the variety of different medicines,
and different ingredients in the same medicine, which are
commonly administered during the course of a disease.

Of late several attempts have been made to reduce me-
dicine into the form of a regular science, by distributing
diseases into classes, orders, genera, and species. Sau-
vage was the first, and indeed the only person who ever at-
tempted to complete this great work. Others, as Lin-
naeus, Vogel, Dr Cullen &c. have since endeavoured to
improve Sauvage's method of classing; but they have con-
tented themselves with an enumeration of the characters
and arrangement of the different genera, without enter-
ing into their history or cure. Sauvage enumerates 315
genera, Linnæus 325, Vogel 560, and Dr Cullen has re-
duced them to 132. The bare inspection of these num-
bers shows, that physicians are far from being agreed with
regard to what constitutes the generic or specific charac-
ters of a disease. Indeed we may venture to affirm, that
they never will agree upon this point: The diagnostic
symptoms of diseases are not so easily discovered as the fla-
mina or petals in a flower, or the number of teeth or toes

in
in a quadruped. However, before making any observations on the advantages or disadvantages that may probably result from the classification of diseases, we shall lay before our readers the last and shortest distribution, published last year by Dr. Cullen, one of the professors of medicine in the university of Edinburgh, under the title [Sympathetic Method, or rather, Genera Morborum Præcipuæ.]

The doctor divides diseases into the four following classes, viz.

**Class I. Pyrexia, or Feverish Disorders.**

**Class II. Neuroses, or Nervous Diseases.**

**Class III. Cachexia, or Diseases comprehending such disorders as proceed from a diseased state of the whole or any part of the body, without an original fever, or any nervous complaint.**

**Class IV. Locales; comprehending diseases which affect a part only, not the whole body.**

The first class (Pyrexia) is subdivided into five orders, viz.

**Order I. Fevers, or Fevers, is subdivided into three sections, viz.**

1. Intermittent; and, 2. Continued fevers.

**Order II. Phlegmasia, or fevers accompanied with any local pain.**

**Order III. Exanthemata, or diseases accompanied with a flux of blood, not proceeding from any local pain.**

The fourth class (Locales, or diseases affecting only a part of the body,) is subdivided into seven orders, viz.

**Order I. Dysthesia, or diseases arising from any of the senses being destroyed or impaired by a fault in the external organs of sensation.** There are 8 genera in this order, viz. 1. Caligo; 2. Amblyopia; 3. Dysecece; 4. Paracusis; 5. Anomia; 6. Amentia; 7. Anæsthesia; 8. Anaphrodisia.

**Order II. Dyscinesia, or diseases attended with the destruction or defect of motion in any part through a fault of the organs.** This order contains 6 genera, viz. 1. Aphonia; 2. Mutitas; 3. Paraphonia; 4. Pelliophora; 5. Strobilus; 6. Contraction.

**Order III. Apopleneses, or diseases attended with an increased flux of the blood or other humours, without a fever, or increased motion of the fluids.** This order contains 5 genera, viz. 1. Profusio; 2. Epiphora; 3. Peltorrhoeas; 4. Enuresis; 5. Gonorrhoea.

**Order IV. Episcenses, or diseases arising from suppression or obstruction of any usual excretions.** This order contains 3 genera, viz. 1. Oblipitio; 2. Ichthia; 3. Amenorrhœa.

**Order VI. Exoplia, comprehending diseases arising from...**
fing from any part's being removed from its proper situation, and causing a tumor. This order contains 3. genera, viz. 1. Hernia; 2. Prolapsus; 3. Luxatio.

It is needless to enter into an examination of the propriety or impropriety of this or any of the other modes of distribution. Every one of them are defective in many particulars. Sauvage, Vogel, Linnaeus, Dr Cullen, have each adopted peculiar theories of particular diseases. These theories constitute the basis of their different classifications. A person, therefore, who is not previously acquainted with these theories will naturally be surprised to find some diseases arranged under certain classes and orders. For example, who would expect to find a diarrhoea ranked under the class of Neuroses, and in the order of the other methods, but that particular one which he has been taught to believe as infallible.

However, notwithstanding these defects arising from the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to

The formal or fundamental cause of a fever consists in the spasmatic affection of the whole nervous and fibrous genus. This plainly appears from the usual phenomena of a fever, viz: a pain in the back, more particularly about the loins; a coldness, especially of the extreme parts; a shrunken, dry skin; a yawning; a stretching; a pale, livid countenance; a trembling and palpitating motion of the heart; an anxiety of the mind, difficult breathing, inquietude, restlessness; a sensation of an ebullition of the blood about the heart; a contracted, weak, small pulse; a naufea, and an inclination to vomit; a suppression of perspiration; colic in the bowels, with thin watery urine.

Hence it naturally follows, that whatever has a power to irritate and solicit the nervous and vascular system to spasms, is most likely to generate a fever. To this class belong violent passions of the mind, especially terror and anger; a poisonous, subtile, caustic matter, either bred within the body, or received by infection; a foppage of perspiration; a suppression of the sweat; eruptions driven back; an abundance of purulent ulcerous matter adhering to various parts; aliments too acrid and sharp; corrupt and bilious crudities lodged in the prime viscére; excessive watching; a violent pain and tension of the nervous parts; inflammations, tumours, and abscesses; hurting the nervous parts by sharp instruments; acrid and corrosive drugs; cold baths, and, on the contrary, those that are too hot or astringent.

According to the different nature of these causes, and the various manner of affecting the nerves, arise fevers of divers kinds. Some are benign, others malignant; some are intermittent, others continual; some are simple, others compound; others regular or anomalous; eruptive, spotted, putrid, hectic, or流程。Some admit, of an easy cure, others a difficult; some are protracted a long time; and many hurry the patient suddenly out of the world.

Yet, every frequent fyslole of the heart and arteries discoverable by the pulse ought not to be called a fever. For these may often arise from violent bodily exercise; or, from a commotion in the blood caused by hot and spirituous liquors. That only which arises from internal causes, and is preceded by shivering, shaking, and coldness.
nefts of the extreme parts, is properly a fever: For there is always, as it were, a double motion in a fever; the one from the circumference to the centre, or from the external parts to the internal, the heart and lungs; the other from the centre to the circumference. The first motion is attended with a small, contracted, weak, pulse, with an anxiety of the praecordia and difficulty of breathing; the second with an increased motion of the arteries, a large pulse, and heat extended even to the extreme parts.

The cause of the febrile motion is an universal ipasm; and that motion never ceases till the ipasm is resolved. The signs of its being resolved are, a free perspiration, and a breathing sweat; the pulse, which before was hard, impetuous, and quick, becomes soft, moderate, and slow; the urine lets fall a sediment, and the strength gradually returns. When these appear all together, they declare the solution of the disease, and are called the crisis.

Of Intermittent Fevers, or Agues.

This fever is of the regular kind, and is attended with the following symptoms. At first, the head aches, the limbs seem weary; there is a pain in the loins about the first vertebra of the back, which ascends towards the epigastrium, with a painful sense of a tension in the hypochondria, and costiveness: then comes on a coldness of the external parts, especially of the nose and ears; a stretching, yawning; a shivering and shaking, sometimes even to make the bed tremble under the patient; the pulse is small, contracted, and weak: again the patient is troubled with thirst; then follows a nausea, with a fruitful reaching to vomit; again, a pituitous, bilious, or green matter is brought up, commonly joined with a green matter is brought up, commonly joined with a dryness of the mouth, a lightness of the head, a disturbance of the senses, and anxiety about the praecordia. These symptoms continue about two or three hours. In some there is a nausea or vomiting, with a continuance of the fit. The fits sometimes come on in the morning, sometimes in the afternoon, in the evening, or at midnight. The paroxysm is sometimes longer, sometimes shorter; the urine lets fall no sediment within the time of remission or intermission; the sweating is either too sparing or too profuse. The pulse is often on all the other symptoms may appear; as, a looseness, a bleeding at the nose, fickness at the stomach, a violent headache, pain in the belly, or the groans. These symptoms are generally Epidemic, and most commonly appear in the summer and autumn.

Sometimes a tertian ague is double, which may be distinguished from a quotidian, by the time of the fits, which is not the same every day, but every other day.

There is sometimes a Continual Tertian, which begins with shivering and shaking, an anxiety, vomiting, loss of strength, and then a violent heat. The fits do not intermit, but only remit. The pulse continues frequent with heat and debility, and all the symptoms return with fresh vigour every other day; but at length admit a perfect intermission.

An Endemic Tertian is proper to certain places; as a low situation, and full of marshes, producing a great number of gnats and other insects, like some parts of Kent, and the hundreds of Essex. In such places, the natives themselves have a little of it every year; and strangers seldom or never escape, without a preservative, which is only the bark infused in brandy, with a little flax root, of which two ounces night and morning are to be taken.

A Quartan Ague has two fits in four days, or two days quite free from a fit. It begins about four or five in the afternoon, sometimes sooner and sometimes later, with a great latitude, stretching, a blunt pain in the head, back, loins and legs; the feet and hands are cold; the whole body is pale; the face and nails livid, to which shivering and shaking succeed. The tongue and the lips tremble, the breathing is difficult, with restlessness and tolling; the pulse is contracted and hard, and sometimes unequal; and there is an anxiety about the praecordia. These symptoms continue about two or three hours. In some the body is cold; in others there is a stimulus to stool, and to make water. In some there is a nausea or vomiting, with stools. Some advanced in years have their minds pretty much disturbed; the heat comes on gradually, not burning but dry; the pulse becomes equal, full, and quick; but the dull pain in the head remains, with a vertiginous affection: the skin becomes only a little moist; and in about four or six hours the symptoms vanish, except a dull pain in the bones, joints and feet. The urine in the fit is sometimes thin and watery, sometimes thick and with a sediment.

Sometimes a quartan ague is double, that is, when the fits come on every other day at different hours; and it is Spurious when a paroxysm begins at any other time of the day but that above-mentioned. It is said to be Continual, when on the intercalary days there are shiverings and pandonculations, with a greater heat than usual, a quicker pulse, a want of appetite, a debility, a dryness of the mouth, a lightness of the head, a disturbed.
ed sleep, and a reddish urine, with a thick rose-coloured sediment.

A QUOTIDIAN AGUE or fever returns every day, and is not so common as the tertian or quartan.

The accession of this fever is about four or five in the morning, with cold and shivering; to which succeeds a cardialgic nausea, and inflation of the belly; in some, a pain in the head; in others, fainting fits; in most, vomiting or fifts, or both. Then comes on a moderate heat, with thirst, but not very intense. The pulse, which was before irregular and weak, becomes more quick, but not very hard. The urine is not of a flame but rather of a citron colour, and turbid. Some are exceeding sleepy. At length a moderate sleep supervenes; and in about ten hours or longer, the fit goes off, leaving the body dull and heavy.

From these symptoms it appears, that the whole nervous system is agitated and suffers greatly by spastic constrictions; which proceeding chiefly from the medulla spinalis, affect preternaturally not only the coats of the vessels, but all the fibres throughout the body, thereby greatly disturbing the motion both of the solids and fluids.

The material cause of this, and all other fevers, according to Hoffman, is a fluid of an astive nature, emitted chiefly in the bile ducts and flexures of the duodenum; where the vitiated, bilious salivary and pancreatic juices meeting with the crudities of a bad digestion, ferment together, and, not being timely expelled, become virulent. This matter passing through the lacteals, into the blood, and thence into the nervous parts of the head, medulla spinalis, intestines, and stomach, as also to the nervous coats of the excretory and secretory vessels, excites an universal spasm, which first forces the blood to the interior and greater vessels; and afterwards the sphygmal motion of the heart and arteries being increased, the motion of the whole mass of blood and humours is accelerated, and the obstructions of the small vessels of the nervous parts are opened; upon which the spasm ceasing, the excretory ducts are relaxed, the fibrillar matter passes off through the pores of the skin by perspiration or sweat, and the fit ceases, till by the generation of fresh matter a new paroxysm is brought on.

As to the cure, when a load of vitiated humours in the stomach and duodenum require depletion, which is known from having indulged in too plentiful eating, from an anxiety of the precordia, from eruptions, and a bitter taste in the mouth, a vomit, after the first fit, in the time of intermission, is to be given. In tender constitutions, 10 grains of ipecacuanha may be given at a time, 3 grains of salt of wormwood, a scruple; 4 ounces of fennel water. Mix them together for a drink. Let the patient take it just as the fit comes on, and be well covered with bed-cloaths.

Bleeding is proper only in a hot season, when the heat of the patient is excessive, attended with a delirium, and in the prime of life, full of blood, and subject to passion. Opiates will appease the symptoms; but they disturb the crisis, and protract the disease. Likewise aluminous, chalybeates, and vitriolic remedies will stop the fits; and if they are given to patients of the lowest class, care must be taken that they sweat after them, by drinking hot decoctions, or by exercise.

Absorents have often a happy effect in these diseases; but if given in too great a quantity, they will not dissolve in the stomach. Harris advises 2 scruples of the simple powder of crabs claws, two hours before the fit, and to be repeated in an hour, in mint-water; no small beer is to be drank for eight hours after. It may be repeated in the same manner against the next time the fit is expected; as likewise a third time.

Langeilh afferts, that in long continued agues or intermitting fevers, which have baffled the bark and many other medicines, he has met with more advantage from rhubarb and calomel exhibited in small doses, than from anything else he had tried.

To prevent the return of an ague, the bark must be repeated every week or ten days, for three several times, with the same intervals. Likewise bitters and chalybeates are very serviceable for the same purpose.

Of the CATARRHAL FEVER, or the Continual Quotidian of the ancients.

It generally begins in the evening, with a shivering and
and a coldness of the extreme parts, especially of the feet, and soles of the feet; a cough; a frequent desire of making water, but the urine is small in quantity; a weakness of the head, an universal languor of the whole body, a fulness of the head, and a lassitude of the whole body, and a loss of appetite.

The immediate cause of this disorder is a sharp acid ferment or lymph, suffocating in the glandulous tunics, and irritating them with pain, tumour, and redness. This happens in the whole region of the nostrils, palate, and fauces; as also in the affera arteria, with the bronchial branches; and farther in the oesophagus, stomach, and intestines. Hence a hoarseness, a cough, a hawking up of viscid matter, a sneezing, a defluxion of the lungs: likewise a nausea, sometimes a vomiting; a heat about the praecordia; a griping of the guts, followed with a fa
dular flux.

It more frequently attacks women and children than men, and those that indulge themselves in strong liquors. It sometimes happens from the drying up of a fecal head and other eruptions. Sometimes it is epidemic.

This disease is most frequent in the spring and autumn, in sudden changes of the weather from hot to cold, from dry to moist, and vice versa; as also from change of air, if of different qualities; from being exposed to the cold air of the night, and from throwing off winter-garments too soon.

This disease is not dangerous in itself, if rightly managed, and terminates in seven or fourteen days at farthest: for the latitude of the body then disappears; and the other complaints, especially the head-ache and hemiplegia are appeased, when the catarrh appears, and there is a plentiful discharge from the nostrils.

It often goes off, in some, in the beginning, with an increased perspiration or by sweat; in others after a few days, by hawking up a large quantity of viscid matter, or a plentiful discharge of a mucous ferment by the nose; in others, by a loofeness, when the urine at the same time, which before was thin and little, becomes copious and heavy, with twice the quantity of sediment as in a natural state.

The intentions of cure are three, 1. To sheath the acrimony of the lympha. 2. To increase perspiration. 3. To promote the expectoration of the viscid mucus.

The saline sharpness of the lympha may be taken off by the absorbent and diaphoretic powders, humetty and oleous remedies; such as, oil of sweet almonds, iperma ceti, milk, cream, almond emulsions, with the addition of white poppy seeds, barley broth, water-gruel, chicken broth, with the yolk of an egg; as also liquorice-juice, liquorice-tea, dried figs and raisins. If the acrimony is very subtle and corroding, gentle anodynes should take place, such as faffron, diacodium, and florax pills.

To promote a diaphoresis,
1. Take a scruple of the powder of contrayerva; Vit-
barley-water to make the expectoration easy, and afterwards going into the air well cloathed.

Of the Semiterrian Fever.

This is an epidemic fever, compounded of an intermittent tertian and a continual quotient.

It generally makes its onset before noon, with coldness, shaking, and a contracted pulse; to which succeeds a frequent pulse, with heat, which continues some hours, till a warm sweat appears, without a complete intermission. The heat, after a slight chills, increases towards night, with a quick pulse; which is more moderate the next day, without thirst, till the evening, when a slight shivering comes on, and the symptoms return. On the third day, the shaking fit appears again with more intense heat, and proceeds in the same track as before; so that the fever is never quite off, but has an exacerbation in the evening: however, the shaking fit is most conspicuous every third day in the morning.

Besides the foregoing symptoms, the strength fails, the appetite is languid, sleep is wanting, the urine is thin and crude; but after the fit on the third day, it is thick and coloured, and a small quantity of crude matter is brought up with coughing. It is sometimes attended with a pain in the back and the abdomen, together with a swelling in the latter. Some at the access of the fit of the tertian, are affected with a nausea and cardialgia. Some vomit, others faint, and others again are delirious. The heat, after a slight chilness, increases to a temperature, diurnal and a continual quotidian.

The heat, after a flight chills, increases towards night, with a quick pulse; which is more moderate the next day, without thirst, till the evening, when a slight shivering comes on, and the symptoms return. On the third day, the shaking fit appears again with more intense heat, and proceeds in the same track as before; so that the fever is never quite off, but has an exacerbation in the evening: however, the shaking fit is most conspicuous every third day in the morning.

But the tertian fever, if the patient is plethoric, the heat urgent, the strength not much impaired, and when some critical hemorrhage is suppressed. All heating medicines are to be avoided, as well as fixt astringent earthy tinctuous powders; and also the bark, unless there is a perfect intermission; for this last, as Baglivj observes, has brought on fatal inflammations, or flow hectic fevers.

Of the Nervous Fever.

In a nervous fever, the patients at first are subject to phlegmatic transient chills, and then, with uncertain flushings of heat; they have a little chill, latitude, and weariness; they are apt to figh, and complain of a heaviness, dejection, and anxiety, with a load, pain, or giddiness of the head, with an inclination to yawn and doze; they want appetite, and disrelish every thing; they have a dryness of the lips and tongue without any considerable thirst; they have frequent nausea's, with reaching to vomit: the breathing is difficult by intervals, and especially towards night there is an exacerbation of the symptoms, with a low, quick, unequal pulse; the urine is pale, and made often and suddenly; a torpor, or obviety, pain and coldness often affect the hind-part of the head, or a heavy pain is felt along the coronary future. These commonly precede some degree of a delirium.

The countenance is heavy, pale, and dejected: sometimes they are quite wakeful; and when they fall asleep, they are lo insensible of it, that they disown it.

The pulse is very remarkable in this disease, and requires the most diligent attention; for it is generally low, quick, and unequal: the inequality consists in this, that a few pulsations shall be more swift, frequent, and large, sometimes fluttering; and then prefently it returns to be low and quick.

The urine has generally no sediment; and when it has, it is like bran; it is sometimes of a whey-colour, or like dead small-beer. The dryness of the tongue seldom appears at the beginning, though it is then sometimes covered with a thin whitish mucus; but at the close of the disease, it often appears very dry, red, and chapped.

About the seventh or eighth day the giddiness, pain, or heaviness of the head, become much greater, with a constant
frequently the forerunner of a delirium.

Now, cold sweats appear suddenly on the forehead and back of the hands, while the cheeks and palms glow with heat, and as suddenly go off. If the urine grows more pale and limpid, a delirium is certainly at hand, with universal tremors and subflexus tendinum; the delirium is generally little more than a confusion of thought and action, a continual muttering and faulting of speech. Sometimes they awake in a hurry and confusion, and presently recollect themselves, but forthwith fall into a muttering, then doze again.

At the flat, the tongue grows often dry, with a yellow lift on each side; and when the patient attempts to put it out, it trembles greatly. If at this time a copious spitting comes on, it is a very good sign. When there is a difficulty of swallowing or continual gulping, it is a dangerous symptom, especially with a hiccough.

On the ninth, tenth, or twelfth day, the patient often falls into profuse sweats, which at the extremities are commonly cold and clammy; and frequently there are thin floors, which are generally both colliquative and very weakening. A warm moifurine on the skin is reckoned falutary; and a gentle diarrhoea often carries off the delirium and sleepiness.

When the extremities grow cold, the nails livid, the pulse exceeding weak and quick, insomuch that it rather trembles and flutters than beats, or creeps surprizingly slow, with frequent intermissions; then nature sinks apace, the cordial and diaphoretic kind, in order to promote perspiration; by application of blifters, and by a proper regimen and method of diet. It will bear no other evacuations than moderate cordial diaphoretics, and blifters; unless a gentle emetic should be indicated in the beginning, or a small dose of rhubarb when it has continued long. Bleeding is very prejudicial, and much sweating hurtful. In giving diaphoretics, we should always have regard to the urine; for if that, from being pale, gradually heightens to an amber colour, we are right in our dose, especially if, when in bed, a gentle dew or moisture comes on without a rufllnsfnsf; and we must always remember, that over-sweating will raise the fever, and endanger the patient.

If the patient is inclined to deliquia or faintings on

If rest is wanted, give a few grains of the flores martiales; and if a loofenefs is not feared, the flores martiales may be more freely given.

A vomit ruffles nature much less than a common purge, and is necessary where a naufa, load, and ficknefs of the stomach, are urgent. If the body is cold, cliysters of milk, fugar, and falt, may be injected with safety and advantage every second or third day. The temperate cordial and diaphoretic medicines are certainly moft proper in these fevers; a supporting, well regulated, diluting diet is necessary, and will go a great way in the cure, especially if affifted by well timed blifters, and keeping the patient quiet in body and mind. Opiates are commonly very pernicious; mild diaphoretics, as pulv. contrayerv. compof. with a little caffer and faffron, and small quantities of theriac. androm. or elixir paregoricum, will have very much better effects. Where the confusion or defcription of spirits are considerable, galbanum or philum, with a little campfire, fould be added; and blifters fould be forthwith applied to the neck, occiput, and behind the ears: during all this, a free ufe of thin wine whey, fome pleafant ptisan, with a little foft wine, must be indulged. A little chicken-broth alfo is of fervice, both as food and phyfic, especially towards the decline of the disorder; and for the fame reafon, thin jellies of harthorn, fago, and panada, are useful, adding a little wine to them, with juice of Seville oranges or lemons.

It was faid above, that profufe sweats fhould never be encouraged; yet the patient is never fo eafy as while he is in a gentle, eafy sweat, for it foon removes the exacerbation of the heat, hurry, &c. when there are irregular partial heats, with great anxiety, ruflesnefs, delirium, difficulty of breathing, and a vast load and oppression on the præcordia, fo as to refeemble a peripneumonic cafe: yet beware of bleeding; for the small, low, quick, and unequal pulse utterly forbids it, as well as pale, waterly, limpid urine.

Here then the nervous cordial medicines are indicated, and blifters to the thighs, legs, and arms.

Take of the compound powder of contrayerva, 15 grains; of English faffron, 3 grains; a fecruple of the cardiac confection; and a fufficient quantity of fyrup of faffron to make a bolus.

When great tremors and subflexus tendinum come on, instead of the pulv. contrayerv. a fecruple of milk may be used.

This bolus fould be taken every fifth, fixth, or eighth hour, and a temperate cordial julep may be given now and then out of thin wine or cyder-whey, or, which in many cafes is better, out of thin muffard-whey.

But this difficulty of breathing, anxiety, and opprefion of the præcordia, often precede a military eruption on the feventh, ninth, or eleventh day, which fhould be promoted by soft, eafy cordials, proper diuents, sometimes with a little theriac. androm. or elixir afthma, as tending to calm the uneafines, and to promote a diaphorefis.

In profufe, colliquative sweats, give a little generous

R. 2 red
Towards the decline of the fever, when the sweats are copious and weakening, give small doses of the tincture of the bark, with saffron and snake-root, interposing now and then a dose of rhubarb, to carry off the putrid colic, which makes the intermissions or remissions more difficult and manifold.

When there is an evident intermission, give preparations of the bark out of draughts made with salt of wormwood and juice of lemon. This method will shorten these fevers, even with miliary eruptions.

Under any evacuations, diluting nourishment is absolutely necessary to keep up the spirits and repair the losses of the juices, and the patient should be frequently prompted to take them. When any discharges are very immoderate, they may be prudently restrained, but not rejected.

Gilchrist affirms, that to all the warming, attenuating, stimulating, or anti-pasmodic remedies, cinnamon should be added, and that in no small quantity. And he highly recommends the use of the bark in the decline of long nervous fevers, or after a remission. And when there is occasion for blistering, he thinks the head most preferable whenever it is much affected, though he does not disapprove the laying of blisters on the back and limbs.

When the low, depressing, nervous symptoms are stronger, the higher methods of stimulating are necessarily and easily borne; in raving, with a low, intermitting pulse, subsfultus, fainting, and coldness of the extremities, besides frequent blistering, we must give camphire and caltor. The use of Virginian snake-root, valerian, azailetida, myrrh, and terraceous absorbents, are well enough known, and the forms in which they are given. Refreshing juleps should not be taken by spoonfuls, but by draughts. Acidic cataplasmis may be laid to the feet till they begin to stimulate or raise a jiff degree of heat: then apply poultices of bread, milk, and vinegar, especially during the exacerbation, to allay the heat and fluridge; renewing them alternately, in order to keep up a gentle heat and fluimus. A quick, hard, and more contracted pulse, with smart heat, toiling and anxiety, shew it is over-done.

Of Epidemic, Catarhal, Eruptive Fears.

These fevers are continual, but not violent: they are attended with a profusion of strength, watching, loss of appetite, and are sometimes joined with an eruption of spots on the skin, arising from the plenty and intense diffusion of an excrementitious ferment, not without contagion and danger of life.

These fevers were called by the ancients, continual, quotidian, furous fevers; and by some of the moderns, malignant catarhal fevers, because they are mild at first, and attended with a running at the nofe, a catarh, an inflammation of the fauces from the stomach itself. If blood is taken away in these fevers, it is a sign of health: and this the more certain, if the contracted pulse enlarges, the hard grows soft and becomes more equal; if the patient is more cheerful, and his lying in bed more sedate, with a hardnees of hearing, and a turbid urine depositing a sediment. If this happens about the critical days, it is a certain sign of a happy event. After this the sleep, appetite, and strength, gradually return; and on other days except the critical. Those that die are carried off by a phrensy, or an inflammation of the meninges, or of the esophagus and fauces from the stomach itself. If blood is taken away in these fevers, it is either of a bright red, very fluid and serous, or too thick and blackish.

In the cure of this disease, the physician should take care not to disturb the salutary excretions, but proceed cautiously, and abstinence from strong medicines of every kind, watching and affhling the motions of nature as much as possible. The indications are, 1. To refrain and prevent...
M E D I C I N E.

vent the entire dissolution of the blood and humours. 2. To temperate and dilute the albuminous acrimony of the humours, and at the same time to keep the fluids fluid. 3. To promote gently the excretions by foot, urine, the skin, and spit.

To prevent the putrid dissolution of the humours, direct vinegar, the juices of oranges and lemons, and syrups of the same; spirit of vitriol, spirit of salt, spirit of nitre, especially those that are dulcified.

To abate the acrimony, absorbent, tinctures, and bezoardic powders will be proper. To dilute at the same time, you may order a decoction of barley with scorzonera and thavings of hartthorn; as also the syrup of orange juice, chicken broth, and the like.

To promote the cuticular excretions, give diaphoretic simple waters, aperient waters, with the tincture of valerian root, or black root. To all the excretions by foot, common domestic clysters will be useful; or those made of a decoction of barley, oil of sweet almonds, camomile flowers, elder flowers, syrup of violets, common salt, or nitre.

Or you may order the following laxative, which must be given with caution.

Take 2 ounces of manna, a dram of cream of tartar, 3 ounces of scorzonera water, half an ounce of syrup of violets, 3 drops of oil of juniper. Mix and make them into a draught.

To raise the spirits and restore the strength, a little wine will not be improper, with hartshorn jellies, China orange or Seville orange juice with sugar.

A congruous regimen in these febrile diseases is of very great consequence; for if the patient is kept too hot, the dissolution of the blood will be promoted, a coagulation will be induced, the anxiety will be increased, the impure and acid humours will be actuated, the strength will be exhausted, the sweating will be too speedy and profuse, and spots will appear on the skin. On the other hand, if cold is incausiously admitted, especially to the feet, perspiration will be checked, the eruptions and spots will be driven back: There will be griping pains, a loofeness, and the critical evacuations will be disturbed. All sudden changes from hot to cold, or cold to hot, are equally bad. A temperate regimen is best. However, care should be taken that the patient does not breathe his own atmosphere full of morbid exhalations, so very prejudicial to health; but the air should be drawn out of the room, and fresh admitted.

The perspiration should constantly be kept up, and the linen of any kind should not rashly be changed; nor should the patient be removed from one bed to another. He should be enjoined not to rise frequently. And if the bed cloaths are wet and must needs be changed, let them be well aired, and pretty much worn.

An erect posture of the head and body is to be shunned either in or out of bed, especially if the pulse is very weak and the strength little; as also when the disease is near the state.

The mind should be kept as cheerful as possible, and all occasions shunned of exciting anger, fear, terror, or pusillanimity in the patient. His hope of recovery should

be kept up as much as possible, instead of being terrified with the prediction of death.

It is an undoubted axiom, that all strong medicines are hurtful in this disease; such as emetics, purgatives, and diuretics; as also sudorifics of a too spirituous nature. But temperate and moderate things are very useful.

It must be remembered likewise, that these febrile diseases have certain times and periods, and exacerbations and remissions at certain times; which a physician should always carefully observe. In the febrile heat, and when the symptoms are most intense, humectants, diluents, and the absorbent nitrous powders abovementioned will be most proper, with a very moderate external regimen. When the pyrexym is ended, the skin lax, more soft, and disposed for excretions; then analeptics, medicines that stimulate; and if there is occasion, bezoardies, and things that promote perspiration; as also the infusion of veronica, scorodon, and liquorice, drank as tea, are likely to do the greatest service. And because a diarrhoea frequently carries off the disease, it is never to be fopt, especially about the critical times, neither with astringents, sedatives or opiates: But if nature tends to this excretion, and is too sluggish, she is to be assisted by the laxative draught above described, with the addition of tamarinds.

There is no evacuation so dangerous as bleeding at the nose; for then there is a conglutination of blood in the head from the spasms of the lower parts. However, if the flux of blood is moderate, and the body abounds with it, instead of being hurtful, it will relieve the head, though this seldom happens. When there are a few drops only without alleviation, they portend a delirium and an inflammation of the face: But when the flux is copious, the strength will diminish, and the eruptions return inwards not without danger. Therefore, to prevent a conflux of blood to the head, the feet must be always kept in a moderate heat and moisture; mild blisters should be laid to the calves of the legs, and the body should be opened with clysters or solutions of manna. These will also be serviceable when the hemorrhage is too large. But when it is too little, and the eyes look red and wild, with a strong pulsation of the temporal arteries, besides the former, it will be proper to apply cupping-glasses to the nape of the neck, or to thrust a straw up the nose, if possible, to cause it to bleed, or to use a scarifying instrument.

Bleeding in these febrile diseases must be used with great circumspection; for it is much more proper as a preservative than a cure. But when the disease has made its onset with great losses of strength, complicated with catarrhal disorders, and when putrid and malignant fevers are ripe, it must be always omitted. If the stomach has lately been surfeited with incongruous aliment, a grain or two of tartar emetic in a solution of manna will be necessary. Blisters will be of great use when a retrocession of the eruptions is apprehended, when the excretions are slow, and when there is a sleepiness and torpor; in which cases, they may be laid to the arms and calves of the legs.

Of the Malignant, Goal, and Spotted Fevers.

The true spotted fevers are very malignant, contagious, and detrimental to the head and strength, attended with spots of various colours, arising from a corruption of
of the vital fluids, and a putrid dissolution consequent thereupon.

These putrid fevers are deservedly called malignant, or poisonous, as they generally proceed from a most subtle, active, virulent vapour, or miasma, which is infectious. At first they often seem mild and gentle, and have the appearance of catarrhal fevers; but they soon exert their virulent effects in a most fatal manner.

At first the patient complains of great weakness and loss of strength, and is apt to faint away.

The head aches, and from the very beginning is hot, dull, attended with a dejection of mind. There is constant watchfulness; the appetite is lost; the pulse is languid, small, and unequal; there is an oppression of the breast, sometimes a dry cough, an undulatory and tremulous twitching of the muscular and tendinous fibres, with a subsultus tendinum. Many neither complain of heat, nor pain, nor anxiety, and affect that they feel nothing bad, but weakness and want of sleep. The urine is generally thin at first, and like that of sound people. On the fourth, or the seventh day, the spots appear principally on the back and loins, of various colours, generally without relief; wherefore they are rather symptomatic than critical.

Huxham says, these fevers attack with much more violence than the flow and nervous; the rigors, if any, are greater, the heats sharper and more lasting, yet at first sudden, transient, and remittent; the pulse more tenet or hard, but commonly quick and small, though sometimes flow and seemingly regular for a time, and then fluttering and unequal. The head-ach, giddines, nausea, and vomiting, are much more considerable, even from the very beginning. Sometimes a severe fixed pain is felt in one or both temples, or over one or both eye brows, frequently in the advance of the fever, though the pulse at the wrist may be small, nay, even low: This is a certain sign of an impending delirium.

The prostration of spirits, weakness, and faintness, are often surprizingly great and sudden; sometimes, when the pulse seems tolerably strong, the respiration is very laborious, and interrupted with a kind of sighing or foaming, and the breath is hot and offensive.

There is generally a sort of lumbago, or pain in the back and loins, a wearinefs, sorenefs, and pain in the limbs. Sometimes a great heat, load, and pain at the pit of the belly, with a perpetual vomiting of porridge or black bile, of a nauseous smell, with a troublesome hiccup.

The tongue at the beginning is white, but grows daily more dark and dry, or of a hissing; vivid colour, with a kind of bubble at the top; sometimes exceeding black for many days: At the height, it is generally dry, fliff, and black, and the speech scarcely intelligible.

The thirst, in the increase of the fever, is commonly very great, sometimes unquenchable; and all the drinks seem bitter and nauseous; at other times there is no thirst, though the mouth and tongue are exceedingly foul and dry; this is a dangerous symptom, and ends in a phrenzy or coma. The lips and teeth, near the palate, are furred with a very black tenacious fords.

At the onset of the fever, the urine is often crude, pale, and rapid; but grows to fo high a colour as to resemble a strong lixivium, or citron urine, tinged with a very small quantity of blood: it has no sediment, or cloud, for many days together; but by degrees grows darker, like dead strong beer, and smells offensive.

The ftoois, especially near the palate, or in the decline of the fever, are for the most part very offensive; green, livid, or black, frequently with severe gripes or blood. When they are more yellow or brown, the lefs is the danger: but the danger is greatest of all when they come away insensibly. If the belly be hard, swelled, and tenfe, it is a very bad symptom. A gentle diarrhoea is often very beneficial, by which nature carries off the morbific matter.

The more florid the spots are, the lefs is the danger; and it is a good sign, if the black or violet become of a brighter colour. The large, black, or livid spots, are almost always attended with profuse bleedings. The small dulcey, brown spots, like freckles, are almost as bad as the livid and black. Sometimes they are attended with profuoe, cold, clammy sweats; at which time the spots va-nish without any advantage.

The eruption of the spots is uncertain; sometimes they appear on the fourth or fifth day; sometimes not till the eleventh, or later. The vibices, or large livid or dark greenish marks, seldom appear till very near the fatal period. Sometimes about the eleventh or fourteenth day, when the sweats are profufe, the spots disappear, and vast quantities of small, white, military pustule break out. If there is an itching, smarting, red rash, it commonly greatly relieves the fick, as well as large, fretting, watery bladders on the back, breast, and shoulders. A scabby eruption about the lips and nofe is a falutary symptom; the more hot and angry the better. Brown dark aphthae are more uncertain and dangerous, as well as those exceeding white and thick like lard. They are followed with difficulty of swallowing, pain and ulceration of the fauces and oesophagus, with incessant hiccup; the whole prieme vie are at length affected, a bloody dysenterie comes on, and a mortification of the intestines.

Pringle observes, that in hospital, goal, or camp fevers, the first complaints are gentle horrors, and little feverish heats, alternately succeeding each other, with lofs of appetite; the disorder being greatest at night, the body is hot, the sleep interrupted and not refreshing. They have constantly some pain and confusion in the head, chiefly about their forehead; the pulse is at first but little quicker than the natural, and the drought, if any, is incon siderable. They are too ill to mind business, and too well to be confined. In this stage, a change of air, with a vomit and sweat, will perform a cure; yet a large bleeding at this time will sink the pulse, and bring on a delirium.

When the symptoms come on quick and violent, the fever seems to be inflammatory, and can only be distinguished by a knowledge of the circumstances; and bleeding yields no
no relief, but exasperates the complaints. The aforesaid symptoms are now more high, with great lassitude, nausea, and pains in the back, with pain and confusion in the head, and great dejection of spirits.

The pulse at this time is generally quick and full; now a moderate bleeding affects the pulse but little; if large, it will sink, and bring on a delirium. The worst kind of blood is when the craftamentum is dissolved, which is a sign of high putrefaction.

If the patients lie warm, the body is generally covered; if cold, there is a diaphora. If they have bilious fluids when they are warm, they are critical, and not to be checked unless immediate. In the worst kind of these fevers, in the last stage, a diaphora commonly carries the patient off; but then the fluids are involuntary, colliquative, ichorous, or blackish, and of a cadaverous smell, which are the effects of a mortification in the bowels. The heat of the body at first is not considerable; but if the pulse is felt for a while, there is an uncommon heat, which remains upon the fingers some minutes afterwards. A day or two before death, the extremities feel quite cold, and then the pulse is hardly to be distinguished. The skin is generally dry and parched; yet in the beginning there are often imperfect sweats, without any relief. A continued and generous sweat is the surest cure.

The tongue is generally dry, hard and black, with deep chaps; but towards the last it is soft and moist, and the colour is a mixture of green and yellow. The drought is sometimes great, at other times very little. Some preferve their senses through the course of the disease, except a confusion and slumber; but few keep them till death, if it prove favorable. They sleep seldom and seem to be penive and in deep thought. The face is not ghastly nor morbid, till towards the last. The confusion of the head often riles to a delirium, especially at night, but seldom changes to rage. A tremor is more common than a slumber or delirium, if the excrements come away insensibly, or if the urine is at the same time turbid, the fauces inflamed and beset with scabs, with difficult breathing and straitness of the breath remains and gains ground; or if a delirium increases after sweating, and a flux of the belly, the urine being at the same time turbid, and depositing no sediments; lastly, if the eyes are dim, the patient catching at straws; if there is a subsultus tendinum, if the excrements come away insensibly, or if there is a cold sweat with convulsions.

As to the prognostics, the spots are so far from being salutary, that the more plentiful they are the greater is the degree of the corruption: when they are livid, lead-coloured, and of a greenish black, they show a phlegmatic corruption. Those who escape are not freed by a cutaneous excretion, but by large sweats, breathing in a sinking acor or by critical fluxes of the belly; which happen by the benefit of nature, when the corruption of the fluids is not great. Many are apt to fall into a phlegmatic corruption of the stomach, intestines, and other viscerae, or into a phreny, or more frequently into an anginous inflammation of the fauces and oesophagus, as appears from the intolerable smell which happens after death. This unhappy event is prefaged, if there is no thirst, or one that is unequal; if the tongue is dry, chapt, black; if the fauces inflamed and beset with scabs, with difficult swallowing; if, after the eruption of the spots, a difficult breathing and straitness of the breath remains and gains ground; or if a delirium increases after sweating, and a flux of the belly, the urine being at the same time turbid, and depositing no sediments; lastly, if the eyes are dim, the patient catching at straws; if there is a subsultus tendinum, if the excrements come away insensibly, or if there is a cold sweat with convulsions.

Pringle observes, that those who are weakened by other distempers, or their cures, are more susceptible of the goal or hospital fevers than the strong and vigorous; and that one who is recovered is more subject to relapse, than he who is to be first attacked.

All the prognoptics, says he, taken singly, are uncertain. The following signs are good: to have no delirium; to have the pulse neither very low nor quick, or, if sunk, to have it rife by wine or cordials, with an agreement of the delirium; and to have the tongue moist, and of a natural colour. It seems peculiar to this fever, that deafness is generally a good sign. The natural and best crisis is by sweat, when the pulse rises, and the symptoms as well as the spots, do not appear till after death. This fever, on account of its exacerbations at night, may be looked upon as the lowest degree of the remitting kind.

The duration is uncertain, and in proportion to the virulence. Their course is generally from fourteen to twenty days: some have died or recovered after four weeks. When the course is long, it commonly terminates in abscesses of the parotid or axillary glands, sometimes in an hectic: Some, after this fever is over, fall into an irregular intermittent; many complain of a pain in their limbs, and want of rest; and almost all of great weakness, confusion in their heads, and noise in their ears. When the air is highly malignant, the disease terminates, in five or six days, either in death or a critical sweat.

The most peculiar symptoms of this disease, are always a singular attack upon the head, as a fuper, or pain; and if it lingers, a slow low voice, and sinking of the spirits, without any large evacuation; pale urine, petechial spots, the bad effects of large bleeding, or too many clysters; lastly, the disagreement of cooling medicines, excepting in the beginning; and on the other hand, the agreement with wine, volatiles, and other cordials, during the greatest part of the disease.
toms abate; next to that is an insensible perspiration, which is known by the softness of the skin, moisture of the tongue, and a remission of the other symptoms. Bilious fluids, with turbid urine, and a moist tongue, may be considered as signs of a favourable crisis. But the contrary of all these are bad; as also the fibrius tendini-um, inflamed eyes, and great anxiety. It is observed to be among the worst signs, when the patient complains of blindness, or when he cannot lie but on his back, and pulls up his knees; or if, when insensible, he endeavours to uncover his breast, or makes frequent attempts to get out of bed. If there are ichorous, cadaverous, and involuntary fluids, it is a sign of certain death.

The formal ratio of these pernicious fevers, consists in the putrid dilution or collection of the blood and vital fluids, especially of that highly elastic fine fluid which is contained in the blood, and separated in the brain and spinal marrow, by which it is distributed by the nerves to all the body, induced with sense and motion, for it greatly vitiates and desiles this liquid. However, such is the nature and power of that poisonous vapour, by which found bodies are infected, that it not only induces a putrid fermentation into the blood and other fluids, but acts immediately on the inward and nervous parts of the brain, which it corrupts, and produces a languor in the vital and animal powers, even while the state of the blood and humours remain free from corruption.

This virulent vapour enters the body by the nostrils, fauces, and bronchia; whence it immediately reaches the nerves in the brain, and renders the patient light-headed, with a dulness of the head, and a loss of strength, and a vertiginous affectation. It likewise mixes with the saliva, descends into the stomach, which is a nervous part, and there takes up its principal residence: whence the bad symptoms generally appear first in the stomach and praecordia, with a naufea and an inclination to vomit, as also a diarrhoea with gripes, or a colliquenes, with loathing of food, anxiety of the praecordia, and watery eruptions from the stomach.

Hence the reason evidently appears, why nothing is more proper to guard against this disease than turning away one's face from the patient, frequent spitting, chewing angelica, zedoary, or pimpernel, and smoking tobacco: hence likewise appears, why the force of this poison is exerted in the stomach, which is befit with copious crudities, and putrid and salivar fordes; and likewise why gentle emetics, joined to alexipharmics, commonly destroy the disease in the bud.

It may be induced by a bad state of the air: for a long moist, rainy, cloudy, and southerly state of the air, dulls and depresses the motions of the solids and fluids necessary for life: to this may be added a long and frequent inundation of water, which is apt to generate putrid diseases; as likewise the exhalations arising from purrid unburied bodies, or from the excrements of animals, especially if confined and shut up from the air.

In the regimen, it is necessary, if possible, to breathe a serene, temperately warm air. The room should not be heated too much, it being found to be hurtful. The patient should eat nothing solid in the decline of the disease, nor after it. A free use of food, of nourishing and comforting broths abounding with oleous particles is pernicious, especially about the critical days, in the state of the disease, or where there is any critical evacuation. Nothing is more hurtful than an erect situation. Alexipharmics, volatile farts, hot and spirituous bezardies, are hurtful, especially with a hot regimen: for they dilute the blood, and increase the number of spots; or cause head-aches, inflammations, or copious sweats.

Bleeding has been good in plethoric bodies, and in those who have been accustomed to hemorhages; on the contrary, if the patient is low or weak, bleeding is hurtful.

Gentle vomits are useful by way of prevention, and in the very beginning of the disease; but in the progress and state have had a bad effect. Blisters have been greatly praised in the state of the disease, when there has been a delirium, a sopor and convulsions, being applied to the neck.

We reject all opiates and soporiferous medicines, on account of the pulse and want of strength; because they retard the excretions, increase the malignity, and shorten death.

The medicines used are elder-flower water, that of limes, elms, roes, of the tops of scorzonia, scabious, and cardus benedictus; as also syrups of pomegranates, and the juice of roes; powders of mother of pearl, diaphoretic anthimony, crabs-eyes, amber, terra sigillata, burnt hartshorn, pure nitre. Alexipharmics are, camphire, essence and extract of scorzonia, vincetoxicum, the bezardie spirit and tincture, the essence or spirit of vitriol, and dulcified spirit of nitre: Moideners, the decoction of scorzonia, thavings and jelly of hartshorn: Analectics, orange-flower water, fresh oil of citrons, with sugar, confection of alkermes, and balsam of life: Antispasmodics, essence of caffor, eunabur, and succedent spirit of hartshorn.

In the beginning of the disease, use a bezardic powder of nitre, and a little camphire, often repeated in the progress and state of it, a mixture of temperate waters, diaphoretics, analectics, antispasmodics, and cordial bezardic powders, with a little juice of citrons. In the drink put nitre, or philosophic spirit of vitriol, or sulphurated chlaries of antimony, to keep the body open. Also give drink of the filtrated decoction of hartshorn, and root of scorzonia, either hot or cold. About the critical day give gentle alexipharmics, with things to promote sweat when nature seems to tend that way.

This is the best and surest method of cure. But if the vomiting is too great, with an anxiety of the praecordia, and profuse diarrhœa, accompanied with gripes, apply outwardly Venice treacle, expressed oil of nutmegs, camphire, oil of cloves, and balsam of Peru, mixt together, to the region of the stomach. If a diarrhoea exhausts the patient too much, give a nitrous bezardic powder, with a little camphire, and theriac caelestis. If the body is colitive, with gripes, prescribe lenient chyfiers, or such as are made entirely of oil. To raise the strength, allow spirituous things, such as comfort and are aromatic; but they must be externally applied to the pulses or pit of the stomach, or nostrils. To quench thirst, give an electuary of Molocovada sugar and dulcified spirit of nitre.
Nature many times strives in vain to discharge the irritative matter, by vomit, without the assistance of art; and therefore something to promote it will render it much easier; which may be done by an infusion or decoction of ipecacuanha, or oxymel scilliticum, with a light infusion of camomile flowers.

The prime vice should be unloaded by very gentle methods, such as clysters of milk, figar and salt; laxatives of manna, cream of tartar; Glauber’s purging salt, tamarinds, and rhubarb.

When there are signs of redundancy of the bile, it should be forthwith discharged by vomit or stool, as nature points out; which is often succeeded by an amazing change for the better, where an inexpressible anxiety, load on the precordia, perpetual sickness, eructation, and faintness, had preceded.

Between the seventh and fourteenth day, nature endeavours to relieve herself by vomit, or more frequently by loose stools; then given a gentle laxative the eighth and ninth day, unless some eruption appear, or a kindly sweat forbid it.

But the constant and grand effort of nature, is to throw off the putrid malignancy through the pores of the skin. If it be a breathing sweat at the state of the disease, and the pulse grows more open, soft, and calm, a little before and during its continuance, it is always salutary; but if it be profuse, cold, clammy, or partial, about the head and breast only, the sign is not good. Profuse sweats in the beginning are generally pernicious, especially if a rigor supervenes.

Sweats should never be forced by violent hot medicines, regimen, &c. Plentiful subacid diluents will be sufficient, and gentle cordial diaphoretics.

As acids and subarisingents are given to preserve the virtues of the blood and tone of the vessels, and to prevent the farther putrefaction of the humours, diaphoretics, especially camphire, should be joined with them.

Dr Brookes used the following prescription of the bark for many years with success, not only in intermittent and slow nervous fevers, but also in the putrid, pestilential and petechial, in the decline, though the remissions have been very obscure; but if the patient is colicive, or hath a tense or tumid abdomen, he permitted a dose of rhubarb, manna, or the like.

Take two ounces of Peruvian bark in powder, an ounce and a half of orange-skin, 3 drams of Virginia snake-root, 4 scruples of English saffron, 2 scruples of cochineal, and 20 ounces of spirit of wine. Mix and infuse the ingredients in a close vessel for three or four days, and then filtrate the infusion.

Of this give from a dram to half an ounce every fourth, sixth, or eighth hour, with ten, fifteen, or twenty drops of elixir of vitriol, out of any appropriated draught, or diluted wine. The above composition tends to strengthen the solids, to prevent the farther diffusion and corruption of the blood, and in the event to restore its crafts.

With this view also give a generous red wine, as a most noble, natural, subarisingent cordial, which is of high service in the flate, but more especially in the decline of these fevers, acidulated with the juice of Seville oranges or lemons, as also with cinnamon, the rind of Seville oranges, and the like, to which a few drops of elixir of vitriol may be added. Rheum and French white wines, when diluted, are also a most salutary drink, and generous cyder is little inferior to either.

Of the Pestilential Fever.

A pestilential fever is a most acute one, arising from a poisonous miaisma, brought from eastern countries; and unless it is immediately expelled out of the body, by the strength of the vital motions, by buboes and carbuncles, it is fatal.

It differs from other contagious, malignant, and eruptive fevers, because it is the most acute; for it sometimes kills on the first, and sometimes on the second day. Besides, in our climate it is not epidemic or sporadic, from a bad way of living, or unhealthful air; but happens when it is most salutary, from contagion alone. There is something very singular in this infectious miaisma; for though it is apt to spread at a strange rate, yet it will abate by intense cold, and be plainly extinguished: whereas in a cold season, and very cold countries, it either does not appear at all, or in a very mild degree; whereas if the climate is hot, it is not only most vehement, but most common.

In this, as in all other contagious diseases, the venous miaisma is swallowed in with the air, and infinuates itself in the salivale juice, where its tragedy is first acted. Whence it assails the head, brain, nerves, and animal spirits, producing a torpor in the head, a heaviness, a sleepiness, a violent pain, a flutter of the senes, a forgetfulness, inquietude, watching, and loss of strength. From the sauces it proceeds to the stomach, creating loathing of food, nausea, anxiety of the precordia, a cardialgia, attended with fasting, reaching to vomit, and vomiting itself. Hence it proceeds to the membranes of the spinal marrow, and the coats of the arteries, producing horrors, a languid, small, contracted, quick pulse, and even fainting. All these are generally signs and symptoms of the plague; which are of a more violent and quick operation, in proportion to the virulence of the pestilential miaisma.

All plagues are not of the same nature, but vary according to different constitutions and circumstances. Those who have written of the plague universally agree, that spungy and porous bodies of an obese habit, of sanguine and phlegmatico-sanguine constitutions; women, young persons, and children; persons of a timid disposition, that are poor, live hard, or are given to luxury, and fit and gentle cordial diaphoretics.
among the soldiers, they are called camp-fevers; in Hungary, an Hungarian fever. But the plague, or pestilence, is known when buboes and carbuncles arise in various parts of the body. The sweating sickness had its rise in England, in which the patient fell into a violent sweat, of which many died in a day's time.

The pestilential poison disturbs all the functions of the body; for unless it be expelled to the external parts, it is certainly fatal. Nor is this to be done as in other fevers, by large sweats, by floods, by a flux of urine, by cutaneous evacuations of blood, or by bleeding at the nofe, either natural or artificial, for they rather hallow destruction. The fulfatory and critical excrétion which perfectly solves the pestilential disease, is by tumours in the surface of the body not otherwise than the erysipelas, between the third and fourth day; and the sooner the better, for then the symptoms are mitigated. The pestilential tumours are of two kinds; the firft arifes in glandulous places, most commonly in the groin and arm-pits, sometimes in the parotid and mammary glands, as also the lower maxillary, under the chin, and in those near the aspera arteria. It is a hard, painful, teneive swelling of the glands, with great heat; and if they are fulitarian, being swollen, they grow soft, and suppurate. The other fort is the anthrax or carbuncle. Celsius describes it in this manner. It is a swelling on which there are pustules, which rise but little; they are black, sometimes sublivid or pale. In this there seems to be a fainess, it is black underneath. The body itself is more dry and harder than usual. There is as it were a crust about it, furounded with an inflammation; nor can the skin be raised up in the part, but is joined to the flesh underneath. Mindererus, who was precent at the plague, fays, that a carbuncle is of the size of a grain of mustard feed; and about its edge, there is a circle, or pufidard feed; and about its edge, there is a circle, or whitifh purple colour, or fometimes black. When the pufidules are prefsed, they feem to be full of pus; under which there is an ah-coloured crust, which being taken away, the flesh appears corrupted and flponge, with intolerable pain and burning of the circumjacent flesh, which is followed by a mortification of the part.

When the plague is fatal, some die of a fainting the firft or second day. But in many, when the poison is not expelled, or, if expelled, returns back, it brings on a mortification of the nervous coats of the noble parts, of the pleura, oesophagus, flomach and intestines, or the menings of the brain; which creeps speedily to all the vifcera, and the blood itself; whence the carcasses fwell, and have a moft intolerable fench. Sometimes, when the pestilential tumours are too plentiful, they die of a symptomatic fever, from the inflammation, pain, and intolerable heat.

It has been before remarked, that the plague is not a native of our country, but is brought from remote pla-
boiled, repeating them pretty often for twenty-four hours; in the mean while, the spirits of the patient are to be kept up with comforting broths. The by-flanders should forbear to wipe off the sweat, nor should the patient change his linen all that time, which is a necessary caution; if it be stopped before that time, it will be to no manner of purpose; during the sweat, the diarrhoea, if any, and the vomiting, will stop of their own accord.

Theriaca, and the like solid medicines, being offensive to the stomack, are not the most proper sudorifics. An infusion of Virginia snake-root, in boiling water, or, for want of this, of some other warm aromatic, with the addition of about a fourth part of aqua theriacalis, is safer.

Those who are obliged to be near the sick, must take care that the misfumata do not approach their vital juices, nor yet the saliva. To this purpose, frequent spitting, and washing the mouth with vinegar, or wine, or sniffing them up the nose, are useful. The efficacy will be still greater, if they are imbued with rue or citron rind. For an acid is the genuine antidote of a putrid and sulphurous misfma. Wherefore it is much safer to hold acids in the mouth, than alexipharmic roots. It will be like-\(\text{wise proper to get a few spoonfuls of Rhenish wine, or}\) bezoardic vinegar, diluted with water or wine, and so take them. The Turks deal much in the juice of lemons.

When the plague is actually begun, and the body is coltive, a gentleclyster should be used. Then a sweat should be promoted (twenty-four hours at least,) that the poison may exhale and pass through the skin; and epimathes to the heart will not be without benefit, though they reach only to the right orifice of the stomack, and its nervous coats; they may be made of theriac, expressed oil of nutmegs, camphire, saffron, caltior, and balsam of Peru. But above all, acids are highly praised; such as, juice of citrons, Seville oranges, lemons, vinegar, &c. which repel poison, purtexfaction, and prevent the dissolution of the blood.

When the strength of the disease is vanquished, gentle laxatives will be proper to expel the fordes during the course of this disease.

It is worthy observation, that few medicines are best; for which reason people of the lower clafs generally come off better than perfons of disting. and there is nothing worere than to give alexipharmics abounding with a hot volatile oil; much less ought volatile spirits to be given, for they fix the poison upon the nervous parts. Yet herbs and roots of this kind are not altogether to be condemned, if mixed with acids and nitre. A mixture of cardus benedictus water, and wine vinegar, when given to four spoonfuls, with a dram of crabs-eyes and theriaca, and repeated, were very useful in the plague at Hall in 1682. In the plague likewise in Lombardy, 1526, many re cured with the juice of goats-riue, vinegar, water of cardus benedictus, and a little theriac, given to make the patient sweat: and Thoper observes, that nothing was of any advantage in the plague except theriacal vine gar given in the beginning to promote a sweat. And in the year 1544, when a malignant fever raged among the foldiers, a whole regiment was saved, to whom this vinegar was given in due time, except a very few. And in the plague at Rome, vinegar with rue, pimpernal roots betony, garlic, and juniper-berries, with a little camp phire added to the infusion, caused many to escape. Likewise the preservative water of Sylvius has been greatly esteemed, because of the vinegar. And Mindererus afferts, that unlefs alexiterials be given within twenty-four hours, all medicines are vain.

Of the Miliary Fever.

A miliary fever is not unlike a cattarrhal, and is attended with a more intense motion of the vascular and nervous system, whereby a corrupt lymphatic matter of a peculiar nature is expelled from the inward, and more especially the nervous parts, to the surface of the skin, in the form of small, rough, miliary pustules, sometimes red, and sometimes white.

These small pustules are exceeding numerous, causing a corrugation, roughness, and dryness of the skin, and have a fetid smell peculiar to themselves. There is no eruption so inconstant as this, for it will sometimes strike in suddenly, and as suddenly appear again, and is attended with an itching pricking sensaion more than any other kind. Other eruptions are common to all countries, and are equally vexatious to men as well as women; but the miliary feems familiar and endemic to some places only, and more frequently attacks the female sex, especi ally in child-bed. It is neither epidemic nor contagious; and feems rather owing to a fault in the vicera and fluids, than the intemperature of the air.

The miliary eruptions are either red or white, and are both more or lefs acute, benign or malignant. The red are lefs dangerous, are generally free from a fever, and then are miliary, appearing at flated feasons of the year; but sometimes they are accompanied with an acute fever. The white seldom or never appear without a fever, and therefore are more dangerous. In these the lymph is affected with a kind of acidity; for the patient discharges plenty of serum by sweat, urine, foal or fali vation, which are the effects of an acid which coagulates the thicker part of the blood, and separates the serum from it. Besides, all kinds of acids and refrigerants, not excepting nitre, freely taken, are moss hurtful in this dis ease. On the contrary, absorbents and anti-acids, and things which render the blood spiritious, are moss fel autive. Women who eat much fruit, and such like trash, of the acceftent kind, and live idle fedentary lives, are moss subjeft to this disease.

Sometimes the miliary eruptions are idiopathic, and sometimes symptomatic, and suprervene to other fevers, especially the continual, when on the decline. They likewise appear very commonly with the measles, small-pox, putrid and spotted fevers, when drawing towards an end; and then they raise a new fever, whole attack the debilitated patient is not able to stand.

The idiopathic begins with a flight shivering, succeed ed with heat and loss of strength, sometimes even to fainting. There is a freartness about the breath, attended with anxiety and deep sighs. Rellifenehs and watching. There is a pricking kind of a heat perceived in the back, with an alternate succession of cold, shivering, and heat under the skin, but moss sensiible in the palms of the hands.
hands. Women in child bed have the flux of the lochia flopped, and the milk recedes from their breasts. To these succeds a roughness of the skin like that of a goose; and a great number of pustules appear, sometimes white and sometimes red, or both together, of the size of millet (or mustard) feed. They first befet the neck, then the breast and back, and afterwards the arms and hands. When these begin to rise on the surface of the skin, the more grievous symptoms cease. The pule, which before was hard, contracted and quick, grows more soft, free, and slow; the dejection of mind goes off, the skin becomes moist, and the belly, which was bound so much that the patient could not break wind, now spontaneously admits him to go to stool. Afterwards the pustules ripen, and are full of a flinking ichor. The urine appears more saturated, and a singular fetid sweat, proper to this disease, breaks forth; the flux of the lochia in females returns, and within the space of seven or eight days the pustules disappear, with great itching in the extreme parts, drying up and falling off in scales. Then the patient recovers strength, and regains health.

It is hard to determine the day of the eruption of the pustules; but it is generally the tenth or eleventh day from the beginning, if the fever makes a regular progress; sometimes on the eighteenth, and sometimes on the twenty-sixth, or twenty-second day.

Bad signs are, when the miliary pustules appear and vanish by turns, and the symptoms continue violent; but it is worse if they quite disappear: Hence an oppression of the breast, with fighs, a fainting fit, arising from a mortification of the digestive organs, in the stomach, intestines, brain, or womb.

Fatal signs are, when the morbid matter not being thrown out again, there is an inward heat and the extreme parts are affected with cold and thivering, and there is a cold profuse sweat; or, on the contrary, when the extreme parts are hot, and a notable sense of coldness is perceived in the abdomen, then the patient dies in a fainting fit, arising from a mortification of the stomach, intestines, brain, or womb.

The cure of this fever depends on the following things. 1. To correct and temperate the acrid morbidic matter which disturbs the nervous parts. 2. To relax the spastic fibrillae of the nervous fibres proceeding from thence. 3. To evacuate the prepared morbidic matter through the pores of the skin, and prevent its striking in. To dilute the spiciness of the humours, and to appease the irritation of the nervous parts, the following decoction may serve for common drink.

Take shavings of hartshorn, scorzonera root, and farfaparilla, of each two ounces; and boil them in 6 pounds of water.

Let the patient be always kept in an equal moderate heat, and abstain from strong aperitives, and things actually hot, because they throw him into too profuse a sweat. But when there is an apprehension of the pustules striking in, then the decoction may be drank hot, with moderate aperitives, as the exigence requires. Nor should the medicines be too cooling, because they increase the anxiety and faintness. In the red hot, when there is an internal heat, with thirst and great pule, diaphoretics with a little nitre will be proper; even though red and white pustules appear together. But nitre alone should be used with caution, especially when there are signs of malignity. No malt liquor should be drank, but the former decoction.

The belly should be neither too much bound nor too open; yet even the gentle laxatives are not to be given till the pustules begin to dry; and then there is nothing else required but an emollient clyster.

Bleeding should be very cautiously used; for when the weakness is excessive, the sweats profuse, and the pulse quick, it must be omitted. On the contrary, it is necessary for childbed women, when the lochia are suppressed, and the symptoms of a miliary fever begin to appear; but then it must be done speedily, and the great anxiety, fainting, and difficulty of breathing will cease, and the pustules break out.

Blister on the back are very proper for this disease; for they help to draw off the impure mercurial humours, and dilate the fatigued nervous fibres to a contraction, so as to expel the morbidic matter.

Of the Scarlet Fever.

The scarlet fever may happen at any season of the year, but it appears most commonly towards autumn. It reigns chiefly among children. It begins with coldness and thivering, as in other fevers, without any violent sickness. Afterwards the skin is covered with red spots, which are larger, more florid, and not so uniform as the measeles. The redness remains two or three days, and then disappears; then the cuticle falls off, and leaves behind it a fort of mealy scales, scattered over the body, which appear and disappear two or three times.

Let the patient abstain from flesh, all hot cordials, and spirituous liquors; let him not go out of doors, nor be confined constantly to his bed; and then medicines will be of little use.

Apply a blistering plaster to the neck, and every night give a paregoric of diacodium; and after the fever ceases, let the patient be purged with a very gentle cathartic, agreeable to the age and constitution.

Of the Measles.

The measeles are an eruptive catarrhal fever, generally epidemic, which by the increased vital motion of the heart and arteries throws on the skin an acrid, caustic, inflammatory matter, in the form of red spots. They begin with chills and thivering, and heat and cold succeed by turns. The next day the fever comes on with great sickness, thirst, and loss of appetite: the tongue is white, but not dry. There is a little cough, a heaviness of the head and eyes, and a continual sleepiness. There is a sneezing and a swelling of the eye-lids, a serous humour oft diffils from the nose and eyes, which are certain signs the eruption is at hand. In the face the spots are small; but on the breast broad and red, not rising above the surface of the skin. The patient often has a looseness, with greenish fots.

These symptoms continue and increase till the fourth, sometimes the fifth day; at which time spots like fleabites appear, increasing in number and magnitude, and in some places run together, rendering the face variously spotted.
MEDICINE.

The small-pox is commonly divided into two kinds; the distint and confluent.

The distinct fort begins with chilines and shivering, intense heat, a violent pain of the head and back, an inclination to vomit: in adults, a great propensity to sweat; a pain at the pit of the stomach, if it be pressed with the hand; a dulness and chrowniness, and sometimes epileptic fits, especially in children; and if the breeding of teeth is over, it is a sign the small-pox is at hand; for if the fit happens over night, the small-pox will appear in the morning, and are, generally speaking, of the favourable fort.

On the fourth day from the beginning they break out, sometimes later, seldom before, at which time the symptoms either abate or wholly disappear.

The spots at first are reddish, and spread themselves over the face, neck, breast, and the whole body. Then there is a pain in the fauces, which increases as the pustules grow turgid.

On the eighth day the spaces between the pustules, which hitherto were white, begin to grow red and swell, and to be afflicted with a tensive pain. The eye lids are puffed up, and close the eyes; next to the face, the hands begin to swell, and the fingers are dilated; the pustules of the face, before smooth and red, begin to be rough, (the first sign of maturation,) and whitish, and throw out a yellowish matter, in colour like a honey-cob.
The inflammation of the face and hands being now at its height, the interstices between the pustules are of the colour of damask roses; and the more mild the disease is, the greater is the likeness.

The pustules about the face, as they ripen, grow more rough and yellow. But on the hands and the other parts of the body, they grow whiter and less rough.

On the eleventh day the swelling of the face and inflammation disappear; and the pustules being ripe, and of the size of a large pea, grow dry, and fall off.

On the fourteenth or fifteenth day they vanish entirely; except some obstinate pustules on the hands, which continue a day or two longer, and then break. The rest come off in branny scales, and in the face leave pits behind them.

Through the whole course of this disease the patient's body is either wholly bound, or he goes to stool but very seldom. Generally those who die of the small-pox die on the eighth day in the distemper, and on the eleventh in the confluent fort. Then the face, which ought to be turgid, and the interstices florid, on the contrary is flaccid, and whitish, at the same time that the pustules are red and elevated, even after the death of the patient. The sweat, which was injudiciously promoted by cordials and a hot regimen, suddenly ceases; in the mean time the patient is seized with a phrensy, a violent anxiety, a trembling and sickness; he makes water often and little, and a few hours close the tragical scene.

In the confluent fort there are the same symptoms, but much more violent. The fever, anxiety, sickness, vomiting, &c. more cruelly torment the patient; yet he does not so soon fall into a sweat, as in the distinct kind. A looseness sometimes precedes the eruption, and continues a day or two after it.

On the third day, sometimes before, seldom later, the spots appear; and the sooner, the more will they run together. Sometimes the eruption is retarded till the fourth or fifth day, by some terrible symptom; such as, a most acute pain in the loins, like a fit of the gravel; in the side, like a pleurisy; in the joints, like the rheumatism; in the stomach, with a sickness and vomiting.

But the symptoms do not remit after the eruption, as in the distinct fort; but the fever and other complaints continue to molest the patient many days after. Sometimes the spots appear like an erysipelas, sometimes like the measles, but are distinguished from them by the time of the eruption. As the disease increases, they do not rise to any considerable height, being intercepted with each other in the face; but appear like a red blister, and cover all the countenance, which swells sooner than in the distinct kind. Afterwards they seem not unlike a white pellece glued to the face, and are not much higher than its surface.

The eighth day being past, the white pellicle grows daily more rough, and of a dusky colour. The pain of the skin becomes more intense, and at last, in the more cruel kind of this disease, they do not fall off in broad large scales, till after the twentieth day. But this in the mean time is worthy of observation, that the more the ripening pustules are of a brownish colour, they are the worse, and the longer in falling off; and the more yellow they are, the less they run together, and the sooner they disappear.

When the pellicle falls off, there is no roughness on the face, but branny scales soon appear in its room, of a very corrosive nature, which leave deep pits behind them, and sometimes ugly scars; sometimes the shoulders and back are quite deprived of their cuticle.

The danger of the disease is to be estimated from the number and multitude of the pustules on the face alone. The pustules of the hands and feet are the greatest, and the farther they are removed from the extremities, the less they are; in adults a salivation, and in children a diarrhoea, is a sign, though not always, of the confluent fort. The spitting sometimes begins with the eruption, sometimes two or three days after it; the matter is at first thin, but on the eleventh day it is viscid, and hawked up with difficulty; the patient is thirsty and hoarse, extremely sleepy, and his senses exceeding dull: he sometimes coughs when he is drinking, and the liquor regurgitates through his nostrils: then the salivation generally ceases, but the swelling of the face ought not to go down quite till a day or two after, when the spitting is over; if the hands do not begin to swell remarkably, and continue so for some time, the patient will suddenly leave the world.

The diarrhoea does not so soon attack children as the salivation does men. In both forts of this disease the fever predominates from the first onfet till the eruption; then it abates till the pustules are ripe, at which time it terminates.

The day on which the patient is most in danger, in the least crude and most common fort of the confluent, is the eleventh from the first attack of the disease; in the more crude, the fourteenth; and in the most crude, the seventeenth: sometimes, but very seldom, the patient does not die till the twenty-first. But in the space of time from the eleventh to the seventeenth, as the evening comes on, the patient is daily tormented with a fit of inquietude.

In the management of the patient in the distinct fort, regard should be had to the season of the year, and the strength of the patient. Let this be a general rule, to keep the patient in bed during the first days of the distemper, taking care to defend him from the inclemency of the winter by proper means; and to moderate the excessive heat in summer by cool air. For the patient ought not to be dressed by heat and cloaths, nor should the eruption and perspiration be checked by cold. However, great care ought to be taken in general to supply him with pure and cool air; because a hot air causes difficulty of breathing, checks the secretion of urine, and increases the number of pustules on the internal organs of the body.

With regard to Diet, it ought to be very slender, moistening, and cooling; such as oatmeal or barley-greuel; and in the beginning, the best regimen is that which keeps the body open, and promotes urine. This end is obtained by boiling preferred fruits with their food, such as figs, Damascene plums, and tamarinds; and by giving them subacid liquors for drink; as small-beer acidulated with orange or lemon juice; whey turned with apples, boiled
boiled in milk; emollients made with barley-water and
almonds; Moselle, or Rhenish wine plentifully diluted with
water; or any other things of this kind.

In the cure, Sydenham directs bleeding on any of the
three first days to nine or ten ounces; and then an
ounce, or an ounce and a half of emetic wine. But some
physicians will not allow a vomit by any means, unless
there is a nausea, and the head is much affected. Yet
Hoffman judges it to be proper on the first day of the
invasion, and prescribes two grains of emetic tartar disso-
vled in cinnamon water, to adults.

In youths and adults, it is often necessary to take away
blood two or three times, only with an intermission of
two or three days between each time. Blood-letting is
so far from being an obstacle to the eruption of the pu-
stules, if the patient is not too weak, that it forwards it
considerably.

After Bleeding, a vomit should be given, if the stom-
ach abounds with phlegm or bile, or be loaded with
food unfeasonably taken. Otherwise a purge may be
prescribed before the eruption of the pustules: which
may be the infusion of fena with manna, or manna alone,
evenly for children; for no disturbances to be raised
in the body.

To keep the inflammation of the blood within due
bounds, and to assist the expulsion of the morbid matter
through the skin,

Take half an ounce of bezoar in powder, 2 drams of
purified nitre. Mix, and beat into a powder.

Half a dram of this may be taken by an adult three or
four times in a day; diminishing the quantity for chil-
dren in proportion to their age.

Sometimes equal parts of these ingredients may be pre-
scribed; and if the evidence of the fever runs very
high, a proper quantity of the spirit of vitriol may be
added to the patient's drink. But if there be any reach-
ings to vomit, they will be removed by draughts con-
taining half an ounce of the juice of lemons, with one
scirpule of the salt of wormwood.

When the eruption of the pustules is compleated, which
generally happens on the sixth day from the attack, let the
patient take an ounce of diacodium every evening till the
tenth day after the invasion. On that night, if the small-
pox be of the confluent kind, the dose must be increa-
sed to an ounce and a half; and an ounce in the morning;
and so an ounce and half every night till the patient is
recovered.

Whatever are the fort, and at whatever time of the
disease a phrensly shall happen, it is to be curbed by pa-
egorics, given one after another till the end is obtained,
only waiting to see the effect of one dose before another
is ordered.

In the mean time, if the patient is colitive, which is
generally the case, and the fever continues, the body
is to be opened with a clyster every second or third day.

If the method is proper in the different small-pox, it will
be found more necessary in the confluent, which is attend-
ed with greater feard and danger.

In every fort of this disease, it is proper to open the
body on the decline, that is, on the ninth or tenth day
from the eruption, because a putrid fever generally comes
on about that time, while the pustules are drying, or up-
on the subsidence of the swelling of the inflamed skin,
where there is no suppuration, which fever cannot be ta-
klen off with equal safety by any other means; but gentle
cathartics alone are to be employed in this case, such as
were directed before the eruption of the pustules.

It will also be of use at this time to take away some
blood, if the heat be too great, and the patient have
strength to bear it.

This putrid fever is by Sydenham called the secondary
fever, which comes on with heat, inquietude, toffing,
&c. and, unless prevented, takes off the patient in two or
three days. He mentions this fever as coming on the
eleventh day, or later; but this is to be understood from
the time of the invasion, whereas Mead reckons from the
time of the eruption. Sydenham prescribes large bleed-
ing, and a cathartic two days after, viz. one ounce of
lentive elecutary dissolved in 4 ounces of simple alexer-
tial water, together with the free use of paregorics.

If the spittle through heat is so tough that it cannot be
hawkèd up, let a gargle be frequently injected into the
throat with a yringe. It may be compounded of barley-
water and honey of roses.

When the matter of salivation grows very vifcid, and
begins to clog the larynx and trachea, the bell me-
thod is to boil marf mallows, myrhh, and honey, in a
sufficient quantity of water and vinegar, and to tranmit
the team of the decoction into the patient's mouth, thro'
a glafs or tin tube, of fuch a shape and length as is most
commidious for a recumbent posture.

From the eighth day to the end of the disease, gar-
llick may be applied to the soles of the feet; which must
be renewed every day, especially when the brain is af-
feated.

When the pustules are perfectly dry and withered, the
face may be anointed with a liniment, made of equal parts
of oil of sweet almonds and pomatum, for two days and
no longer.

Twenty one days after the invasion, let a vein be op-
ened in the arm, and the next day give a cathartic,
which may be repeated every other day three times more.

This is necessary, because no species of fever requires
the body to be thoroughly cleared of the remains of the
disease more than this. After the cathartics, the body
is to be restored to its former state by a course of milk,
especially that of affes, with suitable food, and the air
and amufements of the country.

As there are particular accidents in the small-pox which
do not commonly occur, it will be proper to lay some-
ting of them. Sometimes the patient is feized with con-
vulsions jult before the eruption, which is rather a good
than a bad sign in children. In this case, blood-letting is
carefully to be avoided; but a blister is to be applied to
the neck, and to the soles of the feet. Pluifters made
of equal parts of the cephalic and blistering plasters; not
forgetting to give antispafmodic medicines inwardly.
The chief are wild Valerian root, Russian caftar, and the
spirits of volatile salts chemically extracted from animals.

In adults, the thing is otherwife; for they, if not too
weak, may lose a moderate quantity of blood, and then
be put into the foregoing method.
Haller tells us, that camphire afflicts greatly in filling
the small pox of the confluent kind with petechiae; and
Monro, that the Peruvian-bark does the same, that it
filled the empty vesicles with matter, changed the watery
fancies into thick white pus, made the petechiae or spots
turn gradually to a pale colour, and caufed the pox to
blacken sooner than was expected. The dose in powder,
is from ten to twenty grains, in some rich syrup, with
an aromatic diluted water, every four or five hours.
Children may take it in a Clyfter, with a small quantity of
warm milk, after the bowels are unloaded with a prepara-
ory Clyfter. If the Clyfter was retained too short a time,
Syrop of poppies was added, or diafcorid. These injec-
tions were repeated morning or evening or oftner. The
bark has had good effects in mitigating the secondary fever.
When the lungs are greatly diffused, it is not to be given.
When the eruption appears without much fear or pain,
it is not without danger; for the pufules frequently do
not tend to maturity, and there is no fuppuration made.
Hence the fever increafes, with inquietude of body, anxie-
ty of mind, difficulty of breathing, and a delirium, which
carry off the patient in a few days. In this fat, the
fever ought rather to be raised than checked; and then
warm medicines are to be directed which promote fuppua-
ration, by increafing the motion of the blood, and thinning
the humours, fuch as Virginia flake-root, contrarvav-
root, faffron, alia ictida, myrrh, and the like.

But above all, Blisters must be laid on the limbs.
When the matter of the infection is over abundant, as
it happens in bad cafes, nature never fails endeavouring to
throw off the load. Thus in adults a fptting comes on
upon the firft days of the eruption; whereas children have
loofenefs almoft through the whole difeafe, which is
not to be inconsiderably flopped. So in adults, if the
fptting does not go on to our wifhes, it ought to be pro-
moted by medicines which incite. The glands of the
mouth, efpecially gargles made of a decoction of mustard-
feed and pepper, with the addition of oxyymel. For in
the confluent and malignant small-pox, if this flux does
not arife and continue to the end of the difeafe, it is a very
bad sign.
The method of abating the rigour of this difeafe, and
preventing the great mortality with which it was often
attended, by incufation, is now fo well known and fo
generally practifed, that a particular detail of it in this
place is unnecelfary.

Of the Eryfipelas, or St Anthony’s Fire.

An Eryfipelas is an eruptive fever, from which no
part of the body is exempt; but it chiefly attacks the face.
It begins with chills and shivering, and other com-
mon symptoms of a fever. The part affected fwell a
little, with great pain, and infente rednefs, and is befet
with a vast number of little pufules; which when the
inflammation is increafed, are converted into small bliflers.
This difeafe has great affinity with a phæntial fever;
for it begins suddenly, with great flaking, heat, lobs of
strength, violent pain in the back and head; to which
may be added vomiting, and a delirium; but this is to
be underflood of the worst fort. On the third or fourth
day the malignant matter is thrown out on the surface of
the body, and then the fymphs a little abate. There
is often a pain, rednefs, and tumour in the inguinal glands,
from whence matter of a hot fiery quality descends to
the feet. If the head is attacked, the parotid glands are
affected; if the breasts, the axillary. The mammary
and axillary glands are not seldom ulcerated, and affect
the joints with a virulent corruption. And likewife, as
in the plague, there is nothing more dangerous than the
return of the expelled matter back from the surface of
the body to the inward parts.
In some, espefially young perfons, the matter is not
fo virulent, nor the fever fo great; the glands remain
unaffected, and the eruption happens on the second day.
This is not at all dangerous.
An eryfipelas is either true, or fimple and fpurious,
which is likewife called fcorbutic. The fpurious only af-
fects the surface of the skin, and readily yields to proper
remedies. But the fpurious is more chronic, is harder to
cure, and often degenerates into malignant ulcers. Be-
sides, this difeafe is fometimes idiofopathic, or a primary
difeafe; and fometimes symptomatic, or asecondary
one. For inftance, in the anafarca, the afcites, the yel-
low and black jaundice, a symptomatic eryfipelas fomet-
times supervenes, and quickly kills the patient.
If it feizes the Foot, the parts contiguous will fìnn;
if it be attended with great pain, it will ascend to the legs,
and will not bear to be touched.
If it attacks the Face, it fwell and looks red, and
there are plenty of watery vesicles. The eyes are closed
up with the fwellling; there is a difficulty of breathing;
the fauces and noftils are very dry, often attended with a
numbnefs and drowfiness: hence an inflammation of the
brain is to be feared, or a mortal lethargy.
If it affects the Breasts, they fwell, and grow almost
as hard as a flone, with exquisite pain, and they are very
apt to fuppurate. There is a molt violent pain in the
axillary glands, in which an absces is often formed.
In children the umbilical region generally fuffers, with
a fatal event.
In a day or two the tumour fübides, the heat-and
pain ceafe, the rosy colour turns yellow, the cuticle
breaks and falls off in fcales, the danger is over. When
the eryfipelas is large, deep, and falls upon a part of ex-
quifite fenfe, the patient is not very fafe. But if the red
colour changes into black and blue, it will end in a mor-
tification. If the inflammation cannot be difcuffed, it
will fuppurate, and bring on fultulas and a gangrene.
When the patient is cacochymic, the leg will fometimes
fwell three times as big as the natural fize, and is cured
with great difficulty. Thofe who die of this difeafe, die
of breathing, fometimes a delirium, fonretimes with fleepi-
ness; and this in seven days time.
Let the patient’s diet be only water-gruel, or barley-
broth; with roasted apples. If he drinks any beer, let it
be very small; and let him keep out of bed fome hours in
a day.
Take away 9 or 10 ounces of blood, and the next
morning let the patient take the common purging poftion.
It is a confant rule among practitioners, in all acute
and eruptive fevers, to keep the body in a gentle diapho-
refis.
inflammation. The same method is to be observed in this disease.

If the patient is plethoric, addicted to spirituous liquors, and more especially if the disease attack the head, bleeding is necessary.

It will be safest to avoid external applications, unless a powder made of elder-flowers and liquorice sprinkled on the part; or lime water, mixed with a fourth part of spirit of wine and camphire, dipping a linen cloth in it several times doubled, and applying it hot to the part.

An infusion of escorbutum, elder-flowers, and fennel-seed, drank in the manner of tea, is useful to expel the morbid matter.

If the disease does not yield to the first bleeding, let it be repeated; if that will not do, let it be reiterated twice more; one day being interposed between.

On the days free from bleeding, prescribe a cylinder of milk and syrup of violets.

Some think purges not necessary in the beginning of this disease; but in an erysipelas of the head, when it affects the brain with a coma and a delirium, either the cafe is desperate, or cathartics will succeed. However, first apply blisters to the neck.

If, after all, the tumor remains, and begins to turn livid; if the pain is deep, and seems to reach the perioleum, and the part has a tendency to ulcerate; then it will be proper to promote a suppuration; at the same time endeavouring to stop the progress of the putrefaction. For this purpose the common plaster will be proper, with a sufficient quantity of camphire and astrin.

When there is a mortification coming on, give things inwardly that resist putrefaction, as nitre and a little camphire, or rather the Peruvian bark. Outwardly apply a mixture of lime-water, camphorated spirit of wine and vinegar with litharge; as also tincture of myrrh, or of myrrh and aloes made pretty hot, with a linen cloth doubled, and often repeated.

In the scorbutic erysipelas, which continues for some time, it will be proper to give gentle laxatives and purifiers of the blood, with diaphoretics. After the body has been opened for some days, give diuretics and diaphoretics alternately for a considerable time; and for common drink, order a temperate decoction of mucilaginous woods and roots with bitters; particularly fucus roots, dandelion-roots, and raisins.

Of the Synochus, or Continual Fever without remission.

This fever, by some called Synochus, by others a Continual Fever, is an acute sanguineous fever, because it is raised by a congestion of the blood, chiefly in the nervous-membranous parts; which, unless timely diffused by the benefit of nature and art, produces a fatal inflammation.

It begins, in some, with a mild sense of cold, and is soon attended with very grievous symptoms, continuing without remission till the critical time, with a great and full pulse. If the blood is forced to the head, for it always affects one part more than another, the face will swell, the eyes will be red and full of tears; there is a pain in the head, with a pulsation of the temporal arteries, a vertigo, a sleepiness, torpor, or a raving. When the blood rushes impetuously into the ventricles of the heart and pulmonary vessels, causing a distension therein; then the breathing will be thick and difficult, with a straitness of the breath, as also an anxiety and palpitation of the heart, attended with a loss of strength, and a depression of the mind. A slight inflammation of the cœphagus, with a spasmodic stricture of the glands of the fauces, will cause thirst, dryness and blackness of the tongue. If the inflammatory congestion happens in the stomach, it will create a nausea, a reaching to vomit, and sometimes a hiccup. If in the intestines, there will be inflations grievously exasperating the disease, together with a colic, or a severe colic, or an ejection of fetid excrements. If in the vessels proceeding from the mesenteric arteries and veins, there will be a fixed pain at the first vertebra of the loins; if in the membranes of the spinal marrow, the patient will tumble and toss and lie irregularly in bed, and will have a torpor and languor of the limbs, sometimes attended with convulsions.

But all these symptoms never happen to all, nor is their violence constantly alike. Some distinguish this fever into the simple and putrid. The first is caused by a congestion of good blood in improper places. But when it attacks persons full of impure juices, who have been weakened by a preceding disease, confant anguish of the mind, excessive cotto, or inordinate living, the symptoms are much more grievous, with loss of strength, and the disease will continue till the fourteenth or the twenty-first day, sometimes with eruptions, dusky or black spots, with immediate danger.

If the cause is not violent, this disease will often disappear, merely by the benefit of nature, on the fourth, seventh, or eleventh days, with a large sweat or bleeding. At the nofe, and, though very seldom, by a flux of the belly, unless it has something of malignity.

When the disease is rightly managed in the beginning, that is on the first, second, and third day, with bleeding and cooling things, and gentle diaphoretics, it will end on the fourth. But if the bleeding is omitted, or is too little, it may continue till the fourteenth or seventeenth day, with the more grievous symptoms, as also a delirium: but it will terminate at last by a sweat or loosening.

When it proves fatal, the patient generally dies of a spesaceous inflammation of the brain, or other parts, as the stomach or intestines.

The intentions of cure are, 1. To free the vital parts from too great a congestion of blood, which will either dissipate a slight inflammation, or prevent a great one. 2. To appease the exsudation of the blood and the spasmodic affection of the system of the nerves. 3. To dissipate the stagnating and corrupted fluids, and to restore a free circulation of the blood, chiefly to the surface of the body. To answer the first intention, the patient must lose the blood.
blood freely. Then the organic of the blood must be appeased with diluents, acids, and nitrous compositions.

And certainly if any disease requires acids, and the juice of tart fruits, it is this, such as tamarinds, and the juices of currants, oranges, and lemons.

Take two pounds of water; rose-water, white sugar, and juice of oranges, of each one ounce.

The jelly of hawthorn made pretty thin, with the addition of orange-juice, sugar, and rose-water, will make a proper demulcent and cooling drink; or whey turned with juice of lemons or oranges.

To direct the motion of the blood to the surface of the body, gentle diaphoretics will be proper, such as the bezoard, or absorbent powders, sometimes alone, and sometimes with citron juice. Likewise infusions of the leaves of veronica, carduus, or carduus benedictus, with fennel-seed, drank in the manner of tea, especially to promote sweating on the fourth day, when the disease is like to terminate with this salutary excretion.

It will be necessary, whether this fever be simple or putrid, to keep the body open; for which purpose aclyster made of whey, honey, oil of sweet almonds, with a little nitre and salt, will be proper; for by this means the fistula of the intestinal fibres will be relaxed, and flatus will be discharged, which descend the colon. In the decline of the disease, when there are apparent signs of colic in the urine, a laxative of manna and cream of tartar, or calisca and rhubarb, will be of great use.

Of the Bilious Fever.

The bilious is a kind of a burning fever. It begins with intense heat, thirst, anguius, and inquietude. There is likewise a vomiting, or a perpetual reaching to vomit, with frequent bilious fluxes, a coldness of the extremities, internal heat, and cardialgic anxiety. This fever is either acute, or very acute. In this the symptoms are more violent, the bilious purging upwards and downwards is very plentiful, joined to a cardialgia with fainting. It generally kills before the seventh day, with an inflammation of the stomach and duodenum; the signs of which are, a fixed igneous heat about the precordia, with a coldness of the extremities, high inquietude and anxiety, a hiccup, and a plentiful erussion of bile and saliva liquor, a jaundice-colour of the countenance, and a hippocratic face.

Some are so acut, but run a greater length, with now and then a remission, and perhaps an intermission, and have an exacerbation, with vomiting, anxiety, and coldness every other day, or every third day, and ought to be called continual quotas or tertians.

It is caused by a bilious fluid secreted plentifully in the liver, and poured out into the stomach and duodenum, where by its acrimony and corrosiveness it stimulates the nervous tunic, corroding and inflaming them; whence the symptoms proper to this fever arise, such as a burning heat, a cardialgic anxiety, a nausia, a reaching to vomit, and a violent purging upwards and downwards.

Hoffman, in the cure of the bilious fevers mentioned by him, would have the caustic acrimony of the bilious juices abated and theadethed by absorbent powders and nitre, which should be taken in a sufficient quantity of a liquid, and often repeated. He likewise recommends emulsions of almonds, of the cold feeds; elder flower water, rose-water, &c. as also jellies of hawthorn, milk and water, oil of sweet almonds, sweet whey, chicken broth.

After these things, medicines must be given to restrain the impetuous bilious excretions, and to abate the too quick systaltic and peristaltic motion of the biliary ducts, and to prevent the too great excretion of the bile.

In the cure of the Bilious Fever of the camp, Pringle, before it becomes continual, depends on the proper use of evacuations, the neutral salts, and the bark. Bleeding is the first thing to be done in every case, and is to be repeated once or oftener, according to the urgency of the distemper. The vernal and later autumnal remittents are accompanied with rheumatic, pleuritic pains, and other symptoms of high inflammation, which require more bleedings than the intermediate season. To omit this, and give the bark too soon, will bring on an inflammatory fever. A vein may be opened falsely either during the remission, or in the height of the paroxysm.

After bleeding, give an emetic in the remission or intermission of the fever, and rather soon after a paroxysm than before one. But emetics do harm when the stomach is inflamed, or when the disease has continued some time, and has assumed the type of a continual fever. However, we may safely give one when the fever intermits, or has considerable remissions. Ipecacuana is safest, but antimonials most efficacious. If the remissions are small, or the fever great, or there is a tendency to vomit, the former is best. But when the remissions are dilate, or the remission perfect, the latter should be preferred; or it may be joined to the former; that is, two grains of tartar emetic, with a scruple of the powder of ipecacuana. Those vomits are best which produce floops, especially if they procure a plentiful discharge of corrupted bile upwards or downwards.

If the body continues coffive, a laxative will be proper, especially if there is a tenesmus, or pains in the bowels. The saline draught, with falt of wormwood and lemon-juice, will bring the fever sooner to regular intermissions.

Whenever the sweats are not profuse enough in proportion to the fits, the quantity of an ounce of jspir. Minedermi may be given, divided into two or three draughts, before they go off. It promotes a plentiful diaphoresis, without heating.

As the fevers are never without an inflammation in the beginning, and then rarely have complete paroxysms, the bark is not to be given till the urine breaks, and there are entire short intermissions; nor yet before bleeding, as was observed above; nor before the first passages have been cleansed; otherwise the fever will return, or a tympanites will be produced.

It is best to give the bark in subsidence in Rheinifh wine; or an ounce of it may be made into an eleuatory, with fyrup of lemons, and a dram of sal ammoniacum. If the patient has not been purged, it will be proper to add as much rhubarb as will keep the body open for the first two or three days of using that medicine. It is chiefly useful when the bilious humours abound, as they mostly do in marby countries. If the paroxysms are, or the
the intermissions short, it may be necessary to give the back before the sweating is quite over.

If the disease has been neglected in the first stages, or if after the remissions or intermissions it changes to a continual fever, with a full and hard pulse, a vein must be opened. But if there is a pain in the head, or a delirium, and the pulse small, it will be best to apply leeches to the temples. But whether the patient is bled or not, blisters are the best remedy. If the prime vis are loaded, cysts or a laxative may be proper; but neither vomits nor purges; nor are those to be repeated without caution. To these remedies the saline draught may be added.

Sweating is the proper crisis: it is never to be promoted by theriaca or volatile; but when the pulse sinks, and petechiae, or other symptoms appear, it will be proper to use the warmer alexipharmics, and to treat the disease like a malignant fever.

A loose end is the least favourable crisis: yet if there are colic pains, or a tension of the belly, attended with dryness of the skin, it will be proper to procure stools by a clyster, or a gentle laxative, such as the infusion of rhubarb with manna; which is to be repeated as the patient can bear it.

Of a Causus, or Burning Fever.

The principal symptoms of a causus are, a heat almost burning to the touch, most remarkable about the vital parts, but more moderate towards the extremities, which are even sometimes cold; the breath is extremely hot; there is a dryness of the whole skin, nostrils, mouth, and tongue. The respiration is thick, difficult, and quick; the tongue is dry, yellow, black, parched, and rough; the thirst is unquenchable; there is loathing of food, a nausea and vomiting; an anxiety, inquietude, and great languor; a little cough, a shrill voice, a delirium, a phrenzy, a continual watching or a coma, convulsions, and on the odd days an exacerbation of the fever.

In this temperate climate these fort of fevers are very rare; those that are more common among us are the burning, fanguineous, or the continual bilious fevers without remission.

This begins without any remarkable coldness or shivering, with great heat, thirst, watching, anxiety and inquietude. In fanguineo-bilious conflagrations, and in bodies full of hot bilious blood, they terminate in critical days in health or death, being first preceded with a shaking. They terminate in a salutary manner, with a sweat or a bleeding at the nose.

On the third and fourth day it often proves mortal; it seldom exceeds the seventh, if violent.

It is often terminated by an hemorrhage; which if small on the third and fourth day, it is a fatal sign. It is best if it happens on a critical day.

A solution of this fever on a critical day, may also be by vomiting, stool, sweat, urine, or spitting thick phlegm. If the exacerbation of this disease happens on the second or fourth day, it is a bad sign; on the sixth, not so bad.

The urine black, small in quantity, and thin, is fatal; so is spitting or piling of blood. A difficulty of swallowing is a bad sign; but the worst of all is coldness of the extreme parts. The face red and sweaty, is bad; a parotis not tending to suppuration is fatal; the body too loose is fatal. A tremor turning into a delirium is mortal: it often changes into a peripneumon with a delirium. When this disease succeeds gripings of the bowels, it is worst of all.

A critical determination of this fever is usually preceded by a rigor, or shaking.

The cure of a burning fever is most easily obtained in a pure, cool air, frequently renewed; The patient must not be oppression or lifted with bed-cloaths, but should fit up often. He should drink plentifully of soft, sub acid, aqueous, and warm liquors. His diet should be light, made of pearl barley, oatmeal, and sub-acid fruits.

Bleeding is necessary at the beginning, if there is a plethora, or signs of a particular inflammation, or the heat is intolerable, or the rarefaction too great, or a re-vulsion necessary, or the symptoms urgent, in which circumstances the disorder is hardly to be vanquished by any other remedies.

Soft, diluting, laxative, antiphlogistic cooling clysters, are to be repeated as oft as the heat, coughs, and revulsion require them.

The whole body is to be moistened by receiving into the nostrils the streams of warm water; by washing the mouth, throat, feet, and hands, with the same; by fomenting with warm fuppes the places where the vessels are most numerous, and most exposed to the touch.

The medicines should be aqueous, soft, nitrous, gratefully acid, gently laxative, not promoting sweat and urine by their acrimony, but by their plenty; such as remove the contraction of the fibres, resolve the thickness of the humours and dilute, and temper their acrimony.

To appease thirst in this disease, and to moisten the tongue and parched fauces, there is nothing better than sweet whey, in a quart of which half a dram of pure nitre has been dissolved. Small draughts of this, a little cool, may be drank frequently, which will likewise extinguish the pernarial heat. The mouth and throat may also be washed with water, mixt with syrup of mulberries and nitre.

Purgatives are dangerous before the crisis, but clysters may be used, made of milk, honey, and a little nitre. After the crisis, which is known by the sediment in the urine, laxatives made with tamarinds, manna, rhubarb, raisins, or cream of tartar, are absolutely necessary.

Of the Burning Bilious Fever, or Yellow Fever of the West Indies.

The yellow fever begins with a momentary chilness and shivering, which is soon succeeded by a burning heat all over the body, but is felt more intensely about the precordia. The pulse is high, strong, and rapid; the eyes are heavy; with a throbbing pain in the head, and a violent beating of the temporal arteries, and a thick, laborious respiration: There is a nausousness, and reaching to vomit; and when anything is thrown up, it is of the bilious kind: Besides these, great anxiety, pain in the back and loins, and an uneasy lassitude in all the limbs.

About
About twelve hours after the invasion, the tongue is dry, harsh, rough, and discoloured, with inextinguishable thirst; there is a foreboding all over the body, great restlessness, and a delirium.

In the last stage the patient labours under a great coma, oppression of the precordia, heaving of the lungs, an interrupted respiration, tremblings of the tendons, convulsions, and cold clammy sweats.

It usually terminates in a favourable crisis, or the death of the patient, about the fourth day after the attack.

The regular crisis generally discovers itself by a suffusion of the bile all over the surface of the body about the third day. The saffron tincture is frequently discovered in the eyes twelve hours after the invasion: the sooner it appears, the more favourable is the prognostic.

If the jaundice comes on too soon, it is bad; if with livid spots, which sometimes, though rarely, appear, it is fatal. If the skin continues obstinately dry and rough, the cafe is dangerous; and the more so, the longer it continues; for these very seldom recover, be the pulse ever so good. The pulse is not to be depended on; for many have a good pulse a few hours before death. If the vomitings are incessant, grow darker, and the hiccup comes on, it is generally fatal. If the face is greatly flushed, and the vessels of the white of the eye are turgid with blood, as in an opthalmia attended with a phrenzy, the patient is likely to die in a very little time, especially if the skin is dry.

But if the head continues in clear, the pulse becomes soft, the pains, nauseas, and anguishes are relieved by bleeding; and as the humours vomited are carried downwards by laxatives; if then the inquietude ceases, the skin grows soft and moist, and the patient has better spirits; it is probable he will recover.

Bleeding is the first thing to be done, more or less, according to the force of the disease and the strength of the patient; and if the symptoms continue in their full vigour, should be repeated once in six or eight hours, lessening the quantity proportionably each time.

After the first bleeding, give a vomit of ipecacuanha, quickened with three or four grains of emetic tartar, (or rather two grains,) which will bring up a great quantity of yellow, poraceous, and sometimes blackish bile, and carry the humours downwards.

After this the patient may drink plentifully of diluting, refrigerating, and subacid liquors, made with oranges, lemons, tamarinds, spirit of sulphur, spirit of vitriol, and such like, in barley-water, spring water, or other thin and cooling vehicles. He may likewise be allowed tartarjuicy fruits; as bananas, granadilloes, Barbadoes cherries, and water-melons; as also plantains, and bananas, roasted for food; jelly of guavas, &c.

Cooling tellaceous powders are likewise very beneficial.

Towards the evening it will be necessary to inject a clyster, made of the common decoction, with half an ounce of cream of tartar, an ounce of manna, or an ounce of pulp of caffia added to it.

When the operation of the clyster is over, paregorics will be proper, as thus:

*Take 2 ounces of mint-water, one ounce of cinnamon water, 25 drops of the tinctura thebaica, and a sufficient quantity of sugar.*

The room should be kept cool, and sprinkled with vinegar, rose-water, and cooling herbs. Fresh air should be admitted, but not to blow directly on the patient's body.

Blisters are also of great efficacy at this juncture; which if applied before it be too late, a coma, the deadly symptom of this distemper, very rarely ensues.

The patient's diet should be nothing but thin panada and water-gruel, gratefully sweetened and acidulated.

Besides plentiful and frequent draughts of cooling liquor, the patient should be allowed preferred tamarinds, slices of lemon with a little sugar; but above all, penguins, which by their sharpness penetrate the thick tenacious surf, whereby the glands of the mouth will be unloaded. Opiates must also be used in larger doses than in Europe.

Cooling and lenient clysters must also be repeated every eight hours.

When the patient begins to be comatose, the third and last stage of the disease is advancing; in which are, difficulty of breathing, oppression of the precordia, convulsive twitching of the tendons, interruption of the pulse, and at length its total cessation.

In this case, a complete set of blisters must be immediately applied, or the old ones renewed; which must be laid to the nape of the neck, on the wrists, thighs, and legs, and a large one on the crown of the head. To the soles of the feet may be laid a cataplasm of salt herrings and mustard.

With regard to the urgent symptoms; pains of the head, watchfulness, and deliria, are to be relieved by emollient and laxative clysters, gentle purgatives, cupping with scarification, opening the frontal vein, lotions of the feet, and narcotics.

Blisters are also useful for the same purpose.

Convulsions require much the same treatment externally; and internally, aurum nitricum, (the dose from four grains to a scruple.) To restore the strength of the patient, little more is required than a stomach purge or two, mild and agreeable bitters, and a restorative regimen of broths, jellies, and white meats.

If the yellow tincture remains upon the skin, give a vomit of ipecac, and a purge or two with the decoction of fennica, tamarinds. &c. and allow the use of lemons, oranges, and other acid fruits. If this disorder proves obstinate, treat it as the jaundice.

**Of the Senegal Fever.**

The fever which chiefly prevails in this country in the months of July, August, and September, is of the worst kind. It usually begins with drowsiness, latitudinal, and great rigors, which continue frequently three or four hours, and are succeeded by intense heat and sweats. For three or four days it remits, and both the shiverings and hot fits become more moderate. During this period, the pulse is quick and low; but afterwards becomes fuller, unless some evacuation intervene. At this time profuse sweats are easily brought on; in which case there are little hopes of recovery. A parched, dry skin, is as bad a symptom, if it continues more than a day; for an intermitt
Intermitting pulse and a delirium succeed, and continue for seven or eight days, the frequency of the intermissions increasing every day: but if a general moderate moisture comes one at this, or any other time of the disorder, and continues, the patient recovers. A violent pain in the head and back, and difficulty of breathing, are general complaints. Sudden languors, and bilious vomitings, are frequent through a great part of the time.

Some are taken with a great heat, and a strong quick pulse, without any shiverings or remissions, as above-mentioned. In this case the patient sooner dies upon the appearance of bad symptoms, and is longer in recovering upon the appearance of good ones.

The loss of eight or ten ounces of blood, in the first attack of these fevers, has sunk the pulse beyond a possibility of raising it afterwards, and that even in plethoric habits, attended with great pains of the head. It is, indeed, surprising how little these fevers will bear of evacuations of any kind, especially bleeding.

After profuse sweats, the pulse becomes extremely low; and, though the sweating goes off, continues for two or three days, with anxiety and restiflrefles after which the pulse grows quick, the skin parched and hot, and a fever of bad symptoms comes on.

The sick are always comatose and fluid; which symptom is little dangerous when attended with a warm moisture on the skin, but otherwise it is generally fatal.

It is of great consequence to keep up the pulse; but here the common cordial medicines are ineffectual; yet the decoction of the bark, with the camphorated julep, and spirit of vitriol, answers this purpose effectually, so as to render any other medicine unnecessary, except occasionally a gentle emetic or laxative.

Of the Inflammation of the Stomach.

The inflammation of the stomach is known by a burning, fixed and purgient pain in the stomach, which is exasperated at the instant any thing is taken into it; and is succeeded by a most painful vomiting and hiccup. There is always a violent internal heat, high anxiety, a grievous pain about the precordia, chiefly at the pit of the stomach, an acute, continual fever, great thirst, difficult breathing, inquietude, toffing of the body, coldness of the extremities, a conftant stimulus to vomiting, with inquietude: But the heat in the region of the stomach is not fo violent, nor is the thirst and dryness of the tongue so great, nor the pulse so quick and contracted, and the stomach can better bear and retain any thing taken inwardly; nay, is frequently relieved thereby. An inflammation of the intestines has a pain or gripes more about the region of the navel, with frequent, frothy, bilious stools, or a little bloody, with a heat over all the surface of the body, and a quick large pulse: Whereas in this disease the extremities are cold.

If it be caused by drinking cold liquors when the body is hot; or from an effusion of the bile after violent commotions of the mind; the danger is not very great, as there will be room for suitable medicines to take effect. But that which arises from draffic purges, sharp emetics, or caustic poisons, kills quickly without speedy assistance. This disease likewise often proves fatal to the old, the infirm, the scorbutic, and persons full of grief, as also in the end of acute diseases.

When there is a restless toffing of the body; when liquids are immediately thrown up; and when there is a hiccupp, a fainting, an hippocratic face, an intermitting pulse, and convulsions, a fatal mortification will soon terminate the patient's life.

This disease, if not suddenly cured, is generally mortal: And therefore, as soon as it is discovered, plentiful bleeding is necessary, and must be repeated as the violence of the symptoms increases. Let the drink be very hot, antiphlogistic, and emollient; as also clysters of the same kind.

The patient should totally abstain from every thing that is acrimonious; even the cooking, nitrous salts, which are beneficial in other inflammations, irritate too much. Vomits, cordials, and spirituous liquors, are little better than poison.

Aliments should be given frequently, and by a spoonful at a time; for any dilution increases the inflammation. A thin gruel of barley, oatmeal, whey, with very little sugar or honey, or chicken-broth, are proper aliments; whey-emulsions, barley-water, emollient decoctions, are proper drinks.

The indications of cure are, 1. To open the obstructions caused by tenacious juices impacted into incongruous vessels; 2. To remove the spastic strictures which contract the vessels, and to regulate the equable and natural progress of the blood through the substance of the stomach. These ends are to be obtained by diluents, humectants, demulcents, antiphlogistics, and things that restrain the heat which thickens the fluids, and relax the contracted fibres.

But as there are more causes than one that produce an inflammation, they will require different remedies to bring about a cure.

Therefore, if it be owing to a caustic, septic, arsenical poison, or a strong emetic or cathartic, or to metallic medicines ill prepared, and thence the inflammation; oily things are proper, as new milk, cream, oil of sweet almonds, or olive oil taken often and plentifully.

If from a spasm, succeeding a violent commotion of the mind, then a nitrous absorbent powder will be proper, in an emulsion of white poppy seeds. When the spasm is appeased, rhubarb with raisins will be necessary to carry off the bilious fords.

When an eruptive matter is repelled and causes this disease, use emulsions of the greater cold feeds, with temperate absorbents and hartshorn philosophically prepared should be given, with gelatinous decoctions of calves and neat's feet, or hartshorn jellies.
jeffies and water gruel. Outwardly, the following liniment is useful in all cases:
Take of oil of sweet almonds 2 ounces, and a dram of camphor; mix and make them into a liniment, to be applied warm to the fomach.

Of the Quinsey.
A Quinsey is an inflammation of the fauces, with a burning pain, tumor and redness; a difficulty of breathing or swallowing; and a fever, proceeding from a flatulence of blood, or a vicious acid serum in the fanguineous or lymphatic vessels.

It begins with a fever, which is followed with a pain and inflammation of the fauces, causing the uvula, tonsils, and larynx to swell; whence great difficulty of breathing and swallowing ensues.

This disease may be seated at the root of the tongue near the os hyoides; the foramina of the nostrils opening to the bone; the beginning of the oesophagus; the muscles of the pharynx; the internal and external muscles of the larynx; the greater and lesser glands; the tonsils, or the muscles moving the jaws.

When a quinsey affects the internal muscles of the larynx, and there is no outward redness about any part of the neck, but a burning pain inwardly, a loss of voice, and great difficulty of breathing; it often kills in twenty-four hours. This is called a hynanche. When it is seated in the internal muscles of the pharynx, it is called a fynanche; in which there is no external tumor and redness, but a great difficulty of swallowing and breathing, and whatever is drank returns through the nose. When there is an outward tumor and redness, and the external muscles of the pharynx are affected, it is a parafynanche; when the external muscles of the larynx, a parahynanche.

A quinsey is likewise distinguished into the true and spurious. The true arises from the flatulence of the blood; the spurious or ballard from a congestion of the serum. The former is acute, always attended with a rigor and a fever. The latter has rather a lymphatic or catarrhal, then an acute fever. The first has not only a burning, prickling pain in the inner parts of the fauces, but the tongue is turgid with blood, and of a dark reddish colour; the face is likewise red; there is a great pulsation of the temporal arteries; sometimes a head-ach, a torpor of the senses; sometimes fainting.

When it is very violent, there is a difficulty of breathing, high anxiety, and coldness of the extremities; and is very dangerous, requiring speedy help. But in the spurious, those symptoms are either absent, or more mild; nor is the danger so great.

This disease may be cauèd by a suppuration of some fistula fanguineous evacuation; by admitting the cold air after a strong fudorific has been taken; and by lying in rooms new plastered or white-washed. Some caustic poisons affect the throat more than other parts. White hellebore attacks the fauces, and brings on a strangulation. The same enflues from the solanum furiosum, and the bite of a mad dog. The fumes of arfecnical and mercurial minerals, as also the vapours of mineral spirits, will have the fame effects.

M E D I C I N E.
It sometimes comes on spontaneously, and is again the symptom of another disease, as the diarrhoea and dyentery, especially if the flux is halty stopped. It has happened from the striking in of an erysipelas; or sometimes from the gut being injudiciously treated with topicks; as also from the small pox, or a malignant or petillential fever. The cause of the symptomatic disease is collience, or suppurated perforation, or the striking in of eruptions. When it is epidemic, it has something of malignity.

When the swelling, pain, and redness, appear more outwardly, and vanish by degrees, it is a sign of a happy solution of the disease. But when the external swelling suddenly disappears, without a mitigation of the symptoms, it leaves the morbid matter to be tranflated elsewhere, and will change to a phrenzy or peripneumony. Or this disease may terminate in a suppuration or gangrene, or a schirrus. A frothing at the mouth, the tongue vally swollen, and of a purple, blackish colour, portends death.

In thes inflammations a slight diarrhoea relieves: Therefore aliments which promote it are useful, as tamarinds infuded in whey; decoctions of farinaceous vegetables moderately acidulated, and such as abound with a cooling nitrous salt, are proper. Burnet is said to be a specific in this case. Mulberries are beneficial, and all a-
cids.

The mouth and throat must be kept moist, and the nose clear, that the air may have clear passage through it. When the patient cannot swallow, he may be nourished by clysters.

Take away blood plentifully from the arm, and afterwards open a sublingual vein; but bleeding in the jugular yields the best assistance, and is much more safe. If the symptoms continue to be very urgent, the bleeding may be repeated in fix or eight hours time, till they begin to be more mild.

After the first bleeding, lay a strong and large blister on the fore-part of the neck, or a piece of flannel dipp'd in the volatile liniment.

Then let the parts inflamed be touched with the following mixture:

1. Take a sufficient quantity of honey of roses and spirit of sulphur. Mix them.

Then the following gargar is to be used, held in the mouth till it is hot before it be spit out; which is to be repeated pretty often:

2. Take a pound of barley-water, 8 ounces of honey, and 2 drams of spirit of sal ammoniac. Mix them. Emollient steams, or even the steam of hot water taken in at the mouth, are beneficial.

If the patient is not able to swallow any nourishment, the same, or even the steam of hot water taken in at the mouth, are beneficial.

If the patient is not able to swallow any nourishment, the same, or even the steam of hot water taken in at the mouth, are beneficial.

3. Take ten ounces of beef-tea, 10 grains of nitre, and 6 drops of spirit of salt. Mix and make them into a clyster.

Let it be injected every eighth hour, after the belly has been cleansed with a purging clyster.

If the tumour tends to a suppuration, it is best promoted by holding hot, dried figs in the mouth; and when the tonsils are full of an inflammatory ichor, honey of roses mixed with spirit of vitriol, and often applied to the part with a pencil, is excellent.
That inflammatory pain which arises from a sharp salt serum in the glandulous parts of the fauces, with redness, and a copious flux of saliva, but without a fever, may be cured with a gargle of brandy alone. An inflammation of the fauces is sometimes cured with ten drops of camphorated spirit of wine, in which a grain of nitre has been dissolved, and suffered to pass slowly down the throat.

The acute and inflammatory quinsy may be defined, "An inflammation of some part or parts, either within or contiguous to the throat, rendering deglutition painful, and impracticable; and, when it is of the most dangerous kind, likewise affecting respiration."

When only swallowing is impaired, the parts inflamed may be the tonsils, the velum palati, and uvula, the muscles of the pharynx, and thofe of the larynx, which raise it or pull it down in deglutition, but whose action is not concerned in moderating the aperture of the glottis; while the larynx itself and the aspera arteria remain free.

But when the respiration is pinched, beside other parts, thefe muscles, which are employed in opening and shutting the glottis, must be inflamed; and likewise, probably the inner membrane of the larynx, and thofe muscles and fibres that join the rings of the aspera arteria together: And sometimes these minute and remote parts are affected without any redness or tumour. either within the fauces, or outwardly on the throat: This kind of quinsy is the most dangerous and suddenly destructive of all.

The practitioner in every kind of quinsy ought to look carefully into the mouth and fauces, in order to discern where any redness and tumour is; that by comparing the appearance of the parts with the functions impaired, he may be enabled to form the better judgment with respect to the seat of the disease, the prognostic, and method of cure.

If the breathing is remarkably affected, there is absolute necessity of applying all the most efficacious remedies with the greatest briskness and speed possible. These are plentiful and repeated bleedings, a large blister between the fauces, or outwardly on the throat: This kind of the malignant quinsy, or putrid sore throat.

This disease generally comes on with such a giddiness of the head, as often precedes fainting, with a chilliness or shivering like that of an ague fit, followed by great heat; and these alternately succeed each other for some hours, till at length the heat becomes conflant and intense. The patient then complains of an acute pain in the head, of heat and forenefs, rather than pain, in the throat; thickenings of the neck; commonly great fickness, vomiting or purging, or both. The face soon after looks red and swelled, the eyes inflamed and watery, as in the meatus; with rellife of throats, anxiety, and faintnefs.

It frequently seizcs the patient in the fore-part of the day: and as night approaches the heat and rellife of throats increafe, continuing till towards morning; when after a short, disturbed flumber, the only repose during several nights, a sweat breaks out, which mitigates the heat and rellife of throats, and gives the disease sometimes the appearance of an intermittent.

If the mouth and throat be examined soon after the first attack, the uvula and tonsils will appear swelled; and thofe parts together with the velum pendulum palati, as well as the cheeks on each side, near the entrance into the fauces, and as much of the fauces and the pharynx behind as can be seen, appear of a florid red colour. This colour is commonly most observable on the posterior edge of the palate, in theangles above the tonsils, and upon the tonsils themselves. Instead of this redness, a broad patch, or spot, of an irregular figure, and of a pale white colour, surrounded with a florid red, is sometimes to be seen. This whitenefs is commonly like that of the gums after having been pressed with the finger; or as if a matter ready to be discharged lay underneath.

Generally on the second day, the face, neck, breast, and hands, are of a deep erysipelatos colour, with a sensible tumefaction. The fingers are fo frequently tinged in a remarkable manner, that it has been no hard matter to guess at the disease from a bare sight of them.

A great number of small pimplles of a more intense colour than that which surrounds them, appear on the arms and other parts. Where the redness is least intense, they are larger and more prominent, which is generally on the arms, breast, and lower extremities.

As the skin becomes red, the sickness commonly goes off, and the vomiting and purging cease.

The appearance in the fauces continues the same, only the white place becomes of a more opake white, and is discovered to be a slough, concealing an ulcer of the fauces dimensions. These ulcerations are generally first discernible in the angles above the tonsils, or on the tonsils themselves. They are also often seen in the arch formed by the uvula and one of the tonsils; on the pharynx behind, on the inside of the cheeks, the basin of the tongue, which they cover like a thick fur. Where the disorder is mild, there is only a superficial ulcer, of an irregular figure, in one or more of thofe parts, scarce to be distinguided from the found part, but by the inequality of its surface. Likewise the redness and eruption do not always appear, and in some not till the third, fourth, or fifth day, or later.
The parotid glands on each side commonly swell, grow hard, and are painful to the touch; if the disease is violent, the neck and throat are surrouned with a large oedematous tumour, sometimes extending itself to the breast, and by straitening the fauces increase the danger.

Towards night the heat and restlessness increase, and a delirium frequently comes on. This happens to some on the first night. It is very remarkable, that the patient commonly returns a proper answer to any question, but with unusual quickness; yet when they are alone, they generally talk to themselves incoherently. However, at the first tendency to this disorder, they affect too great a compofure. This for the most part happens to those that sleep but little; for some are comatose and stupid, and take but little notice of any thing that passes.

They continue thus for three, four, or more days, commonly growing hot and restless towards the evening. These symptoms and the delirium increase as the night comes on: a sweat, more or less profuse, breaks out towards morning; and from this time they are eaiser during some hours, with a faintness, which is their chief complaint.

Some grow easier from the first day of the attack; others have symptoms of recovery on the third, fourth, or fifth day. First the redness of the skin disappears; the heat grows less; the pulse, bitherto very quick, becomes slower; the external swellings of the neck subside; the floughs in the fauces are cast off; the ulcerations fill up; the patient sleeps without confusion, is composed when awake, and his appetite begins to return towards more solid nourishment.

The pulse, during the course of this disease, is very quick, beating frequently 120 times in a minute. In some it is hard and small, in others soft and full, but not so strong and firm as in genuine inflammatory disorders.

If a vein be opened soon after the distemper comes on, the blood generally appears of a fresh and florid red; the effusion is rather of a lax, gelatinous contexture, then dense or compact; the serum is yellow and in a large proportion.

The urine is at first crude and of a pale whey colour; as the disease advances it turns yellower, as if bile was diluted in it; and soon after any signs of recovery appear, it commonly grows turbid, and deposits a farinaceous sediment.

They seldom have any stools if the symptoms are favourable, from the time the purging, which generally attends the accension, ceases. This discharge is remarkably bilious, yet without pain.

The thirst is commonly less than in other acute diseases; and the tongue generally moist, but not furred. Some have it covered with a thick white coat, and complain of soreness about the root of the tongue.

Though the uvula and tonsils are sometimes so much swelled as to leave a very narrow entrance into the gullet, and this entrance frequently surrouned with ulcer, or floughs; yet the patient swallows with less difficulty and pain than might be expected. Soon after they are taken ill, they frequently complain of an offensive purid smell, which often occasions sickness before any ulcerations appear. The inside of the nostrils, in those that have this disease severe, frequently appears, as high as can be seen, of a deep red or almoft livid colour. After a day or two, a thin corrosive fainey, or with it a white putrid matter, of a thicker conftitution, flows from it, so acid as to excoriate the part it lies upon any considerable time. This is most observable in children, or in young and very tender subjects; whose lips are likewise frequently of a deep red, or almoft liquid colour, and covered on the inside with vesicles containing a thin ichor, which excoriate the angles of the mouth and cheeks where it touches them.

This acid matter seems to pass with the nourishment into the stomach, especially of children; for if they get over the disease, a purging succeeds, yet attended with symptoms of ulcerations in the bowels; thefe, after great pain and misery, at length die emaciated.

The patients sometimes bleed at the nofe towards the beginning of the disease; and the menfes often appear in the female sex, if they are of age, soon after they are feized, though at a distance from the time of their regular period. It brings this evacuation upon some that never had it before. This flux, in full strong habits, is seldom attended either with benefit or with manifest ill effects, unless very copious; yet sometimes it occasions great faintness, and an increafe of the other symptoms. Hemorrhages of the nofe and mouth have carried the patient off suddenly; but this does not happen till several days after the attack; and perhaps may be owing to the separation of a flough from the branch of an artery.

Children and young persons are more exposed to this disease than adults; girls more than boys; women more than men; and the infirm of either sex than the healthy and vigorous. Very few grown people have it. When it breaks out in a family, all the children are commonly infected with it, if the healthy are not kept apart from the sick. And such adults as are frequently with them, and receive their breath near at hand, often undergo the same diseases.

With regard to the cure, bleeding is generally prejudicial. Some admit of it at the first attack without any sensible inconvenience; but a repetition of it in the mildfeet caffes seldom fails to aggravate the symptoms; it has sometimes produced very fatal consequences. It increafes the heat, restlessness, delirium, and difficulty of breathing; nor do the swelling of the fauces, tonsils, &c. receive any benefit therefrom. On the contrary, though the fullness of these parts decreases, yet the floughs thicken and change to a livid black colour, the external tumour grows large, and the spitting commonly diminishes. Indeed, the heat and quickness of the pulse may seem to abate at first by this evacuation; but they commonly return with greater violence, the patient is feized with a difficulty of breathing, falls into cold sweats, a flapor, and dies suddenly.

Nor is purging more beneficial; even gentle cathartics have brought on very dangerous symptoms. Upon procuring a few stools with manna, especially when the disease has continued two or three days, the redness of the skin has disappeared, and the flux to the throat has been surprisingly increased. If this discharge by stool continues,
tinues, the swelling of the neck commonly grows larger, the fauces become flaccid, dry and livid; and the patient a few hours after this expires.

Nitrous cooling medicines frequently produce the like effects; they increase the faintness which accompanies this disease, and either dispose the patient to copious sinking sweats, or floods.

Upon the whole, it appears, that all evacuations which tend to lessen the natural strength of the constitution, are injurious; and those persons are commonly in the greatest danger who have been previously indisposed, or their strength impaired by grief.

If the purging, therefore, continues long after the first exacerbation of the disease, it is a dangerous symptom; for though it may sometimes be restrained for the present with opiates or astringents, yet it commonly returns with greater vehemence when their efficacy ceases, and in a short time exhausts the small degree of strength remaining. In this case they generally sweat very little; the fauces appear dry, glossy, and livid; the external tumour grows large; they void their excrements without perceiving it, and fall into profuse sweats; the respiration becomes difficult and laborious, the pulse sinks, the extreme parts grow cold, and death, in a few hours, closes the scene. The eye loses its lustre, and becomes opaque and dim, sometimes several hours before death.

A copious flux of putridous matter to the glands and other parts about the fauces, have seemed sometimes to be the cause of sudden death.

It is necessary that the patient should be kept in bed as much as may be, though the disease should seem to be slight; for a purging has come on for want of care in this respect, the redness of the skin disappeared, and a disfigurement of superficial or penetrating, ulceration of a greater or lesser depth, as the sloughs are successively separated; since, whenever they come off, they leave an ulcer of a greater or lesser depth, as the sloughs are superficial or penetrating.

The thin, acid ichor, which is discharged from under the sloughs, often proves of bad consequence, especially to children. If gargles are injected, they either prevent them from reaching the seat of the disorder with their tongues, or they swallow them and the putrid taint of the ulcer together; whence fatal purgings ensue, or fatal hemor rhages from the penetrating gangrene. Those that have a plentiful discharge from the fauces, carrying off this ichor, are seldom attended with sickness, vomiting, or excessive faintness; and where there is little or no discharge, the symptoms are commonly most dangerous.

Hence the great advantage of gentle stimulating aromatic gargles appears; because they promote the discharge of putridous matter, and, doubtless, some part of the corrosive fluid along with it. To which, if we add antiseptics and detergents, to check the progress of the mortification, and to cleanse the fordid ulcers, every indication will be answered.

When the disease is mild, the symptoms favourable, the sloughs superficial, order a gargle of sage-tea, with a few rose-leaves in the infusion. Three or four spoonfuls of vinegar may be mixed with half an ounce of the tea, with as much honey as will make it agreeably acid.

If the sloughs are large, and are cast off slowly, they may be touched with mel egyptiacum, by means of an armed probe.

It is not uncommon for hectic fevers, night sweats, want of appetite, and dejection of spirits, to attend those a considerable time who have had the disease in a severe manner. Aftes milk commonly relieves them, together with a decoction of the bark and elixir vitrioli.

The caufe of this disease seems to be a putrid virus, or missna sui generis, introduced into the habit by contagion, principally by means of the breath of the sick person.

The intentions of cure in this disease is to keep up the vital heat; to encourage the cuticular discharges; and to conquer the spreading putrefaction. Therefore, all evacuations which lessen the strength, particularly bleeding and purging, and all the nitrous antiphlogistic medicines, are highly improper.

And since a laxity of fibres predisposes persons to receive this disease, it is manifest, both with regard to the preservation and cure, that tonic medicines are indicated; and among these the bark judiciously claims the first place.
The only certain diagnostics of this disease are aphthous ulcers and sloughs on the tonsils and parts about the pharynx.

Melt perforns in the beginning have a nausea and vomiting, and some a looseness. Those who are coughive, have, upon the use of the genttle ecpoptes, immediately been feized with a diarrhoea, difficult to restrain. All medicines which tend to move the belly, not excepting rhubarb, are extremely dangerous.

Those who have had the disease with most violence, have had the head always heavy and stupid, and the eyes foul and full of tears. Not a few have had the head covered with petechie and purple spots.

The first thing to be done is to order the hot stream of a boiling mixture, of vinegar, myrrh, and honey, to be received into the throat, through an inverted funnel. If it is necessary to make it still more penetrating, add some of the spirit. Mindereri. This steam can scarce be used too frequently, provided it is received with a due degree of heat.

If the prime vie seem foul, or much loaded, it may be necessary to begin the cure by cleansing the stomach with carduus tea, in which a little sal vitrioli is dissolved, and some other gentle and quick emetic. No other medicines which tend to move the belly, not excepting rhubarb, are extremely dangerous.

When it does, and is violent, it often ends in madness; for a phrenzy is to be distinguished from that flight alienation of mind which happens in acute fevers before the critical eruption. This goes off readily, nor is the urine thin and watery, nor is it attended with a rigor and a refrigeration of the external parts. It is also to be distinguished from a deipience and raving, from a great lofs of strength and weakness of the brain after the declination of an acute fever; for this will go as the strength returns, either spontaneouly, or with proper remedies.

Both kinds, when present, have the following symptoms:

A deprivation of the ideas of sensible things, as also of the faculties of the mind and affections; an unruly fierceenefs and wildnefs; an unquiet and often turbulent sleep, a light degree of folly, watching, fadness, fierceenfs, sudden forgetfulness, a gathering of threads from the bedcloaths.

Therefore plentiful bleeding is necessary, through a large inflammatory pain within the head, a redness of the eyes and face, unquiet and troubled sleep, a light degree of folly, watching, sadness, fierceenfs, sudden forgetfulness, a gathering of threads from the bedcloths.

A symptomatic phrenzy succeeds any acute disease; but it is worst when it is preceded by an inflammation of the pleura, lungs, or diaphragm. A black tongue, an obstinate coltiveness, suppression of urine, white fieces, which is always a fatal sign, pale, discoloured, thin urine, a wildnefs in the looks and actions, with a red vifage, a black cloud in the urine, and watching, are signs of an approaching inflammation in the head.

The symptomatic phrenzy sometimes appears in the state of malignant, eruptive, and spotted fevers, the small-pox, malignant catarrhal fevers, camp-fevers, particularly the Hungarie. It generally supervenes about the critical days, with a rigor, trembling of joints, tenion of the precordia, and coldness of the external parts, with thin urine. The patient being weakened with the preceding disease and long watching, which debilitates the tone of the vefels of the membranes of the brain; whence the ftares are not to be resolved, and whence the patient is generally killed on the third day.

A phrenzy is to be distinguished from that flight alienation of mind which happens in acute fevers before the critical eruption. This goes off readily, nor is the urine thin and watery, nor is it attended with a rigor and a refrigeration of the external parts. It is also to be distinguished from a dejipience and raving, from a great los of strength and weakness of the brain after the declination of an acute fever; for this will go as the strength returns, either spontaneouly, or with proper remedies.

Both kinds, when present, have the following symptoms:

A deprivation of the ideas of sensible things, as also of the faculties of the mind and affections; an unruly fierceenfs and wildnefs; an unquiet and often turbulent sleep, a respiration flow and great, the face often exceed-

sults, as water gruel acidulated; the drink, barley-wa-

ter, small-beer, or the decoction of tamarinds.

A phrenzy is generally fatal on the third, fourth, or

feventh day; which last it seldom exceeds.

When it does, and is violent, it often ends in madness; which increasing gradually, the patient becomes raving mad.

The aliment ought to be flender, of farinaceous sub-

stances, as water gruel acidulated; the drink, barley-wa-

ter, small-beer, or the decoction of tamarinds.

This disease, of all others, requires the speediest ap-

lications. Profuse hemorrhages of the nose often resolve it; and copious bleeding, by opening the temporal arteries, is the most efficacious remedy.

The cure of this disease requires diligent attention to the following things:

Varices of the veins, or the bleeding piles, are beneficial.

A looseenfs is likewise good.

A pain in the breast and feet, or a violent cough supervening, often put an end to the disease; as also an hemorrhage.

Therefore plentiful bleeding is necessary, through a large
large orifice; or open several veins at the same time, eiz.
the jugular, the frontal, and a vein in the foot.

Hoffman prefers the bleeding at the nofe, procured by
thrufhing up a fhrow, a pen, or a faber; or, as Prin
gle advises, apply fix or feven leeches to the temples.
The refi of the cure confifts in blifters, and things com-
mon to other inflammatory fevers.

The cure of the fymptomatie phrenzy, if the pulfe
will bear it, is by opening a vein; but if this cannot be
done by reafon of great lowness, it is to be attempted by
leeches and blifters. It is usual to begin with bliftering
the head, but in military hospitais that is to be left to the
laft. The beft internai medicines are nitre and camphor.
Hoffman's proportion is fix grains of nitre to one of
camphor; small doxes of which are to be often repeat-
ed.

The patient's drink fhould be sweet whey, or acidula-
ted by turning the milk with citron or lemon juice, and
sweetened with fyr. e meconio. To every quart add a
dram of purified nitre or fal prunella. Also emulions
are convenient, of the four cold feeds, with barley-water,
to every quart of which add two fcropules of nitre.

Antiphlogiftic clyfters are likewise proper: but if all
these means fail, recourse muft be had to cupping in the
lower parts, to opiates, and mild blifters.

Of the Pleurisy.

The pleurisy is moft predominant between the spring
and the summer.

It begins with chilnefs and fhivering, which are foon
succeeded by heat, thirft, inquietude, and the other com-
mon symptoms of a fever.

After a few hours the patient is feized with a violent
pricking pain in one of his fides, about the ribs; which
sometimes extends itfelf towards the fhoiuler-blades,
sometimes towards the back-bone, and sometimes towards
the fore-parts of the breath; and this is attended with
frequent coughing.

The matter which the patient fhews at firft is little and
thin, and mixed with particles of blood; but as the dif-
eafe advances, it is more plentiful and more concocted,
but not without a mixture of the blood.

The fever keeps an equal pace with the cough, pain,
and spitting of blood; and in proportion as the expec-
toration becomes more free, it fenfibly decreases; fome-
times the body is coflve, fometimes too open.

The blood drawn from a vein, as foon as it is cold, looks
like melted feet.

In this difeafe the pulfe is remarkably hard, and feems
to vibrate like a tenfe fhring of a musical ftrument, which
is the pathognomonic fein.

Hence pleurifies are diftinguithed into the moif and the
dry. It is likewife obfervable, that the pain in the fide
is more intenfe at the time of inspiration, but more mild
at the time of expiration.

There is no fever wherein the crifes are more regular
than in the pleurisy and peripneumony: for in young pe-
ople, and thofe of a full habit of body, bloody fhpirit ge-
nerally appears on the fourth day, and on the feventh the
difeafe terminates by a profufe feat. But in the phleg-
matic and more inactive, as alfo thofe in whom the difeafe

has taken deeper hold of the lungs, it will continue till
the eleventh or fourteenth day; going off partly by ex-
pectoration, partly by feat: then the pulfe becomes
more fof, and the patient falls into an eafy refreshing
feep.

But when on critical days the crifes is imperfect, there
is indeed a feat; but it neither eafes the patient, nor
terminates the difeafe. When it continues till the twenty-
fiuft day, there is reafon to fear a dangerous abfecfs in
the breath. It is therefore a good fign when the expec-
toration proceeds from the bottom of the lungs, bringing
up a vficid matter on the fourth day, mixed with blood,
afterwards yellow, and fometimes purulent. The sooner
the expectoration happens, the greater the hopes of re-
cover.

A loofenefs is not fafe; urine without a fediment is a
fufpectfed fign; and a profufe feat, unles on critical
days, is still worfe. On the eleventh and twelfth days a
loofenefs is not much to be feared, unles too great, for
it fometimes carries off purulent matter. If a bleeding
at the nofe happens about the fourth day, it is generally
attended with a remarkable alteration of the difeafe.

Those who die of an inflammation of the lungs are fuf-
cated, becaufe the matter adhering to the vehicles and
bronchial duffs cannot be coughed up.

In all inflammatory fevers, too hot a regimen is to be
flunned, both with refpeft to the bedcloaths and the heat
of the room; nor muft the patient be expofed to the cold-
air, nor drink things actually cold. Likewife all ftrong
fudorifics, diuretics, and cathartics, are hurtful. Nor, if
the patient has three or four ftools, muft the courfe of
nature be flopped.

The Diet fhould be cooling, relaxing, flider, and
diluting. Moistening things taken warm are preferable
to all others. Hence, barley oroat meal gruel, sweeten-
ed with honey, is proper; as alfo fweet whey.

The indications of cure are, 1. To prevent the farther
flaffs and dilatation of the blood. 2. To dilute and dif-
solve the fentor of the blood in pleuritics. 3. To mol-
lify, cafe, and relax the fpamin, pain, and copious aflux,
in order to put the impacted blood again into motion by
the help of the appulfe of the arterial blood. 4. To pro-
mote the excretion of the vficid, bloody, and purulent
matter, adhering to the bronchia of the lungs, fo that it
may be brought up and an abfecfs prevented.

Take away ten ounces of blood on the side of the part
affected. If the phyfician is called before the third day,
the patient lying on his back, muft lofe a large quantity
of blood from a wide orifice in a large vefsel, and fetch
deep fhights, or cough, to promote its cerelrity; and the
part affected fhouid be rubifhed gently at the fame time.

The bleeding fhould be continued till the pain remits, or
the patient is ready to faint. It fhould be repeated as often
as the symptoms return which it was intended to remove.

The abfence of the white inflammatory pellicle from the
surface of the blood, when cold, fhews it is time to leave it off.

This Huflham confirms by his own experience; and adds,
that after the fourth day bleeding is not fafe. He like-
wife recommends fomenting the part; which often eafes
the pain, and terminates the difeafe. But if it is obli-
mate, he recommends flight fcarifications; then cupping;

Vol. III. No. 72.
and afterwards a blister on the same place, which has been successful when the usual methods failed. An emollient cooling clyster should immediately succeed bleeding, especially if the body is collic; and nitrous medicines, with a cooling, emollient, diluting regimen, should be forthwith entered upon. Thin whey, a decoction of barley and red poppies, and emulsions, will serve for drink.

Though the symptoms should vanish on blistering, it will be more secure to bleed again; unless a profuse sweat comes on with relief from pain, and makes all other remedies unnecessary. But if the lungs are likewise inflamed, the cure cannot be so speedy; for though the first bleeding and a blister should give ease, yet a repetition will be needful. Sometimes the blister returns and fixes on the other side; but this may be treated as the first with the same success.

Huxham says a great reliance on camphor and nitre joined with small doses of the paregoric elixir; and if there is a vehement pain, he thinks opiates may properly be joined with them, as they have a great power of relaxing the over tense fibres, of moderating the too rapid course of the blood, and of promoting the concoction of the morbid matter. Hence, after the use of opium, there is generally a copious sediment of the urine.

It is necessary that the body be kept open, and the bowels free from spasms; to which purposes emollient clysters are proper, with oil of sweet almonds.

In the first stage of the pleurisy or peripneumony, laxative clysters and the cooler diaphoretics are proper; but all cathartics and warm sudorifics do harm. The time of attending the diaphoretics is when the person finds ease by the blister: But whenever the spitting begins, the diaphoretics must either be omitted, or joined to expectorants; whereas the chief is oxymel of squills; or, in great heat or drought, some more pleasant acid. But in lowness, after repeated bleedings, give salt of hartshorn joined to some oil: This will raise the pulse, and promote expectoration when it fails.

If, notwithstanding the discharge, the breath continues to labour, bleeding is still requisite: For the lungs are not to be overpowered by the omission of bleeding; nor is the suppression of the spitting to be hazarded by bleeding too freely. But with regard to blisters, there need little caution; as they are always efficacious, to raise, relieve the breast, and to promote expectoration.

In the course of expectoration, a vomit will sometimes be useful in discharging the load of viscid phlegm. If the phlegm is tough, or the patient collic, and opiates are given, they must be joined with squills.

When the pleurisy ends in a suppuration, or abscesses, the signs are, a slight vague shivering, which often returns without any evident cause; a remission of the pain, while the difficulty of breathing remains; a redness of the cheeks and lips; thirst; a febricula, or slight fever, especially in the evening; a weak, soft pulse.

When the abscess is actually formed, there is an obliate dry cough, which increases after feeding or motion; the breathing is difficult, small, thick, short, and wheezing, worse after eating and motion; the patient can only lie on the side affected; a flow, periodical fever, which is exasperated with stirring and eating; a decayed appetite, great thirst, nocturnal sweats, paleness, leannees, and excessive weaknesses.

This either ends in a consumption; or the matter falls into the cavity of the thorax, and so becomes an empyema.

Of the Bastard Pleurisy.

Hoffman says, that the seat of every genuine pleurisy is in the lungs, as appears from the opening of those that die of this disease.

Therefore, if the inflammation occupies the external parts only, it is a Bastard Pleurisy: if the external surface of the lungs, like an erysipelas, it is a genuine pleurisy.

A Bastard Pleurisy is attended with a very acute and pricking pain in the side, which is exasperated by the touch; lying on the affected side is difficult; there is a dry cough, without the ejection of purulent or bloody matter, which, if strong, increases the pain. There is likewise a fever, with a hardish, depressed, and frequent pulse.

The cause does not seem to be in the blood, but rather in the vessels of an acrid serum at the conjunction of the ends of the fine azygous arteries and veins; as also of the lymphatic vessels of the pleura, and likewise in the perifleum of the ribs, where the senfe is more acute.

Hence it is nothing else but a kind of rhumatism, and is common to those who are now and then troubled with catarrhs, rheumatic and arthritic pains, or a hemorhania; especially if they come out of a hot air into a cold, or the contrary, particularly in the evening.

This does not require bleeding, unless there is a remarkable plethora; but a diaphoretics, and a more free perspiration. On the seventh day it generally disappears, and is without danger.

Lancifius advises to bleed plentifully in the arm, and to scourify the part affected. After this two cupping glasses are to be applied thereto, which will cure the disease as if by enchantment.

Hoffman observes, that those are apt to fall into a bastard pleurisy who are much exposed to a moist cold autumnal or wintry air: For there are no diseases or inflammatory fevers so soon generated by the intermecries, inequality, and change of the air, as those of the throat. When the summer has been hot and dry, and the weather has suddenly changed to cold, with a northerly wind, not only cartarhal defluxions have ensued, but rheumatisms and pleurises, with bloody spittle and violent pains in the side, have been very frequent. For the air, from continual inspiration, immediately affects the lungs internally, and externally the thorax and ribs, which are beset with thin muscles, membranous nerves and vessels; for which reason spastic crifpatures are readily induced; and the free circulation of the humours flot.

The best way is to keep the part affected in a temperate and equal heat, in a warm bed; especially as the skin of every patient, as in the gout and erysipelas, cannot bear topics.
**MEDICINE.**

*Of a Peripneumony.*

There are several kinds of this disease. For it may arise from a violent inflammation of the lungs, by a very fizy, dense blood obstructing very many of the pulmonic and bronchial arteries; or from an obstruction of the lungs by a heavy, viscid, pituitous matter; which is called a spurious or bastard peripneumony: or from a thin, acrid fluxion on the lungs; and then it is a catarrhal peripneumony.

The symptoms common to all, are, a load at the breast, a short difficult breathing, and more or less of a fever. But in a true peripneumony, there is a more tenfive pain than in the pleurisy; besides, it is rather more obtuse and pressuring than acute, and shoots as far as the back and scapula. But the difficulty of breathing is greater, as well as the anxiety and expectoration, whereby a variegated spittle is brought up, which lay as it were deep: for in this disease the vessels of the lungs themselves, whereby the blood circulates from one ventricle of the heart to the other, are affected; being stuffed and obstructed with a thick blood, which is apt to grow more viscous and solid. Wherefore it is the more dangerous and fatal, especially if it attacks old persons, and if bleeding is not timely administered. Boerhaave says, the pulse is soft, slender, and in every sense unequal: and Huxham, that if the pulse is hardly felt before bleeding, it will afterwards beat very strongly.

In the cure, great regard must be had to the different stages of this disease, and the different symptoms that attend it. Bleeding is indispensably necessary at the beginning of a severe inflammation of the lungs; but if, after the second or third bleeding, the patient begins to spit a well-concocted matter, freely tinged with blood, you must forbear to repeat it, otherwise the patient will be weakened, and a fatal suppression of the expectoration will ensue. But if he brings up a considerable quantity of florid, thin, spumous blood, by spitting; then bleed again, quiet the cough with diacodium, and give proper acids pretty freely, with soft cooling incipients. If a thin, gleetly, dark-coloured mater is expectorated, it is generally a mark of greater malignity, and that the blood is in a putrefying dissolving state, and will not bear a large loss of blood.

Generally the more violent the rigor or horror is at the attack, the more violent the succeeding fever will be, which will in some measure guide us in drawing of blood. If the symptoms are not relieved by the first bleeding, after eight, ten, or twelve hours, let it be repeated; or sooner, if they become aggravated. If the fever, anxiety, oppression, and difficulty of breathing, increase, bleed again, especially if it appears very firm and dense, or covered over with a thick yellowish coat or buff. However, it does not appear sometimes till the second or third bleeding, though the symptoms indicate a very high inflammation. This often happens from the blood not spouting out in a full stream. This appearance of the blood, with a firm strong pulse, will warrant the taking away more, till the breathing becomes free and easy.

If the craffamentum is of a very loose texture, and not covered with a buff coat, and the pulse on bleeding sinks, flutters, or grows more weak and small, it is time to defist. A bluish film on the blood, with a kind of a soft greenish jelly underneath, while the crust itself is livid, loose and soft, with a turbid, reddish, or green serum, is a sign of a very lax crust of the blood, and great acrimony, which will not bear great quantities to be drawn off. If the blood is very florid, thin and loose, with little or no serum after standing for some time, it generally argues a considerable advance to a purulent and very acrid state.

A strong, throbbing, thick pulse, always indicates farther bleeding; at least till the patient breathes more easily, or a free expectoration of laudable matter is obtained. It often happens, that the pulse at the very beginning seems obscure and oppressed, irregular, sluggish, and sometimes interrupting, with weakens and oppression. But this does not arise from the defect, but from the too great quantity of blood; for the blood-vessels being over-loaded and diffused, cannot act with sufficient vigour. This is succeeded with a dreadful train of symptoms, and even death itself, if not prevented with sufficient bleeding.

In some very violent peripneumonies, an immediate and excessive weakens comes on, with an inexpressible anxiety and oppression of the breath; a very small, weak, trembling pulse, coldness of the extremities, with clammy, coldish, partial sweats, the eyes flattering, fixed and inflamed, the face bloated and almost livid. This has soon been followed with a florid, delirium, and sometimes with a complete paraplegia.

Some kinds of peripneumonies will not bear large bleeding, especially the epidemic or malignant. The pulse and strength of these patients have funk to a surprising degree; and the disease has turned into a sort of a nervous fever, with great tremors, subfulbus tendinum, profuse sweats, or an atarabulous diarrhoea, with a black tongue, coma, or delirium; though at the beginning the pulse seemed to be full and throbbing, and the pain, cough, and oppression is very urgent, as to indicate bleeding pretty strongly. In these cases the blood was seldom buoyant to any considerable degree, but commonly very florid, of a very loose and soft consistence, or very dark-coloured, and coated with a thin and bluish or greenish film, under which was a soft greenish jelly, and a dark livid crust at the bottom. Sometimes the coat was much thicker and more tough, but of a pale red colour, resembling the cornelian stone, or a dilute jelly of red currants. When the blood is thus dissolved, abstain from farther bleeding, especially, if the pulse or patient becomes more languid after it, though the oppression, load, or even pain, may seem to require it.

When the fizy coat on the blood is excessively tough, and extremely yellow, or of a pale red colour, it threatens danger; for the inflammatory lensor will scarcely mix with any diluents. Sometimes, after repeated bleeding, the craffamentum has scarce been a sixth part of the volume of the blood, and yet as solid as a piece of flesh. This is generally mortal.

When the peripneumonic symptoms continue for four or five days or more, we may justly fear an abscess, or a mortification; and little advantage is to be expected from farther.
... farther bleeding. But if the pain returns with violence after having ceased a considerable time, it is a sign that a new inflammation is forming, which indicates bleeding as much as the primary, but not in the same degree.

The strength of the patient and pulse, the violence of the pain and difficulty of respiration, are, in a great measure, to determine the quantity. When the pulse and strength seem to require bleeding, cupping on the shoulders will relieve the breast and head. Likewise the use of blisters, infus, fefts, are very serviceable in inflammations of the lungs.

Laying a blister on the part affected is the proper cure of a pleurisy; but a peripneumony is naturally more dangerous; and the more so as the epipatitic cannot operate so directly on the lungs as the pleura. But even in this case, blistering is most to be relied on after bleeding. You may first blister the back, and afterwards one or both sides. Epipatitics tend to relieve the breast, not only when applied to the chest, but also to the extremities; and promote expectoration: Whereas bleeding must be used cautiously, if at all, after the spitting appears.

The fever and the inflammation require a cool, diluting regimen, and nitrous and relaxing medicines; together with a moderately cool, free air, and quiet both of body and mind. A close room is very incommodious; if it cannot be avoided, it should be prudently aired. There is nothing more proper than thin whey, a barley ptisan with liquorice, figs, &c. the infusion of pectoral herbs, such as ground-ivy, maiden-hair, colt's-foot, hyflop, &c. These should be gently acidulated with juice of Seville oranges or lemons. Honey will render them more serviceable in inflammations of the lungs.

When much sincere, florid, or frothy blood is spit up, take away as much blood immediately as the patient's strength will bear. If the haemoptoe continues, bleeding in the saphoena will be found of the utmost service. Then direct cooling emulsions, nitrous, demonic, and mucilaginous medicines; and vegetable and even mineral acids, if the spitting of blood is very considerable. The drink may be a decoction of red poppies, colt's-foot, and figs, acidulated with elixir of vitriol. The cough may be appeased with diacodium, or elixir paragaries. A valuable drink. Direct diacodium, or elixir paragaries, to moderate the cough, in small doses often repeated; psorura ceti, olibanum, myrrh, and camphor, tend to increafate the thin catarrhal humour, and abate the iritation.

In the Putrid Peripneumony the expectoration is livid, gleyey, and faniouf, frequently reftembling the lees of red wine; sometimes more black, and sometimes very fetid. This is often the cafe of the highly scorbutic; particularly sailors, after a long voyage. Blood taken from these, appears to be in a dissolving putrefcent state. The craffamentum is loofe and tender, the serum turbid and reddish; the tongue is black; the teeth furred with a dark, thick fordes; the breath offensive; the urine high-coloured or blackifh. Black spots, or a dysentery, frequently appear on the fifth, fifth, or seventh day. The pulse and strength sink after bleeding: sometimes a vast anxiety, fainting, a cold sweat, a thready intermitting pulse soon after. This has sometimes happened in pleuro-peripneumonies, where the pain of the side was violent, the load at the breast great, and the cough considerable.

This will never bear a second bleeding to advantage; seldom the first, unless there is a considerable degree of firmness and tension in the pulse. When there is reason to be diffident, order scarifications and cupping.

In this disease give a decoction of figs, colt's-foot, and red poppies, well acidulated first with juice of Seville oranges or lemons, and afterwards with gas sulphuris; or elixir vitriol. Sitre, olibanum, myrrh, flowers of sulphur and bole may be administered, with conserv. lujule, rob of elder, currants, mucilage of quince-feeds, and syrup. de rubeo ida: camphorated vinegar, with syrup of elder or raspberries, is an excellent medicine. A spoonful or two of these latter should be given ever and anon. Sound cyder, and wine and water with Seville orange or lemon juice, drank warm, promote expectoration when deficient. Tincture of roes with red poppy flowers, has moderated an inordinate defluxion of thin bloody ichor. However, oxymel of squills, and strong cinnamon-water, are frequently necessary to pump up the ichor, when a great rattling in the throat and difficulty of breathing indicate a vast quantity of it in the lungs. And yet the violence of the cough may be often appeased by elixir athmaticum or diacodium. The patient is to be supported with fago, panada, harthorn jelly, roasted apples, cream of barley, or thick gruel, with a little wine and juice of lemons, giving a little at a time, and often. Strawberries, raspberries, currants, cherries, may sometimes be indulged.

At the close, the whole depends on a well-regulated diet. A toft with diluted red port wine, mulled with Seville orange-peel, mace, or cinnamon, and well acidulated, may be very useful. Bliffers are seldom beneficial in this cafe, but often mischievous.

A very thin yellow spitting, either shows that nothing but the thinnest part of the blood is strained through the arteries of the lungs, or that the whole mass of blood begins to dissolve; that its bilious principles are highly excited, and that all tends to a general putrefaction. It is commonly
of the faculties of the mind, thick and short breathing, beginning with an oppression of the breath. The com-
motions it excites are so small, that the heat and fever 
are scarce sufficient to make the patient sensible of his 
danger. Afterward, slight shiverings which come on by 
fits, and the attacks of a gentle fever, appear; whence 
the difficulty of breathing and weakness suddenly increa-

When perpetual, laborious wheezing, great anxiety 
and constant oppression on the precordia, comatous symp-
toms, cold extremities, and dark bad-coloured nails 
and vifage come on, the patient is in immediate danger. 

When comatous symptoms and a very difficult breathing 
remain after bleeding, cup and scarify the neck 
and shoulders. This has frequently had a surprizing ef-
fect. When the cafe is very threatening, blister the sac-
ifications.

After bleeding, let the patient have the following clytter, 
which must be repeated daily till the lungs are relieved. 
Take 3 ounces of honey, the yolk of an egg, and 8 
ounces of barley-water. Make them into a clytter.

Let the patient’s diet be very slender, such as weak 
broths, sharpened a little with orange or lemon juice, 
and he may drink a weak mixture of honey and water; 
the fumes of warm water may be taken in at the mouth. 

Likewise let the legs and feet be bathed, and large 
blisters applied. Sydenham advises a repetition of the 
bleeding and purging alternately, every other day, or at 
greater intervals, as the strength and symptoms require. 
But he has generally found twice bleeding sufficient.

Of the Inflammation of the Liver.

When the liver is inflamed, it compresses the stomach, 
diaphragm, and the neighbouring viscera of the abdomen; 
it stops the circulation of the fluids, hinders the genera-
tion and excretion of the gall, and all digestion. It pro-
duces a great many bad symptoms, as the jundice, with 
all the diseases depending thereon; for the liver receives 
the refluent blood from almost all the parts of the ab-
domen, and is the chief instrument of almost all the di-

gestions that are made there.

A fever, an inflammation, and pungent pain on the 
region of the liver and diaphragm, a tension of the hy-
pochondria, yellowness of the skin and eyes, and a faffron-
coloured urine, are signs of an inflammatory disposition 
of the liver.

It begins with cold and shivering, sometimes with vo-
mitting and a fever, watching, difficult breathing, in-
quietude, and collynefs. This is a kind of rheumatic 
or erysipelas fever, proceeding from a sharp viscid 
serum, lancinating the nervous fibrille. It is sometimes 
accompanied with a bastard pleurisy, to which it is akin.

It is not very dangerous, and rarely kills, unless the 
viscera are unfound.

Narcotics and sudorifics are to be shunned.

This disease terminates as other inflammations, being 
cured by resolution, concoction, and excretion of the mor-
bid matter; or else in an abscess, seirrhous, or gangrene.

During the first stage, a warm regimen and saffron are 
improper.

Cooling resolving liquors, taken inwardly, as whey 

Vol. III. No 73.
with forrel boiled in it. Outward fomentations, and fre-
quent injections of cryflers, bathing, and friction, relax,
and render the matter fluid. Honey, with a little Rhenifh
wine, or vinegar; the juices and jellies of some ripe
garden fruits; and thofe of fome lacteal plants, as
endive, dandelion, and lettuce, are refolvent.

Fat oily epithems, and plaiters, are to be fhunned.
Camphor in croceated spirit of wine is only to be used in
the beginning, or when the fever is moderate, and na-
ture fluggilh. Bleeding at firft is neceffary on the affected
fide, in the hand or foot.

Violent purging hurts; gently relaxing the belly re-
lieves: diluents, with nitrous fahs, are beneficial, or
tamarinds boiled in warm water or whey.

A cryfler purely oleous is benefial, with a bladder-full
of an emollient decoction. Inwardly, diluting and refolvent
mixtures.

If it is attended with the judicious, then apply epithems
of carduus benediflus, fcorfium, wormwood, elder flow-
ers, chamomile, feeds of lovage and cummin boiled in wine,
and often applied.

Pringle fays, the beft remedy, after plentiful bleeding,
is to lay a large bliffer over the part affected.

Bloody flools, not in an extreme degree, or ftruck
with blood, ought not to be flopped, because they help to
refolve the diftemper: bleeding at the nofe often does
the fame.

The feveth matter is frequently carried off by urine;
and therefore diuretics not highly stimulating are proper.

Sweating ought not to be promoted by hot cordials,
but encouraged by warm diluting liquors.

The cafe is deplorable, when the inflammation termi-
nates in a fuppuration, unlefs the abfcefs points outward-
ly, fo as it may be opened. For if the pus is evacuated
into the abdomen, it produces putrefadion, or an incu-
vable hepatic dyfentery or bloody-flux.

Of a Paraphrenitis.

This difeafe is an inflammation of the diaphragm, and
parts adjacent. A paraphrenitis is attended with a very
acute continual fever, an intolerable inflammatory pain of
the part affected; which is extremely augmented by in-
spiration, coughing, fneezing, repletion of the flomach,
a naufea, vomiting, compreflion of the abdomen in going
or to ftool or making water. Hence, the breathing is thick,
short and fufficiently, and performed only by the motion
of the thorax. There is also a conftant delirium; a
drawing of the hypochondria inwards and upwards, an
involuntary laughter, convulfions, and madnefis.

This difeafe terminates as in a pleurisy; but is attended
with more violent fymptoms, and is much more fatal. If
the part affected fuppurates, the matter will fall into the
abdomen, and produce a purulent afcites.

The cure muft likewife be attempted in the fame manner
as in a pleurisy.

Of the Inflammation of the Inteftines.

This difeafe contrabies the intestines, and flops up the
passage through them. There is a vehement, fixed, burn-
ing pain, which is irritated by things taken inwardly.
When the inflammation is in the upper part of the inte-
ftines, the flomach will be greatly diffended by wind.
When the pain is exasperated, it produces convulfions of
the diaphragm and abdominal muscles, vomiting, painful
inflations, with rumblings, and sharp gripping pains which
may bring on the iliac paflion, or twifting of the guts.

When there is a burning pain in the abdomen, with a
preternatural heat of the whole body, as also a quick pulse,
lofs of strength, anxiety, and inquietude, the feat of the
difeafe may juftly be fuppofed to be in the intestines. If
the sharp pain is above the navel and below the flomach,
attended with a fever, naufea, and reaching, it is a fign
that that part of the colon is affected which lies beneath
the flomach, and is extended from the right to the left-
side. If the pain lies in the right hypochondrium, un-
der the fpurious ribs, it fheves that part of the colon to
be inflamed where it joins to the ilium. When the com-
plaint is of the left fide, under the loins, where the ploas
mucle is placed, it is a fign the colon and that part of
the mefentery joined thereto is the feat of the dif-
eafe, efpecially when it adheres to the peritonaeum. But
when the pain is in the middle of the abdomen about the
navel, it fheves the small-guts are certainly affected. In
all these cafes the pain is fuppofed to be attended with a
fever.

When there is a fever, and a burning pain in the low-
er part of the belly, attended with a swelling, which ends
in a copious, putrid, or purulent flux, with a great difor-
sation, the patient fhould only be nouriflied with
animals, applied to the body, are extremely beneficial,
Arbuth. The patient fhould only be nouriflied with

After bleeding and clysters, if the pain still continues violent, there will be no manner of danger in giving opiates, by which means the excruciating pain will be alleviated, the fluxes appeased, and a breathing sweat will follow. When this is done, and the fever is abated, there will be no occasion to continue the diluting, relaxing, and moistening medicines, but rather the nervous and corroborating.

If the patient survives three days, and the acute pains of the pain abates, with a chill or shivering throughout the body, it is a sign of a suppuration; then within fourteen days the impothesis will break; and if it falls into the cavity of the abdomen, it will corrupt the whole mass of fluids, putrefy the viscera, and turn to an ascites.

In this case, whey and chalybeate waters are likely to prove most beneficial.

If the fever continues, with clammy sweats, paleness, an ichorous diarrhea, fetid, black, or like the washings of flesh, a small intermitting pulse, and at last a total cessation of pain; they are signs of a gangrene and an approaching death.

Of the Nephritis, or Inflammation of the Kidneys.

The symptoms of a nephritis are, a great inflammatory, pungent, burning pain, in the place where the kidneys are situated, attended with a fever; the urine is made heavy, but small in quantity, and very red or flame-colored, yet, in the highest degree of the disease, watery. There is a numbness of the thigh, and a pain in the groin and the testicle, of the same side; a pain in the ilium, bilious vomiting, and continual eruptions.

When the inflammation is deep, the fever violent, the burning pain in the loins lafting, the difficulty of making water great, the body very collyve, the anxiety and straitness of the praecordia exquisite, the urine crude and white; likewise, if the pain continues till the fourteenth day, the kidney will suppurate; which is known from the abating of the pain, and from the thick purulent sediment of the urine. This will sometimes last several years, till there is nothing left of the kidney but a bag: it is attended with a hectic fever, and the patient before he dies is almost reduced to a skeleton. If the bag happens to burst, it brings on a retention of urine, and intolerable pains, which end in death.

If it continues beyond the seventh day, an abscess is to be feared, which is known to be forming by a remission of the pain, succeeded by a pulsation in the part, and chills and shivering often returning.

When the disease is favourable, it is cured by resolution, of a copious, red, and thick urine discharged at one time, or by a large flux of blood from the hemorrhoidal veins, in the beginning of the disease.

It is cured by plentiful bleeding, revulsion and dilution; by soft, emollient, antiphlogistic decoctions.

When a burning and fixed pain in the loins continues for some time, it is a sign that the venal veins are stuffed and obstructed with a thick blood, which requires immediate bleeding in the foot; or if there is a disposition to a hemorrhoidal flux, apply leeches to the anus.

Afterwards give such things as temperate the heat of the blood, and promote a free circulation, with a diaphoretic. For which purpose, emulsions, demulcents, diluents, antispasmodics, diaphoretic powders, with cinnaubar and nitre, are preferable to every thing else.

Emollient clysters, without any saline or purging flux, are the principal help in this disease. They may be made of milk, whey, or soft water, in which elder and chamomile flowers have been boiled; to which add an ounce or two of syrup of marshmallows, and a dram of nitre.

When there are convulsions, or excessive pain, opiates are proper. If the vomiting, a symptom of this disease, is too frequent, warm water sweetened with honey is beneficial.

The patient should avoid all acrimonious aliment; he should neither lie too hot, nor on his back.

When an abscess is formed, the medicines must be powerfully maturing and emollient: When the urine appears purulent, they must be diuretics of medicated waters, whey, and the like; together with balfamics.

Emulsions are likewise useful of the four cold seeds and sweet almonds. Some attribute a great virtue to cherry-tree gum dissolved in whey or water, and taken often. Also syrup of marshmallows is very useful. Add to these, the decoction of veronica, sweetened with honey, and mixed with powder of nutmegs.

Butter-milk, not very four, has been reckoned a great secret in ulcers of the kidneys; and chalybeate waters have been beneficial to some. Spruce-beer is a good balsamic in this case.

Of the Inflammation of the Bladder.

The pathognomonic sort of this disease are, an acute, burning, piercing pain in the region of the pubes, attended with a fever, a continual tenesmus or desire of going to stool, and a perpetual striving to make water.

Other symptoms are, a rumbling of the bowels, gripping pains, great anxiety of the praecordia, difficult breathing, want of appetite, vomiting, coldness of the extremities, a hard, quick, unequal, contracted pulse, inquietude, and sometimes convulsions.

There is another kind which is more superficial, and is either rheumatic or erysipelas, in which the fever is more easily and speedily cured by promoting a diaphoretic:

And persins in years, or who are affected with the scurvy, gout, rheumatism, or violent head-aches, are most subject to it; especially if they catch cold by being exposed to the rigour of a cold north-wind.

The former arises most commonly from the floppage of the menes, bleeding piles, or other utal fanguinary evacuations; and not seldom from a violent gonorrhoea unskillfully suppressed by antirhagens, or when treated by medicines of too sharp and hot a nature.

This disease is mortal, if it terminates in an ulcer or mortification.

The cure must be attempted with bleeding in the feet, if a suppreffion of the menes or hemorrhoidal flux be the cause.

If it proceeds from the scurvy, &c. recourse must be had to gentle diaphoretics, diluents, and remedies which obstruct.
obtund the acrimony of the humours, such as decoctions of the roots of scorzonera, china, skirrets, and fennel; also infusions, in the manner of tea, of the tops of yarrow, flowers of mallow, winter-cherries, and seed of daucus, made with milk, and sweetened with frup de althea. If the patient’s body is collyve, manna will be proper, with nitrum flihiatun; to which rhubarb may be joined, as occasion requires.

Externally, antispafmodics and gentle diocutients will be proper: For this purpose apply bladders filled with a decoction of the emollent flowers.

If the tenseness and difficulty of urine arise from spafms, there is nothing better than the vapours of a decoction in milk of the flowers of melilot, elder, chamomile and mallow, and the tops of yarrow. This decoction may be put into a clofe-floid; and the patient fit over it.

Tulpius informs us, that a desperate ulcer of the bladder was cured by the constant use of spaw water.

Of the Ophthalmia, or Inflammation of the Eyes.

An inflammation of the membranes which invest the eye is a very common disease, especially of the adnata or albuginous coat of the eye.

The eyes are very much inflamed, with great pain, tension, tumour, heat, and redness; and sometimes there is such a strong sensation of pricking in the eye, as if it was caufed by a needle or thorn. The eyes at first are full of scalding tears; which are followed by a pituitous parts will fwell even as far as the cheeks, with a ftrong pulfation of the adjacent arteries. The fmail blood-veffels are vifible, which in health are not to be feen, and all the white of the eye becomes red.

If, besides these external signs, there is an appearance of moths, duft, flies, &c. floating in the air, there is an inflammation of the retina.

As in all difeafes of the eyes, fo especially in their inflammation, the patient must abstain from all spirituous liquors, the fmoak of tobacco and flernatatories; he must likewise avoid fmoaky rooms, and the vapours of onions and garlic, as also all vivid lights and glaring colours. The drink may be water alone, or a decoction of fennel-feeds, harthorn, and barley; the aliment must be light of digeftion.

Intemperance of all kinds renders persons liable to this disease; as alfo a keen north-wind, and looking earnestly at the fire, fun, or glaring colours; likewife fmoaky rooms, metallic vapours, coftivenefs, and unual refregrations of the extreme parts, especially in the time of menftruation. Sometimes it is owing to other difeafes, as external injuries; but not when they proceed from a ferontious or venereal caufe. In bad cafes, after the inflammation has yielded a little to evacuations, the coagulum aluminofum, fpread on lint, and applied at bed-time, is the beft external remedy.

In the mean while, blifters muft be applied to the neck, and kept running for fome days; and after that, fetsons, or iffues at leaft. It is hard to fay, of what vaft advan- tage blifters and fetsons are in this difeafe.

The expreffed juice of millepedes may alfo be given [25 are a dofe] on the days purging is omitted, in four ounces of beer, or Rhenifh or French white-wine: let them ftand, when mixt, all night; and then take it with a little fugar in the morning, after the mixture is drained.

But according to the later experience of Dr Fordyce, Fothergill, and others, a ftrumous ophthalmia may be cer- tainly and fafely cured by half a dram of the bark given twice a-day.

The length of time in which the bark is to be taken is uncertain; for in fome the cure is performed in lefs time than others.

Hoffman, besides blifters, fetsons, &c. recommends cupping, with fcarification, in the nape of the neck, and behind the ears; and in the violent fort of this difeafe, bleeding in the jugular; as alfo fnaipifms of rocket-feeds boiled in wine, and then put into small bags and applied to the nape of the neck or under the armpits. For in- ward ufe, he prefers to all other remedies, an infusion, in the manner of tea, of valerian-root, liquorice, elder-flowers and fennel-feeds, drank plentifully; and before the
The drinking of it to receive the vapour or steam into the eyes.

Of the Apoplexy.

This disease is a sudden abolition of all the senses, external and internal, and off all voluntary motion, commonly attended with a strong pulse, laborious breathing, a deep sleep, and snorting.

There is no difference between a person asleep and in an apoplexy, but that the one can be awakened, and the other cannot.

The causes of this disease are a particular conformation of the body, as a short neck, for some have fewer vertebrae in their necks than others; a groat, plethoric, fat, phlegmatic constitution; polyphous concretions in the carotid and vertebral arteries, or about the heart, or within the skull, which are known by an unequal pulse, a vertigo, and sometimes a momentary loss of sight; an inflammatory thickening of the blood, preceded by a fever attended by the head aching, redness of the face and eyes, an advanced age, attended with a glutinous, cold, catarrhal, leucophonegetic constitution.

The forerunners of an apoplexy in these last, are, dulness, inactivity, drowsiness, sleepiness, flux of speech and in giving answers, vertigoes, tormsigns, oppressions in sleep, night mares; weak, watery, and turgid eyes; pituitous vomiting, and laborious breathing on the leaf motion.

Other causes may be, whatever compresses the vessels of the brain; as, a plethora, a cachexy, attended with fulness of the vessels; a hot constitution; tumors within the skull; the velocity of the blood increased towards the head, and diminished downwards; compression of the veins without the skull, which bring the blood back from the brain; the effusion of any fluid compreings the dura and pia mater externally; the effusion of any fluid within the brain; which by its pressure hurts the origin of the nerves; this is the most common cause of apoplexies, and proceeds from blood in the plethoric, from a sharp serum in the hydroptic and leucophonegetic, and from an atrabilious acrimony in the melancholic, the scorbutic, the phlegmatic constitution; polypous concretions in the carotid and vertebral arteries, or about the heart, or within the skull, which are known by an unequal pulse, a vertigo, and sometimes a momentary loss of sight; an inflammatory thickening of the blood, preceded by a fever attended by the head aching, redness of the face and eyes, an advanced age, attended with a glutinous, cold, catarrhal, leucophonegetic constitution.

The immediate forerunners of an apoplexy, are tremblings, flagging, a giddiness in the head, a vertigo, dimness of sight, a stupor, sleepiness, forgetfulness, noise in the ears, more deep and laborious breathing, the night mare.

A slight apoplexy goes off in a profile, equal, resided, warm sweat; a large quantity of thick urine, by the bleeding piles, the flowing of the menses, a diarrhoea, or a fever. If it is more severe, it usually terminates in a paralytic disorder; and is seldom curable, but always leaves behind it a great defect of memory, judgment, and motion.

Bleed in the arm to 12 ounces, and then in the jugular to 7 ounces; immediately after which, give an ounce and a half, or two ounces, of emetic wine.

Apply a large strong blister to the neck, hold the patient upright in bed, and let the spirit of sal ammoniac, highly rectified, be held to his nose.

Let there be strong frictions of the head, feet, andhands; and let the patient be carried upright backwards and forwardsways the room, by two strong men. Strong blisters should be applied to the head, neck, back, and calves of the legs. Sharp clysters should be thrown up into the body, which have a tendency to excite the patient, and to cause a revulsion.

Shaw advises, during the fit, to bleed largely in the arm, or rather in the jugular, to apply strong volatiles to the nose, to blow sneezing powders up the nose, as also to rub the temples with spiritous cebaline mixtures.

Likewise to blow in the mouth and nostrils the smoke of tobacco from an inverted pipe.

Those who have once had a fit of the apoplexy, are very liable to be seized with it again; and if they are plethoric, the best preventative is bleeding once in three months, and using themselves to a spare diet; taking medicines which strengthen gently, and abstaining from cares and all intense applications of the mind; not neglecting infusions and infusions, nor the drinking suitable mineral waters.

Of the Palsy.

A Palsy is a lax immobility of any muscle, not to be overcome by the will of the patient. Sometimes the fentation of the part is absolutely abolished, and sometimes there remains a dull sense of feeling, with a kind of tingling therein.

It may be caused by all things that bring on an apoplexy; that render the nerves unfit to transmit the animal spirits; that hinder the entrance of the arterial blood into the muscles. Hence the nature of a paraplegia or hemiplegia, and the palsy of a particular part, may be understood.

Hence a palsy may proceed from an apoplexy, an epileptic, extreme and lasting pains, oppressions of the usual evacuations,
evacuations, translations of the morbific matter in acute
								
temperatures; whatever diffuses, diffuses, compresses, or
									contracts the nerves, strong ligatures, luxations, frac-
									tures, wounds, gangrenes, inflammatory and other tumors
									of the coats of the nerves, in the ganglia, or the nerves
									themselves; extreme heat, violent cold, mineral effluvia,
									and the too frequent use of hot water.

Pallies of the heart, lungs, and muscles serving for
									respiration, are soon fatal; of the stomach, bowels and
									bladder, from internal cauzes, very dangerous; of the
									face is bad, and easily changes to an apoplexy.

If the part is cold, insensible, and waifes away, it fel-
								
dom admits a cure; if attended with a violent convulsion
									and great heat of the opposite part, it is very bad.

The regimen in this discafe ought to be warm and at-
									temuating, consisting of spicy and cephalic vegetables, such
									as create a feverish heat, because it is necessary to dispel
									the viscofitv. Soapy vegetables are best, and such as consist
									of an acrid volatile salt, and oil, mustard, horfe radish,
									&c. stimulating by vomits; freezing; relaxing the belly;
									promoting sweat by such motions as can be used, or other
									means; by strong fridtion, &c.

The cure of the palfy is to be attempted by attenuants and
discutients; such as, aromatic, cephalic, nervous and
terine vegetables; the fixed and volatile salts; as also
by their oils; soaps made of their oils and salts; the stronc-
scnted parts of animals; the juices, spirits, oils, and
									liniments of infects; foflile salts, metallic crydials, and
									medicines compounded of these.

Likewise by things which stimulate strongly, and which,
									by exciting a tremulous and convulsive motion of the
								
ers, drive out the impacted matter; to this class, ftermu-
tatories and emetics chiefly belong, especially if often
									used at first.

By purging with warm, opening, aromatic vegetables,
									with acrid foflils, with mercurial and antimonal prepara-
tions, in a large dose, and repeated successively for fe-
								
tveral days, by the means of which a copious and lading
								
diarhoea may be excited.

By filling the vessels of the body with drinking a large
									quantity of the attenuants above mentioned, and then by
									exciting a greater motion and sweat by the vapours of spi-
								
ters set on fire.

Outwardly, fridtions may be used, either dry and hot,
till the part is red; or with spirits enued with a stimu-
lating virtue; or with nervous oils, liniments, balsams,
or ointments; vapour or immerfive baths; acrid, aroma-
tic, and drawing plaisters; cupping, fcarifications, blisters;
whipping the part with rods; exciting a flight inflamma-
tion with nettles, and the like.

A course of electricity for some weeks has been known
to have cured some invererate pallies, though it hath fail-
ed in others. See Electricity.

Of the Epilepsy, or Falling Sickness.

Sometimes this discafe comes on suddenly and una-
wares; but it oftener gives notice of its accession by some
preceding symptoms; the chief of which are, a laitude of
the whole body, a heavy pain of the head with some
disturbance of the senses, unquiet sleep, unusual dread,
dimmess of sight, a noise in the ears; in some there is a
violent palpitition of the heart, a puffing or inflammation
of the praecordia, a stopping of respiration, a murmuring
noise in the belly, fedit ftools, a flux of urine, a refrig-
eration of the joints; in others, there is a fene, as it
were, of a cold air ascending from the extreme parts to
the heart and brain.

Then they fall suddenly on the ground, (whence the
name of the falling sickness;) the thumbs are shut up close
in the palms of the hands, and are with difficulty taken
out; the eyes are distorted or inverted, so as nothing but
the whites appear; all fentation is suspended, infomuch
that by no smell, no noise, nor even by pinching the
body, can they be brought to themselves; they froth at
the mouth with a hissing kind of a noife, the tongue is la-
cerated by the teeth, and there is a shaking or trembling
of the joints.

However, the convulsions vary, as well as the defect
of the senses, both in degree and kind; for sometimes, in-
stead of convulsive motions, the limbs are all stif, and
the patient is as unmoveable as a statue. In infants
the penis is erected; in young men there is an emifion
of semen, and the urine very often streams out to a great
distance.

At length there is a remiflion of the symptoms, and the
patients come to themselves after a longer or shorter in-
terval; then they complain of a pain, torpor and heav-
iness of the head, and a laitude of all their joints.

These fits are more frequent or seldom, or longer or
shorter, according to their different causes. Some re-
turn on certain days or hours, or even months, according
to the quadratures of the moon, but especially about the
new or full moon; in women, chiefly about the time of
menstruation; and what is most remarkable, often upon
a very, flight occasion; for instance, any sudden perturba-
tion of the mind, as a fright, anger, sudden joy, intenf
application, ftrong liquors, excessive heat or cold, or ve-
nereal exercises.

As to the prognostics; in boys, this discafe terminates
about the seventh, the fourteenth, or the seventeenth year,
that is, about the time of puberty; in women, about the
fourteenth, viz. the time of menstruation. Likewise it has
been found by experience, that chronological epilepsies have
spontaneously ceased by the change of place, diet, and way of
life. Sometimes a quartan ague will put an end to an epilep-
sy and convulsion-fits. It is also remarkable, that the only,
or any other cutaneous disfemper, such as the small pox,
measles, military eruptions, &c. will either abate the viol-
ence, or quite stif the discafe.

The patient therefore need not defpair of a cure, if
the discafe is not of long standing, the fits short, the
disorder not hereditary, and the years advancing to the
time of puberty; or if it proceeds from a fault in the
prime vifor, from worms, from a bad regimen, or from a
subcutaneous discafe ill cured. Nor is there thefe deprete
if the epilepsy be flight, and when the fit is foreseen by a
feentation of cold air, arising from the extreme parts to
the back, praecordia, and head. and also when it is thuf-
pered in by anxiety, by want of strength, and a pro-
penity to vomit; or when the fenes are not quite abol-
ished in the time of the fit, or when it comes on in the
night, without the incurvation of the thumbs.
It is a bad sign if the epilepsy makes its first attack after the twenty first year, but much worse if the fits grow more frequent; for then the animal functions are often destroyed, and not only the memory, wit, and judgment are impaired, but the patient grows stupid and foolish. It sometimes ends in melancholy or madness. When it turns to a palsy or apoplexy, it is mortal.

The epilepsy is extremely difficult to be cured in adults, but in children it is the reverse. Blitters laid to the back part of the head are of great use a little before the paroxysm is expected: and the time may more certainly be foreknown, as this disease is influenced by the moon, and attends upon its phases, especially the new or full moon. The most proper medicines to correct the juices seem to be native cinnabar, and wild valerian root; a dram of which may be given morning and evening for three or four months, and afterwards two or three days before the new and full.

However, it must not be forgot, that this disease owes its origin to so many different causes, and is bred in so many different constitutions of the body, and the same remedy which succeeds in one case often fails in another; and therefore different medicines are to be tried, especially on adults. And great regard must be had to the times in which the paroxysms usually return, in order to effect a cure.

If the stools are full of blood, or it is carried with too great an impetuosity towards the head, then bleeding in the ankles will be proper, or leeches applied to the haemorrhoidal veins. This often happens to hypochondriacal or hysterical persons, to the melancholic, and women with child. Sometimes it will be proper to bleed in the jugulars; or to apply cupping-glasses with scarifications to the neck, and parts near the head.

It has its origin from a sharp, impure serum in the head, or in the membranes and vessels, as in cachectical or scabrous persons, or those who have been inconsiderately cured of edematous swellings of the feet, old ulcers, or blisters dried up; the driving in of the itch, scabs, or the ulcerating humour of a scald head; then the cure may be attempted by cathartics, by purifiers of the blood, by evacuating the impure humours with fomenta, infusions, cauterities, and blisters.

If it proceeds from violent pain, as for instance, from a fit of convulsion in the uterus, from the tooth-ache, ear-ache, or scab of the stomach and bowels; then clysters of oil of sweet almonds, or the like, are to be administered.

If, in children, it proceeds from gripes, or the breeding of teeth, nothing is better than to cleanse the prime vitre from filth, by milk-clysters, with a little venetian soap dissolved in them.

If from worms, after antiseptics and soft oily things, anthelmintics must be given, such as tansey, garlic, camphor, asea fettida, worm-feed, mercurius dulcis, and ethiops mineral, or powder of tin.

When the fits return at certain periods, or at the quadratures of the moon, a clyster or a vomit will be proper first of all, of half a dram of ipecuanha, in a decoction of raisins.

In the time of the fits, too free a use of volatiles, spirits, hot food, strong drinks, and strong stimulants, will add to the disorder. The fits are often occasioned by the surprising heat of the sun and moon; by strong sweet odours; by moving the body suddenly after being quiet a long time; by the discharging of vomit, and often by a kind of sleep, when the animal spirits are most active; or by being too much affected with cold.

generally keep on their legs without falling; yet some
will grovel on the earth like epileptic persons, and will
weep, laugh, gnash their teeth, gape with their mouths,
put out their tongues, roll their eyes, and whirl their
heads about in a strange manner.

After the fit, some are inexpressibly weak; some faint
away, others fall into a deep sleep; in others, again, the
fit is terminated with eruptions, wind, vomiting, and
throwing out plenty of water. Very often a mucous di-
stin from the nose, or blood issues from thence, or from
the uterus or haemorrhoidal veins.

These persons have generally unquiet sleep, and full of
dread and terror, an uncertain appetite, their bodies ge-
erally a little collyve; they sweat with difficulty, but are
subject to great passions of the mind. The accesions of
the fits keep exact pace with the phases of the moon. In
women they precede or accompany the eruption of the
menstrual flow. They are most frequent and worst after meals;
and are easily excited by the passions of the mind.

The fits are generally preceded with a coldness of the
feet and limbs, or a kind of tingling sensation; which
also affects the os coccygis, and like cold air ascends up
the spinal marrow; there is a dilated flutulent pain in the
left hypochondrium, and such a constricting of the body
that neither wind nor excrements can make their exit,
nor will the anus admit a enema-pipe, or, if it does, the
enema and excrements are thrown up by vomit. The
bladder is likewise affected, that no urine can be made,
or at least but little, and thin and white. In others,
the accession begins with yawning, fretching, anxiety
about the heart; a hard unequally contracted pulse, the
heart-burn, nausea, vomiting, palpitations of the heart,
difficulty of swallowing, pain of the head and teeth, noise
in the ears, giddiness, &c. and then come on the con-
vulsions.

Though this is a terrible disease, it never kills suddenly.
When it is recent, the person young, and otherwise of a
good constitution, there is the greatest hopes of a speedy
cure. If usual evacuations of blood by the uterus or ha-
morrhoids are suppressed, the return will either mitigate
or cure the disease. On the contrary, if the humours are
thick and impure, the suppurition obliterates, their tempe-
rament inclining to great sensibility, the age advanced, or
the disease hereditary, or become habitual, the cure is
difficult. Sometimes, through ill management, it degen-
erates into an epilepsy or hypochondriac melancholy.

To cure the St. Vitus’s dance, take away about 8 ounces
of blood, more or less, according to the age of the patient;
the next day give half, or something more of the com-
mon purging potion according to the age, and in the
evening the following draught:

Take an ounce and a half of alexiterial water; 30 drops
of compound spirit of lavender; a cuple of theri
aca andromachi; and 8 drops of the tinctura theba-
ica. Mix and make them into a draught.

Let the cathartic potion be repeated thrice every other
day, and the same draught in the evening. After which,
bleed again, and repeat the cathartics three or four times;
and this course may be pursued to the third or fourth
time.

Apply to the soles of the feet emplastrum e carannis.

For fear of a relapse, at the same season of the next year,
or a little sooner, in which the disorder appeared, bleed-
ing should be again repeated, and purging two or three
times.

Allen cured two girls of this distemper with the expres-
sion of millipedes, and the Peruvian bark, after bleeding
and a gentle cathartic.

As to the cure of other convulsive disorders, if the pa-
tient be plethoric, or the pulse great, it must be begun
with bleeding either in the arm or foot; and if occasion
requires, it must be repeated two or three times, but not
till the fit is over. The air should be dry and serene, with
constant exercize; the aliment should be easy of digestion,
and all hot spirituous liquors should be avoided. The
constant drink should be the decoction of scorzonera roots,
with strong decoction of hartshorn, or wine, or the Selter’s
mineral waters. Pediluvia are likewise proper, of river-water,
wheat-bran, and chamomile-flowers. They should be used
pretty warm and deep, at the time of going to bed, and
afterwards sweating should be promoted.

The patient’s body, if collyve, must be kept open with
mannia, or with oily enemas; and if the fomes of the
disease is judged to be in the prime vie, it will be pro-
per, at the changes of the moon, to give a vomit with
mannia, that is, an ounce of manna with two or three
grains of tartar emetic.

If, about the time of puberty, this disease proceeds
from too early or excessive coition, or violent passions of
the mind, all things which cause a commotion in the fluids
must be avoided; such as, aromatics, sharp purges, eme-
tics, spirituous liquors, inordinate motions of the body
or mind, and all heating things in general. On the con-
trary, the diet should be soft, emollient, and nourishing;
such as cow’s or ass’s milk, or whey; as also baths of
sweat water mixed with milk. Likewise jellies, and de-
coctions of scorzonera, barley, hartshorn, ivory shavings,
and viper’s flesh, for ordinary drink, and chocolate.

If it proceeds from worms, the cure depends on their
being killed and expelled out of the body: But all an-
themintics, or worm medicines, are not to be made use
of in this case; such as garlick, vitriol, copper, aloes,
sharp purges, and mercurials; because, if they are given
inconsiderately, they are hurtful to the nerves. It will
be better to use enemas, made of milk, sweet things, and
oil; as also limings of a purging quality applied to the
navel and abdomen. Inwardly may be taken fomenta-
nici. If mercurius dulcis is given with a cathartic, it
will be necessary first of all to let the patient take a few
spoonfuls of oil of sweet almonds.

If it is caused by a suppurition of the meninges, emmen-
agogues and hot medicines are to be forbore; but bath-
waters and bleeding will be proper; as also pediluvia, if
made pretty warm; hot infusions of balm flowers, and
flowers of the lime-tree, tincture of caloar, absorbent
powders, antispasmodics, and anodynes.

If from a floppage of the haemorrhoidal flux, besides
bleeding and the above remedies, leeches applied to the
anus will be of very great advantage.

In the observations of the medcal society of London,
we have an account of a deplorable convulsive case being
cured by electricity.
Of the Convulsive Asthma.

An asthma is an impeded and very laborious respiration, attended with unpeakeable anxiety, and a straitness about the precordia, hindering the free circulation of the blood through the lungs, arising from variety of causes, and not without danger of suffocation.

There are several sorts of asthmata. One is, difficulty of breathing, proceeding from corpulency and a very full habit of body; and is most apparent after violent motion: but this is a slight disorder, and free from all danger. The next is the pituitous asthma, attended with a mod habit of body; and is most apparent after violent motion: this is a flight disorder, and free from all danger.

There is a heaviness of the breast, a slowness to perform customary labours, difficult breathing when going up a hill; the patients grow hoarse, cough, and are troubled with frequent cavitations; they cannot sleep, and are scarcely warm in their beds. As the disease grows worse, the cheeks look red, the eyes grow prominent as if they were strangled; they snore or wheeze while waking, but much more when asleep; they are fond of cold air, they keep themselves in an erect posture, and seem to suck in the air with open mouth: they are troubled with sweating about the neck and forehead; then comes on a violent cough, and the patient brings up a little cold froth; the urine is more plentiful, but without a sediment; the voice grows clearer, the deeps longer than are necessary, the breath is slow and gentle, but with a sort of a wheezing.

The longer this disease continues, the more sharp and violent all the symptoms become. The patient’s body grows more cold, and the urine is thin and watry; most commonly the feet swell, then the hands, face and back; there is a numbness of the arms, the countenance is wan and livid, or of a leaden colour. Then comes on a little fever, which grows worse in the evening; the whole body is cachetic, with an edematous swelling of the feet; there is a dropfy of the breast, or an ascites, or anasarca; at least there is a pulley on one side, or of the arm; or, instead, thereof a pulley of the eyelids.

When the disease is recent, and is owing only to the spasmodic contraction of the precordia, there are hopes of a cure; especially if the matter of the gout, ulcers, and exanthemata, are fent back to their proper seats. When the menses or hemorrhoids which were distended, it brings on a drop of the breast, obstructions of the lower belly, edematous swellings of the feet, a cachexy, and an universal droopy. In general, all convulsive asthmata portend a sudden exit, or suffocation, especially if there is a polypus of the heart; if it continues long, then the patient will die of the droopy; in which case it will be soon fatal; when there is a slow fever, an unequal intermitting pulse, a pulley of the arms, a continual palpitation of the heart, little urine, a syncope or swooning, then death is at hand. Some are carried off by an inflammation of the lungs, and the more grievous the disease the more languid the pulse. The asthma, in old persons, continues till death.

In the paroxysm, because the body is generally bound, and the wind and humours are carried upwards, the speediest assistance is from emollient and carminative calomel.

Afterwards use frictions of the feet, which have an incredible efficacy; also let them be put into warm water; for the feet are almost always cold. When there is a violent spasm about the precordia, hot fomentations are necessary, or bladders filled with hot milk, and applied to the part affected; likewise nervous liniments are very useful, rubbed in with a warm hand.

Internally, antispasmodics should be given, with gentle diaphoretics.

And this is all that needs to be administered in the fit.

Out of the fit, if it proceeds from too great a congestion of blood about the breast, or from a polypus of the heart, bleeding in the foot will be proper, as also leeches; in a suppreffion of the hemorrhoids, leeches should be applied to the anus; also gentle laxatives to cleanse the prime vies; likewise bodily motion, slender diet, and soft drink. If there are hypochondriacal or flatulent symptoms, then gentle laxatives will be the more necessary, together with calomel. When the menses or hemorrhoids are suppressed, nothing is better than the bath-waters, both for bathing and drinking; or the waters of Selters taken warm and mixed with milk.

When the asthma proceeds from the driving back some impure matter from the skin, or from the drying up of ulcers, and the humour is translated to the nervous parts of the breast, then gentle diaphoretics will be necessary to fend it back to the supercicies of the body.

After which the patient may drink tea made of balm, or elder, or lime tree-flowers, with the leaves of scorodima, or veronica and fennel seeds, or any thing else of the same kind. Remedies compounded of sulphur are likewise very efficacious in driving back the morbid matter to the skin, though outwardly they are hurtful in cutaneous diseases.

The returns of the fits are to be observed and guarded against, by moderate evacuations, as bleeding, gentle vomits, laxatives, and sometimes cathartics: but every thing that heats the blood should be carefully avoided, especially about the usual times of the paroxysms; because there is generally then a lurking fever, which ought not to be exasperated by heating food or medicines.

In a dry asthma proceeding from fumes of lead, an air replete with exhalations from quick-lime, or the vapours of piccoal; milk, cream, oil of sweet almonds, emulsions of
of sperma ceti, the fat of animals used internally and externally, answers every purpose. Country air, and following the plough, are beneficial to restore the debilitated tone of the lungs; and tea, made with hyssop, veronica, ground ivy, liquorice, and daily flowers, cannot be enough commended. But sweet things, in every kind of asthma, are harmful, especially in the humid or ferous, and the hypochondriacal.

Of a Cough.

The cough now under consideration is a primary diffuse, which greatly disorders the whole body by its vehemence and obstinacy. Its cause is, a flux of serous humours from the outward parts and extremities of the body to the lungs, and is seldom without feverish heats and shiverings towards the evening.

It is either moist or dry: the former afflicts the phlegmatic, whose fibres are lax and muscles soft, and who are more liable to it than men; as also infants, boys, and old men, more than those in the vigour of their age. The dry cough principally attacks the hypochondriac, the scombritic, the cachetic, and those who are lean and slender, and subject to convulsive disorders, and whose bodies like-wise abound with a sharp serum.

The most violent of these kinds of coughs is the tussis convulsiva, or ferina, whose effects are so violent as to put the patient in danger of suffocation: In children, this is called the hooping cough. Sometimes this is dry in the beginning; or the patient brings up a little thin serum, more or less sharp. Sometimes it is moist; and then after a very laborious fit, the patient expectorates a sublivid, and commonly a moist tough mucus. The extreme parts grow cold, the body is couvive, the urines and the vital fluids are driven in greater plenty and force towards the breasts and head; so that while the paroxysm lasts, the face is red and turgid with blood, the veins swell, the arteries beat quicker and stronger, the eyes are ready to start out of the head, the tears flow, the eyelids swell, and sometimes the blood, after sneezing, springs from the nose. Sometimes the very vesicles of the lungs burst, and a spitting of blood ensues. Sometimes a hiccup supervenes, and then at the same time the patient is affected with laborious vomiting; some discharge their excrements and urines incessantly; and the coughing of others is so violent as to cause ruptures, especially in children.

As to the prognostics, a dry cough often turns to a moist, by hurting the digestion, and rendering the patient cachetic. When a moist cough becomes suddenly dry, and the breast remains oppressed, we may conclude that a putrid or hectic fever, or an exalciation of the lungs, are near at hand. In the convulsive cough of children there is danger of a suffocation; which cough sometimes happens in difficult digestion, and in the measles. It sometimes causes gibbosity and ruptures in boys; in women abortion; in adults a spitting of blood and a phthisis. Coughs that proceed from a schirrus of the lungs or other viscera, are incurable; if from driving in of exanthemata, or breaking out of the skin, it grows easy as soon as they are thrown out again. All coughs attended with lots of sleep are bad; as also that which is frequent, tedious, obstinate, and proceeds from a defluxion on the lungs. On the contrary, a moderate heat in the night time, with an equal breathing sweat throughout the whole body, a larger flux of urines, and the body open at the same time, a more quiet sleep, and an easier expectoration, are certain signs that the disorder is going off.

If the cough is recent, and there is no fever, nor other signs of a balsam peripneumony; or if it is not the consequence of a pleurisy or peripneumony ill cured, by a neglect of sufficient bleeding; the patient need only abate from wine and flesh for some days, and use the following remedy.

1. Take 10 drops of balsam of sulphur, with a bit of candied sugar; to be used twice or thrice in the day.

Recent coughs, after bleeding, are softened by a mucilage of linseed, or by any common sweet oil: But the oils are made more efficacious by the addition of a volatile alkaline salt, in this manner:

2. Take an ounce and a half of oil of olives, 6 ounces of water, 60 drops of spirit of hartshorn, an ounce of peptoral syrup. Take three or four spoonfuls every fourth hour.

If the cough will not yield to these remedies, then it will be to no purpose to rely on peptorals, especially if there is a fever along with it, or if it proceeds from a pleurisy or peripneumony; for then it is to be cured by bleeding and purging, in the same manner as the balsam peripneumony.

When there is a thin, soft, sharp defluxion, jellies are proper, and a decoction made of barle, thavings of hartshorn, vipers-grass root, and liquorice; or the decoction of turpentine with sugar; and above all things, oil of sweet almonds fresh drawn.

When a tussis catarrhalis affects the whole habit or body, with a loss of appetite and a tabes, the cure must be at once. The patient should, as much as possible, breathe a temperate air, shunning all sauced and smoked dried meats, poignant
poignant fauces, for they render the blood and serum sharp and impure; he should also abstain from malt liquors, but more especially acid wines. The drink should be hydromel; or, if the patient is scorbatic, water alone, the cold being first taken off with toasted bread. The vulgar pour hot water upon wheat bran, and drink the infusion cold, not without success.

As to bleeding in this disease, it is necessary for those who are full of blood and whose veins are very prominent; or when the usual excretions of it are suppressed; it is also a good preservative, though the person has past his seventieth year. Blisters may likewise be used, in oblate cafes.

Of a Phthisis, or Consumption of the Lungs.

If an ulcer of the lungs consumes them so far that the whole habit of body waffles away, it is called a consumption of the lungs. This ulcer may proceed from any cause which may detain the blood in the lungs so as to change it into a purulent matter.

The causes may be referred.

I. To that temperament of the body which tends first to spitting of blood, then to an ulcer of the part where the blood has made its way through. This consuits.

In a tenderness of the arterial vessels, and in the impetus of a more or less acrimonious blood. This is known from a view of the tender and fine vessels, and of the tender make of the whole body, a long neck, a flat and narrow thorax, deprefed scapula; the blood of a bright red, thin, sharp, and hot; the skin transparent, very white and fair, with a blooming red in the cheeks; the wit quick, subtle, and early ripe with regard to the age, and a merry cheerfull disposition.

In such a debility of the viscera as disposes their too tenacious contents to produce obstructions, putrefactions, and to grow acrimonious, whereby the vessels are corroded, first causing spitting of blood, and then ulcers. This is discovered by a slight febricula, a little dry cough, an unusual heat, a redness of the lips and mouth, a flushing in the face; which are most apparent when the new chyle enters into the blood; a propensity to sweating when asleep, a weakness, a shortness of breath increasing upon the leaff motion.

In that age, when the vessels have attained their full growth, and will not admit of any further lengthening; when at the same time the blood increases in quantity, acrimony, and force; which happens between the sixteenth and thirty-sixth year of the patient's age.

In an hereditary disposition to this disease.

These dispositions to a phthisis are heightened,

By a suppression of accustiomary evacuations, especially the fanguineous; as the hemmorrhoids, menes, lochus, bleeding at the nose, usual blood-letting, chiefly in the plethoric, and those who have lost a limb.

By any violent shock of the lungs, by coughing, shorting, sighing, running, violent efforts of the body, anger, and wounds.

By sharp, saline, aromatic aliment, or drink; by the particular manner of living; by another disease, whence the quantity, acrimony, velocity, rarefaction and heat of

the blood are increased. Hence it frequently happens from acute fevers, the plague, small-pox, and scurvy. II. Likewise this collection of pus may proceed from a peripneumony, which terminates in an apoplexy.

III. When there is an empyema formed, it may corrode, destroy, and consume the lungs, and so produce the same disease as if they were waffed away by an ulcer generated in their own substance.

The sign of an approaching phthisis is a dry cough, which may continue for some months; whereas a simple catarrh is attended with spitting, and is but of short duration. Vomiting, or a disposition to vomit after eating, excited by the above mentioned cough, is a most certain sign of a phthisis.

It invades persons from eighteen to thirty-five years of age; the whole body waftes away. There is a hectic fever, which is most apparent after meals, and is known by the quickneis of the pulse, and the redness or flushing of the cheeks: The matter brought up by the cough is bloody or purulent; if it is spit into the fire, it yields an offensive smell; if into a vessel of water, it falls to the bottom. Though it is thick, it is not glutinous or tenacious, but fluid, and of different colours, viz. yellow, green, but mostly of an ash-colour.

This disease begins with a flight pain, moderate heat, and an uneasy or oppressive irritnnes of the breath. When blood is brought up by coughing, it is generally of a florid, scarlet colour, and frothy, and proceeds from the lungs with a remarkable noise. It is mixt with fibres, films, and small portions of arterial, venal, and bronchial vessels: The pulse is soft, small, and undulating; the breathing is difficult; and these symptoms are preceded by a saltish taste in the mouth.

Blood is coughed up from the lungs sometimes without any pain; and if there is a vessel broken, it most commonly flows out in a great quantity at the first eruption, and afterwards more sparingly.

Spitting of blood is cured by copious bleeding every third day, to the fourth time, or till the inflammatory pellicle entirely disappears. Sydenham advises the taking away 10 ounces of blood, to take the common purging potion the next morning, and at night an ounce of diascodium. Hoffman likewise advises gentle purging and pediluvia, as also putting the hands into warm water. For appeasing the anguish of the blood, he thinks nothing better than spirit of vitriol, but more especially the tincture of roes acidulated therewith. Morton very judiciously prefers the Peruvian bark. Refrigerating, thickening, styptic lenient remedies, used a considerable time, are serviceable, with which may now and then be mixed the most lenient balsamics.

Hoffman advises the following powder, as preferable to every thing else, in appeasing the spasmatic irritations of the lungs.

1. Take seeds of white henbane, and crabs-eyes, of each a dram; 12 grains of nitre; and one grain of camphor. Make them into a powder.

A prudent use of the nonnaturals is likewise necessary, that may bel oppofe the cause of the diseaf: and chiefly a proper aliment, and manner of living; a milk-diet is preferable to any other.
When the cure is performed, it will be necessary, by way of prevention, to bleed once in six months, for several years together.

But if, by reason of the violence of the disorder, or the unskilful use of phthisics, there should, after the spitting of blood, arise a difficulty of breathing, which continually increases, a wandering shivering heat and redness of the cheeks, a dry husky cough, a fit hectic fever, a preternatural thirst, a weakness, or sense of weight in the breast, it is a sight that the wound from whence the blood flowed has already begun to change to matter about its lips. Then under the crust of dried blood pus is formed; and this collection degenerates into a la

vicular and wandering shivering heat and redness of years together.

ulcer of the lungs.

of blood, arise a difficulty of breathing, which continually

into pus; a purulent consumption of the whole lungs, or

off by the constant concussions of the cough; a conversion

of one of its lobes; a continual dry cough, or spittle (hook

stained; a conversion of the blood-vessels and the bronchia

and quantity of the putrid pus, a dilatation and corro-

sion generally thefe which follow: An increase of the acrimony

ter Vomica; and that being broken, becomes an open

ulcer of the lungs.

The effects of an ulcer of the lungs thus formed, are

generally those which follow: An increase of the acrimony and quantity of the putrid pus, a dilatation and corro-
ding maceration of the membrane or bag in which it is con-

ained; a conversion of the blood-vessels and the bronchia

into pus; a purulent consumption of the whole lungs, or

of one of its lobes; a continual dry cough, or spittle (hook

stained; a conversion of the blood-vessels and the bronchia

into the tube of the larynx; the sometimes suffocating

discharge of the pus, or the daily coughing up of matter,

which sinks in water, and is thick, sweet, fat, fetid, white,

red, yellow, livid, ah-coloured, or trenched, and which,

put into the fire, has the smell of burnt flesh. Sometimes

the vomica breaks into the cavity of the thorax; from

whence proceeds difficulty of breathing, and the other

symptoms of an empyema. Then the respiration grows

exceeding bad; the chyle and the whole mass of blood

are converted into pus; the usual method of nourishment

is destroyed, the solids continually consume and waste

away; a hectic fever appears, with a small languid pulse,

and the heat in the upper parts intense, the cheeks look

red, and the face hippocratic. General there is an in-

expressible anxiety towards the evening; an unusual thirst;

profuse nocturnal sweats; red pulvules; a swelling of the

feet or hands on the side affected; excessive weakness; a

hoarse voice; a falling off of the hair; an itching throughout

the body, with watery pulvules; a debilitating diarrhoea,

with yellow, fetid, purulent, cadaverous stools; a suppression of the spitting; and then death.

Hence the following prognostics may be formed.

An hereditary phthisis is the most dangerous of all, and

is incurable unless the spitting of blood be prevented.

A phthisis from external violence, that is, proceeding

from spitting of blood caused thereby, is the fright-

est of all.

A phthisis in which the vomica breaks suddenly, and the

patient easily brings up a white, concocted, smooth

pus, and in quantity proportionable to the ulcer, with-

out thirst, and with a good appetite and digestion, due

secretions and excretions, is curable, though with diffi-

culty.

Heavy, solid, stinking, sweet spittle, with night-sweats,

livid cheeks, paleness of the face, the redness pinched up,

finking in the temples, incrustation of the nails, falling off

of the hair, and a colliquative diarrhoea, are signs of ap-

proaching death.

When a vomica is known to be formed in the lungs, then the physician must endeavour to ripen and break it; which is to be done by milk-diet, riding on horseback, warm vapoors and expectorants: Which done,

1. The blood must be guarded and defended against

the purulent infection, by remedies which are moderately

and agreeably acid and saltish, by vulnerary herbs, smooth

balfamics given in various forms, in great plenty, and

continued a long time.

2. The ulcer must be cleared as soon as possible from

the purulent matter, the lips of it cleaned and consoli-

dated, which is to be done by liquid medicines, by things

which promote coughing, by motion, riding, country-air;

these are expelients. The cleansers are detergent balfa-

mics, used inwardly and outwardly. The consolidators

are paregorics.

3. The aliment must be such as requires the least force

to make it pass freely through the lungs, and be there

affimilated, and at the same time be fit for nourishment.

Asks milk is very suitable to this intention, as also but-

termilk.

Small repeated bleedings are not only beneficial in old

coughs, threatening consumptions, but also after purulent

spitting and hectic symptoms have appeared. The quan-
ty of blood to be drawn is from four to seven or eight

ounces, once in eight or ten days.

Setsons, or issues made in the side of the part that is most

affected, are very beneficial.

We must endeavour to diminish the defluxion on the

lungs, by bleeding and gentle purging, as well as pec-

torals, accommodated to the various states of the dila-

mper, viz. by thickening medicines and attenuants, and

such as temperate the heptic fever, with emulsions

and ashs milk, &c. and lastly, by healing the ulcer with

balfamics, as opobalsamum; the dose is 20 drops upon

sugar; but this is not to be taken before due evacuations

have been first made.

After evacuations, great care must be taken that the

cough be appeased, lest the lungs should be weakened by

the continual agitation.

The most sovereign remedy to restore the lungs to their

pristine vigour is to get on horseback every day; and

he that will put himself upon this exercise for a cure, need not be tied down to any strict rules of diet,

nor be debarred from any sort of meat or drink, since the

whole fires of the matter depends wholly on the constant

and continual exercise of riding. Long sea-voyages have

of late been greatly recommended.

In the first stage of this disease, when the lungs,

trachea, and glands, throughout the whole pulmonary

tube, are stuffed with a piritous matter, separates from

the mass of blood, and the patient is afflicted with a con-

tinual cough, especially in the night-time, all proper

methods must be used to stop the influx of this catarrh, and to concoct the humours already impacted.

First, Blood must be taken from the arm, from six to

ten ounces: if the patient be plethoric, or accustomed to

bleeding; this is to be repeated once, twice, or thrice, at

proper intervals, especially if the flux of serum is like a

suffocating
The diet should be water gruel, ptisanos of boiled apples, pothead-drink, stoned raisins and liquorice, table-beer warmed with a toast, and the like. When the fever is on the decline, chicken broth, poached eggs, &c.

If there is occasion, the body must be loosened with baths of sugared milk, with chamomile flowers, and repeated as occasion requires; then take away ten ounces of blood on the face affected, which should be boldly repeated every, or every other day, according to the urgency of the symptoms.

In colliquative sweats, pearl juleps may be freely given, to which may be added chalk, corals, dragon's blood, or other absorbents. But the Peruvian bark for this purpose, is much better than any other medicine whatever. The patient should not be permitted to sleep too long, the bed-cloths should be light, and he should be removed to fine subtle air.

Of the Nervous Consumption.

A nervous atrophy or phthisis, is a wasting of the body, without any remarkable fever, cough, or difficulty of breathing; but is attended with want of appetite and a bad digestion; whence the whole body grows languid, and is continually falling away.

At first the body is edematosus, and as it was fluttered with a vivid chyle; the face looks pale and bloated, and the stomach lothes every thing but liquids. The patient is forced to keep his bed sooner than the progress of the decay of his flesh seems to require. The colour of the urine is uncertain, but it is generally very red and small in quantity; sometimes it is pale and copious.

No considerable fever is discernible—either by the pulse, heat, or thirst, though the urine is ever so red.

The causes of this disease are generally violent passions of the mind, a too free use of spirituous liquors, and unfavourable air.

Stomachic and nervous remedies are only to be depended upon; such as, chalybeates, antiscorbutics, cephalics, and bitters. If the body be colitive, two ounces of nitre, and a small quantity of tinctura sacra may be taken every fourth evening, and from 30 to 40 drops of elixir aloes, in a glass of white-wine with bitters, before dinner. The elixir of vitriol is excellent in this case, 20, 30, or 40 drops is a dose, in any convenient vehicle, once, twice, or thrice a day. Also about half an ounce of the chalybeate wine, in some proper liquid, in the winter; in the summer, the psw waters: the usual drink may likewise be made bitter with the vinum amarum; but nothing strengthens the stomach more than a decoction of wormwood.

Sometimes the patient may take eight or nine drops of opobalsamum, or spirit of hartnash, or of fal ammoniac, as friendly to the nerves; nor must he forget exercise and cheerful company, with other diversions.

Of an Empyema.

An Empyema is a collection of purulent matter in the cavity of the thorax, between the lungs and the pleura, which always supposes the breaking of a vomica into the said cavity.

Such are the vomicae or abscesses of the lungs, proceeding from inflammations, from spitting of blood, from...
a thick matter which cannot be expectorated. Of the pleura, from an inflammation, from a wound therein, healed outwardly but open inwardly; from a bruise, or a concealed rupture of it, turning to pus. Of the diaphragm, when, after an inflammation, it suppures, and breaks on its upper part. Also of the mediastinum and pericardium affected in the like manner.

An empyema may be foreseen from an inflammation of any of the above mentioned parts, which is not terminated and resolved by concoction, reversion, a crisis, or medicines; but is followed by shiverings, a febricula increasing at night, a wandering heat, a sense of heaviness in the part that was pained, a difficulty of breathing, a want of appetite, and an unusual thirst.

An actual empyema is known from twenty days being elapsed since the inflammation began, without expectoration of the matter; from the signs of a vomica in the above abovementioned parts disappearing; from a new pain, cough, difficulty of breathing, and spitting, arisings, and afterwards going off; from a dry cough, a weight on the diaphragm, not being able to lie but on one side, a noise made by the fluctuation of the pus, upon moving the body; from a low fever, a dullness in the cheeks, hollow eyes, heat in the emts of the fingers, crookedness of the nails, and a swelling of the abdomen.

The consequences of this disease are, a continual accumulation of pus from the ulcer not yet healed; the matter increasing in its acrimony, putrefaction, rank smell, and thinness, by being shut up in a hot, moist place; an impediment in raising the diaphragm and extending the lungs; a shortness and difficulty of breathing, and not easily performed unless in an erect posture, a dread of suffocation when laid down; an inability of lying, but on the affected side; a constant dry cough, with anxiety; a maceration and corroboration of the lungs, pleura, diaphragm, pericardium, and even of the heart itself, converting them gradually into filthy corruption; whence there are always livid, plumbeous, yellow, or violet-washed spots and areas; there is a kind of an itch and dry scabs.

The consequence of which is, a wasting of the whole body; a putrefaction of the fluids, which may be diffused through the corroded lungs, or carried downwards by a fatal copious diarrhoea; night-sweats, pus-flules in the face, crooked nails, a shiring yellowness of the skin, and a hippocrepian countenance.

The cure of this disease is different, according to its different cause and state.

When a vomica or abces is known to be formed in any of the parts before mentioned, all endeavours are to be used, that it may be speedily broken and determined to the outward parts, which must be attempted by actual or potential cauteries, or by incision and proper motion.

When the vomica is actually broke, then it is to be evacuated by the mouth, if nature seems to encourage it; or by urine, if there appear any signs in it of falling that way; or by an aperture of the thorax by a proper instrument. See Surgery.

In general, all inflammations of the lungs or pleura are followed by an adhesion of these parts, which allow nature to make a passage externally: And it is common in abcesse of the pleura and intercostal muscles to find them break outwardly; nor is it uncommon even in the lungs. Therefore, when there is an adhesion, no other operation is necessary than to open the tumour with a lancet, when the pus is formed; and if the suppuration is so plentiful as not to admit the healing of the outward ulcer, it may be kept open with a hollow tent.

Hoffman gives an instance of a person, who, after a peripneumony, fell into an empyema, and was cured by taking milk boiled with sugar of rose. The quantity was three pints a day. As also balsamic pills made of flowers of sulphur, oil of sweet almonds, spermaceti, Venice turpentine, saffron, and oil of aniseed. Likewise a powder made of crab's eyes, spermaceti, sugar, myrrh, liquorice powder, and balsam arnica.

Of the Sculvy.

This distemper chiefly afflicts the inhabitants of cold northern countries, and especially those who live in marshy, low, fat and moist soils, near stagnating water, whether fresh or salt. Those who live idle, sedentary lives are most subject, chiefly in the winter, to the attacks of this disease; as also those who feed upon salted and smoked fish or flesh, sea biscuit, thinking water, unfermented farinaceous vegetables, peas, beans, sharp salted old cheese; likewise those who are subject to melancholic, maniacal, hysterical, or hypochondriacal disorders.

It is known by spontaneous weariness, heaviness of the body, difficulty of breathing, especially after bodily motion; rottenness of the gums, a thickening breath, frequent bleeding of the nose, difficulty of walking; sometimes a swelling, sometimes a falling away of the legs, in which there are always livid, plumbeous, yellow, or violet-coloured spots; the colour of the face is generally of a pale tawny.

The first state of this disease begins with unusual laziness, intermitting weariness; the patient loves to be in a sitting or lying posture; there is a pain in all the muscles, as if he was over tired, especially of the legs and loins; when he wakes in the morning, all his joints and muscles seem to be tired and bruised.

In the second state, the gums swell, grow painful, hot and itching, and bleed upon the least pressure; the roots of the teeth become bare and loose; he feels pains in all the external and internal parts of the body, imitating distempers proper to the various parts.

In the third state, the gums at length grow putrid, with a cadaverous smell; when they are inflamed, blood drips from them, and a gangrene ensues; the loose teeth by degrees grow yellow, black, and rotten; the sublingual veins become varicose, and like rings; there are often fatal hemorrhages, which break out from the external skin, without any appearance of a wound from the lips, gums, mouth, nose, lungs, stomach, liver, spleen, pancreas, intestines, womb, kidneys, &c. Obiinate ulcers arise, of the very worst kind, which no applications will cure, and which are apt to turn to a gangrene; they break out in all parts, but especially the legs, and are attended with a stench. There is a kind of an itch and dry scabs, with
with a dry and mild leprosy. The blood drawn from a vein is black, grumous, thick, and yet wants its due consistence in the fibrous part; the serum is salt, sharp, and abounding with a yellowish green mucus on its surface. There are gawing, rending pains, quickly shifting from place to place, which grow more violent in the night, affecting all the joints, bones, and viscera.

In the fourth state, there are fevers of various kinds, which bring on an atrophy; sometimes diarrhoas, dysenteries, or violent stranguries; as also faintings and mortal anxieties, a dropfly, consumption, convulsions, trembling, a palsy, contusions, black spots, voiding of blood upwards and downwards, a putrefaction and consumption of the liver, spleen, pancreas, mefentery. Now the contagion spreads very quick.

The first sign of the approach of this disease is commonly a change of colour in the face, which becomes pale or yellowish, and bloated, with a little redness, and an aversion to exercise. The caruncles of the eyes appear of a greenish cast, and yet in other respects the patient feems in perfect health. However, the change of colour in the face does not always precede the other symptoms, though it constantly attends them. Then an universal latitude supervenes, and a stiftness and feelableness of the knees, with a difficulty of breathing on the least motion. Soon after this there is an itching of the gums, which swell, and are apt to bleed on the least friction. Then they become livid, soft and spongy, and afterwards extremely purid and fungous. This rottenness of the gums is an insupportable sign of this disease. These are not only subject to bleed, but there are hemorrhages from different parts of the body.

The skin is dry throughout the whole course of this disease, except towards the last, and in many it is rough. It often it appears like the skin of a goose; but it is most frequently smooth and thinning. It is stained with blue, purple, livid, or black spots; some of which are small, and others of a hand's breadth, when the disease is advanced. They are chiefly on the legs and thighs, but sometimes on the arms and trunk of the body. Some have a swelling of the ankles in the evening, which disapppears in the morning. In a little while it advances gradually up the leg, and the whole member becomes edematous. Effuptions, bruises, wounds healed up, and fractured parts, always become fortuitous first. Old ulcers will emit a thin fetid mucus, mixed with blood, and at length coagulated gore will lie on the surface of the fore like a cake. As the disease increases, they shoot out a soft, bloody fungus resembling bullock's liver, which sometimes will rise to a monstrous size in a night's time. The slightest bruises and wounds of scarlet pus defen- dere into such ulcers, and are easily distinguished from all others, by being putrid, bloody, and fungous.

To prevent the scurvy at land, it will be proper to chuse a warm, dry, pure air, with a diet of easy digestion, consisting chiefly of a due mixture of animal and vegetable substances: for those are most liable to it who live in marly, wet soils, and in places subject to great rains and fogs: or in damp, low apartments, unless they keep continual fires, and their chief food be flesh broths, with plenty of fresh greens or vegetables, and well-baked bread made of wheat-flour; as also a cheerful glass of some good wholesome fermented liquor. Cleanliness, entertaining amusements, and moderate exercise, will also be good preservatives in these cases. In garrisons, the soldiers should be kept as dry, clean, and warm as possible, and their provisions should be as wholesome as can be procured, with plenty of good vegetables, particularly fallads of garden-crefles.

The best method of preventing the scurvy at sea will appear from the effects which Dr. Lind has observed several medicines have had, especially those which have been greatly recommended as preservatives. On the 20th of May 1747, being on board the Salisbury at sea, he took twelve scrobal patients under his care. They had putrid gums, spots, and latitude, with weaknesses of their knees. They had a proper apartment in the fore-hold; their diet was water-gruel sweetened, in a morning; sometimes mutton broth for dinner, sometimes light puddings, boiled biscuit with sugar, &c. and for supper, barley and raisins, rice and currants, fago and wine, and the like. Two of these were ordered each a quart of cider in a day; two others twenty-five drops of elixir vitriol, three times a-day, upon an empty stomach, using a gargle acidulated with the same. Two others took two spoonfuls of vinegar three times a-day; having their gruels, other food, and gargles, well acidulated with it. Two of the worst patients, with the tendons of the ham rigid, were put under a course of sea-water, and drank about a pint every day, more or less, according to its operation, which was intended to be as gentle physic. Two others had each two oranges and one lemon given them every day, which they eat with greediness upon an empty stomach, at different times. This course was continued but six days, because no more fruit could be allowed. The two remaining patients took the bigness of a nutmeg, three times a day, of an electuary made of garlic, mulberr seed, balsam of Peru, and gum myrrh; using for common drink barley-water well acidulated with tamarinds; by a decoction of which, and cream, they were gently purged three or four times during the course.

The oranges and lemons had the best effect; for one of those who had taken them, was at the end of six days fit for duty; and he took nothing more but a gargle of the elixir of vitriol for his gums, which were not quite found, and so recovered his health entirely. The other being more recovered than any of the other patients, was appointed to look after them. Next to the oranges the cyder had the best effects, though it was not very good, being prick'd; for those who drank it were in a fairer way of recovery at the end of the fortnight, the time allowed for making the experiments, than any of the rest. Elixir of vitriol did no good unless as a gargle, nor yet any of the rest of the medicines. Oranges are preferable to lemons; for by these the lord Anson's people were so speedily and surprizingly recovered at the island of Tinian. Besides, Mr. Murray affirms, from experience, that oranges and lemons, when properly and sufficiently used, are an infallible cure in every stage and species of this disease, if there is any degree of natural strength left, and where a diarrhœa, lency, or dysentery, are not joined to
the other symptoms. He observes farther, that at the island of St. Thomas, fifty men belonging to the Canterbury, and seven to the Norwich, who were in all the different stages of this distemper, were cured in little more than twelve days.

But as oranges and lemons are apt to spoil, let the juice of these fruits be well cleared from the pulp, and depurated by standing some time; after which it may be poured off from the gross sediment. Let it then be poured into any clean open vessel of china or stone ware, which should be wider at the top than at the bottom, that it may evaporate more readily. But a china basin or punch-bowl is most proper, on account of the form. Put this into a pan of water over a clear fire; let the water come almost to boil, and continue nearly in that state, with the bowl full of juice in the middle of it, till the juice is found of the consistence of a thick syrup when cold. The slower the evaporation of the juice is, the better; that is, it ought to continue twelve or fourteen hours over the fire: When it is cold, it is to be corked up in a bottle for use. Two dozen of good oranges weighing five pounds four ounces, will yield one pound nine ounces and a half of depurated juice; and when evaporated, there will remain five ounces of extract, which in bulk will be equal to less than three ounces of water. So that twelve dozen of oranges may be put in a quart bottle, and preferred several years. The same may be said of lemons. When this is mixed with water and made into punch, few are able to distinguish it from the fresh juice mixed up in the same manner. However, when the fresh fruit can be had, the fragrancy of the peel may contribute somewhat to the cure of the scurvy; and when these are wanting, the same thing may be obtained from a few drops of their essence, or the aromatic oil contained in their rinds; and if a small quantity of this be added to the extract, it will give it the smell and fragrancy of the fresh fruit in great perfection. Or rather add a little of the outer peel to the extract a little before it is taken off the fire, and then the nicest taffe will not be able to distinguish the difference between the fresh fruit and this. The virtues of this extract, thus made, lie in so small a compass, that a bottle will serve one man at sea several years; for in the making of it there is little or nothing flies off besides the water.

It will likewise be of great use to feamen to have gooseberries, and the like, preferred in bottles in the same manner as the pastry-cooks; as also small onions pickled in vinegar, cabbage, french beans, &c. may be preferred, by putting them in clean dry stone-jars, with a layer of salt at the bottom, then a thin layer of the vegetable covered with salt, and so alternately till the jar is full. Then the whole may be peered down with a weight, and its mouth quite stopped that no air or moisture may enter. Thus the vegetable may be kept fresh and green for a whole year. At the time of using, the salt is to be washed off with warm water. This is the manner by which they prefer to never-failing remedy, Greenland scurvy-grass. Every common sailor ought to lay in a flock of onions, for they are a great preservative at sea. The Dutch sailors are preferred from the scurvy by pickled cabbage. Portable soup may be carried to all places. When the scurvy begins to make its appearance, sailors should be abridged in the same degree of their allowance of beef and pork, and eat them with mustard and vinegar; but the peas ought always to be served out in full allowance. It must be observed likewise, that a pound of boiled cabbage and onions will cure an adventitious scurvy in its first stage, either at land or sea, in any part of the world.

Besides fresh and preferred fruits and vegetables, fermented liquors of all sorts are good, but more particularly cider. Among these are included many wines of every kind; or the juices of fruits may be fermented with ale. Poor people that winter in Greenland under vast disadventages in point of air and diet, preserve themselves from the scurvy by spruce-beer, which is their common drink. Likewise the simple decoction of fir-tops has done wonders. The shrub black spruce of America makes this most wholesome drink just mentioned, and affords a balsam superior to molasses, &c. It is of the fir kind. A simple decoction of the tops, cones, leaves, or even of the green bark or wood of these, is an excellent astringiotic; but perhaps it is much more so when fermented, as in making spruce-beer. This is done by molasses, which, by its diaphoretic quality makes it a more suitable medicine. By carrying a few bags of spruce for tea, this wholesome drink may be made at any time. But when spruce cannot be had, the common fir-tops used for fuel in the ship should be first boiled in water, and then the decoction should be fermented with molasses; to which may be added a small quantity of wormwood and root of horse-radish. The freasher it is drank, the better. When other things are wanting, tar-water may be fermented in the same manner.

Those who have been weakened by long fits of illness should have the scurvy prevented by panada of bread newly baked, with a few drops of the extract of lemons, and a spoonful of wine; as also oatmeal and rice, gruels, plum-mercy, flewed barley, with raisins or currants, sago, and wine, &c. But more particularly pickled cabbage, and small onions boiled with the portable soup made weak. Most of their food ought to be acidulated with orange or lemon juice; and then as their strength increases, they should be indulged with more solid food. But before this, they should have a small quantity at a time and often, and they should be brought back to their labour by little and little. Exerce the on a deal-board, with the ends laid on two chests, will be very proper; because it promotes the circulation, and strengthens the fibres, without any lobs of spirits.

Bad air of any kind has a bad effect upon a ship's crew; to remedy which, a red-hot loggerhead should be put into a bucket of tar, and moved about, so that all the ship once or twice a day should be filled with this wholesome antifeptic vapour. In a moist air, whatever promotes perspiration is proper; such as dry linen, cleanliness, using the flesh-brush, garlic of raw onions before going into the rain, and keeping the bedding dry. Plenty of mustard and onions should be used with their viands.

The sure of this disease has been in a great measure anticipated by the means of prevention, much that little remains to be said about it. The diet should be light
light and easy of digestion, such as broths or soups made of fresh meat, with plenty of vegetables, such as cabbage, coleworts, leeks, onions, &c. The bread should be fresh and well baked; and fallals of all kinds are beneficial, but more particularly dandelion, forrecl, endive, lettuce, fumitory, and pariflane; to which may be added, seurvy-grafs, creftes, or the like, to correct the cooling qualities of the former. Summer fruits are all good, as lemons, oranges, apples, &c. The drink may be good found beer, cyder, or Rheinifh wine. Phyfic is never ne-

Of the Dropsy.

Dropsies are of various kinds; but those usually treated of by authors are the anasarca, afcites, and tympany.

When the lymph stagnates throughout the whole habit of the subcutaneous fat, or is shed therein, it produces an anasarca, which extends itself also to the abdomen and scrotum.

When the water is collected in the duplicature of the peritoneum, in the cavity of the abdomen, between the peritoneum and the vifcera of the abdomen, or in the diluted cavities of the glands and vesefls contained in the abdomen, it is called an afcites. If the dropy is owing to the rarefaction of some steam or vapour, arising from water, pus, ichor, or air, pent up and heated till they putrefy, then it is a tympany.

The caufe of these diseases may be, a family disposition thereto; a halfy drinking too great a quantity of cold water, and its not being evacuated upwards or downwards, or by sweat, or urine excited by heat or motion; acute diseases, especially the moist ardent, attended with unquenchable thirst, or otherwife; a lienterious dysentery of a long continuance; all obfinate obstructions of the vifcera; and a chbirus of the liver, spleen, pancreas, mefenteriy, kidneys, womb, or intestines; the jaundice; a violent quartan ague of long duration; the meloey; a diarrhoea; a long dysentery; the colic pain, an empyema; a consumption; the gout; too great evacuations, chiefly the blood; the drinking of harp, fermented, and spirituous liquors; the feeding on tenacious and hard aliment; very large and numerous hydridates hanging in the cavity of the abdomen; melancholy; the curvy, and the like.

The firft sign of the approach of this disease is the swelling of the feet and ankles, which in the evening will pit, if pressed with the fingers; which swelling disappears in the morning, effpecially if there begins to be a difficulty of breathing. And yet it must be remembered, that preg- nant women, or whose menfes are dopped, as alfo when breathing. And yet it must be remembered, that preg- nant women, or whose menfes are dopped, as alfo when breathing.

The firft thing to be done is to evacuate the ferous humours by cathartics.

Mayrne affirms, that mercurius dulcis, without doing any mischief to the body, acts directly upon the morbific caufe, and if poifible destroys it. If a faiivation follows, it is not dangerous, but may be prevented if the mercu- rial be joined to an active cathartic.

Many praffle the juice of the root of iris palustris lutea; and we have an instance of its efficacy in a molt deplorable dropy, in the Med. effays; eighty drops of which were given every hour in a little fyrup of buckthorn, which brought away many quarts of water by the firft night; the quantity was daily increafed till it came to two drams, and at laft was mixt with a fourth part of the fyrup, and given by spoonfils.

Sometimes purgatives are to be entirely omitted, when the patient is of a weak constitution, or women subject to vapours; and then diuretics only should be made ufe of; among which, thofe are molt powerful which conftit of lixivial fials.

Boerhaave likewife proposes to attenuate the humours by fmall dofes of mercurial prepara- tions, to be taken e- very other morning, in a little pulp of a roated apple; as half a grain of turbit hair; ten grains of white ginger; or one grain of red precipitate, with fix grains of nutmeg; or four grains of calomeing, with eight of winter’s bark.

Some have been cured by a pertinacious abjufnence from all liquids, living upon sea bifcuit with a little salt, and a very little rich wine. Externally, frictions of the parts have been found beneficial.

a gangrene, which may be prevented by lime water, exalted with camphorated spirit of wine and sal am- moniac.

But fomentations and cataplafs of the common hem- lock, frequently repeated and duly continued, are found more effectual than all other remedies.

The curatif indications in an anasarca, as well as in an afcites, are to reftrice the humours to their natural fluidity; to invigorate the languid circulation; to brace up and strengthens the relaxed solids; to promote the fecretions; and to carry off the redundant flaginating juices.

Strong draffic purges, steel medicines, abforbents, de- tergents and ftiematics, are belit fuinted to anfwer these in- tentions.

As for the antimonial wine, an ounce and a half, or two ounces, as the patient’s strength will admit, given in the morning, will in due time free the abdomen from the load of water. If it does not purge downwards as well as upwards, mix it with fyrup of buckthorn after the third or fourth dofe.

Some greatly recommend Bonitus’s pills for the drop- hy, the dofe of which is from half a scruple to a scruple; but Heister prefcribes them from half a dram to a dram.

Of the above-mentioned symptoms, there is a heaviness, a torpor, a coffe body, and at length a flow fever; the patient never sweats. In proces of time, the flaginating waters, being pent up in a hot place, become acrimonious; hence ulcers, gangrenes, bleeding at the nofe, a protuberance of the navel, a mortification of the vifcera, and death.

Of the Hydrocele, or Dropsy of the Scrotum.

The hydrocele, called the dropsy of the scrotum, hernia aquosa, and the dropsy of the testicle, is an aqueous tumour of the scrotum. Though authors mention several kinds, there are but two. The first is, when the water is contained in the tunica vaginalis; the second, when it is contained in the cellular membrane of the scrotum. This last is almost always complicated with an anasarca, a kind of dropsy which consists in the extravasation of the water which lodges in the cells of the membrana adipofa. The hydrocele in this case is known without any difficulty; for the skin is thinning and soft, yielding easily to a slight impression, which will remain pitted for some time; the penis is also sometimes prodigiously swelled by the liquor which infinuates into the cellular membrane. There are none of these symptoms in the dropsy of the tunica vaginalis.

In the dropsy of the cellular membrane of the scrotum, some recommend the puncture with a trochoth; others, to make small apertures here and there with the point of a lancet; others, to put a small slice of silk through the skin with a needle, and to let it remain as a feton, till all the water is drained off. But the two first methods yield very little relief, and the last may be more likely to induce a gangrene. Nor is there occasion for any operation at all, because the cellular membrane of the scrotum is nothing but a continuation of the membrana adipofa; and therefore scarifications made in the skin of the small of the legs will effectually empty the scrotum.

Yet sometimes there falls so great a quantity of water into the scrotum that the dilatation is very painful, threatening a mortification. Likewise the prepuce very often is so exquisitely dilated and twisted, that it hinders the patient from making water.

In these cases there should be an incision made on each side the scrotum, three inches in length, quite through the skin, into the cells which contain the water; and likewise two or three, half an inch long, in any part of the penis, with a lancet or knife.

The dropsy of the tunica vaginalis is caused by an excessive accumulation of a serosity, which is naturally separated in the internal surface of that tunic in a small quantity, to moisten and lubricate the testicle. Authors have hitherto distinguished them into two forts: the one on the inside of the tunica vaginalis and the other on the outside, between that and the scrotum, which they suppose to proceed from water in the dropsy afcites. But anatomy shows the absurdity of this opinion. For besides that persons afflicted with this kind of hydrocele have seldom any other dropsy, and those who have the afcites are free from this hydrocele; the tunica vaginalis is like a purer quite shut up on the outside of the abdomen, so that the water cannot infinuate into it from any part.

As to the notion that the water falls from the abdomen into the interface between the tunica vaginalis and the scrotum, it is equally impossible. For though in the intestinal rupture the gut falls into this place, yet it brings the peritoneum along with it, and that will prevent the egress of the water. This is a circumstance the ancients were unacquainted with, and the moderns have not sufficiently attended to.

This disorder is seldom attended with pain in the beginning, contrary to what happens in the hernia of the epiplon, and of the intestine; nor is it often the effect of any accident. It never diminishes when once begun, but generally continues to increase; but in some persons not so quick as in others. In one person it will grow to a very painful dilatation in a few months; in another it shall not be troublesome in many years; nay, it shall cease to swell at a certain period, and afterwards continue in that state without any notable disadvantage. But this is rare.

In proportion as it enlarges, it becomes more tense, and then is said to be transparent; but this is not always the case; for sometimes the scrotum is very much thickened, and the water itself opaque; so that to judge positively if there be a fluid, we must be guided by feeling a fluctuation; and though sometimes it is not very evident, yet we may be sure there is a fluid of some kind, if we are certain that the dilatation of the tunica vaginalis makes the tumour.

When a gut, or the omentum, form the swelling, it is soft and pliable, unless inflamed, and uneven in the surface, and reaches from the scrotum into the very abdomen; whereas the hydrocele is tense and smooth, and ceases before, or when it arrives at the rings of the abdominal muscles.

When the testicle is increased in size, the tumour is rounder, and, if not attended with an enlargement of the spermatic vessels, the cord may be easily distinguished between the tumour and the abdomen; but without this the pain or the very great hardness will discover it to be a difcase of the testicle.

As to the cure, little is to be expected either from inward medicines or outward applications. Therefore it will be most advisable to wait till the tumour becomes troublesome, and then to tap it with a lancet.

Of the Jaundice.

The jaundice is a disease which is principally discovered by the yellow tincture of the skin, but most distinctly in the coasts of the eyes, where it gives the first notice of its invasion.

The symptoms are, heaviness, inactivity, latitude of the whole body, anxiety, uneasiness about the hypochondrium, fickness at the stomach, oppression in the breast, difficult respiration, a dry and harsh skin, coiffuenes, hard white excrements, yellow high-coloured urine, which will tincture linen or paper with a saffron hue; there is a bitter taste in the mouth; and all objects seem to be discoloured.

The immediate cause of a jaundice is an obstructed excretion of the bile from the vesica felsis and liver into the duodenum; which being forced back upon the liver, mixes with the blood, by which it is carried into the whole body, whence the skin and urine will be tinctured with the colour of the bile.

This obstruction may be occasioned by any thing in the duet, which plugs up the paffage, or by external pressure closes its mouth, or by a palp contradic the fibres thereof. Hence we may, conceive why the jaundice succeeds the flatulent ecule, why pregnant women are
tion or fever of the liver, and has not continued long, difficult.

When the patient is young, the disease not complicated with any other, such as a quartan ague, the affection hypochondriaca, or an obstruction or stricture of the liver, and has not continued long, it is easily cured. But if after the cure it frequently returns, with a yellow greenish colour, and an induration of the liver, it generally terminates in a hectic or an haemorrhage. A jaun-fice arising from violent transports of anger, or the spasmodic perturbation of the intestines or biliary ducts, caused by a draffic purge or emetic, is easily cured if taken in time; but if encouraged by grief, or the body is weakened by a previous disorder, the cure is more difficult.

Emetics are highly proper in the cure of the jaundice, and yield speedy relief, if the disease does not proceed from violent anger, spasm of the flomach, a cardialgia, a spasmodic colic, or a stone lodged in the cystic duct, exciting a violent uneasiness about the precordia. But when a bilious fordes, lodged in the duodenum, and closing up the oriifice of the ductus choledochus, intercepts the passage of the bile; or when a tenacious, moveable, and not highly concrected bilious matter, plugs up the hepatic ducts, emetics are of singular efficacy in evacuating it. A scruple of ipecacuanha, with a grain of tartar emetic, will be a proper dose; or two grains of tartar emetic, in a draught of generous wine, or in an infusion of manna, drinking water-gruel after it.

Likewise in this case, after emetics, cathartics will be proper, compounded of aloetics and mercurials: Then faponaceous attenuants, preparations of tartar, and volatiles.

And here we must recommend the terra soliata tartari, otherwise called tartarum regeneratum, and by the college, Sal diureticas, as the greatest diolvent, and the most powerful remedy in this disease. It dissolves the most tenacious substances, and opens all obstructions of the visera; and yet has no acrimony, and may be safely given in the pleurisy and dropsey. Its dose is from five grains to a scruple and upwards.

When a jaundice is attended with an haemorrhage, it is always dangerous, because it denotes a most acrimonious and disolved state of the blood; in which cafe, attenuants, aloetics, volatiles, and chalybeates, are little better than poison; whereas acids, diluents, demulcents, and mineral waters, are very beneficial. Hemp-seed, boiled in milk till it breaks, is often advantageous, [the dose is 5 ounces twice a-day] or an emulsion of white poppy seeds and sweet almonds, after moderate bleeding, (if the patent is feverish, and the pulse will allow it) and gentle purging.

Neither
Neither bleeding nor cathartics have any place in the cure, for they exacerbate the distemper; nay, the most gentle emetics are prejudicial: For this distemper seems rather to proceed from a disorder of the spirits, than from a fault of the humours. It will be proper first to advise the patient to drink upwards of a gallon of polet drink, to clear the stomach of its impurities, by throwing it up again, that the effects of the purgative may not be hindered. Afterwards give 25 drops of the thebaic tincture, in an ounce of cinnamon-water. This last is to be repeated at due intervals, till the symptoms disappear; that is, the effect of one dose must be known, before another is given. Yet sometimes, in phlethoric bodies, if the strength will permit, it is better to prepare the way, by bleeding and purging, or both, for an anodyne.

Of the Flatulent or Wind Colic.

If there is a fixed and tenacious pain in the right or left hypochondrium, or beneath the stomach, it is a certain sign that there is wind or excrements pent up in the flexures of the colon. If the pain is in the small guts, the abdomen will be wonderfully swelled and puffed up; and the force of the wind is often so great, and it dilates the skin to such a degree, that the pain is exacerbated merely by touching it; nor do there want instances of a navel rupture arising therefrom. The pains are very acute, the body extremely colic, there is a fever of a very great strictness or contraction; and if the stomach is inflamed, the breathing becomes very difficult, and the eruptions are attended with some small relief. Afterwards there are cardialgic passions, and an ineffectual reaching to vomit.

If the disorder lies in the flexures of the colon, emollient and diffusive emetics will be proper, as also carminative and emollient liniments applied to the painful part.

When the body is opened, it will be beneficial to give some lenient purge, as manna, cream of tartar, terra fylla late tartari, with a spoonful or two of oil of sweet almonds.

While the pain is violent, the infusion of chamomile flowers and yarrow, in the manner of tea, frequently drank, is a very powerful remedy.

It will be also beneficial to apply hot bricks or tiles to the part affected; also bags with parched oats and carminative ingredients, as caraway seed, juniper and bay berries, with decraptated salt. A clyster of the smock of tobacco, blown through a pipe into the anus, is reckoned an excellent thing.

When indurated faces plug up the intestinum rectum, so that the wind and feybals can make no exit, then the anus is to be fomented with emollient decoctions; and saline suppositories, with fat, are to be used; also some ounces of linseed oil, with an emollient decoction in which venic soap has been dissolved, are to be injected as a clyster.

Of the Colic from Fumes of Lead.

This is a distemper to which all workers in lead are subject; and is attended with an intolerable pain in the intestines, and a most collyw body: the navel is drawn inward, there is the highest inquietude and a contraction of the joints, attended with a nausea, and a constant reaching to vomit. It is apt to terminate in a kind of palsy, or a spasmodic lumbago, and afflicts the patient a long time. It is sometimes owing to the rathsness of medicators, in giving preparations of lead in the gonorrhoea and other distempers.

There is no better preservative against this distemper, than by taking fat broth in a morning; the cure is to be attempted with oleous emetics, and a plentiful use of oil of sweet almonds taken by the mouth, with or without a solution of manna, by which the desired end will generally be obtained. For the cure for the paralyse, baths of sweet water are necessary; after which the spine of the back must be anointed with a liniment made of the fat of a hog, expressed oil of nutmegs, fassfron, and oil of rosemery, which is a speedy and a certain remedy.

This disease is called mill riff by the miners at lead-hills in Scotland, which all the inhabitants have subject to; but mellers of lead have it with the greatest violence.

In the lighter stage of it, there is an uneasiness and weight about the stomach, particularly near the cartilage eniformis, and sometimes it is like a colic in the intestines. The spittle of the patient is sweet, and inclining to a bluish colour, resembling that of a person who chews lead.

The pulse is quick, and the skin is all over cold, with frequent clammy sweats. The legs become feeble, with a prickling numbness; and the whole body is lazy and feeble. Sometimes a spontaneous diarrhoea carries off the disease; but if it continues long, it is very prejudicial. During this stage the patient is able to work.

When these symptoms continue long, and spirituous liquors are drunk on an empty stomach, or after the working of lead, the second stage comes one; and then there is a fixed pain in the stomach and guts, especially in the lower part of the belly, extending from one hip-bone to the other, with colliquescence and a gnawing pain. The pulse then becomes weak, and the skin hot. There is likewise a giddinefs and a violent pain in the head, which is succeeded by an insensibility and a delirium of the worst kind; for they bite their hands and tear their own flesh. Then their extremities tremble with convulsions; and at length they sink with an intermitting pulse, and die of a coma or apoplexy.

If proper medicines are given in the first stage of the disease, the patient generally recovers. If it proceeds till the giddines comes on, the success is doubtful; but after that it almost always proves mortal.

Workers in lead should never go to their business fasting, and their food ought to be oily or fat. A glass of salad oil, with a little brandy, rum, or other spirit, is a good morning’s draught; but spirits alone should never be taken while at work, nor immediately after it. Physick should be taken spring and fall, and no man should go into the cold air while hot with labour, and they should change their working-cloaths for others as soon as possible. Liquid aliment is belt, such as fat broth with good meat; for low living is bad. They should now and then go a little way out of the tainted air.

If the patient is phlegmatic, the cure is to be begun with bleeding.
bleeding, and then the 

POSS X VIE must be cleansed with a double dose of emetic wine, or emetic tartar, otherwise it will have no effect. They will even bear half a dram of glass of antimony in fine powder, with plenty of warm water during the operation. If the vomit works well upwards and downwards, the patient is in a fair way of recovery. Then a milder dose of ipecacuanha must be given with tartar emetic. If the dose does not work either way, he is generally the worse for it, and a stronger dose should be given soon after. If it vomiting, but does not purge, an anatominial cathartic, or jalap and mercury should be exhibited in a larger quantity than ordinary, and then the patient should drink plentifully of warm broth. The vomits and purges should be repeated at proper intervals till the disease disappears. If they work too much, an opiate may be given at night, but with caution, for fear of rendering the patient colicive, which is the worst thing that can befall him. When purgatives do not operate sufficiently, emollient, laxative, and anodyne clysters must be injected frequently to empty the guts.

OF THE IliAC PASSION.

The iliac passion is a pain in the small intestines, apt to turn to an inflammation, in which their peristaltic motion is inverted, and their contents, and even the excrements themselves, are voided by the mouth in vomiting. Nothing will pass downward, not so much as a flatus.

It is preceded with coughing, which is soon followed with most sharp and violent pains, with an inflammation, distension, and a tumour of the umbilical region, which feels hard to the touch; the body is so bound, that neither wind nor excrements can pass downward: Soon after, the wind first makes its way upward, then comes on a nausea and a frequent vomiting of a bilious and putrid matter: The breathing grows difficult, and whatever is eaten or drunk is soon thrown up again; reddish faces, with a flinking smell, are afterwards forced up by vomiting: This is succeeded by loss of strength, a preternatural heat, a hard and contracted pulse, with great thirst; the urine is red, and voided with difficulty. When the vae becomes desperate, a hiccup and delirium appear; the nerves are distended, the body is all in a cold sweat, and violent convulsions and fainting fits put an end to the tragedy.

In some who have been dissected, the gut seemed to be twisted; but most commonly one part of the gut enters into the other. This disease may also proceed from a rupture either of the scrotum or the groin; from poisons; from anything that stops up the passages through the small guts, such as hard dry food, quinces, pears, unripe acerb fruit, when eaten in large quantities; to which drinking little, a sedentary life, and melancholy disposition of mind, will greatly contribute. These all tend to harden the faces. The gross intestines may also be plugged up with sybols; especially if a person, either through shame, or for want of convenience, does not listen to the calls of nature.

As to the prognostics; there is hope of recovery while there is no inflammation, and while clysters are admitted into the body, and rendered back the same way; as also while the pain shifts from one place to another, and the pain and vomiting are not continual; likewise when the disease proceeds from causes obstructing the intestines. The hope is still greater, if laxative medicines begin to make their way downward. But if there is an inflammation, which is known from a fever, the vehemence of the pain, a suppression of urine, a hard and quick pulse, an unquenchable thirst, a toasting of the body, and extreme debility, with coldness of the extreme parts, the case is desperate. A sudden cessation of pain, and absolute want of strength, with a weak pulse, fainting fits, and a flinking breath, show the intestines are mortified.

As to the cure; first of all it is necessary to bleed in the arm, and afterwards, in an hour or two, exhibit a powerful clyster. The smoke of tobacco blown into the bowels, through an inverted pipe, is very efficacious: This may be repeated after some time, unless the effect of the first renders it unnecessary. If the disease will not yield to this, a pretty strong cathartic is advisable.

If the patient cannot retain the cathartic, let him take 25 drops of the thick tincture in half an ounce of spirtuous cinnamon water; and when the vomiting and pain remit, let the cathartic be repeated; if the pain returns, give the anodyne again, and repeat it every fourth or sixth hour till the intestines are easy, and the cathartic begins to pass downwards.

After the pain has been mitigated with anodynes, a tapas, which should be applied to the hypogastric region to stop the vomiting and hiccup; which may be composed of equal parts of old venice treacle and expressed oil of nutmegs, with the addition of oil of mint and camphor. This done, a gentle laxative of manna, cream of tartar, and oil of sweet almonds, may be given.

When there is an inflammation, nothing is better than six or eight grains of purified nitre, and half a grain of camphor mixed with some antispasmodic powder, and taken in a convenient vehicle. Outwardly apply a liniment of an ounce of axungia humana, any other penetrating fat will do as well] and a dram of camphor.

But when other things fail in the cure of the iliac passion, recourse must be had to quicksilver, which sometimes has surprising effects; half a pound, or a pound at mol, is sufficient, with fat broth or oil; and the patient should lie on his right side, or walk gently about the room, that its descent may be easier. But if there is an actual inflammation, the use of quicksilver should be forborne; if the patient dies, from what cause soever, the bystanders will probably affirm the quicksilver killed him.

There is no manner of danger in the use of opiates, to mitigate the pain, provided they are exhibited in the beginning, after bleeding, or before there are any signs of a mortification.

Clysters are generally very advantageous; for they relax the spasms of the gross intestines: and for this purpose warm water with syrup of marshmallows will be sufficient; and if the strength will permit, they should be injected every two hours, from the first day of the attack. They likewise restrain the inversion of the peristaltic motion, and soften the faces.
VOMITING.

Vomiting is a spasmodic, retrograde motion of the muscular fibres of the oesophagus, stomach and intestines, together with strong convulsions of the abdominal muscles and diaphragm. Those that are slight, create nausea; those that are strong, vomiting.

Vomiting generally begins with a nausea, a tension and weight in the epigastic region, a bitterness in the mouth, anxieties of the precordia, plenty of thin saliva in the mouth, a trembling of the neither lip; to these may be added, a dizziness of the head, a sudden dimness of sight, redness of the face, a fruitless eructation; and then the contents of the stomach are discharged upwards.

Vomiting is caused by excesses in eating and drinking; by the acidity of the aliment; by the translation of the morbid matter of ulcers, the gout, erysipelas, and other diseases, to the stomach; from a looseness or bloody flux too suddenly stopped; from a congection of blood in the stomach, which happens to women in the first months of pregnancy, or when there is a suppression of the menses, or bleeding piles; from sympathetic, by tickling or irritating the throat or oesophagus with the finger or a feather; from the colic, iliac passion, a rupture, fit, of the gravel, worms; from poisons; from hurts of the brain, such as contusions, compressions, wounds or inflammations of the diaphragm, stomach, intestines, spleen, liver, kidneys, pancreas or mesentery; from an unusual motion of the spirits in a cart, coach, or ship; from the idea of some nauseous thing, or which has formerly occasioned sickness or vomiting; from a regurgitation of bile into the stomach.

As to the prognostics; a critical vomiting is salutary; a symptomatic bad; and that which proceeds from a subtil caustic acrimony, which vellicates the nerves, worst of all. All violent excessive vomiting is bad, as it may occasion abortions, ruptures, &c. Bilious vomiting, especially the green, porraceous, and claydenous, confiding of a corroding acid, portends danger of an inflammation; vomiting from worms which gnaw the stomach, is generally pernicious; vomiting of dead worms, if at the same time the convulsions of the limbs and other grievous symptoms suddenly cease, shews a mortification. All faeculent vomiting is a sign of internal corruption, and therefore bad.

When vomiting proceeds from a depraved digestive faculty, by bitters, candied orange-peel, &c., the stomach is made to press on the stomach, and accelerate the discharge of its contents; but if an inclination to vomit, from the same causes, comes on unawares, a prettily strong and often repeated friction of the hypogastric region with the hand, will prevent it.

Pituitous vomiting, from crudities of the primary vitiated blood, is best cured by a vomit, and especially if there is a troublesome reaching to vomit attended with a nausea and a cardiaalgia; then having first prescribed neutral farts, or squills, to incite the phlegm, give warm water mixed with unaltered butter, very plentifully, or powder of ipecacuana.

Bilious vomiting, which proceeds from a depraved digestion, and has its seat in the duodenum, is cured by absorbents and gentle laxatives of manna and rhubarb. When it proceeds from too great a laxity of the biliary ducts, then cortex Peruvianus, cortex eleuteria, and bitter tinctures and chalybeates, will be most efficacious; if from a coagulum or stone in the gall-bladder, mineral waters are more likely to succeed.

When vomiting is caused by a sharp matter vellicating the nerves of the stomach, proceeding from the gout, or an erysipelas, besides giving quieting medicines, it ought to be drove back by diaphoretic powders, with a small addition of camphor. Also externally, frictions, pellucia, and clysters, are useful.

When it proceeds from poisons, nothing is better at the beginning than drinking large quantities of milk, and fat oily things, to shelf their acrimony, and bring them up by vomiting.

Vomiting from a suppression of the menses, or from the o污染防治 of the bleeding piles, is cured by absorbents, by gentle laxatives, by clysters and strengtheners; and more especially by bleeding or causing the flux to return. Emetics, in this case, are as bad as poison, and either cause a vomiting of blood, or a fatal inflammation of the stomach.

Morning teachings, caused by hard drinking, are cured by absorbents and anti-acids, and by strengthening the digestive faculty, by bitters, candied orange-peel, &c.

The immoderate and frequent vomiting of pregnant women requires bleeding in the foot, and rest both of mind and body.

VOMITING of Blood.

Vomiting of blood is generally preceded with a terrific pricking pain in the left hypochondrium; and the eruption itself is almost always attended with anxiety of the precordia, and a compressing pain, as also a kind of girding on the same side. It is frequently attended with fainting fits, especially if the blood has an ill smell, or is corrupted.

The seat of this disease is in the stomach, though the spleen sometimes has a share in its production. Persons more subject to it are the lean and slender; women irregular in their menstrual, and who have been hastily cured of intermittent fevers, which has brought on a suppression of the menses, and then have taken hot forcing emmenagogues; as also women about the time their menses leave them; likewise plethoric women in the time of pregnancy, and hard labour; and men of a weak constitution, subject to the bleeding piles, which either cease to flow, or flow in too small a quantity.

The danger which attends this disease, is not the same in all, though no hemorrhage is more dangerous than this. If there is no fever, and if it proceeds from suppressed evacuations, caused by a plethora, the cafe is not to deter your. On the contrary, if there is a fever; if the blood is corrupted, flaming, and black; if it proceeds from a large, diseased spleen, or an indurated liver, attended with swooning; there is no hope of recovery left. It is still worse, when the flowers are black; then the seat of the disease is in the ilium, from a rupture of the mesentric vessels.

In the paroxysm, if the patient is plethoric, bleed according to his age and strength.
A diarrhoea is a frequent and copious evacuation of liquid excrements by stool; and may proceed from aliments, or humours of various kinds, derived from different parts into the intestines.

The cause is a stimulus which irritates the visera, occasioning the expulsion of their fluids; and may therefore proceed from the vessels of the liver, pancreas, metentery, and intestines; when at the same time the mouths of the mesenteric veins and the fistulae are obstructed. Or there may be an extraordinary laxity of the intestinal fibres; or, lastly it may arise from a stoppage of other excretions. It is frequently attended with gripings.

The patient is weak, makes but little urine, has a depressed pulse, a depraved appetite, and is sometimes feverish.

In a diarrhoea arising from sharp fermenting juices in the prime vitæ, which accelerate the peristaltic motion of the intestines, the first indication is to discharge the stimulating matter; which may be effected by a dose or two of rhubarb.

At night the patient may take fifteen drops of the thebaic tincture, in two or three spoonfuls of simple cinnamon water. The rhubarb is to be repeated till the looseness abates, which is generally after the second dose.

If there is a fauburra of ill concocted matter in the stomach, a vomit will be necessary of ipecacuanha, [or an ounce of its wine.]

If the diarrhoea continues to be violent, it will be proper to mix astringents with the rhubarb.

If the diarrhoea proceeds from suppressed perspiration; and if the stools are thin, and the patient feverish; first bleed, then give an emetic, afterwards a purge of rhubarb, and last of all astringents.

But the best and safest astringent of all is logwood, given in decoction.

A bilious diarrhoea ought not to be too suddenly stopped, but the humours are to be corrected gradually; for which purpose, a scruple of rhubarb slightly toasted, with a few grains of nitre, is very useful. Likewise half a dram of the expressed oil of nutmegs, either alone or mixed with a grain of opium, and given in broth, is very efficacious. The humours are likewise corrected with thin emulsions of almonds and white poppy-seeds, with the addition of diacodium.

When a diarrhoea is very obstinate, after toasted rhubarb has been given for some days, prescribe a sweat with a dram of new Venice treacle, and twelve grains of burnt hartshorn, calx antimon, and purified nitre.

An habitual diarrhoea is greatly relieved by wearing a flannel shirt, and keeping the body warm.

In Vol. I. of the London Medical Observations and Inquiries, Dr. Pye proves, by a long enumeration of instances, that in all loosenesses where emetics are advisable in every age and sex, though the patient be in the weakest circumstances, ipecacuanha, from half a grain, to four or six grains, may be given with the utmost safety, and will seldom fail of answering the intention of the prescriber; and adds, that for many years he had experienced the great efficacy of it, in curing or shifting in the cure of diarrhoeas in children, when administered in clysters.
MEDICE.

Of the Cholera Morbus, or Vomiting and Looseness.

A CHOLERA, or vomiting and looseness, is a sudden violent purging upwards and downwards, proceeding from a convulsive contraction of the stomach and intestines, caused by sharp caustic matter of various kinds.

It generally begins in August, and seldom reaches the first weeks of September, unless it be a spurious kind which arises from excess.

It discover itself by enormous vomiting, and a voiding of vitiated humours by flux. There is a violent pain, inflammation and distention of the belly and intestines, also a cardialgia and thirst; the pulse is quick and frequent, small and unequal; there is heat and anxiety, a most troublesome nausea, sweating, a contraction of the legs and arms, fainting, coldness of the extreme parts, and the like which kill the patient in twenty-four hours.

Though this disease is generally preceded with acid, noxious belchings, purgant and cardialgic pains in the stomach and intestines; yet soon after, all of a sudden, and at the same instant, the vomiting and looseness make their attack. The remains of the last meal are voided first; afterwards bilious humours, mixed more or less with mucus; then those that are yellow, then eructs, then black, often exceeding acid, and almost corrosive, together with frequent expectorations and wind, and sometimes blood itself. The returns of the evacuations are very frequent. Besides, there is most acute, wringing, gripping, gnawing, biting pains, with inflammation and swelling of the intestines, chiefly above the navel, and most racking cardialgias. As the disease increases, the thirst becomes great, the extreme parts grow cold: there is a palpitation of the heart, and then hiccups; the urine is a dark purplish, then black, death is inevitable. The case is as bad for old persons, or children, or such as are weakened with the more intense are the thirst and heat, and the more certain the danger. If it be black bile, and mixed with black blood, death is inevitable. The case is as bad when there are faintings, hiccups, convulsions, coldness of the extreme parts, and cold sweats. Nor is any thing better to be expected from a flippage of the evacuations, while the rest of the symptoms continue. But if the vomiting ceases, and the patient sleeps soon after, or the disease is protracted beyond the seventh day, he may recover; if he begins to break wind downward, it is a good sign.

This disease requires the most speedy assistance, and therefore the physician cannot be called too soon. The indications of cure are, 1. To correct and heal the morbid matter, and to fit it for evacuation. 2. To appease the irregular spasmodic motions. 3. To strengthen the nervous parts which the disease has weakened.

Boil a large chicken in three gallons of water, that so there may be a taste of the flesh, and give the patient a large quantity of it to drink; or, for want of it, a warm pint of water, and large quantity of it to drink; or, for want of it, a warm posset-drink; and also repeated Clysters of the same liquor; now and then an ounce of syrup of violets may be added to the draught or clyster. These operations may be completed in three or four hours, and then a paregoric will crown the whole.

But if the physician is not called in time, and the patient has been exhausted with vomiting and purging for many hours, and the extreme parts begin to grow cold, then immediate recourse must be had to liquid laudanum in a large dose. And when the symptoms cease, it is to be repeated morning and evening, till the patient’s strength returns.

Neither cathartics nor emetics, properly speaking, are of use in this disease; but the vomiting may be promoted by drinking a large quantity of warm water mixed with fresh butter or oil; and the purging by oily and emollient clysters. Or the patient may drink small chickens broth. Whey is of great use to quench the thirst; to which may be added, the absorbent and teffaceous powders.

If the patient is not too much exhausted, make him drink plentifully of warm water three or four times, to dilute and blunt the acrimony of the humours, and to bring them up by vomiting: Then he must take as freely of a decoction of oat bread, baked without leaven or yeast, carefully roasted, without burning, as brown as coffee; which decoction ought to be of the colour of weak coffee. This is grateful to the stomach, and is seldom brought up again.

When the patient is much exhausted with evacuations upwards and downwards, give him a large draught of the decoction; and, when the nausea is pretty well settled, two thirds of a grain of opium, more or less, according to the strength and age of the patient.

But if the patient is convulsed, the extreme parts cold, and the pulse weak and intermitting, twenty-five drops of liquid laudanum, in an ounce of strong cinnamon water, is more proper; and afterwards a draught of any wine in an equal quantity of the decoction. After this, he may take the decoction to quench his thirst, and a little wine now and then as a cordial.

To prevent a relapse, repeat the opiate in a moderate quantity for some days, morning and evening; and care must be taken not to overload the stomach, or to eat anything but what is of good nourishment, easy to digest, and grateful to the stomach.

Of the Dyseutery, or Bloody-Flux.

A Dysentery begins with shivering and shaking, succeeded by heat of the whole body; which are followed by griping of the guts, and soon after by frequent voiding of slimy stools, attended with violent pain, and a most troublesome pressing down or seeming descent of all the bowels, and this every time the patient has a stool. In process of time the stools are mixt with blood, and afterwards pure blood is only evacuated, and the intestines are affected with an incurable gangrene. Yet sometimes there has been no blood through the whole progress of the disease.

If the patient is in the flower of his age, or has been heated with cordials, he is very feverish, his tongue is Whitish,
whitish, and beset with a thick mucus; sometimes it is black and dry; he becomes excessively weak, and is quite delirious; a purple or a thrush appear in his mouth and throat, especially if the evacuation of the morbid matter has been improperly prevented by astringents, and the fomes of the disease has not been expelled by cathartics. Sometimes, when a fever is abating, the gripes lead the van, and the rest of the symptoms follow.

Those whose stomachs are loaded with much indigestible matter, are troubled with a nausea, reaching and vomiting; many have an intolerable heartburn and anxiety of the praecordia. All are afflicted with a perpetual desire of going to stool, and such a violent tenesmus as is not seldom attended with a procidentia ani.

In febile, the extreme parts are cold, while the inward seem to burn, and a perpetual sense of heat and a pulsation torture the intestines. To these succeed hiccups, cold sweats, a pale countenance, walking of the body, inflammations, and aphthae of the fauces. At last, all pain ceases at once, the thirst vanishes, the stools come away insensibly with a cadaverous fcent, the pulse becomes flenser, and death is at hand. This disease is often contagious.

Prognostics. Dyfenteries are dangerous to pregnant women, to old men, and to boys. There is commonly little hope when it attacks the scrophulous, the consumptive, and the cachectic; those that are weak and afflicted in mind, or troubled with worms. When it begins with vomiting, succeeded with hiccups, there is danger of an inflammation of the stomac. Nor is the case better when the stools are green, black, mixed with caruncles, and of an offalme fcent. It is a fatal omen when chlysters are immediately returned, or the anus so obstinately closed that nothing can be injected; for it is a sign of a palsy of the rectum. When the pulse is weak, the extreme parts cold, and the inward burn, or are without sense, nothing good can be expected. When swallowing is attended with a murrining noise, it shews the approach of a delirium, an inflammation of the fauces, aphthae, or a palsy of the whole otopus. It is necessary to know, that this disease sometimes quickly terminates, especially if there be a malignant fever, and then it kills in seven, nine, or fourteen days; sometimes it does not cease till the fortieth or upwards; when it continues a long while, it either kills the patient, or brings on a dropy, a leantery, the celiac affion, a tabes or hemicrania; it is a terrible disease in Ireland, when all other remedies failed.

Hoffman directs a scruple or half a dram of the ipecacuanha, when it begins with vomiting. After the first vomit, give two or three grains of ipecacuanha every eight or ten hours, in a bolus, with diaezordin, or the like, with some proper julep. Hoffman would have the rhubarb given in substance, that is, half a dram in powder; Dener gives it twelve hours after the vomit, repeating it in small doses.

Mr Ray says, that the fomous substance between the lobes of a walnut, dried and powdered, and given in a moderate quantity in wine, cured the English army in a terrible dysentery in Ireland, when all other remedies failed.

Jussieu says, a thick yellow bark, called simaruba, has been found successful in the cure of a dysentery. The dose is a third part of a quart of a decoction made with two drams of the bark. And Cramer assures us, we may depend upon the same effect from the decoction of common millet-feed, called St Ambrose's syrup, which Luther looked upon as a cure for the colic. Count Argenton took it first by his advice, merely to quench his thirst, in the manner of tea, by which means he got rid of his thirst and dysentery in twelve hours time.

Another specific is the vitrium antimonii ceratum, which has been in use for some time, but was kept a secret till it was communicated by Dr Young of Edinburgh to the public.

The manner of preparing it is as follows:

Take of glafs of antimony in powder, one ounce; bees-wax, one dram: melt the wax in an iron laddle, then add the powder: let them on a draw fire without flame, for the space of half an hour, continuously stirring them with a spatula; then take it from the fire; pour it upon a piece of clean white paper, powder it, and keep it for use.

The ordinary dose for an adult is ten or twelve grains; but for greater safety begin with six.

Never give opiates in the beginning, especially where there is great sickness; because, though opiates give relief to some, yet at other times both the ficks and purging increase the following day.

Bonitus, in his account of the diseases of the East-Indies, affirms, that extract of saffron is a specific in the dysentery of those parts, even though it should proceed from poison.

Of the Head-Ach.

The head-ach is a most troublesome sensation in the nervous membranes of the head, produced by various causes, and attended with different symptoms, according to its different degrees, and the place where it is seated.

The most common seat of this disease is the pericranium; a membrane which invells the skull, coheres with the muscles next the skull, and is joined to the dura mater by some fibres which pass through the future. It is a thin nervous membrane of exquisite sense. It may likewise be in the skin that covers the skull, and in the dura mater. This last but seldom happens; but when it does, it is very dangerous. There may likewise be a very acute pain in the thin membrane which covers the sinuses of the os frontis.

If the head-ach be slight, and affeds a particular part of the head, it is called cephalalgia; if the whole, cephalae; if one side only, hemicrania; if there is a fixed pain on the forehead, which may be covered with the end of the thumb, it is called clavus hyflericus.

The general cause of the head-ach is a hindrance of the free circulation of the blood through the vessels of the head.
When the blood rushes with impetuosity, and in too great plenty into the membranes, which may happen to the plethoric, to those whose usual bleeding at the nose is suppressed, and to young persons, there is a pain in the whole head, which becomes hot, swells, aches, and looks red; the vessels swell, and there is a strong pulsation in those of the neck and temples. The nostrils are dry and parched, there is a burning heat and drought in the fauces.

When the vessels of the head are stuffed with a mucous serum from a fopagination of the running of the nose, then there is a heavy, obtuse, pressing pain, chiefly in the fore-part of the head, in which there seems to be such a weight, that the patient can scarce hold it up. Sometimes the skin is so swelled, that it will pit.

Sometimes it happens from the feverous, sharp, caustic matter of the French disease, which infects the periostium, and often causes a caries in the skull.

Sometimes it may proceed from matter of a saline caustic nature, driven back from the external parts; as, in the gout, itch, erysipelas of the head, gutta roacea; in the small-pox and measles, before the morbid matter is expelled to the outward skin, or, which is worse, when it is driven back. In these cases, when a small quantity of caustic matter causes the pain, it rather proceeds from a violent stricture of the membranes than from their disposition.

There is likewise a most violent, fixed, constant, and almost intolerable head-ache, which brings on a debility both of body and mind, hinders sleep, disturbs digestion, destroys the appetite, causes a vertigo, dimness of sight, blindness, a noise in the ears, convulsions, and the epilepsy; and, by consent of the other nervous parts of the body, produces vomiting, colic, coldness of the extreme parts, and the countenance of a dying person.

Sometimes the head-ach is symptomatic, and attends upon continual and intermitting fevers, and especially the quartan irregular flowing of the menphis, the hypochondriac passion, and the like. A hemicrania generally proceeds from a fault in the stomach, from crudities or indigestion, and commonly appears when digestion is performed.

The head-ach is not always without danger: if the cauſe of the pain is within the skull, and is violent and constant, attended with a fever and want of sleep, it portends a phrensy. If it sudenly attacks the hypochondriac; or those that are prone to melancholy, especially if preceded by a violent passion of the mind, and deprives the patient of sleep and appetite, and is joined to difficulty of hearing, and an internal pulsation of the vessels, and all these without a fever, it preages madness. But when the pain in the head is sudden and very acute, with a noise in the ears, difficult walking, a weakness of the body, produces vomiting, colic, coldness of the extreme parts, and the countenance of a dying person.

The curative indications are, 1. To divert the impetus of the blood and humours from the head, and to diffuse them by suitable remedies. 2. To relax the spatical stricitures of the membranes of the head, the cauſe of which is a sharp caustic matter, that the fluids may have a freer circulation. 3. To correct the peculant matter, and evacuate it gently through the most convenient eminenturies. 4. To prevent a return by strengthening the whole nervous system by proper remedies, and especially by an accurate diet and a suitable regimen.

When the head rushes to the head in too great quantity, bleeding is necessary, more particularly under the tongue, in the forehead, in the jugulars, or by leeches behind the ears. If the body abounds with too much blood, it will be best to bleed in the angle first, and the next day, or the day after, in a vein about the head. But first of all cleanse the body by any emollient clys, or by giving an infusion of rhubarb and manna, with cream of tartar.

To refrain the organ of the blood, it will be proper to give a diaphoretic and absorbent mixture, with diaphoretic antimony, purified nitre, burnt hartshorn, and diaedemum, diluted with a sufficient quantity of suitable simple distilled waters.

When there is an intense pain remaining fixed in one place, lying pretty deep in the membranes, the herb ranunculus, used as a vesicatory, has a wonderful efficacy. It is the upright meadow-crawfoot, with leaves like the anemone, and, if tasted, is extremely biting to the tongue. The leaves must be bruised in a marble mortar, and, if hairy, shaved; then a flicking plaiher is to be laid on it, with a hole about the bigness of a silver penny, and the leaves over that; just in the same manner as a caustic. This is an experiment of Chefsnaull's; and like successes may be had by mixing equal parts of volatile sal ammoniac and powder of mustard-seed, laying it on the part in the same manner.

When it is caused by a suppression of a coryza or running of the nose, a snuffing-bottle of volatile salts should be held frequently thereto. Or the patient may take herb-snuff, with the addition made of flowers of benjamin and powder of cloves.

When the head-ach arises from a corrupted mass of blood and an impure serum, as in the scurvy and lues venerum; a decoction of the woods with crude antimony may be serviceable, after evacuations, lasting a day now and then, with labour and exercise, will likewise be useful; as also a fudorific.

A hemicrania, especially a periodical one, is generally owing to a foulness in the stomack and prime vie; for which gentle emetics will be beneficial, as also purgatives to derive the humours from the head; afterwards stomatics. If it proceeds from profuse evacuations of the menphis or hemorrhoids, those fluxes must be reduced within bounds.

If the head-ach is so intolerable as to endanger the patient's life, or is attended with continual watching, fainting-fits, a fever, an inflammation, or a delirium, recourse must be immediately had to opiates with native cinchaba, after a clyster has been first given.

When there is an intolerable pain in the sinuses of the nose, or the bony sinuses of the head, produced by an extravagination of some fluid, the only cure is levigation of the nostrils, or causing the nose to bleed with a straw suddenly thrust therein.
If there is an extravasation under the pericranium, and the humour is so sharp as to begin to render the bone carious, then recourse must be had to an incision, as in a whitlow.

In some kinds of head-ach, it will be proper to open the frontal vein.

When the patient's strength will not bear the loss of blood, temperate pediluvia will be beneficial, and strong frictions of the feet with a coarse cloth; as also cataplasm of horse-radish and salt laid thereon.

**Of the Heart-Burn.**

The heart-burn is a pain more or less violent about the pit of the stomach, with anxiety, a nausea, and often a reaching, or actual vomiting.

The causes are, vitiated humours in the stomach, velluating and gnawing the stomach itself, or its left orifice, which the ancients call cardia. The stomach thus irritated, a painful sensibility is excited, and spasmodic constrictions, which occasion a nausea and vomiting. But common heart-burns are generally without vomiting. The heart-burn may also proceed from wind and indigestion, and now and then from worms; but more frequently from congestions of blood about the stomach, which may happen to those who are full of blood, but more especially to the hypochondriac and hysterical, when vomiting of blood not seldom ensues.

The cure of a common heart-burn from indigestion and the acrimony of the contents of the stomach, which chiefly happens in a morning with wind, may be performed only by drinking tea or coffee, or a decoction of camomile flowers; as also by taking bitters, or a dram of powder of orange peel, or camomile flowers, in a small glass of water made pretty hot, and sweetened with sugar. The tinctuous and absorbent powders are excellent in this case; such as the tabellae cardiae, or lozenges for the heart-burn, which may be carried in the pocket and taken at pleasure; about a dram is sufficient for a dose.

When it arises from a crampula, gentle emetics will be useful. If the patient begins to vomit without them, large draughts of warm water will assist to cleanse the stomach; or carduus benedictus tea taken freely.

If the cardialgia proceeds from a congestion of blood, and the painful strings then arising, bleeding will be convenient, and emetics hurtful. If the meninges are flopped, bleed in the foot.

Nor must anodyne and emollient clysters be omitted. It will likewise be proper to apply a bladder filled with a decoction of chamomile, pretty hot, to the stomach. After recovery, riding will be convenient to regain the lost strength.

If worms are the cause of the heart burn, no acrid anthelmintics must be given, but warm milk mixed with oil of sweet almonds, which, if drank in sufficient quantity, may cause them to be thrown up.

**Of the Tooth-Ach.**

The tooth-ach is caused by impure serum, which corrodes and rends the ligaments and nervous-glandulous coats, by which the roots of the teeth are kept firm in their sockets, and wherewith they are invested.

It is a kind of rheumatic disorder; for we have often observed that pains of the joints and shoulders have shifted to the side of the head, and have invaded the teeth and gums with violent pain. On the contrary, pains of the head and teeth have fallen into the arms and shoulders.

The feat of the tooth-ach may also be in the cavity or internal parts of the teeth themselves, that is, in the little vesicular cord composed of the nervous membrane, an artery, a vein, and a lymphatic vessel, which may either be distended by stagnating serum, or be affected with a pannic constringence, especially if the tooth is carious, and the caries reaches the said cord.

As in the gout there is a pain, redness, a tumour, and a little fever, so they sometimes appear with the tooth-ach. There is also frequently a copious discharge of saliva, which proceeds from a painful lip, which constringes the lymphatic and venous vessels.

As the rhematism appears in temperate, and a sudden change of weather; so it is with the tooth-ach, especially when the weather is hot and cold by fits.

The whole intention of cure consists in deriving and diverting the impure scorbatic serum from the head, and then carrying it off through proper emunctories; and afterwards in strengthening the parts.

This is to be done by saline, emollient, purgative clysters; by warm pediluvia of rain-water and wheat bran, with venice soap, and used just before bed-time; by laxatives of manna and calis dissolved in whey or affes-milk or mineral waters. If the patient is plethoric or full of blood, bleeding in the foot will derive the humours from the head.

Sudorific remedies are also proper, but more especially an electuary made of rob of elder-berries, burnt hart's-horn, diaphoretic antimony, and a few grains of nitre, which cannot be too highly praised. Or an ounce of the rob may be taken in broth to promote a diaphoresis; and it may be used externally, dissolved in beer, in the manner of a gargle, which will yield immediate relief to the patient.

Outwardly may be applied bags, filled with paregoric and emollient species, such as elder, melilot, and camomile flowers, bay and juniper-berries, caraway and millet feeds, and decrepitated salt. They must be laid on warm, and are very safe.

A drop or two of oil of cloves, or box, applied to a carious tooth with cotton, are medicines not to be despised. Camphorated spirit of wine mixed with saffron, saltor, and opium made into a liniment, and laid to the gums and hollow teeth, often gives the patient ease.

When the tooth-ach proceeds from a rotten, hollow tooth, it will be best to burn the little nervous cord, which is the seat of the pain, with an actual cautery; and then the cavity may be filled up with a mixture of wax and mallich.

If this cannot, or is not permitted to be done, the only remedy left is to have the tooth drawn. But if the patient is plethoric, it will be safest to bleed first, for fear of a fatal haemorrhage.
A small pill, made of equal quantities of camphor and opium, and put into a hollow tooth, is often beneficial. Some greatly recommend a small plaster of tacamahac laid on the side of the face, upon the articulation of the jaw bone, or upon the temples.

But above all, the root of iris lactea, or the yellow water flower, demi lune, rubbed upon the tooth that is painful, or the root itself chewed in the mouth, in an infant, as if by a charm, drives away the pains of the teeth, arising from what cause ever.

It is now become a practice, especially in France, upon drawing a found tooth, to replace it in its socket; where, with proper precautions, it will settle again. Mufgrave is the first who recommends this practice. After the extraction of the tooth, he advises a gargle of honey, mixed with the juice of the herb mercury, common salt, and spring-water, and then to put it in its former place; and adds, it will become more useful than before.

The French operators have improved this hint; and when the tooth is rotten, or otherwise unfit to be replaced, they put another found human tooth in the room of it, when it can be had; otherwise one of any other animal that is of a size suitable for the purpose.

De la Motte, in the tooth-ache, advises to make a small round flicking plaster, about the bigness of a silver groat, and to put a flat bit of opium in the middle of it, of a size not to prevent the adhesion of the other. This is to be laid on the artery near the cavity of the ear, where the pulsation is most sensible. He affirms, there are few cases that this will not relieve.

Of the Ear-Ach.

The ear-ache is a grievous pain in the meatus auditorius, or cavity of the ears, proceeding from a sharp extravasated serum affecting the nervous membrane which lines the meatus auditorius.

This disorder frequently attacks those who are subject to rheumatic and feverish defluxions; or it may arise from a sudden suppression of sweat, or from the head being exposed to cold winds when it is moist with sweating. The cause is often an inflammation or ulcer of the ear, attended with a remarkable heat, and tenfive burning pain, a redness, a fever, and even sometimes a delirium. Sometimes it is excited by worms; and then there is a wandering, cutting, gnawing pain.

The ear-ache is sometimes so violent as to cause a delirium, with the highest inquietude and anxiety, insomuch that the patients often fall into an epilepsy through the violence of the pain.

The ear-ache is sometimes a symptom of acute fevers, when the morbid matter is translated to the ear, as in the Hungarice disease, when deafness or difficulty of hearing arises. When it happens in the declension of a fever, it is a certain sign of recovery; but then the disorder is in the internal part of the ear, and the auditory nerve. When the matter is translated to the external part, then the ear-ache arises; which, unless speedily appeased, may deprive the patient of life. Tho'se who have the ear-ache from a fall, and a famous matter runs out of the ear, are all carried off.

The principal scope is to ease the pain, which may be done with nitrous and cinnabarine powders, and with emulsions of the greater cold seeds; but if these are ineffectual, we must have recourse to opiates, such as the florax pills, or the thebaic tincture.

Outwardly, lay a plaster to the temple of the affected side, composed of maltich, galbanum, saffron, express'd oil of nutmegs, and opium. Afterwards let the ear be held over the vapour of milk, with the fragrant and emollient spices. Also, fill a hog's bladder with the decoction of milk of flowers of mallow, mullein, elder, melilot, camomile, linseed, and a little saffron, and apply it to the part affected. Likewise the smoke of tobacco blown into the ear, and an infusion of millepedes in falad oil, are thought of great efficacy when the inflammation is caused by a sharp serum.

Camphorated spirit of wine, especially with saffron, made pretty hot, and a few drops of it put into the ear with cotton-wool, is a great resolvent; it should also be rubbed into the parts behind the ear. Or oil of almonds with camphor may be used in the same manner; laying over either of them a hot bag filled with resolvent herbs, as sage, pennyroyal, wild thyme, wild marjoram, camomile flowers, Florentine orris, fennel and caraway seeds, with camphor. When the patient is plethoric, bleeding is convenient.

The most violent ear-ache, from taking cold; may be insensibly cured, in a very short time, by applying the ear close to the mouth of a bellied jug, filled with a hot strong decoction of camomile-flowers.

When the inflammation will not resolve, a poultice of white bread and milk, or onions roasted under the cinders, or the like, may be often laid hot to the part affected, till it breaks, or the abscess is evident to the eye.

If the ear-ache is caused by any thing got into the ear, it will be best to relax the membranes by oil of almonds, and then cause the patient to escheeze, which forces it out.

When there is a copious flux from the ear after an abscess, the humours must be diverted by gentle laxatives, blisters, cupping, and pediluvia, if the patient is an adult. It should not be suddenly stopped by externals.

Of the Stone in the Gall-Bladder.

The signs of it are a fixed pain in the right hypochondrium in the region of the liver, which is constant, precluding, heavy, and sometimes acute; often attended with an ill colour in the face. The pain sometimes reaches to the epigastric region and the pit of the stomach. And the exacerbation is so great, at certain intervals, that the gripes and torture affect the whole cavity of the abdomen; joined with inappetence, a nausis, reaching to vomit, anxiety of the precordial, cardial alburn, colicvinae. At length, if the disease be oblitinate, and will not yield to the bell remedies, the jaundice supervenes. Some of these patients are continually afflicted with gripes, and live in this condition for many years, and generally die of the dropsy. Some feel a heavy, obtuse, deep, obilitinate pain, with a tenfe weight, when the gall-bladder is greatly distended with small soft stones.

If the pain continues very intense and sharp, it draws the whole system of the nervous parts into content, causing spastic stristrictures, not only of the adjacent parts, but also...
of the remote; distentions of the arms and joints, epileptic convulsions, and likewise a fever with a hard quick pulse, which shews a large rough stone is firmly fixed in the biliary ducts, that will soon hurry the patient out of the world.

But nothing is a more certain sign that these terrible disorders proceed from gall-stones, than when they are voided with the excrements, and then all the symptoms cease at once, except the jaundice, which disappears by little and little, or is easily cured.

If the stones are soft, and of a light colour; or tophaceous and like mortar of plaster, they most probably proceed from the hepatic ducts: If they are rough, hard, angular, and of a deep colour, they proceed from the gall-bladder, especially if attended with most cruel symptoms in their passage through that slender canal. However, stones have been found in the gall bladder after death, which have produced no extraordinary symptoms.

There are two times of the disease, which require two different methods of treatment; in the fit, and out of the fit.

In the fit, the spasms are to be appeased with anodynes and demulcents, such as oil of sweet almonds, and fresh sperma ceti, internally; externally, the fat of a wild cat, or a beaver, &c.

Demulcents are, milk, sweet whey, emulsions of the cold seeds, infusions or decoctions of marshmallow roots, with wild poppies, elder, syrup of marshmallows.

Powders may be made with crabs eyes, cinnabar, and nitre, with a little saffron, powder of earthworms, elkshoofs, &c.

Externally, emollient epithems, and facculi, filled with carminative ingredients. As also lenient clysters and laxatives of manna, rhubarb, cream of tartar, and the like.

Out of the fits, opening infusions and decoctions; which resolve, disperse, and promote excretions; such as tincture of rhubarb, dog-grafs, asparagus, parley, pimpinel, afterwards adding rhubarb, terra soliata, tartar, or sal. polychred, and syrup of marshmallows, which must be used a long while.

Some praise the roots of dog-grafs, and the juice of dog-grafs, as a specific.

Some use the powder of millipedes with neutral Salts. Epithems made of camomile flowers, leaves of scor-dium, wormwood, and cardus benedictus, elder-flowers, water and red wine, used often in a day, are beneficial.

But if these fail, after long use, the only refuge is in mineral waters, among which the Pyrmont is not the least ineffectual.

These are also properly used by way of prevention, with exercise, and decoctions of the aperient roots.

Of the Gravel and Stone.

A nephritic paroxysm is attended with a fixed pain in the region of the loins, bloody urine, voiding of gravel or small stones, a numbness of the thigh on the side of the part affected, a drawing up of the tefficle on the same side, a naufea and vomiting. After the stone is fallen into the bladder, the urine presently becomes very thick, turbid, blackish, and in great quantity.

When the stone or gravel begins to move and make its way into the ureters, then the pain begins, which is more, or less sharp according to the size and figure of the stone. It is sometimes so violent, that, besides a coldness of the extreme parts, there is a naufea, vomiting, and a spasmodic contraction of the precordia; a difficulty of making water, a conflabilation of the belly, a ftrainings of breath, a fplendor of the thigh, a retraction of the tefficle to the os pubis, inquietude, lobe of strength, a syncope, convulsion-fits, or a fatal fkipage of urine.

When the violent pain has continued for several days and nights without intermission, and has brought the patient exceeding low, attended with an entire suppression of urine, with a coldness of the extreme parts and convulsions of the tendons, it is a sign that death is at hand.

Nor is it a good sign when the stone has continued a long while in the ureter; for then the appetite decays, and a naufea and reaching to vomit supervene, till the patient is confumed with a hectic heat, and the approach of death is hastened. Sometimes the pain is attended with an inflammation of the stomach or intestines. Some, from a fkipage of urine, fall into a dropfy of the bread, a lethargy, or convulsions.

The whole intention of cure conflits in the easy exclusion of the stone, and the preventing the breeding of others.

Hoffman.

If the patient is of a fanguineous temperament, take away ten ounces of blood on the affected side; and then let him drink, as soon as possible, a gallon of posset-drink, in which two ounces of marshmallow roots have been boiled. Then gave an emollient clyster.

When the posset-drink has been vomited up, and the clyster returned back, give a pretty large dose of an opiate; that is about 25 drops of the thebaic tincture, or 15 grains of the pil. faponacese.

Also let a bath or semicupium be prepared, of a decoction of althea roots, linseed, fennegreek seeds, and chamomile flowers; to these may be added, a few white poppy heads.

In the nephritic disorder, the grand point is the evacuation of the subiliary matter lodged in the pelvis of the kidneys, or in the ureters. Bleeding serves to remove the tension and inflammation; and emollient clysters are of a double service, because, by fomenting the flender tubes, they relax the contraction, and, by unloding the lower bowels, they remove the pressure against the ureters. The warm bath opens the passage yet more, greatly relaxing the abdominal muscles, peritonizm, and intestines; the bladder is also relaxed by it, and consequently the oblique infinitation of the ureters through its cellular membranes is less liable to obstruct the evacuation of this sandy matter into its cavity.

By moderate diuretics, and emollient medicines, this discharge is assisted; while anodynes suspend the pain, and procure a paralytic resolution or a spasmodic contraction of the ureters, and thereby contribute not a little to open the passage.

These appear to be the most considerable methods for the relief of this disorder, which is but imperfectly managed without the united affifiance of all, and which, used together, seem the utmost art can furnish.
A turpentine clyster is generally accounted very serviceable in a fit of the gravel.

Haffer recommends the solution per deliquium of the tal diuretics, or the terra foliata tartari, mixed with a fifth part of the thebaic tincture, of which 50 or 60 drops may be given now and then, which will ease the pain, and gently expel the stone or gravel.

When the stone is too big to pass, the diet ought to be cool and diluent, to hinder the growth as far as possible. The diuretics that gently resolve, are parsley, fennel, scorzonera, mallows, and tea; dandelion, succory, oats, barley, honey, honey and vinegar; nitrous salts, as dulcified spirit of nitre; the most soft cooling diluter is whey; the best emollients are a decoction of marshmallows and linseed tea.

When a small stone passes through the ureters into the bladder, it is generally expelled; but if it happens to stay in the bladder, it increases by the apposition of fresh matter, or in an orbicular manner, while the original stone remains like a real kernel. These additional coats are either red, white, ash-coloured, or bluish.

The stone in the bladder may cause an inflammation, with its symptoms; as also prefaces, attractions, ulcers, purulent urine, stranguries, obstructions of the urethra, an inability to discharge the urine, unless in a supine position; a hectic fever, and a consumption. Sometimes the stone gets into the urethra, and plucks up the passage.

A stone in the kidneys may be known from a dull obtuse pain therein; from bloody urine after walking in a rough way, or after violent motion of the body, especially by being shook in a coach or other wheel'd carriage; from having voided stones formerly; and from the urine's being mixed with caruncles, pus, and filaments.

A stone of the bladder is known from a pain at the time of, as well before and after making water; from the urine coming away by drops, or flowing suddenly when in a full stream; by a violent pain in the neck of the bladder upon motion, especially on horseback, or in a coach over the stones; from a white, thick, copious, thickening, mucous sediment; from an itching in the head of the penis; from a tenesmus while the urine is discharged; by searching, with introducing the finger in the anus, or with a catheter; as also from the effects produced by the stone before mentioned.

As to the cure of the stone in the bladder, the medicines of Mrs. Stephens were lately much in vogue as a dissolvent; and Dr. Hartley, by leaving out the superslusive part of them, has reduced them to the following form.

1. Take 2 or 2½ scruples of calcined egg-shells, thrice a day, in any convenient liquid, drinking after each dose a third part of the following decoction.

2. Take 2 or 2½ ounces of Spanish soap, and dissolve it in a sufficient quantity of boiling water; filter, and sweeten with honey or white sugar.

The powder may be taken in three or four spoonfuls of any liquor that is not acid; if the largest quantity of the decoction is taken, it will be best to divide it into four doses.

The egg-shells must be calcined in a crucible eight or ten hours, to bring it to a lime; and then be exposed to a dry air, for six weeks or two months, that is, till they flacken or fall off into an impalpable powder, which must be sifted and put into bottles well corked.

The taking of these medicines must be continued for some time after the complaint ceases, lest any part of the stone should remain, which would be then rugged and unequal, and occasion exquisite pain afterwards.

It is common, after a few days use of these medicines, to have a great increase of pain in making water; at which time, opiates, emollients, warm baths, fomentations, a soft diet, and rest, are proper.

Dr Hales, after several trials of the different ingredients of Stephen's medicines, found that the dissolving power of them lay in the lime. And Dr Jurin, having taken soap-lees, the ingredients of which are potash and lime, beginning with a few drops, and increasing the quantity, till he took an ounce, or an ounce and a half, every day in a proper vehicle, was cured of bloody urine, pain, &c. and passed several stones; after which he had no uneasiness. Hartley thinks the capital soap-lees are best taken in milk, half an ounce of which requires half a pint of milk. He thinks an ounce and a half, or two ounces, may be taken thus every day with perfect safety.

But Hales rightly conjectured, that lime-water alone was likely to have a good effect in dissolving the stone; which put Dr Whytt upon making experiments therewith, which have happily succeeded; whence he proposes the following method of cure.

Let the patient swallow, in any form, an ounce of Alcant soap every day, and drink three pints or more of oyster or cockle shell lime water. If the soap be taken in pills, it may be divided into three doses; the largest may be taken early in the morning fasting, the second at eleven before noon, and the third at five in the afternoon, drinking after each dose a large draught of lime-water, the remainder of which may be drank at meals, instead of the usual liquors.

The disagreeable taste of the lime-water may be mitigated by adding a very small quantity of new milk to it; and is quite destroyed by washing the mouth immediately with a little vinegar and water, and carefully wiping it out again. A dram and a half or two drams of juniper berries, infused in every quart bottle, will mend its taste much. But if the patient dislikes pills, let him dissolve an ounce of soap in a pint and a half of warm lime-water made of shells, which have been long exposed to the weather; and take this at three different times, drinking the rest of the lime-water by itself.

If the shell lime-water cannot be had, let him take the same quantity of lime lime-water, with at least an ounce and a half of soap, because it increases its dissolving power.

If there is an invincible averton to soap, there is reason to think, from experiments that have been made, that oyster shell lime water alone, taken in larger quantities, will have greater effects in dissolving the stone, than lime water even when diluted by soap.

At first the patient should begin with smaller quantities of lime water than that mentioned above, which he may increase by degrees, and ought to preserve in the use of it, especially if he finds any abatement of his complaints or symptoms of the stone's dissolving, for several months, or, if the stone be large, years; during which he should abstain from acid or fermented liquors.
MEDICINE.

For his drink, he may use milk and water, or a potion made with roots of marshmallows, parsley, and liquorice. But if he has been accustomed to more generous liquors, he may drink small punch made without acids. Spirits must not be drank at all, nor the weak punch but very sparingly. It will be also proper to forbear the use of falt meats, honey, and acid fruits, or at most to use them sparingly. Artichoaks, asparagus, spinnage, lettuce, succory, parsley, purslane, turnips, carrots, potatoes, radishes, green peas, may be safely used; but onions, leeks, and celery, should be preferred to most other vegetables.

The patient ought to drink no more of any liquor than is sufficient to quench his thirst; and he should retain his urine as long as he can without uneafiness, that it may have the greater time to act on the stone.

If the lime water occasions suffocativeness, it will be necessary now and then to take a purgative; the most proper are aloes, manna, rhubarb, fenna, or jalap.

Such as have a stone in the bladder, should, while they are taking the medicines, have four ounces or upwards of tepid shell lime-water injected into the bladder every day, and retain it as long as they can without pain, and should evacuate their urine immediately before injection.

Were it not for the trouble of introducing the catheter, an injection might be made at least twice or three times a day; and if a flexible catheter were always kept in the bladder, it might be done at pleasure, and the dissolution of the largest stone quickly procured.

That the injection of the bladder may be more safe, and attended with less uneafiness, a dram of starch may be boiled in six or seven ounces of lime-water, and just be brought to boil over the fire. The fourth part of the yolk of an egg, being mixt with six ounces of lime-water, does not weaken its virtues any more than the starch, and may be occasionally used in its stead.

Such as have no stone in the bladder, but are frequently troubled with fits of gravel in the kidneys, may probably prevent them, by drinking every morning a pint of shell lime-water, two or three hours before breakfast; and though it may be too small a quantity to dissolve the stone, yet it may prevent any new concretions.

Olive the Rheumatism.

The rheumatism chiefly attacks persons in the flower of their age, after violent exercise, or a great heat of the body from any other cause, and then being too suddenly cooled; but spares neither men nor women, old nor young, especially if the person is full of blood depraved with any kind of astringency. The disease is nearly akin to the gout. It begins with chilines and shivering, followed by inquietude and thirst. Which is preceded with spontaneous latitudine, a heaviness of the joints, and coldness of the extreme parts. When the fever appears, there is an inward heat, chiefly about the precordia, attended with anxiety. The pulse is quick and reat, the appetite is lost, and the body collyve. In a day or two, sometimes sooner, the patient feels a rackling pain, sometimes in one joint, sometimes in another, but more frequently in the wrists, shoulders, and knees; frequently shifting from place to place, and leaving a redness and swelling in the part visited last. The pain is exasperated upon the least motion; it sometimes attacks the loins and cox.undix.

When it seizes the loins, it is called the lumbago; and there is a more violent pain in the small of the back, which sometimes extends to the os sacrum, and is like a fit of the gravel, only the patient does not vomit. If this disease is undiscovered, it may continue several months or years, but not always with the same violence, but by fits. If it continues and increases, it may cause a stiff joint, which will scarce yield to any remedy.

Its proximate cause seems to be the inflammation of the lymphatic arteries, of the membranes near the ligaments of the joints, but not so violent as to bring on suppuration. The blood is like that of persons afflicted with the pleurisy.

Take away ten ounces of blood on the side affected. This must be repeated three or four times, or oftener, once every other or every third day, according as the strength of the patient will bear.

The diet must be very thin, and an emulsion of the four cold feeds may be prescribed; and also a poultice of white bread and milk, tinged with a little saffon, may be laid on the parts affected.

If the patient cannot bear frequent bleeding, after the second or third time, give the common purging potion every other day, and an ounce of diacodium at night, till the patient recovers.

If the rheumatism begins with a febrile effervescence, temperate diaphoretics, with nitrous things, in a moderate dose, and often repeated, are beneficial; such as crabs-eyes, burnt hartthorn, amber, cinnabar, purified nitre, with diaphoic and gently anodyne waters, also citron-juice, or its syrup. The common drink should be whey acidulated with citron-juice or cream of tartar; or decoctions of the shavings of hartthorn, roots of forzonera, succory, liquorice, or fennel-feeds.

To purge, it may be proper to chew or eat rhubarb, from two scruples to a dram, with raisins or currants.

In an incipient rheumatism of the shoulders, nothing is better than a blister laid between the scapulae.

But if the patient happens to be plethoric, nothing is better than a decoction of the fudorifie woods, to the quantity of a quart a-day, for a month or six weeks together.

This last is good in the venereal rheumatism, when afflicted with crude antimony and mercurius dulcis.

Young persons who are temperate livers, and not addicted to strong liquors, may be cured by a simple refrigerating diet, and moderately nourishing, as certainly as by repeated bleeding; for instance.

Let the patient live four days upon whey alone; and after that white bread may be allowed for dinner, and on the last days of his illness, he may be allowed it for supper. When the symptoms cease, he may be allowed boiled chickens, or other things of easy digestion; but every third day he must live upon whey only, till his strength returns.

Boerhaave's method of cure is to the same effect, only he advises warm baths and strong blisters to be laid upon the parts affected, nay, even cauteries themselves.
MEDICINE.

 Arbuthnot says, cream of tartar in water-gruel, taken for several days, will abate the pains and swellings considerably, by its acidity correcting the alkaline salts of the blood.

Ridley used mercurius dulcis in rheumatic cafes, as a purge, with good success, giving a scruple in conserve of violet over night, and three pints of eplom waters, evaporated away to one half, in the morning.

Dr James has wrote a treatise to prove the efficacy of mercurial preparations, as well in the rheumatism as in the gout, which is supported with very good authorities.

And Huxham says, that the obdinate rheumatic pains, which remained after the epidemical fever of 1737, would yield to mercurial cathartics; but he preferred to apply to the patients what he calls the essence of antimony, which is of itself but emetic wine made with glaft of antimony, with the addition of a little spicy stammack. This, given to 20 or 30 drops, operates by gentle sweats, and purges in a larger dose very mildly.

Hoffman likewise recommends mercurials and antimonials in particular cafes; that is, when a violent and obdinate pain afflicts the lower parts of the body, about the offa fchii and the os coccic, and the patient is of a robust constitution, then the more powerful chemical medicines may be made use of, such as mercurius dulcis, the folar precipitate rightly prepared, or the medicinal regulus of antimony, to which a decoction of the sudoulic woods may be added. From such medicines as these great relief may be expected.

Cheyne says the hot and inflammatory rheumatisms have all the symptoms of the gout, and like it change from place to place, and by over violent evacuations may be transmitted upon the noble organs. And by the way it may not be amiss to observe, that excessive bleeding, and other violent evacuations, constantly bring on a hectic or dropisy of the patient in this cafe; diseases of a much more dangerous nature in themselves, and far more difficult to be cured, than the original one. And therefore in this disease, only promoting so much bleeding as will prevent a fever and mortification, and somewhat abate the pain (which gentle doses of calomel and gum guaiacum will do more effectually, than not more speedily, than bleeding itself) the rest is to be done by large doses of the bark and ethiops mineral mixed; and a relapse prevented by gentle doses of gum guaiacum, with antimony diaphoretic, and cinnabar of antimony.

Pringle observes, that rheumatism is generally mild, though they sometimes appeared with all the violence taken notice of by Sydenham. For which reason the first fort were generally cured in two or three days by twice or thrice bleeding, and promoting a diaphoresis by the cooler medicines, particularly by vinegar whey. But if it was intended with an inflammatory swelling of the joints, sweating was improper, and the cure was only to be obtained by repeated and almost daily bleedings. But then it is to be carefully remarked, that those were afflicted with it who were both able to bear these evacuations; and in this disease he thinks frequent bleedings weaken the body less than in any other.

If the pain and swelling of the joints remain after this treatment, three or four leeches must be applied to the part where the inflammation and tumour are the greatest, and the blood is to ooze till it drops of itself. This may be repeated freely without danger. But unless there is both an inflammation and swelling, leeches will do no service. The best internal medicines, in a true acute rheumatism, are neutral salts, with very small doses of camphor. The diet must be of the lowest kind. All outward applications are to be omitted as long as any fever or inflammation remains.

The chronic rheumatism is either the remains of a rheumatic fever, or a continuation of pains that proceeded at first from lefser but neglected colds. The blood in this case is fuly. It is an obdinate disease, but bleeding is the most efficacious remedy. Eight ounces of blood is to be taken away once in eight or ten days, as long as it is fuly, or the complaints remain.

Bleeding has been repeated, in many cases, three or four times, to no manner of purpose; nor would the pains abate without deobstructs, diaphoretics, purges, and anodynes. Sometimes they have yielded to the cold bath alone.

Dr Clerk of Edinburgh declares the Arthritis Vaga, or flying gout, erroneously called the Scorbutic Rheumatism, may be often distinguished by the urine of the patient; for certain filaments float in it not so transparent as the urine itself, but when taken out they appear as pellucid as crystal. They will rove to a great length, and when dried turn to a white cafe. This he takes to be the morbid matter of the gout, gravel, gouty sciatica, and all true arthritic pains, distinct from the rhumatism. Soap is the best diffolvent of it yet known, half an ounce of which to an ounce may be taken in a day for a month together, if necessary, in the sciatic and other arthritic pains.

Of the Gout.

The gout is a very painful disease, whose seat is in the joints and ligaments of the bones of the feet; the principal times of its invasion are the spring and the autumn.

In treating of this disease, we shall first give an account of the regular gout, and afterwards of the irregular.

The regular gout usuallly seizes the patient in the latter end of January or the beginning February, in a sudden and without any previous notice, unless the patient has been troubled with crudities of the flomach and indigetion for some weeks before; the body likewise have seemed to have been puffed up with wind, with a kind of heavines, which daily increases, till at length the fit comes on; a few days before which, there is a torpor, and as it were a deacent of wind down the muscles of the thigh, with a kind of epiplectic affection of them. Likewise, the day before the fit, the appetite is more voracious, but not natural.

Though the patient seems to go to bed in good health, yet about two in the morning he is awakened by a pain which most commonly affects the great toe, sometimes the heel, the ankle, or the calf of the leg, which pain resembles that of dislocated bones; there is likewise a sensation as if water almost cold was poured on the membranes of the part affected. Soon after, a shivering and shaking supervene, with a febrifh disorder. The pain which at first is tolerable, becomes more violent in proportion as the
the shaking decreases, and grows more intense every hour till night, and then it is at the height; settling itself about the little bones of the turfo and metatarso rays, whose ligaments it affects. Now there seems to be a violent extension of the ligaments, or there is a sensibility of their being lacerated, or gnawed by a dog. Sometimes they seem to be pressed or squeezed together. At this time the part affected becomes so exceeding sensible, that they cannot bear the weight of the sheet, nor the shaking of the room by a person's walking about.

The patient is now in great torture, and is continually shifting his foot from place to place in hopes of ease. His body likewise is in a constant agitation as the part affected. This always happens at the accession of the fit, but the pain continues without remission till two or three in the morning, that is, twenty-four hours from the first onset, at which time he begins to be at ease, which he is willing to attribute to the last posture in which he placed the affected member. Now he falls into a gentle breathing sweat, and gets a little sleep, and, when he awakes, perceives the part to be swelled, and the pain much abated; for before, the veins of the member, being turgid, were only more conspicuous than usual.

The next day, or perhaps two or three days afterwards, if the gouty matter is copious, the part affected is a little in pain, which grows more violent towards the evening, and abates at the crowing of the cock.

In a few days the other foot begins to be affected in the same manner; and, if the pain has ceased in the first, the weakness which is left behind soon vanishes. The same tragedy is now acted over again. Sometimes, when the gouty matter is in great plenty, it attacks both feet at once, but it generally seizes one after the other.

After both the feet have been tormented, the fits which follow are out of rule, both as to the time of invasion and the duration; only the pain grows more intense at night, and rests in the morning.

From a series of these small fits arises what is called a fit of the gout, which is longer or shorter, according to the patient's age. For it is not to be supposed that, when a patient has been laid up with the gout two or three months, that it is a single fit, but rather a series or chain of small fits, which continually grow shorter and milder, till the peccant matter is at length consumed, and its rage, in two months; but those who are debilitated with age, or the long stay of the disease, it does not leave, still night, and then it is at the height; settling it in the belly, a spontaneous weariness, and sometimes a disposition to fall into a diarrhoea; which symptoms vanish as often as the pain returns to the joints. And thus, the patient being alternately affected with pain and ficknesh, the paroxysm becomes very long and very tedious. This disease seldom invades any patient till he is upwards of thirty, and men are more subject to it than women; as also persons of acute parts, who follow their studies too closely, especially in the night, with an intense application of mind. Likewise those who live high, and indulge their appetites, drinking plenty of rich generous wines; or who use acids too freely, or white easter wines; or who have been addicted too early to venereal pleasures; or whose bodies are large, gros, and full.

If these are not able to bear the weight of the sheet, nor the shaking of the room by a person's walking about.

The patient is now in great torture, and is continually shifting his foot from place to place in hopes of ease. His body likewise is in a constant agitation as the part affected. This always happens at the accession of the fit, but the pain continues without remission till two or three in the morning, that is, twenty-four hours from the first onset, at which time he begins to be at ease, which he is willing to attribute to the last posture in which he placed the affected member. Now he falls into a gentle breathing sweat, and gets a little sleep, and, when he awakes, perceives the part to be swelled, and the pain much abated; for before, the veins of the member, being turgid, were only more conspicuous than usual.

The next day, or perhaps two or three days afterwards, if the gouty matter is copious, the part affected is a little in pain, which grows more violent towards the evening, and abates at the crowing of the cock.

In a few days the other foot begins to be affected in the same manner; and, if the pain has ceased in the first, the weakness which is left behind soon vanishes. The same tragedy is now acted over again. Sometimes, when the gouty matter is in great plenty, it attacks both feet at once, but it generally seizes one after the other.

After both the feet have been tormented, the fits which follow are out of rule, both as to the time of invasion and the duration; only the pain grows more intense at night, and rests in the morning.

From a series of these small fits arises what is called a fit of the gout, which is longer or shorter, according to the patient's age. For it is not to be supposed that, when a patient has been laid up with the gout two or three months, that it is a single fit, but rather a series or chain of small fits, which continually grow shorter and milder, till the peccant matter is at length consumed, and its rage, in two months; but those who are debilitated with age, or the long stay of the disease, it does not leave, still night, and then it is at the height; settling it in the belly, a spontaneous weariness, and sometimes a disposition to fall into a diarrhoea; which symptoms vanish as often as the pain returns to the joints. And thus, the patient being alternately affected with pain and ficknesh, the paroxysm becomes very long and very tedious. This disease seldom invades any patient till he is upwards of thirty, and men are more subject to it than women; as also persons of acute parts, who follow their studies too closely, especially in the night, with an intense application of mind. Likewise those who live high, and indulge their appetites, drinking plenty of rich generous wines; or who use acids too freely, or white easter wines; or who have been addicted too early to venereal pleasures; or whose bodies are large, gros, and full.
Those also are liable to it, whose sweaty feet are too suddenly chilled; or who suffer their feet to sweat in wet shoes and stockings. Hence hunting and riding in the cold are pernicious. It may likewise be received when the feet are too wet and locked. Hence hunting and riding in a dry, pure, serene air; by friction, and wearing aromatic, antiscorbutic medicines; by alkaline fixed soda, by motion of the affected parts, by going to deep at early hours.

The curative indications require, first, that the prime vice be first free from a load of indigested crudities; and that the visera be restored to their pristine vigour: that by these means the aliments may be duly concocted and assimilated into healthy fluids, and such as will pass freely through the smallest vessels; while whatever is unfit for nourishment may pass off by perpiration, in due time and quantity. Secondly, that the fluid stagnation in, and stultifying up the smallest vessels, may be expelled the body, and a free passage through the contractcd vessels be restored.

The first intention may be answered by vomits and gentle cathartics, repeated as occasion requires; by bitters, aromatics, antiscorbutic medicines; by alkaline fixed soda, taken in small quantities for a long time; by aliments and drinks that are nourishing, light, easy of digestion, quickly assimilated and taken in due quantity; by powerful exercise often repeated and long continued, and especially by riding in a dry, pure, serene air; by friction, by motion of the affected parts, by going to sleep at early hours.

The second intention may be answered partly by the preceding article, as well as by procuring gentle sweats, by bathing in natural and artificial baths; by sweating in a bagno; or by the use of volatile farts, and copious drinking of attenuating liquors actually hot, in the morining while in bed, in order to procure a sweat; as also by mercurial purges, taking a large quantity of di- luents after them; by frictions of the whole body, especially the parts affected, with hot, dry linen cloths, till a redness appear; by cold baths, and the like.

As the proximate cause lies in the vitiated state of the smallest nervous vessels of the body, and of the fluid that passes through them, it is no wonder that bleeding will not reach the matter, state, or cause of the diseafe; yet it may sometimes do good by accident, by causing a small revulsion, and by abating the urgent symptoms.

The curative indications require, first, that the prime vice be set free from a load of indigested crudities, and the visera be restored to their pristine vigour: that by these means the aliments may be duly concocted and assimilated into healthy fluids, and such as will pass freely through the smallest vessels; while whatever is unfit for nourishment may pass off by perpiration, in due time and quantity.

As the proximate cause lies in the vitiated state of the smallest nervous vessels of the body, and of the fluid that passes through them, it is no wonder that bleeding will not reach the matter, state, or cause of the diseafe; yet it may sometimes do good by accident, by causing a small revulsion, and by abating the urgent symptoms.

Nor will emetics or cathartics yield so much relief as is commonly thought, because they often raise a disturbance in the nervous fluid, diminish the other fluids, and weaken the expulsive faculty. But much greater benefit may be expected from Tudorifics rightly administered.

Nothing is more fatal than to hinder the gouty matter, now grown mature, and remaining unexpelled, as well as uncorrected by proper medicines, from falling on the usual parts, which indeed cause great pain, but no danger. If it invades the brain, it will occasion apoplexies, palsy, a delirium, weaknesses, dozing, tremors, or universal convulsions: If it attacks the lungs, it produces an asthma, a cough, or a suffocation: if the intercostals and pleura, a convulsive pleurisy; if the abdominal visera, nausea, anxieties, vomiting, belching, piping, or spasms of the visera. It is almost incredible how many diseases it creates, which are suddenly mortal; or at least not to be cured but by reviving the fit of the gout, which had been disturbed, and rendering it as severe as possible.

The last mentioned evils happen from indiscriminate applications of narcotics, refrigerants, astrigents, or in- crassants; or from medicines which cause a revulsion from the diseased part, or from debilitating, evacuating, or suffocating remedies. Hence bleeding, purging upwards or downwards, plasters, poultices, of the nature above-mentioned, and all opiates, produce these effects: as also a spontaneous weakenes brought on by extreme old age; or from the extreme parts being so obstructed, corrupted, withered, or perished, that the morbid matter cannot pass through them any longer.

To abate the excessive pain in the part affected, if there be an absolute necessity, opiates may be given internally, and the patient may drink plentifully of hot whey, or any other liquor of the like nature. External emollients and anodynes may be used laid on pretty hot or the part affected may be beat with nettles, or it may be anointed with terebinthinated balsam of sulphur, or tow may be burnt thereon.

Though there is nothing of any moment to be done in the fit, yet it will be proper to abstain from flesh for some days, and to live upon water gruel, or such like diet; but no longer than the stomach is averse to flesh, for fear of bringing on a disturbance of the animal spirits; but then great care should be taken in the diet, both as to quantity and quality.

As soon as the pain is almost gone, and the swelling and the weakness only remain, nothing can be better than warm stomachic and spicy purges, dosed and repeated according to the strength of the patient. This being premeditated, if the patient's strength is impaired, and his flesh wasted, give after milk with pearl, half a pint or a pint in a morning early, and at five or six o'clock in the afternoon; and to keep up the appetite which the milk commonly palls, and to prevent its cooling effects on the stomach, a light bitter made of gentian, cinnamon, and orange-peel only, the last double to the other two, infused in sherry or white wine, and taken two hours before meals, may be used most conveniently. This course may be continued two or three weeks; after this a course of Bath or German-spa waters with steel, riding, a light white food diet, and generous wine drank temperately, will be most proper.

Out of the fit, those things are most proper which promote the concoction of the aliment, whether by medicines, exercice, or diet.

In the diet there is a medium to be observed; the patient should neither eat more than the stomach will digest, nor be so abstemious as to defraud the parts of such a proportion of aliment as is necessary to maintain the strength and vigour. As to the quality of the food, the patient's palate is to be conformed: but he should dine upon one dish of meat only; for several kinds of flesh, eaten at the same meal, disturb the digestive faculty more than the same quantity of any one sort. As for other things, the
the patient may feed upon what he likes best, provided it is not sharp, nor lashed, nor seasoned with spices. He should eat no supper; but instead thereof should drink a draught of good small-beer, whereby the breeding of the gravel may be prevented. If the patient is troubled with the gravel or stone, and makes bloody water, he may purge with manna once a week, and take a paregoric at night.

The most suitable drink is such as is not so strong as wine, nor so weak as water, for the latter by its coldness will deprave the stomach. Of this sort is the London table beer, or water with a little wine. But, when the gouty matter has seized the whole body, he must abstain from all fermented liquors, though ever so mild and small.

But if the patient has been used to strong or spirituous liquors, or is advanced in years, or through weakness cannot digest his aliment, he may, at meals, indulge himself with a draught of Spanish wine, which is better than French.

If the patient should come upon the gout, which often happens, let the patient omit all other medicines, and drink a large quantity of posset-drink, in which the leaves and roots of mallows and marshmallows have been boiled. Then let a Clyster be given, and afterwards a large dose of laudanum.

When the gout has seized on the head, it is to be treated as any other head-ache, or as an inflammation of the brain and its membrane; bleeding in the arm or jugular, cupping on the back, and blistering between the shoulders, but especially on the ancles, to give the gouty humour a vent downwards. In young and strong constitutions mercurial and antimonial vomits will do wonders. Likewise gentle stomach purges are to be poured down continually, that is, two or three spoonfuls every third hour, till the effect is obtained.

Mercurial vomits are not only proper for the gout in the stomach, but are absolutely necessary as well as mercurial purges, when the gout becomes fixed to, and permanent in a place, as also when it is dispersed all over the habit like a rheumatism. These active medicines must first render the humour fluid, which gum guaiacum, with diaphoreetic antimony, perished in, will afterwards carry off.

Of the Sciatica, or Hip Gout.

The sciatica is a violent and obstinate pain in the hip, chiefly in the joint where the head of the thigh bone is received into the acetabulum of the coxendix. The pain will sometimes extend itself to the lower part of the loins, to the thigh, leg, and even to the extremity of the foot; yet, outwardly, there is no swelling, no inflammation, nor change of colour in the skin.

Sometimes there is such a spasm of the muscles on the side affected, that the patient cannot stand upright, without the utmost pain.

When the sciatica has continued very long, there is such a collection of pituitous humour in the cavity of the joint, that, by relaxing the ligaments, it often causes a luxation. Sometimes it causes an aridura, or wasting away of the adjacent parts.

When the pain leaves the hip, and moves downwards, it is a sign that the spasms are resolved. A violent motion of the body generally exasperates the pain.

After a gentle cathartic, or Clyster, bleeding will be proper, especially in the ancle; also leeches applied to the hemorrhoidal veins have been found beneficial. Strong purges are hurtful, but mercurius dulcis given with scammony, or some other purgative, will be of service.

If the patient is old or weak, lenient purges will be most proper; and on the intermediate days a dose of calomel, which is afterwards to be purged off; and so repeated alternately for some time.

Baglivi observes, that if nothing else will do, in pains of the external parts, recourse must be had to caufies, particularly the leaves of ranunculus, or a mixture of quicklime and soft soap, which are beneficial in the hip-gout.

Cheyne observes, that when the gout is dispersed over the whole habit, or is fixed and settled on a particular joint, mercurial vomits and purges are necessary to dilodge it; but the sciatica will not yield to this, and but rarely to any other method of use; but, by the following method, a perfect cure may always be obtained, if the distemper is a genuine sciatica, though of many years standing.

It consists in taking one, two, or three draams, to half an ounce, according to the strength of the patient's stomach, of the ethereal oil of turpentine; which is that which comes off between the spirit and the oil in drawing off the common oil of turpentine; this is to be taken in triple the quantity of virgin honey, in a morning fasting, for four, five, six, or eight days at farthest, intermitting a day now and then, as the patient's occasions require, or his stomach suffers by it. Large draughts of sack-whey must be drank after it, to settle it on the stomach, or carry it into the blood; likewise every night must be taken a proper dose of Matthew's pills, or half a scruple of the pil. japonaceae, that is, if the oil has been taken in the morning.

To remove the groffer remains and strengthen the weakened part, the patient must take a dram or two drams of flower of brimstone, for some time twice a day, in a tea-cup full of milk. If through great intemperance, or a violent cold, the patient relapses, let him repeat the former medicine for a day or two. Then, to strengthen the prime vue and enliven the spirits, let him drink the Bath or Spaw waters with fleed, and bitters with volatiles.

Of a Virulent Gonorrhoea.

A virulent Gonorrhoea, or Clap, proceeds from impure coition with an infected woman.

This distemper begins and makes its progress in the following manner. The patient, sooner or later, according as the woman with whom he has had conversation was more
more or less infected, and according to his constitution, by which he may be more or less disposed to receive the infection, is first seized with an unusual pain in the genitals, and a kind of sensation like a rotation of his testicles. Afterwards, if the prepuce constantly cover his glans, there appears an eruption or pustule, which by its size, colour, and figure, resembles a spot of the measles; prefently after appears a weeping matter like semen, which daily changes colour, and becomes more purulent and more yellow, till at length, if the disorder be highly virulent, it assumes a greenish hue, or appears like a thin watery fluid. Then it soon proceeds to the glans of the urethra, then to the prostate; which are porous, and afterwards to the vesicles feminales.

If the infected lymph is conveyed to the inguinal glands through the lymphatic vessels, which Cowper discovered to run from the prepuce to the groin; then a venereal bubo is formed, which is a hard tumour without pain. But if the seat of the gonorrhoea is deeper, and an inflammation arises at the beginning of the urethra, where the vesicles feminales discharge the seminal fluid, then these vessels are so compressed by the tumour, that the semen cannot be conveyed to them from the testicles, whence it happens that the testicles swell.

As to the prognostics, we must observe, that the greater the infection is, the more violent and obdurate the disorder will prove; though it seldom brings on a pox unless the discharge is imprudently dropped by the preponderance of the use of abortifics and astringents; for, immediately on the suppression of the discharge, buboes, tumours of the urethra, and other terrible symptoms appear, together with a confirmed fever, the running is small in quantity, the urine is highly fetid, and the matter yellow or green, it is a bad sign.

It is a certain sign the disorder is mitigated, when the painful constriction of the penis in erection, and the heat of urine, are removed; as also when the impaired strength begins to return, and the countenance, which before was pale, assumes a florid or a natural colour.

It is a sign the gonorrhoea is cured, if, upon compressing the penis, a drop or two of thin limpid liquor, like the white of an egg, is discharged.

The regimen, during the time of the cure, requires the patient to abstain from all oily food; and he must also avoid every thing which by its acrimonious quality stimulates to venery; such as spices, bulbous roots, flesh, eggs, fish, and fermented liquors; for the irritation of the penis retards the cure. This is of the utmost consequence; and therefore all venereal incitements, such as obscene books, and whatever else inflames the fancy, should be shunned like death.

Water and whey are the best drink, and seeds and summer-fruits the best aliment.

All possible care must be taken that cold never reach the penis; and that it be kept always moist, lest the pores contracting repel the flux of matter. An emollient and somewhat antiseptic cataplasm will be beneficial.

In the place of mercurials given internally, Afruc di-
medicines the use of crude quicksilver, as in the common usage, to be rubbed upon the parts, as about the body of the penis, especially under the urethra to the perineum, and to up to the tubes and fistulas.

Turner approves of this method in all local affections, such as chancres, a phimosis and paraphimosis from a venereal taint: As also when there is a callousity in the urinary passage, or an induration of the fistulas, particularly their epididymis, left after the hernia humoralis, and the like. Nor does he disapprove of it in common claps during the course of the purgation.

If there is no discharge of virulent matter from the penis, it is called gonorrhoea fica, or a dry clap, the symptoms of which are a difficulty or difficulty of making water, and after, from the increase of the inflammation and tumefaction, an itch or total suppresion of urine.

In the cure of the dry clap, Astruc advises plentiful bleeding in the beginning, to take off the tension, and to abate the inflammation; as also emollient decoctions of mallows, linseed, &c., in milk, to foment the parts; but perhaps it might be better to make a poultice of these ingredients, after Boerhaave's method, to lay to the parts affected; or, which is best of all, to use them one after the other.

He likewise advises lenient elyters, cooling emollients, and ptifans with sal prunella and anodynes between whiles. During the continuance of the inflammation, no mercurials must be used; and if the symptoms increase, threatening an abscess outwardly in the perineum, it is to be forwarded as much as possible by suppressive poultices, and the matter discharged.

Of the Cure of the Symptoms.

I. Of the Hernia Humoralis, or Swelling of the Fistulas.

Astruc, in the cure, recommends frequent bleeding, and an antiphlogistic regimen, and fomenting the parts with a decoction of mallow-roots and linseed; or milk pretty warm; or an anodyne cataplasms of lily-roots, with leaves of henbane, mallows, and brack urine, boiled to a mucilage, and mixed with the flower of linseed and oil of lilies. After the inflammation and fever are abated, he advises a gentle purge; after mild refolvents externally, and antivenereals internally.

The hardness of the epididymis is to be diffused by succinated balsam of sulphur, mercurial plasters, and ointments. During the use of these applications, a suppository bandage should not be neglected.

When pus is formed in the fistulas, it must be discharged with a lancet. If it should leave a fistulous ulcer, he advises a mercurial ointment.

II. Of a Bubo.

Astruc afferts, that venereal buboes are of two kinds: the first is essential, happening immediately after coition with an infected person; the second symtomatical, which follows the suppresion of the gonorrhoea, or the drying up of the ulceration. He likewise mentions a third, which does not appear so early as the other two, and is therefore a pathognomonic sign of a lues venerea or pox.

He proposes to cure it by mercurial purges, to carry off the humour; in the mean time rubbing a mercurial ointment into the part, to dissolve the induration; which he thinks is more gentle and easy, than to promote the suppuration by ripening poultices, and then opening the tumour by a cautie, giving mercurials inwardly at the same time.

De Salt cures all the symptoms by rubbing into the parts a strong mercurial ointment, causing the patient to anoint himself from the anus all along the urethra to the glans and prepuce. The following day he gives a strong dose of jalap, that is, from two scrupules to a dram. His diet drink is to be spring-water in which mercury revived from cinnabar has been boiled. If the patient cannot bear much purging, he may have a truce for a day or two, but the ointment is to be continued every night. The first friction gives considerable relief, the second yet more, the third commonly makes the pain cease, and the fourth and fifth generally silence the complaints. Five or six weeks generally perfects the cure.

In buboes, the patient is to rub the ointment into the groin, scrotum, and parts in either sex; purging every day, and drinking the mercurial water; by which means the buboes melt away, the phimosis, paraphimosis, and chancres disappear, and the former health returns. If there is matter already formed in the bubo, then he allows it must be opened. Heiffer's method is much the same.

III. Of Caruncles and Carnosities in the Urethra.

The obstacles which hinder the free passage of the urine, according to Astruc, are these which follow. 1. Ulcers in the urethra. 2. Cicatrices left behind after the healing these ulcers. 3. Caruncles. 4. A chirrhous on the verumontanum, or caput gallinaginis. 5. Indurations of the prostate and vesiculae seminales. 6. Carnosities rising in and straitening the canal.

He proposes to cure the ulcers by the same regimen as the first period of a gonorrhoea, viz. by repeated bleedings, lenients and refrigerants, to abate the fluxion, and take off the inflammation.

Turner, in the worst cases, would not have the urethra laid open, but only have the perineum well greased with the mercurial liniment, by which he has known many large callousities insensibly dissolve, while the candle or leaden probe, smeared also therewith, has been kept within.

But there has been lately introduced into practice by Daran a new method of curing these disorders with bougies, the composition of which he keeps a secret.

According to him, if the canal of the urethra be open enough to admit the extremity of the bougie, a suppuration will ensue from the divided part of the urethra, which will in time relax and open the stricture; or, if the stricture opposes the entrance of the bougie, yet still the mere point of the bougie will suppurate it in a small degree, and by and by, though much more tediously than in the other case, by relaxing, open it.

The first discharge procured by a bougie is generally very foamy, and evidently flows from the place where the obstruction is, that part of the bougie only being covered.
covered with matter that answers to the obstruction. Again, the cordex, excited by the use of the bougie, is infinitely more painful where the obstruction is, than in the other parts of the penis. It will, it must be owned, produce a cordex in a found penis; but then it extends through every part of it, and is by no means so painful as the other.

If the symptoms of the strictures, callous scars, caruncles and tumours of the corpus spongiosum urethrae are essentially different, those differences are not mentioned by any writer; except that, when the urethra only is affected, the patient, in making water, voids matter before his urine; but when the prostate glands or vesicular females only are concerned, matter follows the last drop of urine. But it frequently happens that one is complicated with the other.

The properties requisite in a bougie, are a sufficient degree of firmness, that it may be introduced with some force: A suppleness and tenacity, that it may conform to the motions of the body without breaking: A lenient suppurative disposition, to bring on a discharge without pain: And, lastly, a smoothness of surface, that it may not only be introduced with more ease, but that it may lie easy in the passage till it begins to disfigure.

That chiefly made use of is as follows;

Emplast. commun. emu pice Burgund. 3ij. Argent. viv. 3ij. Antimon. crud. pulv. 3ij. M.

The emplast. com. or diachylon, must be made with oil and a little Burgundy pitch added to it, to render it sufficiently tenacious: the antimonymust be finely levigated, that it may give a smoothness and good confidence to the bougie.

The quicksilver, whether it be divided in half sulph. or honey, must not be put into the plaster till the moment before the bougies are made, nor must the plaster be boiling hot at that time. When the quicksilver is mingled with the plaster moderately hot, slips of fine rag must be ready to dip in the composition. They must be of different lengths, from five to nine or ten inches, and about three inches broad. Roll them up loosely, and, taking hold of one extremity with the left hand, let it fall gently on the surface of the plaster, and then draw it out gently. As it is drawn out, it will unroll, and take up a quantity of the plaster upon its surface, equal to the thickness of a silver groat. It may be proper to affist the unrolling with a spatula. The plaster must be hot enough to soak through the quicksilver; it is also exceedingly desirable that it enter within the obstruction. However, it is necessary to desist from pushing it when once it begins to bend. When it meets with any resistance, to avoid the bending, turn it round with your finger and thumb several times, and, as you turn it, press it a little forwards. If by this method it advances, continue to do the same thing till it stops. But it must be owned that the operator in this case may be easily deceived.

Two bougies in a day generally answer the purpose; one in the morning, and one in the evening, as more suitable to the patient's avocation; though some can walk about with them.

If the testicles should inflame, or any feverish disorder come on, they may be kept in an hour, or half an hour in a day, to prevent the urethra from contracting again till the symptom is removed; to prevent these disorders, the patient should observe a cooling regimen during the treatment.

Some are relieved by the bougie in a few weeks, some not till many months. Generally the cure may be performed in seven, eight, nine, or ten weeks. This is known by the removal of every symptom of the disorder; for some degree of running will generally continue as long as the bougie is employed.

When the patient judges himself well, it will be best to desist gradually, wearing it at first only an hour or two in a day, and then two or three times a week, after which it may be entirely left off. If any gleet still remain, or any obstruction threatens to return, it will be necessary to use the bougie four or five weeks longer.

In suppurations of urine it will be always advisable to introduce the catheter if possible, and indeed to keep it in
in the bladder two or three or four days; after which, the canal will perhaps admit a bougie, and then, a suppu-
ration being once procured, it may easily be preferred open.

IV. Of a Gleet.

In what manner, says S H A R P , a gleet is furnished, cannot well be determined, without first ascertaining the ex-
aot fear of a gonorrhoea. That the lacunae of the ure-
ithra are usually ulcerated in a gonorrhoea, is now generally
affected to. Yet though all allow the existence of ulcers
during that disease, they will not admit that a gleet is the
discharge of an ulcer.

But it is most probable, that the running is not all of it a purulent matter, but partly a discharge from the secre-
tory organs, as also from the vesica feminales, when they or their ducts are affect-
ed. For the running is produced in few time after the
infection than is requisite for the formation of matter
in every other instance; and the appearance of matter is
frequently the first alarm in a gonorrhoea, the beat of
urine and other symptoms of an inflammation and ulcera-
tion following sometimes two or three days after.

For these reasons, it is supposed, that the venereal poifon,
in its first operation, irritates only, and thereby increas-
the fecretion; especially as the fame thing happens to the
glans and preputium of men, as well as the labia and
parts with cinnabar fucceful in chancrous ulcerations on

A temporary increafe of a gleet is not wonderful, becaufe
habitual ulcers of every other part of the body are often
in a fluctuating state, and generally suffer from exccfes of
every kind.

A l t r u c , in this disorder, recommends milk, either of
affes, goats, or cows, to be drank morning and evening
for some time; then mineral waters, whether chalybeate
or vitriolic, for 15 or 20 days; and afterwards balsamics,
to deterge and cicatrife the ulcers concealed in the urethra,
such as hulfam of capivi, from 6 to 12 drops, made into
a bolus with powder-fugar; lafit of all, astringents to dry
up the ulcers, and to recover the loft tone of the parts,
such as infusions of the leaves of mint, horehound, agri-
mony, plantain, red roifes, shepherd’s purfe, fage, &c.
or the mint-water of Quercetan, fo often recommended
by R iversius againft obdinate gleets.

V. Of Chancres.

A temporary increaf
the same nature; and even extends them to their nipples, where the ulceration constricting the area or circle round about them irritates the same. The phimosis of women is the contraction of the entrance into the vagina.

He begins the cure with bleeding and gentle purgatives, such as 

\[ \textit{effaia cum manna} \text{ and } \textit{merc. dale.} \] instead of brisk cathartics and emetics, which, as Turner thinks, by making a stronger revulsion, afford speedier relief.

He then advises anodyne emollient fomentations and cataplasms to relax and soften, and afterwards insufficient to breathe forth the humours; and, if the penis is foaked therein an hour or two twice a day, the effect will be more certain; but if a flagration is threatened, and thence a gangrene, the prepuce is to be divided in the phimosis on each side the glans, and the folds of it to be cut through in the paraphimosis; by which the strangled glass may be set free, and the chance, it any, brought into view. The like must be done for the crysalline, in order to discharge the imprisoned lymph, and forward the subsidence of the prepuce, thereby inflating and puffed up.

The affected parts in women should likewise be fomented with the like emollient and mucilaginous decoctions, of the roots of marsh mallows, white-lily, water lily, and the leaves of branc urfine, mallows, linseed, &c. several times a day. Afterwards, a peffary made of linen or sponge dipped in the emollient liquor should be introduced into the vagina.

VII. Of Tubercles and Scirrhous Cords.

The tubercle is a callosity remaining after healing the chancres of the glans, which hinders the free play of the foreskin over the glans. If this will not yield to a strong mercurial unction, the only remedy is circumcision.

The scirrhous cords are tubercles which arise where there has been an ulceration; and may be left under the skin of the penis, sometimes round, and sometimes like a cord. They arise gradually, and disappear with the help of a little mercurial unction, and a course of mercurial purging, unless complicated with other symptoms of a worse kind.

VIII. Of the Porri, Condylomata, Chrifte, and the like Excrefences.

The venereal porri, whose seat is the pudenda, if they are recent, small, and soft, sometimes dry and fall off of themselves, after the poison has been destroyed by mercurial fridions; but if they are hard, large, and have deep roots, they will sometimes continue after them, and grow like warts in other parts of the body. In this case they must be cut with the point of the fciﬀars as near the skin as possible, and a mercurial platter must be prepared with a large proportion of mercury, and mixed with 

\[ \textit{disch. cum gum.} \] to promote a suppuration, and to dissolve the calloﬁties at the bafes of the porri, before a cicatrix is formed.

But if the bafis is hard, and surrounded with hard and deep calloﬁties, flight mercurial fridions must be used; and the wound must be dredis with basilicon, sprinkled with red precipitate, to consume the calloﬁties by little and little, to soften the edges of the ulcers and dispose them to heal. If this should fail, stronger corrosives should be used.

Vol. III. Numb. 74.

The same directions are applicable to the whole tribe of condylomata, chrifte, mora, fci, either about the pudenda or anus.

Of the Lues Venerea, or French Pox.

When a gonorrhoea has continued a long while, or long enough for the poisonous matter to make its way into the blood, or, by affringents given uneafonably, it cannot make its exit, then the patient is infected with the pox.

The buboes in the groin constitute the first degree; then follow pains which cruelly torment the head and joints of the shoulders, arms, and ankles, coming on by fits, but at no certain intervals, unless in the night when the patient is warm in his bed, feldom leaving him till towards the morning.

There are also scars and fcurv in various parts of the body, which are as yellow as a honey-comb, and which disinguishes them from all others. Sometimes they have large surfaces, anfwering the description which authors give of the leprosy. But the more these scars are dispersed over the body, the lefs he is tormentcd.

All these symptoms gradually increase, especially the pain; which becomes fo intense, that the patient is unable to lie in bed. Afterwards nodes or exoftoses arise in the skull, shin-bones, and bones of the arms, which, being attended with conflant pain and inflammation, at length grow curious and putrefied.

Phagedenic ulcers likewise fize various parts of the body; but generally first begin with the throat, and from thence gradually creep by the palate to the cartilage of the nofe, which they deftroy, and the nofe, being deftitute of its prop, falls down flat.

The ulcers and pain daily increafing, the patient finks under the torment; and being not able any longer to struggle with ftech, rottenefs, and the flos of one member after another, his mangled offensive carcafe is hurried into the grave.

Besides the symptoms proper to the pudenda and parts adjacent, which have been already mentioned, the following are obfervable in a confirmed pox; which however do not appear in all patients, nor at the fame time.

1. The skin, especially about the neck and breath, and between the shoulders, is covered with flat spots like freckles, of a rofy, purple, yellow, or livid colour, sometimes fいるとc, small and round like lentils, sometimes more large and extended.

It is full of itchty pufcles, tettets, and ringworms, a fterpigo, a herpes miliaris, and exedens. There are chaps in the palms of the hands and foles of the feet, with itching, from whence proceeds a clear frous liquor, and the epidermis peels off in large flakes.

It abounds with hard, callous, round pufcles, rising a little on the top, generally dry, but sometimes moist, foally, brauny, and yellow; frequently on the corns of the lips, and the fides of the noftrils, but more especifally on the forehead, temples, and behind the ears, where they appear in rows like a string of beads, and gradually creep along the hair.

The hair not only falls off from the head, but all parts of the body where it grows. Then the nails become un-

L 1 2 equal,
equal, thick, wrinkled, and rough; afterwards ulcers arise which cause them to fall off.

II. The inside of the mouth, throat, and nose, are also affected; the uvula and tonsils become painful, hot, inflamed, and ulcerated; phlegmonous ulcers, which rot the bone as far as the nostrils. The pituitary membrane is likewise liable to pustules, which produce malignant ulcerations that infect the bones of the nose with a caries, particularly the vomer; which being eaten away, the nose falls down; the voice becomes hoarse and low; the gums being covered with aphthae, ulcerate and rot; the teeth ache, grow rotten, and fall out; and the breath is very offensive.

III. The patient is excruciated with pains in the nighttime, when in bed and covered with cloaths; these are either tenfive, prickling, pulsative, or rending; fixed or wandering; which sometimes occupy the muscular and membranous parts like the rheumatism, sometimes the tendons and ligaments about the joints resembling the gout; sometimes they are with tumour or inflammation, sometimes without.

IV. The bones are affected in various manners; in the middle exostoses arise, either soft or hard, sometimes with intense pain, sometimes without. The heads of the bones enlarge every way, but unequally, which produces tumours, pains, difficulty of motion, and stiff joints. As the caries increase, they become brittle, and break upon the least effort. Sometimes they are so far dissolved, as to bend like soft wax.

V. When the lymph is infected, the lymphatic or conglobate glands become hard and callous, and form, in the neck, armpits, groin, and mufeteriy, hard, moveable, circumscribed tumours, like the king’s evil. The lymphatic vessels are dilated, extended, and enlarged by a thick flaginating lymph, and form soft encifled tumours or gummata: in the tendons it causes nodes, in the nerves gangions, and in the ligaments of the joints topha.

VI. Neither do the ears and eyes escape the fury of this disease: for the latter are externally affected with pain, redness, itching, and lippitude; and internally, being loaded with humours, the sight is destroyed, and sometimes a suppuration supervenes. If the vitreous humour of the eyes is thickened, it causes a glaucoma; if the crytalline, a cataract; if the aqueous, hairs or spiders webs.

The methods of curing the pox are principally four: 1. The common, by salivation; 2. By giving quicksilver pills; 3. By mercurial frictions, which are to be purged off before a salivation is raised; 4. By sweating, with a decoction of guaiacum.

The safest and most commodious method of salivation is by mercurus dulcis six times sublimed, given inwardly in the milder pox; or by mercurial union, when the disease is got into the bones.

Fifteen grains of mercurius dulcis may be given in a morning, and the like dose at night, with eleffiar, e foerdis. After three, four, or five days with this management, we usually observe the sauces to inflame; the inside of the cheeks to be tumid, or high and thick, being ready to fall within the teeth, upon flushing the mouth; the tongue looks white and foul, the gums stand out, the breath flinks; and the whole inside of the mouth appears shining, as if parboiled, and lying in furrows.

The inside of the mouth thus beginning to be whealed, you may expect soon to see them ulcerated, especially about the salival glands, which empty themselves thereinto. Now it may be proper to desist a day or two, to observe the increase of the ulcers, what floughs are like to be raised, and what their depth and dimensions are like to prove; from which a near conjecture may be made of the duration as well as quantity of the spitting now begun, and the confidence of the draining lympha whether more or less fluid.

When the salivation is thus begun, your only busines is to encourage your patient cheerfully to go on. Let his diet be small chicken-broth, water gruel, and panada. His drink, small fack-whey, or posset-drink, with a draught of good small-beer with a toast between whiles.

Thus, after some days reprieve, if, after the spitting comes on, you find the patient hearty, his chaps but little swelled on the outside, and as little sore within, the ulcers not increasing, with few or no floughs appearing therein, the flux also inconsiderable in quantity, you may now give a scruple of merc. dulcis. in eleff. e foerd. at going to rest, repeating it two or three days following, as you find occasion, and then wait the issue again. This is the safest and most prudent method.

If he should have taken half an ounce of calomel, with little alteration as to the swelling and foreness of his mouth, and as little appearance of his flavoring, his pulse and other circumstances favouring the same, and no ill symptom appearing, you may vomit him with viij or x grains of turpeth pills; 3. By mercurial frictions, which are to be purged off before a salivation is raised; 4. By sweating, with a decoction of guaiacum.

When the spitting goes well forward, it may be left to take its course till it declines of itself; which, in proportion
portion to the ulcers and thickens of the sloughs about
the parts of the mouth, may happen at the end of twenty-
one days, or a month from its rising; that is, from the
time of spitting a pint and a half a day, till it comes to
three pints, or even five pints, in twenty-four hours, when
it gradually goes off again. For often the first four or
days, or a week, are spent in bringing it to the first
proportion.

In the more stubborn and rebellious pox, attended not
only with cruel night pains, gummata, tophs, nodes, and
also rotten or foul bones, if the patient has been used to
mercurials, or if salivated before, then the cure must be
attempted with salivation by union.

You may mix an ounce of quicksilver with three ounces
of azuniga; of which, an eighth part is to be used night
and morning, letting the patient rub it in with his
own hands gently by the fire, beginning with his ankles
up to his shins and knees, all round his joints, and so to
his thighs, which are presently after to be covered with
yarn flannels and flannel drawers; then let him use
what remains of his eighth part about his elbows and
shoulders, wiping his hands clean about the glands of his
arm-pits, or those of his groin. His body, during the
unions, should be screened from the cold with a blanket
hung behind him, and then be wrapped up in a warm flan-
et; that is, he must have a flannel shirt, waistcoat and
drawers, a cap, a muffler pinning it up thereto behind, and
covering all his throat, chin, and cheeks before, to de-
defend them from the cold air. The same things are re-
quited in the former way. The weak need only be a-
pointed once a day.

If, when the ointment is divided into four parts, after
the third union the patient begins to complain of his
chaps, you must flay a day or two before you proceed
farther: The same when gripes or bloody stools approach.

Where there are a gummata, tophs, and nodes, the
ointment must be chafed particularly into those parts, and
then apply the mercurial plaster upon them. If the spitting
deares too suddenly, give a scruple of calomel e-
every day, or every other day, for two or three times, as
you shall see occasion.

When he is a little recovered, and his chaps pretty well,
he may eat a little chicken, veal, rabbit, or mutton, well
roasted, without sauce or gravy.

The patient should be prepared for a salivation by a
leisure purge or two; and, if plethoric, he should bleed:
Likewise bathing in warm water, for some hot, lean, ex-
emaciated people, has been found serviceable. Women
should be laid down just after their menstrual flux is over.
Temperate weather is the most suitable.

If the patient is troubled with falls, knees, and vomiting;
if mild, give him freely of a small chicken-broth, posset-
drink, or thin water-gruel, refreshing him with a little
mulled wine between whiles. But if there is a cardialgia,
and intolerable pains at the mouth of the stomach, with
incessant vomiting, spafs of the members, fainting, cold
sweats of the forehead and eyebrows, the patient is in
the utmost danger, and you must cease giving mercury,
and if possible turn it downwards, by directing the com-
mon clyster with 2 or 3 ounces of brown sugar, and as
much oil-olive.

To prevent the jaws from being locked up, it is ne-
extecessary to use a bit of stick covered with a soft rag, which
must be held between his backward teeth; But, if there
should happen an adhesion of the inside of the cheek to
the gum, hindering the patient from eating and opening
his mouth, the same is to be carefully divided.

If, during the salivation, a blood-veil bursts open,
make a little pellet of lint, and cover it with the fine pow-
ders of alum or vitriol, or dip it in the tinctura flyptica,
and thrust it close down into the cavity, which will se-
cure the effusion, being held tight with the finger for a
little while. If it happens from the separation of the
sloughs from the sides of the cheeks, a little oxycrate held
in the mouth will do the business, or an altringent deco-
cration of oak bark.

If the patient has been without a stool for some days,
give an emollient clyster of warm milk, sugar, and oil.
At this time he may drink freely of small beer with a
toast, barley water, small sack-whey, or posset-drink.
For diet, water-gruel, oatmeal-curd, small chicken or
veal broth, a roasted pippin, or a few stewed prunes.

If, notwithstanding your care in giving small doses of
mercury, the sauces should suddenly inflame and tumefy,
endangering a suffocation of the patient, the most certain
relief is to bring the humours downward by sharp cry-
flers, and, if he can swallow it, a cathartic by the mouth.

An ozana, or ulcer of the nostril, is best cured by a
acinabarine fumigation, which subdues the malignity,
dries up the ulceration, and dispels the caries, if any,
to a separation beyond all others. after which, and some-
times before, calomel must be given and purged off; or,
if there are other symptoms of a profound infection, you
must salivate by union.

The like method must be used for ulcers of the palate,
uvula, and tonsils. The same rarely fails to stop the far-
ther erosion, and therefore it is always to be directed,
though a salivation is intended. It cures, in two or three
days time, the most putrid and corrosive venereal ulcers,
or after the second or third smoking.

Afluce disapproves of any other method of salivation
but by frictions; and he would have pure mercury ground
in a mortar, with just so much turpentine as will reduce
it into a brown or black powder, and mix with it equal
parts of fresh lard, and so well mixt, that the particles of
the mercury shall not be visible by a magnifying glafs.
He also allows that occasionally there may be double the
quantity of lard.

He distinguishes the frictions into weak and strong;
for the strong he allows not less than two drams of the
ointment, nor more than four. The first time, the patient
is to be anointed from the feet to the calves of the legs;
two days after, from thence to the middle of the thigh;
then the third time, as far as the buttocks. If after the
seventh day there appears no sign of a salivation, you must
proceed to the fourth friction, from the buttocks along
the loins and back to the neck, with a large quantity of
ointment. If on the ninth day nothing appears, anoth-
er friction must be from the wrists to the shoulders.

During the salivation, he allows the patient, if he has
strength, to get up sometimes, and sit by the fire; or, if
he cannot, to sit up in bed: when he lies down, he would
have
have him lie in as prone a posture as he can, that the saliva may be evacuated more easily, and not fall into his stomach.

In the weak or slight friction he allows from one to two ounces of the ointment. The first friction is to be only on the feet; the second on the legs; the third on the knees; the fourth on the thighs; the fifth on the buttocks and perineum; the sixth on the loins; the seventh on the back and between the shoulders; the eighth and ninth, if there is occasion, from the arms to the wrists. There may be three, four, five, or even six or seven days between each friction, if the patient is very weak: But the rule is, to look into the patient's mouth before a new friction, that you may be certain not to bring on too plentiful a salivation. The dose of the ointment must be so managed, that, after the fourth or fifth friction, a salivation may come on that is gentle, easy, governable, without a swelling of the head; with only a few aphthae in the mouth, or at most a few superficial ulcers, and the patient not spitting above a pint or two in twenty-four hours: and to this point it must be kept up, with a new friction, if there be occasion. Likewise it may be kept under with clysters and plentiful drinking of the pilian; and, if necessary, with lenitive purges. This treatment may be continued, pro re nata, from 30 to 50 days, or longer.

Till the salivation comes on, the patient may be indulged in weak soups, rice, cream, panada's &c. and even milk for breakfast; but after that they must be left off; and he must drink a large quantity of pilian to dilute the blood. He may sit up all day, if his room be warm.

If, after a due repetition of mercurial frictions, a salivation does not appear, it generally happens that a looseness, a flux of urine, copious sweats, or at least a plentiful transpiration, will supply that defect, and serve in its stead. In this case, the patient may think himself exceeding happy and fortunate, that he has obtained a complete cure by a method more certain and convenient than by salivation, and without its inconveniences and dangers.

The second method of curing the pox is by a quicksilver pill. This was brought into reputation by Bellode; and though he has kept the composition a secret, yet there is no reason to doubt but it is quicksilver mixed with a certain proportion of a cathartic.

The third method of curing the pox is by mercurial frictions, which De Salt gives as follows:

When the patients have a pox of a long continuance, and the venereal poison is dispersed all over the body, they should be prepared by bathing and drinking whey. But in a recent pox the bath is not necessary, or at least need not be used long, because the blood is sufficiently diluted.

After this, instead of raising a salivation, bring on a flux of the belly; the whole secret of which consists in keeping the body open by clysters of a decoction of fenna and the pulp of calia, before the frictions are administered; by which the intestinal glands being opened, the mercury will more readily tend that way. When the looseness does not answer the number of the frictions, nor the quantity of the mercury made use of, purge the patient with powder of jalap, and procure copious fluids, which secure the mouth. While the looseness is going on, the friction does the office of a purge; and in proportion as they are repeated, the flux of the belly revives; and when it slackens or stops, have recourse to the clysters and purges of jalap. Pursue this method till the symptoms cease, and till, by the abundance of the evacuations, the venereal poison is entirely drained off.

The last method is sweating with strong decoctions of guaiacum. This we have the first account of from Sir Ulrick Hutton, who purified it himself. A pound of guaiacum is to be boiled in a gallon of spring-water to one half, and theicum referred to anoint the fores, and a secondary decoction was to be used for common drink.

But, when salivations and other mercurial courses have failed, the best method of cure is by the root of farfaparilla; which discovery we owe to Dr Hunter, who put Mr Fordyce, a surgeon in the army, upon making a trial of it; the result of whose experience is as follows.

1. It will commonly relieve venereal head-aches and nocturnal pains in a very short time; and, if persevered in, he believes it will always cure.

2. In emaciated and consumptive habits, from a venereal caufe, it is the greatest restorer of the appetite, flesh, colour, strength, and vigour, that he knows.

3. When the throat, nose, palate, or the fquinty bones in general, are affected with a Fluent or cares, it will commonly complete the cure, if persevered in long enough, provided a mercurial course by undtion has preceded the use of the farfaparilla.

4. When the body is covered with dry blotches or moist sores from a venereal caufe, it will greatly promote the cure, nay often complete it; but, without the assistance of mercury, there will be danger of a relapse.

5. In simple chancres it will do little service; but, if it is given in cases where the chancres or bubbles will not heal or dissolve after the use of the mercurial undtion, it will often cure, and do always manifest service.

6. It will often answer, and that speedily, without sweating, confinement, or any strict regimen, at all seasons of the year, when mercurial undtions and long continued courses of strong decoctions of guaiacum, either by itself simply, or compounded with a small proportion of farfaparilla, have failed.

7. It seems probable, that farfaparilla root is the only medicine to be depended upon in venereal cases where mercury has failed, or at least has preceded the use of the decoction; for it is not to be trusted alone. When no mercury has been given, it and this decoction may be administered together, and then there will be no room to doubt of success.

8. Mercury alone will cure most venereal complaints, and farfaparilla will perhaps always cure them when they reft the power of mercury; and therefore a proper combination of mercury and farfaparilla will probably cure every caufe that is truly venereal.

The method of using it is this; to three ounces of the farfaparilla root, which has not been spoiled with age, worms, sea-water, or moisture, add three quarts of river-water, and make it boil as speedily as possible, in an open vessel, till two pints of the strained liquor remain, that is, about two pounds avoidupoife weight; a little liquorice-
The yaws are not dangerous, if the cure is skillfully managed at a proper time; but if the patient has been once salivated, or has taken any quantity of mercury, and his skin once cleared thereby, the cure will be very difficult, if not impracticable.

The negroes who have been cured in Africa never have them again in America.

As soon as the yaws begin to appear on a negro, he must be removed to a house by himself; or, if it is not certain whether the eruption is the yaws or not, shut him up seven days, and look on him again, as the Jews were commanded to do with their lepers, and in that time you may be commonly certain.

As soon as you are convinced that it is the yaws, take a scruple of flowers of sulphur; five grains of camphorated spirit of wine; a dram of Andromachus's treacle; and a sufficient quantity of syrup of faffron. Make them into a bolus, to be taken at bed-time.

Repeat this bolus every night for a fortnight or three weeks, or till the yaws come to the height; that is, when they neither increase in size or number. Then throw your patient into a gentle salivation with calomel given in small doses, without farther preparation; five grains repeated once, twice, or thrice a-day, is sufficient, as the patient can bear it.

If he spits a quart in twenty-four hours, it is enough. Generally, when the salivation is at this height, all the yaws are covered with a dry scaly crust, or scab; which, if numerous, look terribly. Thefe fall off daily, or in clusters of a few, and in ten or twelve days leave the skin smooth and clean. Then the calomel may be omitted, and the salivation permitted to go off of itself. A dram of corrosive sublimate dissolved in an ounce of rum or brandy, and the solution daubed on the yaws, will clear the skin in two days time. After the salivation, sweat the patient twice or thrice.

He may like ineffer drink the decoction of guaiacum and sassafras fermented with molasses, for his constant drink.

Sometimes there remains one large yaw, high and knobbed, red and moist; this is called the matter-yaw. This must be consumed an eighth or a tenth part of an inch below the skin, with equal parts of corrosive mercury and burnt alun, and digested with an ounce of yellow balsam and a dram of corrosive mercury, and cicatrized with lint pressed out of spirits of wine, and with the vitriol fome.

To children under fix or seven years old, at the proper time of salivating, [when the yaws are come to their full growth,] give a grain or two of calomel in white sugar, once a-day, one in two days, or once in three days, so as only to keep their mouths a little fop till the yaws dry, and, falling off in white scales, leave the skin clean. This succeeds always, but requires a longer time than in adults.

The venereal disease and the yaws feem to be very different distempers; but the symptoms, in conquence of the yaws ill cured, coincide fo exactly with the symptoms of an invertebrate French pox, that in molt cafes it will be very difficult if not impoflible to diflinguish them.

Of the SCROPHULA, or King's Evil.

The King's evil is attended with hard, feirrhous, and emaciated parts, anus, arm-pits, and face. They are large when fewed in number, and vice versâ. They are not painful to the touch, yet so much resemble. In the mean time, the black hair in the yaws turn to a transparent white.

It is not an easy matter to determine the exact time which the yaws take in going through their different stadia. Lufly well-fed negroes have had several yaws as an infeffious disease.

The operation was either by sweat or urine, efpecially when the medicine proved most effective. It was continued as long as any of the symptoms remained, with a low, spare diet, plenty of barley-water, and a little milk, or fome fuch diluting liquor.

Of the YAWS.

The YAWS is a distemper endemical to Guinea and the hotter climates in Africa; but has of late spread by infection over many parts of Europe. All are liable to it, but more especially in childhood or youth.

It makes its firft appearance in little spots on the cuticle, not bigger than a pin's point, which increafe daily, and become protuberant like pimples. Soon after, the cuticle frets off; and then, instead of pus or ichor, there appear white floughs or fordes, under which is a small red fungus. These increafe gradually, fome to the fize of a small wood-strawberry, others to that of a rafberry, red fungus. Thefe increafe gradually, fome to the fize of a small wood-strawberry, others to that of a rafberry, red fungus. often indolent tumours, which arise by degrees in the
 glands of the neck, under the chin, armpits, groin, hams,
 arms, and wrists; but it is most commonly feated in the
 neck, and beneath the ears.

Likewise cold tumours, which appear on the joints and
 bones, as on the knees, elbows, hands, and feet, but
 more particularly on the fingers, are disorders of the scro-
 phulous kind: as also the great part of those indolent
 fluxions, which fall gradually on the joints, without a
 manifest caufe; and which are attended with an abfece,
 a caries, and swelling of the bones, called the *sina vento-
 fa*; especially of the apophyses and epiphyises. Of the
 glands of the neck, under the chin, armpits, groin, hams,
 the joints. They consist of a jelly or coagulated lymph,
 whence the forerunners of this disease, antecedent to the great
 fluxions which arise in the arms, legs, and feet, principally about
 the joints. They confist of a jelly or coagulated lymph,
 which puff them up, but do not put when prefixed
 with the fingers like dropfical swellings.

In the eyes the scrophulae create inflammations; in
 the eye-lids a pufing up of their edges with great forenens
 and small ulcers; in the angles of the eye a fistula la-
 chrymala, by ulcerating the gland planted there for the
 percolation of tears; in the lips, excessive and preterna-
tural thickness; in the nose it often creates the crufly ul-
car called ozana. All which, except the last, are often
 the forerunners of this disease, antecedent to the great
 swellings and foul ulcers which appear in its mature state.

The glands of the external parts are not alone attacked
 with this disease; for those of the mefentery are almost
 always affected; which appears from the opening of per-
 sons dying of this disease. Sometimes the disease begins
 in the mefentery: and sometimes the liver, spleen, womb,
 lungs, windpipe, brain, and other internal parts, are scro-
 phulous: Hence scirrhous tumours, incurable cancers, ob-
 linate fluxions, rebellious ophthalmies, malignant abcofe-
 s, fistulous ulcers, dangerous quinsies, terrible epilep-
ties, mortal consumptions of the lungs, stubborn jaundices,
 dropfies, cholics, hypochondriac and hysterical affections.

The scrophulae are hard tumours, because they are pro-
 duced by a thick coagulated matter; they are cold, be-
 cause they are caused by a flagellation of the lymph in the
 part affected.

The scrophula may be said to be benign, when they are
 superficial; when they do not much raise the skin, nor
 change its colour; when only the glands are puffed up,
 and are soft, moveable, without adhesion and indolent.

The malignant scrophulae are evident from the Ja-genes
 of the tumour, its hardnes and adhesion; from its be-
 coming livid or red; from its being painful; and, when
 ulcerated, from the callofity of the lips of the ulcer, and
 from their difficult cure.

As to the prophagnias; the benign scrophulae admit of
 an easy cure, especially if they are feated in the conglom-
orate glands, and are moveable, superficial, and soft. Tho
 which attack the joints, the tendons, the ligaments, the
 bones, which are near large vessels, or comprefs the aper-
 ra arteria, or the oeosphagus, are very difficult to cure.
 The internal scrophulae are much more dangerous than the
 external; for when they turn to an abfece, they are incu-
 rable. They are also more or less troublesome in propor-
tion to the progress they have made, the parts which they
 attack, and the temperament of the patient. If the tumours
 have been long ulcerated, and are become sinous and vi-
 rulent, and if they lie near one another, they often find a
 communication, though they appear distinct: In this cafe
 the lips grow callous, and the ulcers corrosive, frequently
 fordid; and the cure is not to be expected as long as one
 cylis remains of the veifs that feed them. Thofe who
 are feized with it from in the neck after forty years of age,
 seldom recover.

If ftrumous tumours arise from a caries in the bones of
 the fingers or hands, the cure is difficult; but more fo in
 the feet and toes. If in the os calcis, joint of the ancle,
 or affragalus, or in the knee-bones, or itchia, or the like,
 where they cannot be safely laid open, the cafe is deplo-
rable, and the patient generally dies of a marasmus.

In the cure, the diet should be thin and attenuating,
 light and easy of digestion; and all falt and smoke-dried
 meat should be carefully avoided; as also beef, pork, fi-
h, hare, cheese, and in general all things that are hard of
 digestion, or which yield indifferent nourifhment. The air
 should be pure, sweet, and dry; and the body should
 be kept always open.

The cure may be begun by bleeding, especially if the
 patient is plethoric, and then a mercurial or antimonial
 vomit; after which he should take a gentle purge, often
 repeated, fuch as the common purging potion of Syden-
 ham; and, as almost all remedies which are good in ve-
 nereal cafes are useful in this, mercurial vomits and purga-
tives will be proper.

Some give ethiops mineral alone for three months; be-
 guing with twelve grains, and increasing the dose gradu-
 ally to a scruple, or half a dram, and decafeing in the fame
 manner.

It is certain that the united force of mercurials and an-
 timonials will do wonders in these cafes, if prudently gi-
 ven and long continued; always beginning with small doses
 at first.

Some make ufe of the decoction of sponge; the dose
 is four ounces: others, burnt or calcined sponge; the
dose is half a dram morning and evening. Turner
 mentions a cure from an electuary made of the moft
 gritty and fabulous sponges that could be got, which
 were dried in an oven so much as to be fit to pulverize.
The dose was a spoonful night and morning.

Others recommend the absorbent powders and diapho-
 retic antimony; others again, tincture of antimony in a
 glass of the decoction of the woods; Dr Francis Fuller,
 the decoction of colts-foot used for a long time. Fallopis
 praiseth the root of butchers-broom; the dose is a dram
 with x, gr. of the root of common flower-de-luce. Arna.
d de Villanova looks on the root of scrophularia or figwort
 as a specific; the dose is a scruple in powder. And Alken
 mentions two cures performed by white arcbangle, boiled
 in milk, which it coagulates; the whey of which must
 be drank, and the card applied to the fores. Of late the
 mineral waters of Moffat in Annandale have been drank
 with great advantage.

Ephom salt dissolved in a pint of water in such a quan-
tity as to keep the body open, and taken like sea water,
has often cured this disease.

After all, we have another medicine whose virtues in
 curing this disease have been lately celebrated, viz. the
 jujuits bark.

1. Take of the beef rhubarb, half an ounce; of flo-
 rentine
A Cancer is a hard, round, unequal, painful, and generally-immovable tumour, of a livid, blackish, or leaden colour, surrounded with swelled, crooked, varicous ves-
Of the Elephantiasis, or Leprosy of the Arabians.

The leprosy is said to be of two kinds; that of the Greeks, and that of the Arabians. The latter is called elephantiasis, from the roughness, inequalities, and tubercles in the skin, resembling that of an elephant. Lucretius supposed it to be generated in Egypt, and no where else; but if the leprosy of the Jews is the same as that of the negroes, which is highly probable, then we may affirm that it is endemic to the southern and inland parts of Africa.

That it was contagious, all histories agree, as well as the Periplus; and the Periplus would not let a leprous person come within the city-walls.

Pliny informs us, that the first appearance of the elephantiasis is in the face, particularly a small speck appears on the nose or nostril; and, as the disease increases, the whole body is full of spots of various colours; the skin is thick in one place, and thin in another, hard and rough, with scabs. In process of time, the skin turns black, and the disease eats away the flesh to the very bones. Celsus observes, that the spots grow tumid and red, and then turn black, and the skin is covered, as it were, with scales. Then the body falls away, the mouth, legs, and fingers swell, and the fingers and toes are hid with a swelling; even the bones themselves do not escape; afterwards a fever arises, to which the patient falls an easy victim.

But to let this matter in a still clearer light, it will be necessary to add the description of this disease from Guido de Chaulias. The leprosy, says he, commonly begins in the face and forehead, in which filthy tubercles make their appearance, and by degrees spread all over the body. The eyebrows swell; the nostrils grow wider outwardly, and straiter inwardly; the lips are disfigured with an unhallowed tumour; the voice is hoarse and snuffling; the ears are turned back; the forehead is protuberant; the face is of a purple colour; the veins under the tongue are varicious and black; the muscles between the for- finger and the thumb are eaten away; the hair falls off from the head and eyebrows; afterwards the skin of the whole body becomes black and full of spots, rough and unequal, with crusty scabs full of knobs and fissures, of horrible aspect, which makes it appear like the skin of an elephant. After this, the fingers and toes begin to swell; and then the legs, which, being covered with rugged inequalities, seem like two sticks for magnitude. Besides all this, the patient is infatiable with regard to vernereal pleasures. The blood is fetid, spotted and black, and will not coagulate.

This disease is hereditary and infectious: for it may be caught by the saliva of a leper, if a found perfon drinks after him; by touch; by lying in the same bed; and by coition.

An inveterate leprosy was judged to be absolutely incurable. But Aurelius says, when the disease is new and recent, there are hopes of a cure. What he and Celsus prescribe in order to the cure, are not worth repeating; for, if any medicines will do, they must be of the Herculean kind. Authors are excessive in the praise of viper’s flesh, which Hoffman judges to be quite insignificant. Joel advises bleeding and purging, with zyg grains of the extract of black hellebore, or ij gr. of the glaft of antimony in conserve of rose; but the vitrum ceratum is more safe, and may be given in a larger dose. Towneconfesses, that antimonial preparations yielded most relief in Barbadoes; but he could not say that they perfected the cure. On the other hand, mercury exasperated the disempem, irritated the ulcers, and made them spread the faster.

Of the Impetigo, or Leprosy of the Greeks.

This disease begins with red pimples or pustules breaking out in various parts of the body; sometimes they appear single; sometimes a great number arise together, especially on the arms and legs: as the disease increases, fresh pimples appear, which joining the former make a fort of clusters, all which enlarge their borders and spread in an orbicular form. The superficies of these pustules are rough, whitish, and scabby; when they are scratched, the scales fall off; upon which a thin ichor oozes out, which soon dries and hardens into a scaly crust.

These clusters of pustules are, at first, small and few, that is, three or four in an arm, or leg only, and of the size of a silver penny. But, if the disease is suffered to increase, they become more numerous, and the clusters enlarge their circumference to the bigness of a crown-piece, but not exactly round. Afterwards it gradually increases in such a manner that the whole body is covered with a leprous scurf.

Willis
itching is greater, are between the fingers, on the arms, dry ford chiefly attacks those that are lean, old, or are places where the eruptions appear very numerous, and the a flight inflammation, which is manifest from the redness of a melancholico-choleric constitution: In these, the pudules are much less, and excite a most intolerable pulation; the pusules are more full of purulent matter, attended with dren and the sanguineo-phlegmatic are most subject, the head only excepted. In the milder sort, to which chil- tion of a serous lymphatic matter, sometimes attended from thence spreads by degrees over all the body, the fymptoms. The itch of the milder sort appears either drinking in bed after it a pint of some proper decoction.

The cure may also be performed with alterative and dia-

the cafe is so desperate as to render it absolutely necessary.

Of \textit{Hæmorrhages in general.}

The blood, which flows spontaneously, generally proceeds from those places which are of a fine and thin texture, in whole surface the slender vessels creep along with various meanders; such as the inward part of the nostrils, the bronchia of the lungs, the flesh of the gums, the left side of the stomach, the gut ilium, and the extremities of the rectum, as also the external substance of the womb and vagina. When these parts are distended, and the small arteries open, the blood often breaks out with violence.

Sometimes, though but seldom, hæmorrhages happen in other places where the vessels lie deeper; as from the little finger, from the hand and knee, the breasts in the time of menstruation. There are likewise instances of periodical fluxes from the penis in men.

They generally happen to persons whose bodies are of a soft, fpongy, tender texture, and whose vessels are turgid with blood and fever. These were formerly said to be of a fanguine constitution, and are subject to hæmorrhages as long as they live. But the choleric, who have larger vessels, whose fibres are more strongly braided, and whose blood circulates with greater rapidity, are liable to a spitting of blood in their youth. The fanguineo-melancholic are subject to the bleeding piles; and to those who have lost a large limb, or who labour under obstructions of the liver and spleen; hence, in an inveterate surry, dropy, and cachexy, there often happens a fatal hæmorrhage.

It differs much as to the quantity; some lose only a few drops, some several ounces, and some five or six pounds. No hæmorrhage is more apt to return; which it does in a few days, to others in a few hours.

To the plethoric it is generally salutary; and there are many instances of a vertigo, a giddiness, dull heavy pains of the head, a phrenzy, and even an epilepsy, being carried off by a bleeding at the nose. On the contrary, from its suppression there have arisen vertigoes, apoplexies, convulsions, noise in the ears, and hardneshes of hearing, and even a gutta perena.

These hæmorrhages are critical and salutary in a synochus on a fermentative day, that is, between the third and fourth, or on a critical day, viz. the seventeenth; for, as these fevers are generally caused by a plethora, they are carried off that way.

But enormous and long-continued bleedings at the nose, when they arise from fponias of the internal parts, and are preceded with coldness of the extremities, and fainting fits, generally terminate in death.

After a revulsion by bleeding, there is nothing equal to nitre to appease the orgasm of the blood, and to relax the spasmodic striae. Next to these are vegetable acids; such as the juice of Seville oranges, barberries, the water and juice of wood-forrel; but more especially the diluted spirit of vitriol, tincture of roes, made with the water of wood-forrel and the spirit of vitriol, and drank with spring-water. [Five or six spoonfuls of the common tincture of roes may be given at a time, and repeated as occasion requires.] If the bleeding is very inordinate, it will be proper to use cooling emulsions, gentle or stronger opiates to moderate the spasmodic striae, as occasion shall require. Camphor, mixed with nitre and calx of antimony, will be highly necessary, if the matter of exanthemata or cutaneous eruptions is the cause of the hæmorrhage, as is often the case.

A revulsion may be made from the head, by bleeding in the lower parts; then by temperate pediluvia, and putting the hands into warm water.

As there is often an acid bilious matter lodged in the hypochondria, the parent of wind and fponias, the powder of rhubarb will be proper, mixed with a few grains of tartar-vitriolate and nitre; as also emollient and carminative clysters, with a due proportion of oil.

Externally, refrigerants may be mixed with discutients, and applied to the forehead, nose, and neck.
But it must be noted, that, when the patient is plethoric, the bleeding must not be stopped hastily, if at all; nor when the menes in women have been suppressed, or the lochia, or the bleeding piles in men accustomed thereto; much less must a flowage be attempted when the bleeding itself is periodical.

In persons of a bilious constitution, cold water alone, drank freely, has had a good effect.

The cachetic should persiffl long in the taking of rhubarb, either alone, or mixed with digestive salts, such as tartar-vitriolate. If there is any scorbatic disorder in the viscera, besides rhubarb, the patient should drink plentifully of whey.

If any disease proceeds from the cessation of this customary hæmorrhage, it should be promoted with a pen or a straw thrust into the nofe.

Some recommend the weaker spirit of vitriol, and would have eight or ten drops of it be given in every draught of liquor. But perhaps the best method of all in obstinate hæmorrhages is that recommended by Mead in the bloody small-pox; or the Peruvian bark alone will generally be sufficient.

Of the Bleeding and Blind Piles.

A Flux of blood from the hæmorrhoidal vessels is called the bleeding piles; when the vessels only swell and discharge no blood, but are exceeding painful, they are termed the blind piles.

All copious fluxes of blood from the anus are not to be reckoned of the morbous kind. For the habit of body, strength, age, and temperament, are to be considered. That which is enormous and excessive to one person, may be moderate and salutary to another. That only is to be esteemed pernicious, which continues too long, and enfeebles the patient; whereby digestion, nutrition, and other functions are hurt, and there is reason to fear the production of dangerous chronic diseases.

An excessive hæmorrhoidal flux is generally preceded by a heavy pressing pain of the back and loins; sometimes a numbness of the legs and thighs; a constrictio of the external parts, with a flight flivering, and a subsidence of the vessels therein; a hard contracted pulse; a dryness of the mouth and face; the urine diminished in quantity, and most commonly pale; a senfe of weight about the anus extending to the perineum; a weakness of the stomach; a flatulency in the lower belly; a frequent desire to make water and to go to stool, with sometimes an exclusion of white bilious mucus; the old and weak have procidentia ani.

In this case, the blood is generally at first black and very gumous, and sometimes comes away in large clots from the varieous vessels; afterwards it becomes red, and at last serous: sometimes it is of a slimy, or like the white of an egg. There are instances of voiding a pint or a quart of blood daily; it often continues long, from twenty to thirty, or even forty days.

This flux entirely proceeds from the hæmorrhoidal vessels. The external or blind piles seldom bleed, but turn to painful varices; which being opened weep a little, but will not yield much blood. But the internal piles, which are the offspring of the splenic branch, and are extended to the inner substance of the reftum, and as far as the sphincter of the anus, together with the small arteries derived from the lower metarteria, not only bleed plentifully, but, when the flux is suppressed, create diseases of the liver, spleen, pancreas, mefentery, and intestines.

The persons subject to this disease are those of a loose, spongy texture, of a bulky size, who live high, and lead a sedentary life; or to whom it is hereditary. Sharp purges, aloetica, high-seasoned food, free drinking of sweet wines, neglect of customary bleeding, anger, fadness, hard riding, and the like, will usher in this disorder.

This hæmorrhage is dangerous, because it decays the strength, wastes the body, and produces a fenfe of weight in the thighs. The sleep is laborious, and the praecordia oppressed; there is a rumbling in the belly, and a weak pulse. When it continues long, the ankles swell, and the countenance is ghastly; there is a ftraitnefs of breathing; and laft of all it terminates in a cachexy, dropfy, or a flow and hectic fever.

If the patient is plethoric, bleed; and let his drink be cold water of the chalybate kind, or whey turned with orange-juice; or juleps made with tincture of rofes, cooling waters, and syrup of rofes; likewise nitre in powder, with absorbents and strentheners; and, to appeafe the flapsms, opiates of the mildeflf kind.

If it continues long, and the flux begins to be serous, then give rhubarb with curants or tamarinds, or, which is much the fame, with cream of tartar. Then gentle diaphoretics may be compounded of burnt hartthorn, calx of antimony, wine-vinegar mixed with crab's-eyes, water of elder-flowers, simple alexitereal water, and diafordium; or hot decoctions of yarrow, veronica, &c. may be taken in bed, in order to sweat; also half a grain of camphor, mixed with nitrous and bezoaric powders.

In the B!nd Piles there is a most intense pain, especially at the time of going to stool, and the excrements are tinged with blood. Sometimes tumours like warts lie hid in the sphincter, or appear in the verge of the anus.

Sometimes the veins, in the blind piles, are so much dilated with blood as to be very painful, and raise tubercles as large as peas, grapes, or eggs: They appear liquid, and black, from the stagnation of a thick blood, and, when pressed with the fingers, feel like a bladder filled with liquor. Some are soft and indolent; others hard, inflamed, and painful; render the patient unable to walk, stand, or fight; and produce such a spasm in the anus as not to admit a clyfter. Sometimes they bleed, or turn to troublesome itching ulcers, and occasion an abfece or a fistula.

Linen dipped in warm spirits of wine, and emollients, are often of infinite service; and, when they fail, leeches may be applied to exhauft the blood: If they are not at hand, and the parts are inflamed, the lancet must be used; then dressings must be made with lint, with compresses and the 'T bandage. The tubercles, which are full and large, may be removed by a ligature, unless inflamed. Sometimes they are high in the reftum; and then a fasculum ani must be used; in which case they must be either scarified with a lancet, or divided with scissors, that the thick noxious blood may be discharged, and the pains relieved.
MEDINE.

Of the Immoderate Flux of the Menses.

The symptoms which attend this disorder, are loss of strength, anxiety of the precordia, fainting, coldness of the extremities, paleness, convulsions, suffocations; and, when it is inveterate, oedematous swellings of the feet, a cachexy, droppings, the flux album, a hectic fever, and an atrophy.

Sometimes the flux returns twice in a month; and at others continues several days longer than usual. It comes sometimes before and sometimes after abortion. Sometimes florid blood rushes out with impetuosity, most frequently before a miscarriage, and after it from a retention of part of the afterbirth, which keeps the orifices of the vessels open. Sometimes clots of blood come away of the size of an egg, when the menses have been stopped for two or three months. A black, grumous, coagulated blood will now and then come away on the first days of childbed, when the patient is slender and plethoric. In the cachectic, the flux will be often thin and watery; in the scrobutic and fetid, attended with sharpness and pain.

It is sometimes caused by a great afflux of blood to the uterus, which is not returned in due quantity by the veins; for which reason the vessels often burst. The same happens from a plethora, and from hard labour. About the fiftieth year, when the menes cease spontaneously, a great and sometimes dangerous flux will happen, and then quite disappears. If it should suddenly and unexpectedly return about sixty, with flooding, it brings on a fatal hectic fever.

This disease is generally preceded and accompanied with a tension and inflation of the hypochondria; a heavy, pressing pain about the loins, with a chills; as also a coldness of the extreme parts, a subsidence of the vessels, a paleness, a quick pulse, an inward heat, a coliciveness, and little urine.

If a child-bed woman is not sufficiently cleansed at her lying-in, a great haemorrhage will follow some months after, with fainting fits, and will not terminate till the excretion of a carnous mass as big as one's fist, which the sex call a mole.

If the body is cachochymic, and fall of depraved juices; scorbute, or infected with the venereal lues; when the visceræ are unfound, and the liver, spleen, and meferia vessels are fluffed with a black, thick blood; this disease is not without danger. The patient's life is greatly in danger when the child is dead before delivery, and a great flux of blood happens. It is dangerous when caused by a violent extraction of the afterbirth; or when pieces of it are left behind, which afterwards become moles, and greatly vitiate and increase the menstrual flux.

If the patient is plethoric, bleed in the arm. If there is no flux, or if it proceeds from the kidneys or bladder, which may be either enlarged, broken, or eroded. It is more or less dangerous, according to the different circumstances which attend it.

If pure blood is voided suddenly without interruption and without pain, we may conclude it proceeds from the kidneys. It likewise comes from the kidneys, if the urine is coffee-coloured or more florid, and generally precedes a fit of the gravel, but sometimes accompanies the passage of a stone through the ureters. But if the blood is small in quantity, and of a dark colour, with or without purulent matter, chiefly if it is emitted with heat and pain in the pubes, it certainly proceeds from the bladder. This is sometimes attended with fainting, difficult breathing, a low, small, and frequent pulse, a nausea, anxiety, and cold sweats.

When it proceeds from the ureters, which are hurt by a large, rough stone, and a small quantity of blood is mixed with the urine, there is a sharp pain in the loins and ilia, and a difficulty of making water, which when made has a fabulous sediment, and other signs of a stone flicking in the ureter. When the coats of the bladder are hurt by a stone, and a little blood follows, it is attended with a mott acute pain and a previous stoppage of the urine, together with grumes and fabulous concretions; which also sometimes happens when a stone is firmly fixed in the kidney.

It may be occasioned by a stoppage of the haemorrhoidal flux; from violent motion of the body, especially riding; from a stone concealed in the kidney: from an erosion and ulcers of the bladder; from external violence; from grapping pains caused by violent purges; from sharp diuretics, especially cantharides.

All bloody urine has some degree of danger; but it is most so when mixed with purulent matter.

If the patient is plethoric, or if it proceeds from the suppression of a fanguineous evacuation, bleeding is necessary; as also cooling nitrous draughts, and purified nitre mixed with absorbents, with whey for a vehicle, or barley-water.
water, or small-beer, acidulated with some drops of the spirit of vitriol. The body must be kept open with laxatives, as rhubarb with currants, or with cream of tartar; as also emollient clysters. The relaxed vessels must be agglutinated with decoctions of vulnerary herbs; such as agrimony, ground-ivy, yarrow, golden rod, and the roots of comfrey dulcified with virgin-honey, to which milk may be occasionally added. Almond milk is likewise good, especially if used as a vehicle with bole-armeniac.

If there is an ulcer in the kidneys or bladder, medicines must be given that thermate the acrimony; such as syrop of marshmallows; also infusions of the vulnerary herbs above mentioned; likewise of the bark of the roots of acacia and cherry tree gum.

When gravous blood plugs up the passage of the ureters into the bladder, or the sphincter of the bladder, and occasions a difficulty or stoppage of urine, warm water drank plentifully, and baths of the fame, are useful; likewise warm water should be injected into the bladder with a syringe, that the sharp humour may be diluted and the grumes dissolved. But, if the urine should be quite stopped with a spasm, then give emulsions of the four cold foods, with crab's-eyes and calx of antimony; or a powder made of sperma ceti, crab's-eyes, and nitre. Externally, apply a bladder filled with the decocction of emollient flowers in milk to the abdomen; and keep the body open with manna, or as emollient oily clyster.

Milk and whey are likewise excellent in these disorders, if a dram of bole-armeniac is taken in every draught.

Of the Lethargy, Carus, and other sleepy diseases.

The lethargy has some affinity to the apoplexy and palsy, and often attends them.

By sleepy diseases are meant a preternatural propensity to sleep, sometimes attended with, and sometimes without a fever: The immediate cause of which is a very languid and diminished influx of the animal spirits from the cortical part of the brain into the medulla oblongata, and from thence into the nerves defined for sense and motion.

There are several kinds of these disorders, the principal of which are a coma vigil, a coma fomnolentum, a carus, and a lethargy.

A coma vigil is known by these signs: a burning and extensive pain in the head, attended with a sense of ebullition therein; they have a strong inclination to sleep, and yet either don't sleep at all, or, if they do, awake immediately with little relief, but have no delirium. This coma differs from the pervigilium, which is frequent in acute fevers, for in this there is no propensity to sleep. This disorder is always symptomatic, and often attends acute, burning, and malignant fevers; as also an inflammation of the dura mater, and utters in a phreny.

In a coma fomnolentum, the patients are languid, and their chief complaint is a constant drowsiness. They often fall asleep at their meals, in conversation, and in the midst of bufines, and, when they are awakened, soon fall asleep again. This disorder principally feizes old men, who live luxuriously, and neglect bleeding. It is a primary disease, and without a fever.

A carus is a profound sleep, out of which the patient cannot be roufed by clamours, shaking, nor even with the picking of a needle; or, if they are sensible of the pain, they continue silent, and fall asleep again. It is sometimes a primary disease, and sometimes symptomatic. When it is symptomatic, it is of three kinds: The first happens in acute fevers, in the beginning or increase; and, if the convulsions and hiccups supervene, it is soon fatal. The second comes after acute fevers; and, when the patient is extremely weak, the sleep will continue for several days; being awaked, he will answer questions, but immediately fall asleep again. When he recovers, he remembers nothing that he laid. If it happens in acute fevers, on critical days, with a sweat, it is a good omen. The third happens a day or two before death: for, the patient's strength being exhausted, he lies deprived of sense and motion, as it were in a profound sleep, and under that expires.

A lethargy is a heavy and perpetual sleep, with scarce any intervals of waking. It is attended with a stupidity, and so surprising a forgetfulness, that, when the patient yawns, he forgets to shut his mouth; or, if he takes the chamber-pot to make water, he forgets to do it, and falls asleep.

A lethargy is attended with a fever, which is a symptom thereof, and is chiefly discovered by the frequency of the pulse; whereas a carus is often a symptom or a consequence of a fever, and is likewise attended with insensibility. It does not invade so suddenly as an apoplexy, which is attended with an abolition of all sense and voluntary motion, and kills sooner than a lethargy.

In the cure of these diseases, three intentions should chiefly be regarded: 1. To roufe the patient from sleep. 2. To remove the difficulty of circulation, and the stagnation or extravasation of the blood or serum in the head. 3. To restore the strength of the membranes and vessels of the brain.

These remedies are efficacious in the first case, which act on the nervous parts, by inducing a tremulous and oscillatory motion through the whole nervous system: such as powerful acids, mixed with tincture of castor; volatile salts; fetid things, as galbanum, burnt partridges feathers; cold water thrown on the head; cataplasms made with vinegar, rue, bay-leaves, tops of savory, mustard-seed, calfor, and camphor, applied to the head, forehead, and temples.

The ferous colluviae is derived from the head by stertoratories; the bull is ten grains of salt of white vitriol dissolved in half an ounce of marjoram water, and drawn up the nofe; blisters on the feet and neck; cupping-glares, either with or without scarification; strong frictions on the lower parts; stimulatory clysters, with the addition of sal. gem. common salt, or the root of squills.

To remove the stagnation, and promote the circulation, if the vessels be turgid with blood, venaeceation is necessary; then gentle laxatives, and nervous medicines with diaphoretics. A powder made of salt of hartshorn, salt of amber, cinnabar of antimony, and bezoar mineral, has very great and salutary effects.

A carus, especially the first species of it, requires plentiful bleeding; and the patient must be roufed by clysters, rendered stimulatory with the powder of squills; by blisters; by putting distilled vinegar in the nostrils; and
and by appeasing the organ of the fluids with cooling fixed diaphoretics and acids. The second species requires but little or no assistance; and the third is incurable, at least if blisters fail.

A coma somnolentum is divided into serous and sanguine. The first requires the natural serous evacuations to be restored or promoted. Gouty fits are to be invited by frictions of the feet, blisters, relaxing applications, and warm baths. Sternutatories are of great use, as they discharge the serum through the nose, and stimulate the nerves. When a viscid phlegm offends the stomach, vomits are useful, with half a scruple or a scruple of powder of squills, or ij gr. of emetic tartar, with a laxative potion.

In a sanguine coma somnolentum, when the blood circulates slowly, or flags in the head, as in the hypertensive or scorbutic, all hot spirituous remedies are as bad as poison: But bleeding, chysters, gentle laxatives, cooling and nervous powders, are useful.

A red face, eyes turgid with blood, indicate bleeding. Warm baths are bad in all sleepy disorders; likewise salfron, poppies, and opiates of all kinds.

Of the Catalepsy.

The catalepsia is also called catochus, and catoche; and whoever is affected with it is in an infant rendered as immovable as a statue, without sense, and without motion; and continues in the same posture they were in at the moment they were seized.

The proximate cause of this disease is the immobility of the common senory from the time of the first attack; therefore there is an absolute rest of the blood in the brain, of the glands of the brain, and of all its emissaries; whereby all the functions of the brain are injured, as well as those that depend thereon: The muscles only remain tense as in the beginning; the respiration and pulse indeed continue, but they are very faint.

But Hoffman afferts, that the pulse is natural, and the breathing free and easy; that the limbs are moveable, but remain in the same situation in which you place them. They neither hear nor see, though their eyes are open; nor feel, though they are pricked ever so much; yet, if you thrust any thing into their mouths, they will swallow it: But their bodies are so bound, that you cannot thrust the fineft pipe into the anus. The colour of the face continues florid. At last they fetch deep sighs, and come to themselves, and tell wonderful things of what they have seen and heard during the paroxysm; some declare they have enjoyed exquisite pleasures, or seen tragicall sights, or have had divine visions, and the conversation of angels.

This disease is generally preceded by obdurate intermitting fevers, especially quartans; by a dry, melancholy, lean temperament of body; by a retention of the menphis, and hemorrhois; by great and sudden frights; by a profound, constant, fixed meditation on one object; or by strong fevers in persons of a sanguine constitution.

The method of cure is various, according to the different causes. The patient should be excited with things that greatly strike the senses; such as light, noife, stimulating things, volatile salts, pain, frictions, continual agitations; by causing an hemorrhois of the nose; by promoting the hemorrhoidal or menstrual flux; by fernu-
On the other hand, those who live a sedentary life, feed violent passions and commotions of the body and mind. Prized of all senses and motion, they immediately fall down. Pression of the menstrual flux. It likewise oftentimes comes grievous passion of the mind; or maids, after a sudden supposition of the belly, that no flatus can be emitted, nor no stricture the belly, that no flatus can be emitted, nor no stricture the belly, that no flatus can be emitted, nor no stricture the belly, that no flatus can be emitted, nor no stricture the belly, that no flatus can be emitted, nor no stricture the belly, that no flatus can be emitted, nor no stricture the belly, that no flatus can be emitted, nor no stricture.

An hysterical fit is generally preceded with a paining pain in the forehead, temples, or eyes, with an effusion of tears and dimness of sight, a dulness of the mind and senses, and a loathing of all things. When the fit comes on, the patient is exceeding coltive, and yet has a strong stimulus to discharge her urine, which is as clear as water; the breathing is uneasy, difficult, and short; and a langour seizes the whole body. To these succeed a pain in the loins, and a great swelling and shaking; the belly is hard and inflamed; afterwars the navel is drawn inwards, and outwardly leaves a great pit; then they feel a fort of a globe arise from the lower part of the belly to the hypeochondria and diaphragm. Soon after, the heart begins to flutter and beat, with a hard, unequal, and sometimes intermitting pulse; the extreme parts grow cold; the fauces are straitened, and seem to be bound with a cord; the face is pale, the breathing exceeding difficult, the voice ceases, the pulse is almost imperceptible; and there is such a stricture of the belly, that no flatus can be emitted, nor no stricture given. In some there are convulsions of the head and limbs; others lie in a profound sleep, without sense or motion; others have their face and neck look red and inflamed, with a strong pulse; and others again break out into immediate laughter, and, regaining their voice, say a great many silly things.

When they begin to come to themselves, the pulse, which was before weak, languid, and obscure, becomes brisk, soft, and strong; heat returns to the extreme parts; the face which was pinched in and pale, begins to expand and look ruddy; the wind forces its way upwards; there is a rumbling in the belly; and at length the patients, waking, to discharge her urine, which is as clear as water; the breathing is uneasy, difficult, and short; and a langour seizes the whole body. To these succeed a pain in the loins, and a great swelling and shaking; the belly is hard and inflamed; afterwars the navel is drawn inwards, and outwardly leaves a great pit; then they feel a fort of a globe arise from the lower part of the belly to the hypeochondria and diaphragm. Soon after, the heart begins to flutter and beat, with a hard, unequal, and sometimes intermitting pulse; the extreme parts grow cold; the fauces are straitened, and seem to be bound with a cord; the face is pale, the breathing exceeding difficult, the voice ceases, the pulse is almost imperceptible; and there is such a stricture of the belly, that no flatus can be emitted, nor no stricture given. In some there are convulsions of the head and limbs; others lie in a profound sleep, without sense or motion; others have their face and neck look red and inflamed, with a strong pulse; and others again break out into immediate laughter, and, regaining their voice, say a great many silly things.

The hysterical passion attacks women that are pregnant, in child-bed: widows that are full of blood, after some grievous passion of the mind; or maids, after a sudden suppression of the menstrual flux. It likewise oftentimes comes on so suddenly, violently, and at unawares, that being deprived of all sense and motion, they immediately fall down.

This disease may be caused by whatever promotes a more plentiful and rapid afflux of blood and the genital fluid to the uterine parts, or impedes the eruption of the menes, or occasions their suppression: hence maids and widows are most subject thereto; also women of a languid or bivious constitution who live high, drink generous wines, feed on high flavoured aliment, and are subject to violent passions and commotions of the body and mind. On the other hand, those who live a sedentary life, feed on coarse, acid, low diet, who have omitted usual bleeding, who are oppressed with sorrows, cares, and disappointments, are liable to this disease; for by these the blood is thickened, the solid parts weakened, and consequently the flowing of the menes rendered more difficult. Likewise sudden terror, and the body being exposed to uncommon cold during the time of the menstrual flux, by giving it a check procure hysterical spasms.

However dreadful and cruel this disease may appear, yet it is not very dangerous in itself, unless ill managed, or the patient be exceeding weak and vacuiterinary: it is most apt to turn into convulsions and an epilepsy. When it proceeds from abortion, or hard labour, it is very liable to return from any slight irritation of the nervous system. Nor is it very uncommon for the hypochondriac and hysterical disorders to be united, and then the cure is very difficult. This happens to women who lead a sedentary life, indulge extravagant affections of the mind, and are guilty of errors in diet and regimen.

In the cure, it must be carefully observed whether the woman is plethoric, or exhausted of blood and strength. In the former case, the spasms or convulsions are more violent, and copious bleeding is a present help; and many have been brought to themselves who were seemingly dead, if the florid colour of their faces had not shewn the contrary.

In the fit, it will be proper to apply fetid things to the nose; such as a Sophia, preparations of calomel, partridges feathers burnt, &c. For women in childbed, a girdle made of Russian leather, and bound pretty tight, is excellent. Likewise clysters made with roots and seeds of loviage, which are specifics, camomile flowers, elder-flowers, veronica, the carminative seeds boiled; to which may be added oil of elder, dill, or camomile.

Externally, plasters made of opoponax, bdellium, galbanum, fagapenum, and afa-fatida, may be applied to the navel; or, some greatly commend fumigations for the uterus of mukul, civet, florax, and benjamin.

Inwardly, the patient may take 30 or 40 drops of tincture of calomel in cold water.

Some hysterical disorders observe the lunar phases, and partake of the nature of an epilepsy: They seldom require bleeding, and purging should be used with caution: Emetics are of greater service, especially a little before the fit. In the fit, the bell medicines are those which repair the losses of spirits, as Russian calomel, gum-ammoniac, salt of amber in pills.

Out of the fit, native cinabarr and wild valerian root are most proper for correcting the juices.

To prevent its degenerating into a chronic disease, particularly the hypochondriac passion, care must be taken to keep the menes regular; which must be done by balfans, composed of myrrh and amber, with bitter and carminative extracts, especially zedoary and orange peel, made into an elixir, with a moderately spirituous menstruum. This, frequently taken, helps the digestion, and promotes a regular menstrual discharge.

But it is necessary to observe, that in hysterical cases remedies have a different effect on different women. Some cannot bear fetid medicines, which to others are an immediate
mediate relief. Some have fallen into a terrible syncope, and have come to themselves by sprinkling cold water on the face, when more powerful and spiritual things have failed. Others cannot endure hot things inwardly nor outwardly, as baths, fomentations, liniments, and nervous applications. Anodynes and opiates, which procure ease and rest to some, are very injurious to others who are greatly debilitated, and whole nerves are weak. Some have recovered from a violent paroxysm, by a draught of cold water; which, given to others, has increased the disorder.

Peruvian bark given morning and evening, a scruple at a time, is an excellent remedy in hysteric convulsions.

Of the Hypochondriac Passion.

The hypochondriac passion is a spasmodico-flatulent affection of the stomach and intestines, arising from an inversion or perversion of their peristaltic motion, and by a consent of parts, throwing the whole nervous system into irregular motions, and disturbing the whole animal economy.

This disease is attended with such a train of symptoms, that it is a difficult task to enumerate them all; for there is no function or part of the body, that is not soon or late a sufferer by its tyranny. It begins with cautions and windy inflations of the stomach and intestines, especially under the spurious ribs of the left hypochondrium, in which a pretty hard tumour may sometimes be perceived.

With regard to the stomach, there is a naufea, a loathing of food, an uncertain appetite, sometimes quite decayed, and sometimes strong; the aliments are ill digested, breeding acid and viscid crudities; there is a preference, heavy pain in the stomach, chiefly after meals; a spasmatic contraction of the gullet, a frequent spitting of limpid phlegm, an impediment of swallowing, a violent heart burn, a heat at the stomach, very acid belching, a reaching to vomit, vomiting, bringing up such acid stuff, that the teeth are not only on edge thereby, but the very linen or sheets are sometimes corroded.

In the volume of the intestines, especially the small ones about the navel, there are felt heavy excreting pains, wringings, gripplings, with a rumbling murmuring noise; in the gros intestines the pains are more acute. Sometimes there is a looseness, sometimes a most obilinate colliquenes, with a retention of the wind; which, when it breaks out either upwards or downwards, is attended with an alleviation of the symptoms, but they soon rage again with as great violence as ever. When there is a frequent urging to stool, tubercles generally arise, and the blind piles beset the anus; nay, sometimes a symptomatical flux of blood will burst out. Making water in some is difficult and painful; the urine is thin, limpid, and pale; sometimes it has a copious sediment mixed with fabulous concretions, and often resembles a fit of the gravel.

In the breath there is a great straitness, contraction, excessive difficulty of breathing, sometimes with a sense of fulness, a fluttering and palpitation of the heart.

As the disease increases, the head is molest with an headache, hemiplegia, various fixed spasmodic pains, and what is commonly called the claus of hystericus. A noise in the ears, with difficulty of hearing; the eyes are clouded with a cataract; some have double vision, or a pain and dryness of the eyes. In the tongue there is a most troublesome burning pain fixed to a certain space, with a plentiful excretion of spittle, as if the patient was in a false.

At length the animal functions are impaired; the mind is disturbed on the most trivial occasions, and is hurried into the most perverse commotions, inquietudes, anxieties, terror, fadness, anger, fear, or diffidence. The patient is prone to entertain wild imaginings and extravagant fancies; the memory grows weak, and the reason fails.

Peruons are most liable to this disease from twenty to fifty, and while solids are soft, lax, and flabby, and their blood vessels small; as also who are naturally languid, or have been weakened by tedious maladies. Likewise those who lead sedentary lives, and study too hard; in whom this is the peculiar disease of the learned.

The remote causes of these disorders are the suppreffion of the hemorrhoids and menfe, and other periodical fluxes of blood; an hereditary disposition thereto; a cold and moist constitution of the air; grofs, impure, flatulent diet; a sedentary, studious life; sadness, cares, troubles, intense thinking on a single object; tedious diseases not rightly treated; hard labour in child-bearing.

As to the prognostics, if the disease be recent and left to itself, it is rather troublesome than dangerous; but if it be inveterate, and not skillfully treated, or a bad regimen is followed, it is attended with more grievous symptoms, producing obstructions and ichirri of the vifera, a cachexy, a dropsey, an hectic, a convulsive althma, an incurable melancholy or madness, a fatal polyphus, &c. But if it is cured by a suppreffion of the menfe, or bleeding piles, the restoring the flux is the cure of the disease.

As continual fear and diffidence are symptoms of this disease, the patients are always foreboding terrible things, and live in constant dread of death; which render them fickle, impatient, and prone to run from one physician to another. Therefore, when a cure is attempted, they must be admonished to be constant and patient; and then the following indications may be purified: 1. To correct and evacuate the acid, vifcid, bilious flux, and flatulent fordes from the prime vise, which yield continual fewel to this disease. 2. The pulses being appeased, to restore the natural order of the peristaltic motion of the intestines, and to recover it from a languid state, that there may be a due concocition of the aliment, and a laudable chyle and other fluids generated. 3. To disperse the flagnated juices; to render the circulation of the blood equable through the abdomen and the rest of the body; and to free the fluids from all acrimony, after facilitating the excretions by urine and through the skin. 4. And lastly, to corroborate the whole nervous system.

To answer the first intention, nothing is better in the fit than clysters made with emollient herbs, water gruel strained, camomile-flowers, the tops of yarrow, the oils of sweet-almonds, dill, camomile, linseed, &c. adding a carminative species made of caraway, dill, but more especially cumin seeds. These should be repeated, if the spasms render them ineffectual. If the fces are harden-
ed, it will be proper to give oil of sweet almonds and water gruel inwardly. Nor must gentle laxatives of mannna, rhubarb, and cream of tartar, be neglected, with a few drops of oil of juniper.

If there is a great deal of acid flux in the stomach, the patient will be necessary, especially a little castor oil. It will also be proper to take a decoction of any of the following things in the morning in bed, to promote a diaphoretic, viz. baln veronica, betony, agrimony, stercordium, carduus benedictus, tops of yarrow, daily flowers, camomile flowers, fennel feed, &c.

To restore the digestive power of the stomach, give essence of orange-peel, tincture of tartar, dulcified spirit of nitre, &c.

The paroxysms are relieved by tepid pediluvia, made of wheat, bran, water, and camomile flowers. The feet must be put pretty deep therein.

Out of the dirt, to diffcuss the stagnation of the blood, bleeding in the foot will be necessary, especially at the equinoxes, and at other times as occasion shall require; but this should be after laxatives and pediluvia. If there is a disposition to an haemorrhoidal flux, leeches should be applied every month to the anus; and the patient should also take balsamic pills, with antispasmodic nitrous powders.

To strengthen the nervous system, nothing is better than chalybeates; for they, by a gentle affection, restore the nerves to their former strength. Outwardly a saponaceous plaster, with camphor, may be laid to the hypochondria with no small advantage.

Nothing is more friendly, nor gives greater energy to the blood and spirits, than riding on horseback almost every day, and for a considerable time together. Nor does riding in a coach want its share of salutary effects.

Of Melancholy and Madness.

Melancholy and madness may be very properly considered as diseases nearly allied; for we find they have both the same origin: that is, an excessive congection of blood in the brain: they only differ in degree, and with regard to the time of invasion. Melancholy may be looked upon as the primary disease, of which madness is only the augmentation.

When persons begin to be melancholy, they are sad, dejected, and dull, without any apparent cause; they tremble for fear, are delirious of courage, subject to watching, and fond of solitude; they are fretful, fickle, captious, and inquisitive; sometimes niggardly to an excess, and sometimes foolishly profuse and prodigal. They are generally covetous; and when they discharge their excrements, they are often dry, round, and covered with a black, bilious humour. Their urine is little, acid, and bilious; they are troubled with flatulencies, putrid and fetid eruptions. Sometimes they vomit an acid humour with bile. Their countenances become pale and wan; they are crazy and weak, and yet devor their victuals with greediness.

Those who are actually mad, are in an excessive rage when provoked to anger. Some wander about; some make a hideous noise; others hint the sight of mankind; others, if permitted, would tear themselves to pieces. Some, in the highest degree of the disorder, see red images before their eyes, and fancy themselves struck with lightning. They are so falacious, that they have no sense of shame in their venereal attempts. When the disease declines, they become stupid, sullen, and mournful, and sensibly affected with their unhappy situation.

The antecedent signs are, a redness and suffusion of the eyes with blood; a tremulous and inconstant vibration of the eye-lids; a change of disposition and behaviour; superficial looks, a haughty carriage, disdainful expressions, a grinding of the teeth, an unaccountable malice to particular persons; also little sleep, a violent headache, quickness of hearing, a singing of the ears; to these may be added incredible strength, infensibility of cold, and, in women, an accumulation of blood in the breasts, in the increasc of this disorder.

These things being duly considered, together with the state of the brain in persons who died of this disease, we may conclude, that melancholy is a strong and lively working of the fancy, with a fixed attention of the mind to a particular object, which it continually dwells upon; together with a delirium, a long continual dejection, dread and sadness without any manifest cause, arising from a difficult circulation of blood through the vessels of the brain, where it is too copiously congested and becomes stagnant. Madness is a violent rage, attended with狂热 and preternatural strength, caused by an impetuous motion of a thick melancholic blood through the vessels of the brain. It differs from a phrenzy, which is a delirium accompanied with a fever, and arises from an inflammatory stagnation of the blood in the brain: for we learn from experience, that all the shining faculties of the mind are changed or depraved, diminished or totally destroyed, when the blood and humours, receding from their natural temper and due quantity, are not conveyed to the brain in a moderate and equitable manner, but on the contrary with an impeded flow, and languid motion, or with too brisk and violent an impetus.

Both these disorders suppose a weakness of the brain, which may proceed from violent disorders of the mind, especially long continued grief, sadness, dread, uneasiness and terror; as also close study and intemperate application of mind, as well as long protracted incursions. It may also arise from violent love in either sex, especially if attended with despair; from profuse evacuations of the fermen from an hereditary disposition; from narcotic and stupefactive medicines: from previous diseases, especially acute fevers. Violent anger will change melancholy into madness; and excessive cold, especially of the lower parts, will force the blood to the lungs heart and brain; whence oppressive anxieties, sighs, and shortnesses of breathing, tremors and palpitations of the heart; thus vertigoes and a sensation of weight in the head, fierceness of the eyes, long watchings, various workings of the fancy intensly fixed upon a single object, are produced by these means. To these may be added a suppression of usual hemorrhages, and omitting culturmary bleeding.
bleeding: hence melancholy is a symptom very frequently attending hysterical and hypochondriac disorders.

The causes which contribute to the generation of a thick blood, are idleness and inactivity, which weaken the body, impair the functions, diminish the salutary excretions, and render the humours thick, viscous, and stagnant: All which are heightened by solitude, which is apt to give rise to various fantastic and gloomy ideas in the patient's mind.

Likewise acid humours in the stomach will increase the appetite, and tempt them to feed on coarse, gross, glutinous aliments, without drinking enough to dilute them sufficiently, whence a matter proper to nourish these diseases will proceed. It is evident from observation, that the blood of manic patients is black, and hotter than in the natural state; besides, the serum separates more slowly and in less quantity than in healthy persons. The excretions are hard, of a dark-red or greyish colour, and the urine is light and thin.

Diseases of the mind have something in them so different from other disorders, that they sometimes remit for a long time, but return at certain periods, especially about the full-moons, the times at which they first appeared. It may likewise be observed, that the raving fits of mad people, which keep the lunar period, are generally accompanied with epileptic symptoms.

This disease, when it is primary or idiopathic, is worse than the symptomatic that accompanies the hysterical or hypochondriac passion, which is easily cured; as is that also which succeeds intermitting fevers, a suppuration of the menes, the lochia, the hemorrhoids, or from narcotics. When the paroxysms are slight in the idiopathic kind, the cure is not very difficult: but if it is invereterate, and has but short remissions, it is most incurable; which is often owing to this, that they reject physicians and their medicines as poison. It is a bad sign, if, after a profound sleep, the patient still continues delirious, and is insensible of cold, or is unaffected with strong draffic medicines. If after want of sleep and long abstinence the patient is exceeding weak, or becomes epileptic, convulsive, or lethargic, death is not far off. Mad people are seldom subject to epidemic or other disorders. Pustules, the itch, and ulcers, have also done the same.

Sometimes this disease terminates by critical excretions of blood from the nose, uterus, or anus. Sometimes diarrhoeas and dysenteries will terminate these disorders. Pustules, the itch, and ulcers, have also done the same.

In the cure, bleeding is the most efficacious of all remedies; and where there is a redundance of thick, glutinous blood, a vein is first to be opened in the foot, then in the jugular vein, or in the nostrils with a straw; and, last of all, the frontal vein with a blunt lancet, for fear of hurting the pericranium, a gature having been first made round the neck to render the veins turgid.

Tepid baths are also convenient, to drive the blood from the head to the inferior parts; and before the patient enters the bath he should have cold water poured on his head, or it should be covered with a cloth dipped therein; for cold water pumped or poured on the head con-
tobacco; for it not only penetrates thick blood, but throws
the fluids into preternatural commotions. Change of air
and travelling may be beneficial.

Though in deliriums bleeding is highly useful, yet it
agrees best with those that are plethoric, bilious, and in
the vigour of youth: these likewise will bear frequent
purges of corrected hellebore; but then the strength must
be repaired by cordial, corroborating, and anodyne fe-
datives. When the patient is exhausted, bleeding is
hurtful, and reforatives good.

As a high degree of the itch has terminated these
diseases, it will be proper to make issues in the back, or
to procure ulcers with a potential cautery near the spine
of the back.

Sedative medicines are good; but not opiates and
narcotics, for these induce stupidity and folly. Those
that are good in an epilepsy, will be beneficial here;
such as caltor, flavings of hartshorn, the roots and seeds
of piony, and anti-epileptic powders, the valerian root,
flowers of the lily of the valley and of the lime tree.

And to the other fort of madness, which proceeds from
being exhausted and weakened by autumnal, violent, and
obfinate intermitting fevers, and from their being inju-
diciously treated with bleedings and purgings, it is only
to be cured by reforatives, cordials, and corroboratives,
long persifled in.

Of the Hydrophobia.

This disease, as it generally proceeds from the bite
of a dog, is called rabies canina, or the canine madness;
and from its most terrible symptom, the dread of water,
hydrophobia. It almost always arises from the infection
communicated by the bite of a mad animal: yet it has
been observed to arise spontaneously in some animals af-
fected with acute difeases.

Almost all kinds of animals may be afflicted with this
disorder, and may infect other animals, and even men;
as dogs, cats, wolves, foxes, horses, asses, mules, horn-
ed cattle, hogs, monkeys, and cocks; but it most fre-
fently attacks the dogs, wolves, and foxes, without any
previous contagion.

A hot climate, excessive heats and sudden colds; a long
and dry seafon; feeding upon putrid, flinking, verminous
flefh; want of water; worms generated in the kidneys,
guts, brain, or nozils; are the preceding caufes of mad-
nefs in these animals.

When they are going to run mad, they appear dejected,
shun company and hide themselves; they will not bark,
but seem to matter or murrur, and are averse to food
and water; they will fly upon strangers, but retain none
regard for their matter; their ears and tails hang down,
and they walk along as if they were sleepy. This is the
first degree of the difeafe; and, though the bite is then
bad, it is not at the worft. Afterwards they begin to
pant, hang out their tongues, froth at the mouth, and
gape. Sometimes they feem dull and half alfeep; some-
times they will run, but not directly forward, and soon
crave to know their mifters. Their eyes are dejected,
look watery and dirty, their tongues are of a lead colour,
they fall away suddenly, and grow raging mad. A bite
at this time is incurable; and the nearer they are to
death, with the more dreadful symptoms it is attended.

There is scarce any poison infectious so many ways as
this: for it takes effect through the cloaths, withoutfetch-
ing blood; by the breath of the animal drawn into the
lungs; by a touch of the froth, if recent; and by ap-
plying it to the lips or tongue, when it has been long
dried; or by kifing a dog that is mad; or by handling
the wound or instrument which was the death of the animal;
or by handling things which have been infected by any of
the former means.

Again, there is scarce any poison which produces such
terrible effects, and caufes such a wonderful change in the
perfon infected. When it begins to work, it is most
violent and quick; and yet, as it is said, it will some-
times lie dormant for years together before it exerts
itself. This diversity depends on the heat of the feafon,
the degree of the difeafe of the infected animal, and the
temperament of the perfon bit. For the bilious are soonest
affected by it; the phlegmatic and hydropic the leaft;
likewise something may be attributed to the way of living,
diet, and medicines.

A healthy man, infected with this contagion, finds the
effects of it discover themselves in the following order.
There is a pain in the place where he was bit, or received
the contagion; and then wandering pains in the other
parts, chiefly those that are near it; a latitude, heav-
nefs, littlefines of the whole body; inquiet troubled
fleep, and terrible dreams, with convoluiions, and labours
of the tendons; continual inquietude; fighs, fadnefs,
love of solitude. This ends the first degree of the difeafe.

Afterwards all the former symptoms increase, with a
prodigious straitnefs or oppression about the praecordia; a
difficult fighing respiration; horror; a fhaking and trem-
bling at the sight of any liquid, or bright, pellucid thing;
lofs of appetite; a poffibility of swallowing any thing
solid; but, if any liquid is touched with the lips and
tongue, it occafions an incredible anxiety, trembling, and
terrible convuluiions, almost forcing the patient into a rage;
then a vomitting of dark, bilious, vitious matter, or por-
ceous bile; an increafed heat, a fever, continual watch-
ing; a priepeps; a confufed feries of wild, extrarent
thoughts: Here the fecond degree of the difeafe may be
faid to terminate. Now all the symptoms grow worfe
and worfe: the tongue hangs out, and is rough; the mouth
is wide open; the voice is hoarfe; the thirst great;
strange horrors, flattering, and wild looks, at the fight of
water; a fothing at the mouth; an involuntary inclina-
tion to spit at the by-fladens, as alfo to bite them, which,
the patient cannot refift. He foams at the mouth, and
gruflhes with his teeth; and would do mifchief, if not
forcibly with-held. His pulse and breathing fail: there
is a cold fweat, and the higheft fury; yet during all this
time, which is wonderful, the patient continues in his
fenes, and is afraid of doing any harm. On the fourth
day from the firft degree of the difeafe, the patient falls
into convuluiions, with great difficulty of breathing; and
then dies.

The defcription of persons who died of this difeafe has
been given, that the organs of swallowing have been in some
measure inflamed; that various kinds of bilious vitious
vividities are collected in the flomach; that the gall-bladder is full
of
of a black bile; that the pericardium is dry; that the lungs are incredibly distended with blood; that the heart is full of an almost dry blood; that the arteries are full, and the veins almost empty; that the blood is very fluid, and will hardly coagulate when exposed to the air; whereas that which was drawn from a vein three days before, coagulated as usual; that all the muscles, viscera, brain, cerebellum, and spinal marrow, are more dry than common.

The prevention and care of this disease, except in a few instances, are very doubtful and uncertain: which may be attributed to the boasting pretences of some to specifics, and the neglect of a due method of care, founded on the history of the disorder.

So far therefore as may be conjectured from the preceding history of the disorder, and from comparing it with other diseases, as also from the few instances which have been attended with a happy event, it seems chiefly to consist in an affection of the nerves, which most nearly resembles convulsions, which occupy the viscera and the vessels thereof; whence arises a disorder in the blood and humours, which is not unlike a gangrenous inflammation. The seat of the disease is chiefly about the stomach and neighbouring parts.

The preventive cure consists in making deep scarifications, as soon as possible after the bite, in the part affected, and thence adjacent to it; that they make a considerable discharge of blood, and apply large cupping-glasses thereon; or it may be burnt pretty deep with an actual cautery. Then it should be made to suppurate by some corrosive application proper for that purpose; and during all that time it should be continually fomented with a pickle made with vinegar and salt: this should be continued for six months at least. The garments he had on at the time of the bite should be cautiously laid aside or destroyed. He should likewise with all convenient speed be dipped in a river, or the sea, making him believe that he is going to be drowned. This is to be often repeated; for the effect consists in terrifying the mind, not in the fatal water, as we have learnt from experience. Then he should also be often and strongly purged with rhubarb, aperic, and the juice of elder-bark.

The patient should also be put into a sweat every morning fasting, with a mixture of aromatic vinegar, tea-salt, and hot water. His feet and hands should also be daily fomented in a warm bath; and he should wash his head, mouth, and face.

Let him often drink cold water, and throw it up again by vomiting; and let his drink be acidulated. His aliment should be moist, light, and laxative, and often taken in such a quantity as to vomit it up again. He should likewise abstain from things that are too spicy, from wine, from heating things, from violent exercise, and from commotions of the mind.

The cure should be attempted when the disease is in the first degree, and in the beginning of the second, by treating it as highly inflammatory, by letting blood from a large orifice even to a deliquium, by giving clysters soon after with nitrous or moderately salt water.

After this let the patient be blind-folded, and thrown into a pond of cold water; or let cold water be thrown upon him till the dread of it almost ceases; then let a large quantity be forced down his throat: let this be his treatment daily, and at night let sleep be procured. And this method is better than that pernicious one of giving him the most acid heating and drying medicines; which exasperate the nervous system, and are in this case as bad as poison, to a patient already almost parched with heat.

Celsus informs us, that it was the practice of old to put the patient bit by a mad dog into a bath, and there to let him sweat as long as his strength will permit, at the same time keeping the wound open, that the virus might be discharged from it; and then to give him plenty of good generous wine. This being done for three days, they judged him out of danger.

This may give some light into the nature of the pulvis antiysius published by Dr. Mead, and received into the dispensatory of the college, wherein pepper is one of the ingredients:

1. Take four drams of ash-coloured ground liver-wort, and two drams of black pepper, beat into a powder.

This is to be divided into four doses, whereof one to be taken in warm milk in a morning, fasting, for four mornings successively. After this he is to be put into a cold bath, pond, or river, for thirty days together, early in the morning before breakfast.

Another famous specific is the East-india medicine; which is doubtless an egregious antispasmodic, and is as follows:

2. Take native and factitious cinnabar, of each 24 grains, and 16 grains of musk. Make them into a powder.

This is to be taken in a tea-cup full of arrac or brandy, and is said to secure the patient for thirty days, at the expiration of which it is to be repeated; but, if he has any symptoms of the disease, it must be repeated in three hours, which is said to be sufficient for a cure.

Dr. Wall of Worcester has found two doses of musk, of xy grains each, to produce very happy effects on two persons labouring under a fibulitus tendonum, with extreme anxiety, and want of sleep, from the bite of a mad dog; for it perfectly relieved them from their complaints. We have a singular case of a woman actually seized with an hydroprobia, given by Dr. Nugent; who was cured. He ordered this powder to be taken in honey every three hours, after she had lost 15 ounces of blood, and a pill of 2 grains of pure opium along with the powder, till rest was procured.

Of Poisons.

There are three essential marks of poisons which distinguish them from other things that are noxious to human bodies. The first is, that they consist of most subtle parts, and consequently are pernicious in a small quantity. The second, that they pervert, in a short time, the regular motions of the solids and fluids throughout the body, and induce the most grievous symptoms, even death itself. And the third, that they exercise their cruelty on the most subtle fluid, and the most nervous parts.

All the three kingdoms have poisons peculiar to themselves; but the animal kingdom affords the most subtle, which are communicated by the bite of mad or venomous.
MEDICINE.

The bite of a Rattle-Snake, hitherto looked upon as a most terrible accident, may now be cured in a simple, easy manner. It is the invention of a negro; for the discovery of which, he had his freedom purchased, and an hundred pounds per annum settled upon him during his life by the general assembly of Carolina.

Take of the roots of plantain and horseradish (in the summer the roots and branches together) a sufficient quantity; bruise them in a mortar, and squeeze out the juice, of which give as soon as possible one large spoonful; if the patient be swelled, you must force it down his throat. This generally will cure; but, if he finds no relief in an hour after, you may give another spoonful, which never fails.

If the roots are dried, they must be moistened with a little water. To the wound may be applied a leaf of good tobacco moistened with rum.

The mineral kingdom furnishes very few real poisons: the only natural one is cobalt; the factitious are arsene, corrosive sublimate, and glafs of antimony.

Cobalt is a kind of a marcasite, which is found in great plenty in the mines of Millina; and is well known for its poisonous quality, so fatal to insects, brutes, and men. In making the blue glafs, or enamel, called smalt, from this mineral, a sort of white flowers arifes, which, being melted in a stronger fire, is called white arsene. If this be melted again with an eleventh part of sulphur, it becomes yellow arsene, and, with a sixth part of sulphur, red. Of these, the white is the most deadly poison.

As for the true mineral poisons, they were entirely unknown to the ancients; for they reckoned quicksilver, crude antimony, all kinds of vitriol as well as cersus, and the laps lazuli, in that class; but orpiment, which they called arseneick, as Celsus testifies, and looked upon as a poison, is void of all virulence and deleterious qualities; and sandarach they termed red arsene, which is made of melted orpiment, but is no more noxious than the former. Indeed, it must be owned, that the above catalogue are not altogether friendly to human nature, or may be endued with a corroding quality; but they want the true characteristic of poisons.

Quicksilver, dissolvd in acid mineral spirits, is Likewise a poison, though of itself it is entirely innocent. This has chiefly appeared from errors in practice, when the mercury has not been rightly prepared and corrected.

Likewise glafs of antimony reduced into powder, and exhibited, causes enormous vomiting, with most cruel gripings, which often end in death.

Arsene, taken inwardly, creates a pricking, vellicating, irritating, burning sensation, with a heat and most violent pain in the flamach, a racking torture in the bowels, vomiting, unquenchable thirst, a roughness and dryness of the tongue, saucers and gullet, with hiccups: then follow most cruel anxieties, palpitation of the heart; fainting, coldness of the extremities; sometimes black vomits, and fluids with a fetid cadaverous smell; a gangrene and mortification of the flamach and intestines, which either in death.

Milk is very useful against all corrosive poisons, by its soft, oleous contexture, blunting their acrimony; and is a good vehicle to bring them up by vomit.
In all cases where a person is suspected to have been poisoned by swallowing any substance of a corrosive nature, oil with milk for a vehicle yields the most certain relief; and even when acid mineral spirits are taken by mistake, they will blunt or hatch the acrimony sooner than fixed salts and tannaceous powder will change their nature: besides, fallad-oil is generally at hand in all places as a decoction of barley with raisins, or a decoction of china-root, saffrafas, cinnamon, wood-lace, either in infusion or powder; the juice of wood-lace newly expressed, and taken for some weeks, increasing the dose, is of excellent use; as likewise mercurials, taken in very small doses, and a long while together.

If it arises from a suppression of usual hemorrhages, they are to be restored; but, if this cannot be done, artificial bleeding is to be substituted.

Externally, issues are held to be good, clysters and fections, especially in the phlegmatic. The eyes may be washed with fennel, valerian, eye-bright, or rofe-water, spirit of wine, Hungary water, and sal-volatile oleofum diluted, or an infusion of fennel-seeds in wine, with bags of strengthening herbs and fennel-seeds often put thereon. Sneezeing powders may likewise be proper, especially florentine orice, or horse chechefuts; likewise spirits of hart-horn, or sal-volatile oleofum, may be applied to the nose.

In all disorders of the eyes, but particularly in this, the body must always be kept open, that the humours may be inveterate, ripe, or perfect, as the rudiments of a cataract. But, if these have no effect, and the cataract grows inveterate, ripe, or perfect, it is to be depressed; for which, see Surgery.

Of a Glaucoma.

A Glaucoma is a change of the crystalline humour into an azure colour, from its dryness and conflagration, as some affirm; but Heister says, it arises from an opacity of the vitreous humour, which becomes of a whitish green colour; for, in a suffusion, an opaque body is placed behind the pupil, or is next to the aqueous part.

Sennertus says, this malady is known from a very remarkable whitenss appearing in the eyes, and lying deep behind the pupil, and all things are seen as through a smoke or cloud; it is said to be incurable.
Of the Amblyopia, or Obscurity of Sight.

The amblyopia is an obscurity of sight, and is four-fold: myopia, or short-sightedness; presbyopia, or seeing only at too great a distance; nyctaliopia, or seeing only in the night; amaurosis, of which before.

Myopia proceeds from the too great convexity of the cornea, or crystalline humour, or from the eyes being larger than common, as we learn from optics. This is best fold: myopia, or short-sightedness; presbyopia, or seeing only at too great a distance; myopia, or short-sightedness; presbyopia, or seeing only at too great a distance; nyctaliopia, or seeing only in the night; amaurosis, of which before.

The presbyopia may likewise be assisted by cephalic and strengthening medicines, by watery and vinous infusions, and comforting eye-waters.

Of a Strabismus, or Squinting.

A Strabismus, commonly called squinting, is an unequal contraction of the muscles of the eye, either from a fall, an epilepsy, or a palsy, whereby the axis of the pupil is drawn towards the nose, temples, forehead, or cheeks; so that the person cannot behold an object directly. Infants readily contract this distemper, sometimes for want of care in the nurses, who place the cradles in a wrong position, with regard to the light. Children likewise, while growing up, sometimes fall into this disorder, either from all customs contracted in playing, or by looking on others who are affected with it.

This disorder is very difficult to cure, therefore the utmost care should be taken to prevent it, and the cradle should be so placed, as not to occasion the child to look awry. Against it is contrived a mock, and so adapted to the face, that nothing could be seen except through two holes straight forward; and for the same purpose what we call goggles are used.

Of the Albugo, or Spot in the Eye.

An Albugo, or leucosis, is a whitish spot of the transparent cornea; the broader and thicker it is, the more it obscures the sight; when it is superficial, it appears the whiter; and, when it is deep rooted, it tends to blackness, and is scarce curable. That which is in reality a cicatrix, or scar, left after a wound or ulcer in the eye, is very difficult to be disfigured; that which follows an inflammation of the eye often goes away of its own accord.

It may be distinguished from a cicatrix, because this is of a thinning white and without pain; whereas the albugo looks like chalk, is attended with a slight fluxion, and some degree of an inflammation with pain. It is generally the forerunner of an ulcer.

The intentions of cure are answered by emollients, roylewents, and difcutients, which must be used with great care: and, if they fail, we may proceed to stronger.

Of a Sanguillation, or Bloodshot Eye.

A Sanguillation first appears of a reddish colour, and afterwards livid or black. It is caused by a stroke or fall, or violent vomiting, whereby the blood is extravasated in the coats of the eye. If the cornea is affected very much, all objects appear of a reddish colour; for some veins run to the cornea, in the part towards the iris, or the blood may be poured out into it from the neighbouring vessels.

If the disorder is great, there will be occasion for bleeding and purging, for the granulated blood in the fuggitation is to be resolved and disfigured, which may be done by difcutients, such as juice of fenon, with balm of Peru, juice of celandine, simple honey-water, mixed with other eye-waters.

If from this or any other cause there should happen to be an ulcer of the eye, Demours recommends coarse sugar as a good ingredient for deterging those of the cornea, in which adstringents are hurtful; but it must be mixed with collyria. When the aqueous humour of the eye is evacuated at a wound or ulcer of the cornea, he exposes the patient to the light, from time to time, till the cornea is again raised by the aqueous humour; for the light occasions a motion in the iris, which may prevent its adhesion to the cornea.

Of the Epiphora, or Lippitude of the Eyes.

An epiphora is a defluxion of a salt sharp humour upon the eyes, attended with itching, pain, and redness; as also a dimness of sight. It is but light when there is no defect in the bulb of the eye, when the eye-lids swell and look red, when the matter of the fluxion is thick and sometimes glues the eye-lids together in the night, continuing in this state for some time.

Children are often afflicted with this disease, particularly those who have had scald-head improperly cured; or who have swellings in the glands of the neck or about the ears, and then it cannot be cured until these tumours are diffused. It sometimes likewise succeeds the small-pox and measles.

The seat of this disease is in the glands of the eye, especially in those called the lachrymal glands.

This disease may be certainly cured in the beginning, by a plentiful drinking the infusion of the leaves of veronica, in the manner of tea, for some time. When it is inveterate, the patient must be very regular in his diet, and must avoid every thing salt, sharp, acid, wine, strong beer, and drugs. His common drink may be a decoction of barthorn and fennel seeds, using warm pediluvia at night going to bed.

Externally a grain of vitriol may be mixed with unsalted butter, to which a small portion of sugar of lead may be added and put into the greater corner of the eye. This is a most useful medicine. When the lippitude is of the dry kind, all acid applications must be avoided, and the eyes must be covered with a poultice of white bread.
bread and milk, with a little saffron mixed with it. The
success of feins and issues is uncertain, but a perpetual
blister on the neck is of great service. But it
must be continued for a considerable time.

Of the Fistula Lachrymalis.
The fistula lachrymalis is a disease which attacks the
great caruncle in the inward corner of the eye, and
stopping up the natural passage of the tears, forces them
to run down the cheek: but this is the first degree of the
disease. The second is, when pus is mixed with the
tears, which proceeds sometimes from an opening in the
skin between the nose and the great corner of the eye,
The laff is, when the pus has not only corroded the neigh-
bouring parts which are soft, but has affected the bone
which lies underneath. This sort of fistula sometimes
turns cancerous; and Riverius advises not to meddle with
it at all.

Whatever may be the cause of this disorder, whether
the small-pox or the French disease, it always stops up the
nasal conduit, which is opened by an operation. See
Surgery.

Of Deafness.
The causes of deafness are a cutting off the external
ear, or an obstruction of the auditory passage from wax
or other things; from a rupture of the membrane of the
tympanum, or when it is corroded or ulcerated, or the
auditory nerve is obstructed or compressed. External
causes are, falls from high places, excessive noise, such as
the explosion of cannon; likewise acute disorders near
their state, which are like to terminate by a critical ha-
emorrhage.

As to the prognostics, those who are born deaf are
rarely cured. A real deafness is hard to remedy. A
deafness in acute diseases, with crude urine, foretells a
delirium; but, when the signs of coddion are good, it
portends a critical haemorrhage.

With regard to the cure; if the obstruction be in the
external cavity of the ear, it is discernible by the sight.
If there is occasion to syringe the ear, a decoction of fage
and rosemary-flowers will be proper, with equal parts of
water and white-wine; but great caution should be used.
Some pump the head with warm bath waters. Some
say, the eggs of ants bruised and put into the ear, with
the juice of an onion, cure the most inveterate deafness.
Others affirm, that a salivation will sometimes perform a
cure.

A critical deafness will cease of itself. Etmüller re-
commends amber and musk.

Hoffman says, deafness sometimes arises from a slack-
ness of the auditory nerves, which often happens from too
great a humidity, which, if neglected, will terminate in
a perpetual and incurable deafness, and may be dispersed,
if taken in time, by proper cephalics and sudorifics.
Some for this purpose recommend equal parts of spirit of
lavender and hungary water, which should be drop warm
into the ear. Lindanus advises the gall of an eel mixed
with spirit of wine; and others, the fumes of sulphur
conveyed into the ear, with a pipe or funnel. But regard
must be had to the cause, if discoverable.

Of a Tinnitus, or Noise in the Ears.
Hoffman observes, that this is caused by the spasms
of the coats of the ear, which line the inward parts,
such as the labyrinth, cornea, and auditory passage, which
is often attended with intolerable anxiety.

The cure is to be performed, says Heißer, by temper-
ate diaphoretic powders, and resolving essences, com-
monly called antitachrales; as of amber, the woods,
rosemary; together with diaphoretics and alexipharmacs,
taken often in a day, with tea of betony, with rosemery
flowers, fage, or lavender and saffraffas. In the morning,
and at noon, the essences are to be taken; and at night
the powders.

Outwardly, essence of amber may be applied, either
evening; or a grain or two of amber and musk, or
calvator in cotton, either alone or with Peruvian balsam;
or carminative oils, such as anise, fennel, caraways, or
camom; not neglecting pediluvia, and frequent rubbing
of the feet and head.

Of a Coryza, or Catarrh of the Nose.
A Coryza is too great a moisturer of the nose, by a
thin sharp serum, which gradually becomes thick, and
sometimes coloured.

The cause of this disorder proceeds from the lymph
and mafs of blood, most commonly in the winter-time,
which hurts the nostrils; at first it arises from a thin,
sharp humour, which excoriates the parts, which, beco-
ming more thick, almost stops the nostrils and hinders
breathing. Sometimes it arises from irritants too often
taken, and from mineral fumes; this is accompanied with
spitting and a cough. Sometimes the effluvia, affecting
the nostrils, have the nature of a ferment, and become
infectious.

As to the prognostics, it is without danger, unless the
lymph is exceeding sharp and ulcerates the nostrils, and
so degenerates into an ozaena, or forsid ulcer of the
nostrils. Hoffman says, this excretion is often salutary,
and is exasperated by purges.

With regard to the cure, the irritation is to be stopped
in the beginning, by joining laxatives with sudorifics, ac-
cording to the condition of the patient, the season of the
year, and the reigning diseases. To stop the irritation,
oil of aniseed is very proper; but if the nostrils are red,
painful, and excoriated, it must be mixed with barley-
flour well dried. Camphor dissolved in oil of almonds is
likewise good externally applied, and the smell of horns
when rasped, as well as the vapours of gum-anime, re-
cived into the mouth and nose. The vapours of amber,
frankincence, myrrh, and benjamin, are likewise useful.
A coagulation of the mucus may be evacuated by distilled
oil of marjoram, amber and aniseed, mixed with leaves of
marjoram, and made into snuff; or, by a fynurnatory of
calcined white vitriol, twelve grains of which may be
mixed with two ounces of marjoram water, and filtrated.
If the nostrils are obstructed, the vapour of vinegar upon
hot iron will be profitable. If the head is heavy and dull,
the vertex should be anointed with balsam of Peru, which
may
may be made stronger with oil of amber. To preserve the mouth, troches may be held therein, made with mithridate and obisnum.

To preserve the fauces and windpipe, it is common to take raisins steeped in spirit of anisefd.

Of the Ozena.

The ozena is a forbid ulcer affecting the noftrils; wherein the humour is very acid or corrosive, intolerably fted, faniouf, and often mixed with a bloody mucus.

With regard to the cure, the leaves of tobacco, or tobacco ointment, are very useful: If it gathers to a crust, it may be removed by oil of sweet almonds. Some make use of the fumes of cinnabar, or inject mercurius dulcis; others use precipitate mixed with an emollient ointment, and applied with tents. Some use an injection of oil of sweet almonds, an ounce and a dram of oil of catoor to soften the acrimony of the humours. If the pain be great, they add a scruple of camphor and faffron, with half a scruple of opium. To take away the crust, they make a powder of rofemary and lavender fowers, dried lemon-peel, and commifi fruitt.

When the matter is well digested, the running abated, and the pain gone, it may be made stronger with lotions, and washed with warm milk.

Of Watching.

Watching is produced by too great a determination of the nervous fluid to the organs of the fenses: from its too great influence in the brain, while the lower parts are obftreced with colds or other causes, as in hypochondriac, melancholic, and mad patients, whose lower parts are cold: by any irritatng body, in whatsoever part it is placed, which disturbs the fenses, and efpecially the brain: from too great a motion of the humours, while the passages of the brain are open: from disorders, in which the caufes above-mentioned are predominant: as fevers, phrensy, melancholy, pains, suppurations, and fuch-like disorders.

When the caufe is known, it must be removed, if poiffible; and the irritatng spirits must be appeafed with emollitions, especially of poppy feed, or with the thebaic tincture, or theriaca and other opiates in general, nor neglecting the original difeafes. In fevers, a moift foftening diet is beneficial: as also preparations of barley, emollitions of poppy-feeds, and almonds, decoction of corzoner roots, almond cream, and winter flummery, used as aliment; likewife tea made of cowflip-flowers, and gentle laxatives. When the patient is reflelfed and wakeful the night before a crisis, no hypnoftics fhould be given.

When there is no other difeafe, the patient fhould have all care, and intenfe thinking, efpecially in the evening; he fhould ufe exercife, and eat light fuppers. If it is caufed by pains, they fhould be appeafed by antifpafmodics, things which temperate, and diaphoretics: if these will not do, mild opiates muft be added. In old perflons, all care and folicitude fhould be banifhed, the mind fhould be quiet, and the moderate ufe of generous wine may be allowed in the evening; likewife medi-

Of the Syncope, or Fainting.

Heister obferves, that this disorder may arise from want of strength from profufe bleeding, from fpasms and violent terror and dread, or from the flight of any greatly affecting thing. The patient is deprived of fenfe and motion, either wholly or in part, with paleneff of the face, and a very weak or low pulfe. They are generally roufed by fhaeking and pulling, or by volatile medicines; which diftinguifhes it from the apoplexy.

There are two kinds; the one flight, the other grievous. The flight kind is attended with paleneff of the face, difturbed vision, finging of the ears, and sometimes with a vertigo; the strength fails, and the patient is almost deprived of fenfe, falls or sinks down, till fome proper remedy is applied to the nofe and mouth. The more grievous fort is," when the patient falls into a delirium, and is deprived of all fenfe and motion, except breathing, and a very small pulfe; but yet he may be rouzed by spirituous medicines and other means, much more easily than in the apoplexy.

Besides the caufes already mentioned, there may be added the hyfpernic passion, which feems to proceed from fpasms; fome of this fort are thus affected with the smell of sweet things. Some incur this disorder by deep study, great inanitions, and fafting.

With regard to the prognoftics, it has generally more terror than danger attending it, unless it proceeds from profufe bleeding, or wounds, or a lefe of strength by other.
medicines have been used according to the diversity of causes, as vitriol, are applied to stop the blood, the cure must be when the nerves are hurt, or when sharp things, such as when persons are neither open his mouth, nor eat, as when persons are wounded, and something foreign is lodged therein, or when the nerves are hurt, or when sharp things, such as vitriol, are applied to stop the blood, the cure must be performed according to the diversity of causes, as particularly treated of in surgery. But when this happens spontaneously in infants, they generally die, though the best nervous and antispasmodic medicines have been used both inwardly and outwardly.

Of the Spasm of the Lower Jaw.

In the spasm of the lower jaw, when the patient can neither open his mouth, nor eat, as when persons are wounded, and something foreign is lodged therein, or when the nerves are hurt, or when sharp things, such as vitriol, are applied to stop the blood, the cure must be performed according to the diversity of causes, as particularly treated of in surgery. But when this happens spontaneously in infants, they generally die, though the best nervous and antispasmodic medicines have been used both inwardly and outwardly.

Of the Cynic Spasm, or Convulsion of the Muscles of the Mouth.

A Cynic spasm, if it proceeds from vegetable poisons, as it generally does, they are to be expelled immediately from the body by a vomit, and then giving generous wine, warm with ginger or pepper. If it happens from other causes, it must be treated with antispasmodics and nervous medicines, both inwardly and outwardly; and chiefly with piaffer of betony and bay-berries, prepared with oil of amber, and applied to the temples, and behind the ears.

Of the Palpitation of the Heart.

The heart often palpitates so much as to be heard at a distance by the bystanders, which they suppose to be an affection of the thorax. This may sometimes happen, from a violent motion of the body, chiefly when ascending high places, and principally in those who are plethoric and hypochondriac. Sometimes it is caused by fear or dread, when the blood is forced too violently to the heart. When it proceeds from violent motion or terror, and returns often, it causes a kind of polypus, as is evident from the distension of those bodies who have died of this disease. Hence, almost a continual palpitation arises. Sometimes it proceeds from a bad conformation of the heart and the neighbouring vessels, such as an aneurism of the aorta, when it becomes hony.

Others affirm, it sometimes may be caused by wounds in the ventricles or abscences in the heart; or from wind, or a disorder of the animal spirits, inducing spasmodic affections.

In the beginning of the cure, if the patient is plethoric, or when usual bleedings have been stoped, it will be proper to bleed, by way of prevension, in the spring and autumn.

Besides this, saline, nitrous, and cinnaabarine tempering medicines are to be used, particularly antispasmodics, to appease the motion of the heart, and render the blood more fluid. The aqueous infusions of tea, balm, veronica, primroses, or citrons, are likewise proper, especially with the essence of scorndum, cardius benedictus, curion, or orange-peel, with a little dulciified spirit of nitre, taken morning and evening; as also temperate and diluvia, moderate frequent exercise, riding, moderate diet, plenty of thin drink, whey, mineral waters, especially the chalybeate kind, are very useful in this disease.

Of a Polypus of the Heart.

A Polypus is a mass composed of various pellicles and fibres, generated in the heart and large vessels. They are generally founded in acute as well as chronic diseases; and there are few bodies to be met with, wherein they are not to be found after death. Its principal seat is in the heart, pulmonary artery, and the aorta.

They principally attack the sanguine constitutions, and patients who have smaller vessels, soft fibres, of a sedentary life, who drink little, or are free in the use of acid wines and spirituous liquors, as also those who eat large suppers.

The beginning of a polypus may be known by a compression of the breast, a fixed pain about the heart, and when it increases there is a frequent palpitation of the heart, from a slight cause, and the pulse is strangely unequal and often intermits. When there is a violent motion of the body, the patient has taken a medicine which disturbs the blood, or the mind is violently affected, a shortness of breath and an incredible anxiety of the heart will arise. Lastly, there are frequent faintings without any evident cause, or from a certain position of the body. If the blood is let fall into hot water, it will congeal like jelly, and cleave into white filaments.

In the cure, an exact regimen and diet must be made use of, with a frequent exercise and motion of the body, and mineral waters, especially those of the chalybeate kind, and abounding with alkalious salt.

Of the Hiccup.

A Hiccup is a spasmolic affection of the stomach and diaphragm, arising from any thing that irritates andvellicates their nervous coats. When it proceeds from a slight error in diet, it will soon end spontaneously, or by drinking any thing which dilutes the acrid matter. Sometimes
it is of a more grievous kind, and may proceed from a hurt of the stomach, poison, an inflammation of the stomach, intestines, bladder, diaphragm, or the rest of the viscera. Sometimes, immediately before death, it may proceed from gangrenes of the outward parts. In acute fevers, and chiefly the malignant, a hiccup is frequent, and often fatal.

When it happens in old or weak persons, from a plentiful meal, especially from hard and flatulent aliment, a draught of generous wine, or a dram of any spirituous liquor, will generally take it away. Likewise stomachic powders mixt with Peruvian bark, and taken in generous wine, are profitable; as also if it proceeds from cold, or drinking cold liquors.

When it proceeds from other causes, especially from acid humours in the stomach, absorbent and alkalious medicines are good. If it proceeds from an acute fever, or an inflammation of the stomach, it is a dangerous disease. However, dulcified spirit of nitre, joined to an apharmacès, and given often, is proper; a dram or two of diasordium, given in the evening, may perform a cure. If it proceeds from a gangrene or mortification, it is generally incurable: but Peruvian bark, with medicines against internal inflammations, is most likely to succeed.

If a poison is the cause, plenty of milk must be taken with oil, as has been already taught.

Of the Soda, or Heart-burn.

This disorder is a heat or troublesome burning about the pit of the stomach, or its left orifice, which sometimes is extended the whole length of the oesophagus, with a pressure or spasmodic constriction, usually attacking the patient by fits. The caufe is generally hot aliment, if cold drink be taken soon after. In some it proceeds from acids, in others from aromatics, spirituous liquors, or bilious humours. It frequently torments pregnant women. This disorder is generally slight, and vanishes of its own accord; but in some it is of long duration.

In the cure, the caufe must always be attended to: If from acids, absorbents are proper, particularly crabs-eyes and prepared shrubs, mixed with a fourth or fifth part of powder of nutmeg, given to half a dram. It is common to take chalk alone, or mixed with nutmeg; but care should be taken not to be too free in its use. Oil of tartar per deliquium, given from 20 to 30 drops, in tea, coffee, broth, or warm beer, is usually efficacious; as also tincture of tartar and spirit of hartshorn. If it proceeds from bilious humours, 30 or 50 drops of dulcified spirit of nitre in water, tea, or coffee, will take away the pain. When it is caused by hot things, and draughts of cold liquor, a dram of brandy is good. Now and then laxatives should be given, to carry of the humours. In sanguine constitutions, bleeding may be proper.

Of the Cardialgia, or Pain of the Stomach.

Of all pains of the stomach, the cardialgia is the most severe. It is a spasmodic pain of the orifice of the stomach; sometimes of the right and sometimes of the left. One kind of this disorder may proceed from a sharp caustic, or poisonous matter; sometimes it arises from a redundant or caustic boil, or from a dysentery. At other times it may proceed from the blood, when any usual evacuations are suppressed, and the nervous membranes of the stomach are dilated thereby. Hence it often happens to women after the fiftieth year; and, in the cure, bleeding or scarifications are proper: on the other hand, if it is deduced from a caustic matter in the stomach, oily appeasing things, affes milk, an infusion of camomile flowers, cream, with absorbents, are proper. It must be distinguished from a painful inflammation of the stomach, in which there is a tumour like a bladder under the false ribs, chiefly on the left side, and under the pit of the stomach; but the inflammation is generally on the right side, with great difficulty of breathing. This is common in infants before they are weaned; but more so in hypochondriacs, if they are too luxurious.

If it proceeds from the remains of the aliment grown sharp, whence flatulencies arise, it generally gives way to tea or coffee alone, or a decoction of camomile flowers, especially mixed with stomachics; likewise preparations of fennel, anise, orange peel, and other carminatives are useful; as also a dram of the powder of orange peel, or camomile-flowers, with a few grains of saffron, in an ounce or two of wine.

When the stomach is too much filled with aliment difficult of digestion, or fat things, a gentle emetic will be necessary, especially if there is a naufea or reaching to vomit; after which, a sufficient quantity of warm water must be drank, to wash the stomach: this will be best promoted with a decoction of carduous benedictus, or half a dram of tartar-vitriolate, salt of worm-wood, and the like; after which stomachics must be given.

In a very violent cardialgia, from congestions of blood, vomits are improper, but bleeding necessary, with anti-spasmodics of tartar-vitriolate, nitre, cinnabar, crabs eyes, and the like, in a proper vehicle; as also spirit of hartshorn mixt with tincture of tartar to 50 or 60 drops. To these may be added emollient and anodyne clysters, and a bladder of hot milk, with camomile flowers, applied to the pit of the stomach.

Of Flatulencies and Eructations.

The cause of these disorders is generally a weak stomach, and crude flatulent aliment, such as peas, beans, lentils, coleworts, turnips, radishes, hard fat flesh, and the like; which degenerate into wind, creating great anxiety, if not evacuated, and difficulty of breathing. It is a disorder familiar to hypochondriacs, and the stomach being strongly contracted, the wind breaks out with violence.

Another cause of flatulencies are congestions of blood in the branches of the vena portae; whence proceed anxieters of the pavis cordia, difficult breathing, colic pains, and the cardialgia, and, by confluence of the stomach with the head, pains in the head, the vertigo, and watchfulness. If it arises from eructations in the stomach, evacuations are necessary first of all; and then strengtheners, aromatics, bitters, and carminatives, such as have been mentioned in the preceding discharges, with a sparing diet, and exercise.

If it proceeds from congestions of the blood in the branches of the vena portae, which is the case of hypochondriacs, or when usual bleedings are suppressed, a vein:—
WORMS are various with respect to their shape and magnitude; and their seat is in the stomach and intestines. The round are furnished with a proboscis, and a kind of crooked claws, wherefore they sometimes gnaw and tear the membranes. If these lodge in the stomach, their bites are attended with an inexplicable pain, anxiety, indigestion, nauséa, and flux of spittle; a fetid smell exhales from the mouth; the countenance is now pale, and then red; there is an itching of the nostrils, with an inclination to vomit, and a dry and troublesome cough by fits, and sometimes fainting.

When they are contained in the intestines, especially in infants, and they seem to be affisted with the tympany, with now and then a diarrhoea, and the faeces are of an asti-colour, not red; there is an itching of the nose, with an inclination to vomit, and a dry and troublesome cough by fits, and sometimes fainting.

The powder of tin has been used many years as a remedy against worms, and particularly the flat kind which often elude the force of other medicines; but the success of this depends upon the proper dose, and then it will have remarkable effects.

Take an ounce and a half of pewter, and grind it to a fine powder, and mix it with half a pint of treacle.

To adults give two ounces of the powder of pure tin, sifted through the finest hair sieve, mix it with eight ounces of treacle, after the patient has been purged with an infusion of fenam and manna.

D O F D I F F I C U L T Y O R S U P P R E S S I O N O F U R I N E.

Difficulty of urine arises generally from a stone, or from an inflammation of the kidneys or the neck of the bladder. In sanguine persons, it may proceed from the suppression of some usual hemorrhage, or from the blind piles; or there may be a congestion of blood in the spunge or cavernous part of the urethra, which may be so distended and inflated, as not to transmit the urine, or at least with great difficulty. In some it may be owing to a spasm of the neck of the bladder, or to sharp urine; in others to a palsy of the bladder, or a caruncle of the urethra; or from a tumour, abscesses, or ulcer, in the prostate gland; or from its being too large, or indurated, as often happens. Likewise in bloody urine it is not seldom suppressed; at least it is expelled with great pain and trouble, which proceeds from a congestion of blood. Emöller affirms, that a dysuria is generally occasioned from the want of mucus of the urinary passage, or its being worn off.

As the causes of an ichury are various, they ought to be carefully distinguished from each other. When it proceeds from an inflammation of the kidneys, the pain and heat are principally in that region, attended with a fever; if from a stone in the kidneys, it is accompanied with vomiting; if from a stone in the bladder, there is a violent pain.
pain in the bladder, which is extended to the very extremity of the urethra; a mucous or pus is excreted with pale urine; and, upon proper examination, the stone may be felt; but the most certain sign is searching the bladder with a catheter. When this disorder arises from a stone in the urethra, it may be easily felt. If from an inflammation of the neck of the bladder, there is a tumour and pain in the peritoneum; but it may be felt perceived by throbbing the finger into the anus, and turning it up towards the bladder; for a tumour will be perceived by the physician, and by the patient a burning and pressing pain; and when a catheter is introduced into the urethra, an impediment will be felt near the neck of the bladder, which will hinder it from proceeding further. To these signs may be added, when the disorder is great, a tenesmus, a constrictiion of the anus, an anxiety of the praedicordia, coldness of the extreme parts, vomiting, and a freble pulse. When the cavernous substance of the urethra is too much distended with blood, and the urine is suppressed, a silver pipe cannot be admitted into the urethra, especially if the patient abounds with blood. When there is a spasm in the neck of the bladder, it appears from the causes aforesaid; and likewise the patient perceives a spasmmodic constringion about the neck of the bladder, and a catheter will pass thereto, but no farther; and there are no signs of a stone in the urethra or bladder.

If the urine is sharp, and produces a spasm, we may discover it from its being very flinking, especially if the patient is old or sebaceous; and there are many saline particles in the urine like lime. When there is a caruncle in the neck of the bladder, it may be known from the signs mentioned in the lues venerea, where the cure is treated of. An aboeel in the prostate gland often is mistaken for a caruncle. When a feirrus of the prostate gland is the cause of a supreflion, there is a hard or indolent tumour in the perineum, or at least the pain is not great.

When the urinary passages are obstructed by solid bodies, that is, the pelvis of the kidneys, the ureters, or the neck of the bladder, or the urethra, from a stone contained therein; if it be small, diuretics will be proper, which are mentioned in a fit of the gravel or done; to which may be added a decoction of eringo-root and Ephom salt or Selters waters taken often therewith. But if the stone is large, and cannot be excreted by this means, strong diuretics are highly hurtful, and must be cured by fection; (see Surgery.) But if the patient is too weak, or too old, and cannot undergo the operation, the stone, if possible, must be driven back; and the pains must be appeased with antispasmodics internally, and with lenients, lubricant and oily medicines, as well as gentle anodynes: Externally, with emollient clysters, ointments, liniments, and baths. If the pains are violent, lenient injections may be thrown up into the bladder, of falad, linseed, and white poppy oil, or oil of sweet almonds, or a decoction of linseed or roots of mallows in milk, with the addition of a little fresh butter. This done, the patient must have recourse to lime-water.

If the urine is suppreffed from an inflammation of the kidneys or bladder, diuretics are pernicious, and mineral waters not safe; but rather refrigerating nitrous remedies,
especially if the cafe is venereal. Then mineral waters
may be drank, either alone or with warm milk, for se-
veral weeks, or the hot bath waters: to these may be
added injections of a decoction of the traumatic herbs,
such as agrimony, St John's wort, plantain, or yarrow;
or, in their stead, milk with syrup of marsh-mallows, or
fresh butter, or oil of St John's wort.

If there is a difficulty of urine in pregnant women
towards the laft months, diuretics must be fhunned. The
best remedy in this cafe is to cafe the pressure upon
the part; but, if that will not do, to ufe a catheter.

Lastly, if it proceeds from a swelling of the proftate
 gland, or if it is become feirchous, it must be treated as
fuch, as will be hereafter taught.

But, if these remedies will not do, the bladder muft
be pierced with a trochar, which is called the puncture
of the perinaeum; and, when the perforation is made,
the water must be evacuated, as in the droify: The in-
strument muft be left in the wound, and be faftened in
such a manner that it does not fall out, that fo the urine
may be made as often as there is occafion: It is a trouble-
some operation, but the only one left.

Of the Diabetes.

A Diabetes happens when the urine comes away
crede, exceeding the quantity of liquids drank, attended
with weaknefs, which generally proceeds from the kid-
nels, which are too weak and lax, especially in thofe who
have been accuftomed to drink too much. Heift.

Liftier obferves, that a diabetes comes flowly on, and
is a long while in breeding. In the beginning, the mouth
is dry, and the fpittle a little white and frothy; the urine
being something more than usual, with a small thrill. A
heat begins to be perceived in the bowels, which is a little
punfent; the patient falls away, and the mind is anxious
and untable. In time the thrill greatly increafes, the
urine is plentiful, and the body waftes. When they
make water without intermiffion, the thrill becomes in-
tolerable; and, though much is drank, it is not proportion-
able to the water. When the urine is retained a little
while, there is a swelling of the loins, ilia, and teffes,
and it comes away with pain. Now death is at hand.
The urine is pale, not fweet, but it is more fweetish at
laft than at firft.

Strengtheners, moderate aftringents, and species of
hyacinth, with coccus maris, are good in this difeafe,
efpecially with anodynes: or Japan earth, or the tincture
of vitriol of mars, red wine with water in a small quan-
tity; the drink should be fparring, and all exceffes avoid-
ed. Exercise and frictions of the body are likewise prof-
bitable, becaufe they Strengthen the parts, and increafe
perpiration.

Liftier fays, almonds and a milk diet are proper in this
dilemper; as also wine with ginger; allowing in the mean
time a draught of milk and water to allay the thrill.

Wilfs declares, he has often prefcribed tincture of an-
timony with good success; and lime water with faflafra,
aufieeds, raifins, or liquorice.

Of the Chlorosis, or Green-Sickness.

Sydenham looks upon this to be a species of the hy-
feric affection, and is known by a paleness and discolora-
tion of the face and the whole body. The complexion
appears a little subluid or greenish, with a red or dark
circle under the eyes; the face is bloated, the eyelids and
ancles are apt to fwell; the whole body is heavy and dull;
there is a tenfive laffitude of the legs and feet, difficulty
of breathing, palpitation of the heart, pain of the head,
a feverifh pulse, a drowfinefs; a pica, or defire of eating
unfit things, fhuch as coals, chalk, &c. and a fuppreffion
of the menfes. The clavus hyftericus often attacks pa-
tients in the height of this disorder.

The cure is to be attempted with chalybeate medicines,
such as are prefcribed in the hyferic disorder, given ac-
cording to the patient's age, drinking wine after them;
or the correlorating infefion with angelifa root. If the
patient is not very weak, he may be purged once or twice
before the courfe is entered upon.

Heiftier recommends attendants, evacuants, and Streng-
heners, with a good diet and exercife; particularly from
v to vij grains of powder of feel, with half a scrupps of a
proper eliafaccharum, or with bitter extracts given in the
evening; as alfo emmenagogues at due times, with pe-
diluvia and bleeding in the foot about the time of men-
struation. If these will not fuffice, he thinks marriage
a certain cure.

Of the Suppression of the Menses.

As soon as a healthy female arrives at her full growth,
she generates more blood than can be conveniently con-
tained in the veffels; wherefore the superfluity is evacu-
ated by the uterine arteries, and is called the Menfes.

Boerhaave obferves, that in a fuppreffion of the men-
ifes there is a plethora, with a litleffnefs to motion; a heavi-
nefs, a paleness, a pain of the loins and of the groin;
all the functions, whether natural, vital, or animal, are
deprieved. Sometimes the menfes will force a way thro'
the eyes, ears, noftrils, gums, the falivial ducts, bladder,
breafes, skin, wounds, or ulcers.

Hence often arifes a depravation of all the viftera, as
alsoiffeafes without number, partly from a putrefaction
already begun, and partly from the hurt which the veffels
have received.

From this disorder proceed want of appetite; the pica
and malacia, or a depraved appetite. If it is habitual
and obfinate, a feirrus or dropfy of the womb are to be
feared, or a rupture of some blood-veffel, efcpecially of
the lungs. It is not fo dangerous when the uterus is not
infarfed, or when there is no other fymptom of the men-
ifes. If this difeafe is attended with the fluor albus, it
may become habitual, and from yellow become green and
acid, corroding the uterus, and laying a foundation of a
dropfy therein.

Things which retard the menfes are, immoderate cold,
sorrow, a fudden fright, too great evacuations, increafa-
ing
This disorder is to be cured in the same manner as the
ytic affection; but, if the remedies for that fail, the
patient must take every morning five spoonfuls of an hy-
tic julep, with twelve drops of spirit of hartshorn; and
every night a scruple of compound powder of myrrh made
into a bolus, or pills with syrup of lemons. Allen recom-
meds cantharides and camphor; the dose is from two
grains to fix.

Hoffman directs chalybeates, or pills made of aloes,
myrrh, saffron, amber, caltor, and round birthwort. Pit-
corn thinks mercury more efficacious than steel.

The cause may be referred to a copious and impetuous-
flux of blood to the uterus, and an unequal and im-
peded reflux by the veins; which diffusing and relaxing the
uterine vessels, make the orifices too wide, or rend and
corrode them, by which the blood flows too freely.
This may happen from a plethora, or when there has
been a long supposition, or an abortion, or a difficult la-
bour. It generally happens to women about the fiftieth
year, when the menes are going to leave them; and not
always without danger. It sometimes happens to women
upwards of sixty, which, if attended with a flow fever,
haunts death.

The concomitant signs are generally these: A tension
and inflation of the hypochondia, a heavy pressing pain
about the loins, sometimes with a chilnfs; a cold hs of
the extremities, a sinking of the veins, a paleness of
the face, a quiok pulse, with an internal heat, a coldive-
ufes, and little urine; all which fhew there is not only
a debility and laxity of the uterus, but fpasmotic fric-
tures of the vafcular and nervous parts, which force the
blood to the uterus.

If the body is cacochymic or scorbatic, or full of bad
humours, or afflicted with the venereal disease; when the
terica are unfound, and the liver, ffeen, and meferic
veins, are fuffed with thick blood, the cafe is dangerous
and troublesome; for the fault of the fluids and cachexy
continually increafe: Besides, the more the strength is
weakened, the more the morfhach and digestion are hurt;
the blood is depraved, and the excrementis disturbed and
leffened. When this happens to women when the child
is dead, their lives are in great danger, and nothing but
fpeditous affifance from a man-midwife can fave them. The
cafe is also dangerous when the fecondines are violently
extracted, or parts of them are retained, and which some-
times degenerates into moles.

Immoderate evacuations are produced by a fedentary
life, which gives room for abundance of thick chyle and
milk. It is caufed likewise by too frequent ufe of falt,
ae, and feafoned meats; by fpirituous liquors, &c. by
violent agitation and paffions of the mind, from loffes,
gaming, love, anger, &c. It may be obferved likewise,
that violent exercife does as much harm as the moderate
is serviceable, especially if the patient is subject to this
vex from other cafes; fuch as immoderate repetitions of
the venereal act, efpecially in women of a delicate confi-
uation; too frequent child-bearing.

The cure fhould refti the refraining a prefent flux,
and the keeping within bounds a future one.

It should be begun with reft, if convenient, in bed;
the patient lying on her back, and filent as much as pos-
fible. Bleed in the arm, according as the constitution and
strength of the patient, as well as the urgency of the
symptoms, will admit or require. Avoid ligatures of the
limbs. Let the patient fare flenderly on veal and chicken-
broths,
broths, 6th soups; and drink a pint of nettle-tops, yar-
row, and plantains, with orange-peel, or of the greater
comfrey; if he be hot and bilious, with linseed.
If these fail, have recourse to astringents.

Of the Fluor Albus, or Whites.

The fluor albus consists in the efflux of a whitish,
lymphatic, serous, or aqueous humour, from the matrix.
It is sometimes white, sometimes pale, yellow, green,
or blackish; sometimes it is sharp and corrosive, some-
times foul and fetid; the face is discoloured, there is a
pain in the spine of the back, the appetite is lost, and
the eyes and feet swell. Some women have a periodical
flux of whites instead of the menses.

The symptoms are, a pain and weight in the loins,
which is worst in the lymphatic flux, as being attended
with a swelling of the uterus, turrid urine, barremefs,
a proneness to abortion; a loathing of some things, and
longing for others; indigestion; thicknefs and crudity of
secretion becomes morbid, it is called the fluor albus.

At first the parts of the membrana adipofa of the loins,
and carry off all the fat of the body.

The fluor albus sometimes is discharged from the ute-
rine vesicles, and sometimes from the glands of the vagina:
at first it flow by day, and of the face by night; difficult breathing,
palpitation of the heart, syncope, relaxation of the liga-
ments of the heart, a total or partial procdentia uteri:
if the flux is acrid and corrosive, it ulcerates the vulva;
creates phlyctenae; which last generally proceed from a
scirrhus or cancer in the uterus; a fever fever; droplings
of different parts; of which, or a consumption, the patient
generally dies.

It may be known from a virulent gonorrhoea; because
this is attended with pain and an inflammation of the ex-
ternal parts of the pudenda, chiefly about the clitoris;
heat, sharpness and difficulty of urine, pain in coition;
it makes its progress sooner. If the gonorrhoea is inve-
ently confined to fewer objedts.

Besides arterial blood, the menses consist of redundant
lymph or serum, chiefly from the membranous cells, and
ventricles of the glands of thofe parts of the membrana
cellulofa which are more immediately connected with the
kidneys, uterus, and ovarium. When this lymphatic
secretion becomes morbid, it is called the fluor albus.

The parts of the membrana adipofa of the loins,
and carry off all the fat of the body.

Salacity in women, attended with impudence, refl-
lefsness, and a delirium, is called the furor uterinus.

It arises from a too great sensibility or inflammation
of the pudenda, or parts wherein the venereal stimulus
refides, which are chiefly the clitoris and vagina; or the
too great abundance and acrimony of the fluids of thofe
parts; or both these caufes may exift together.

In the delirium maniacum, the patient is entirely flame-
ufs; in the melancholicum more referred, and her folly
is confined to fewer objects.

When this flux is attended with a virulent gonorrhoea;
because this is attended with pain and an inflammation of the ex-
ternal parts of the pudenda, chiefly about the clitoris;
heat, sharpness and difficulty of urine, pain in coition;
it makes its progress sooner. If the gonorrhoea is inve-

The indications of cure, are to diminifh the heat and
feverilaty maniacum, than when the delirium is effential,
and the furor uterinus ensued.

It is difficult to cure in those whose menses are difficult
at first; in inveterate cafes; in old subjefts. It is easier
cured, when the furor uterinus is effential, and the deli-
rium symptomatic, than when the delirium is effential,
and the furor symptomatic. The maniccal delirium is
harder to manage than the melancholic. If it continues
a month or two, the fault of the brain becomes obli-
uate, for it degenerates into real madness.

The indications of cure, are to diminish the heat and
senifibility of the affected parts; to cool, sweeten, and
dilute the blood, and to render it bafmatic; or to pursue
both intentions at once.

The firft indication is answered by frequent and copious
bleedings, as in an incipient madness; even to eight times
in
Of an Inflammation of the Womb.

An inflammation of the uterus appears from extraordinary heat, and a fixed pain in the groin, with an acute fever, a pain in the loins and belly, an inflammation of the abdomen, a flux of pus and blood; heat, and difficulty of urine; tumour, pain, heat, and tension of the hypogastric region; redness of the os uteri, and great heat of the vagina. If the fore-part of the uterus is affected, there is a dysuria or heat of urine; if the back part, a tenesmus, frequenttings and cardialgia, a burning fever; or, if the inflammation is violent, a lypyinia, in which the external parts or extremities are cold, and the internal burn, and the pulse is imperceptible; a delirium and phrensy: the breasts swell in proportion as the inflamed uterus.

This disease may be said to be superficial or more grievous and profound. It is easy formed in child-bed women, and frequently accompanies the milk fever; and may be cured in a few days, if rightly managed: But when it is very intense, and attended with grievous symptoms without remission, it kills on the seventh, ninth, or eleventh day; and a white miliary fever generally supervenes, which is the worstomen, for it shows a mortification of the uterus. When this fever happens, there are spastic and painful strictures in the abdomen, the flux of the uterus is stopped, the body is coltive, the feet are cold; there is an urgeing to make water, which is painful; the head looks red, and swells; the eyes shine: drops of blood fall from the nose; the mind is disturbed; the sleep is little, with terrifying dreams: there is likewise a most difficult breathing, faintings, convulsions, a phrenetic delirium, which commonly have a fatal tendency.

This disease should be distinguished from an inflammation of the bladder or rectum; which may be done from the place of the pain: in that of the bladder it is superficial, as it were in the integuments; in that of the rectum it is very deep; as if about the os sacrum; in that of the uterus it is in the middle, with a violent heat in the vagina, if the finger is introduced. If the bladder is affected, there is an extraordinary heat and retention of urine; and a tenesmus, if in the rectum: In the bladder; the pain is precisely on the os pubis; in the rectum, the anus is affected. If these symptoms happen in an inflammation of the uterus, they are more flight. If the inflammation is not resolved, it generally ends in a mortification, ulcer, or cancer. A mortification four days, if nothing forbids; if the pains, there is no danger. She must likewise be purged, as mad folks are, with jalap, fcammony, diastiglid. The dose must be increased one third, as being hard to purge. A vomit may be gave on the third day; and then, if it is still retained, a vomit may be given on the fourth day, and is known by a weak, languishing, and intermitting pulse, and by a sudden cessation of all the symptoms.

A gangrene or mortification happens on the fourth or fifth day, and is known by a weak, languishing, and intermitting pulse, and by a sudden cessation of all the symptoms.

If the disease exceeds the time of the former terminations, and the inflammation is superficial, it is apt to turn into an induration or firrhous; which ulcerating, becomes a cancer, and is incurable. If, about the twenty second day, there is a renitency or hardness, and a dull heavy pain in the region of the uterus, there is a firrhous formed.

Women in child-bed sometimes have the womb inflamed from the fault of unskilful midwives, or hard labour; or the lochia are stopped by pains, or hysterical spasms, dread, or cold; wherefore proper precautions should be used to prevent it; which may be done by keeping them under a gentle diaphoretic regimen, and by allaying the almost febrile heat. Oil of almonds is proper alone, or with a fourth part of sperma ceti, given daily to half an ounce in chicken-broth; externally the whole abdomen should be anointed with oil of dill, camomile and white lilies, of each an ounce, oil of caraways a dram, or a dram of camphor; laying a warm napkin doubled over the fame.

The tumult being thus appeased, the lochia are to be promoted with pills of bitter extracts, temperate rhenatious gums, and aloes well corrected, of which xv gr. is a dose morning and evening, to be continued from five to eight days. These are also good when the after-birth or part of it is retained.

If there is a fever, the belly is diffended with wind, the lochia are retained, and the spasms tend to the upper parts, you must bleed in the foot.

The drink may be chicken-broth, with scorzonera root, fucory, and shavings of hartshorn boiled therein. As also temperating and resolving powders made of crabs-eyes, and their solution nitre, and fai polychrest. To which may be added clysters of whey, camomile-flowers, mug-wort, sedge, &c. with honey, nitre, and fat of hens.

In women out of child-bed the inflammation generally happens in the neck of the uterus and the vagina; and then, besides the foregoing things, you must apply episthmes to the pubes, uterine injections, peffaries, and fuppositories. The epithem may be of arquedebutic water four ounces, essence of saffron, camphorated spirit of wine, of each two ounces, nitre a dram, diffolved in elder-flow water; and, as circumstances require, mixed with vinegar, or rue, or fcorbim, and applied with a double cloth. The injection may confit of afeis milk, with flowers of elder-myrt, and saffron; and a little nitre may be added to the decoction. The tenesmus may be appeased with emollient half baths, or with an ounce of oil of sweet almonds, and xij grains of saffron, injected into the anus. These remedies are useful in case of a suppuration.
Of the Abscess of the Womb.

Abscesses of the womb are either inflammatory, tuberculous, or septicatus.

The symptoms of an incipient abscess are the same as the inflammation, such as pain, heat, tension, etc., which intermit for some time, and appear again, when the suppuration begins; of which the purulent is most fertile, the septicatus the least. When the abscess is formed, all the symptoms of inflammation vanish: but coldness of the extremities, a lowering of the fever, and marasmus, gradually increase from the absorption of the pus into the blood.

If no inflammation has preceded, and the patient was subject to obstructions, especially of the glands of the uterus, and had a lymphatic flour albus, it may be tuberculous; if the tumour is soft and indolent, it may be septicatus; but these are rare. The place may be partly covered by the touch, but more especially by the complaints of the patients.

If it breaks into the bladder, and passes off by urine, or into the rectum, and is discharged by fistula, or into the groin, it is dangerous; if into the abdomen, incurable.

If it breaks into the vagina, it may become an ulcer, which is commonly mortal; or the patient may perish by the symptoms of the poison.

with a soft fungous flesh about the suture; you have the
progres to a confirmed cancer. The matter never be-
comes pus.

An ulcer of the uterus resembles a cancer, when a pu-
trid tances ulices from the corrupted fulbance of the womb,
with great vench, exquisite pain, and grievous symptoms.
This disease is almost incurable.

The principal symptom of a cancer is pain, which is
attended with reddiness, burning, indigestion; which
produce a low fever, consumption, marasmus, and the like.
A hard, renient, painful tumour, preceded by an in-
dolent scirrhus, plainly evinces the existence of a cancer.
If nothing is discharged by the uterus, but a limpid, pel-
ucid lymph, it is an occult cancer; if acrid serum, or
ichor, it is open.

There is nothing to be done in this case, but by demul-
cents and lenients. If there is any hope of cure, it must
be placed in foies milk, the Selters waters, and in bath-
ing in soft water wherein wheat-bran has been boiled;
in which the patient must fit for an hour, or longer. She
must abstain from all sharp, acrid, stimulating, and heating
things.

Of the Procidentia Uteri.

It is a common disorder; and the uterus presents it-
self in the vagina between the labia, or is quite visible.
Sometimes it is only the internal membrane of the vagina,
somtimes the body of the womb.

This disorder is rarely dangerous, for women bear it
a long time.

The cure consists in reducing the uterus, and retaining
it in its place. To reduce it, order a simple clyster to
evacuate the rectum; the patient should also bleed three
or four times; Then emollient cataplaams should be used
of white bread and milk, or of emollient plants; emol-
lient baths are also to be employed. The parts being
thus relaxed, the patient must lie on her back, with her
hips higher than her head, and her legs quite asunder;
then put back the uterus by degrees, where you find the
least resistance, and without any violence. This done,
the patient must be confined to her bed for about fifteen
days, with her thighs closed, or her legs acroos, and her
hips raised.

The cure must be completed with astringent injections,
baths, and pessaries; with emulsions of frankincense,
red roes, and maltich.

Of CHILDRENS DISEASES.

Of Disorders from a Retention of the Meconium.

Infants newly born, from a retention of the meco-
num and other forbid matter in the prime vitre, are sub-
ject to gripings or pains in the belly, which produce con-
stant crying, hiccups, the jaundice, wakefulness, red-
leensfs. fallings, frights, convulsions, and epilepsies;
which, unless timely prevented, are fatal.

To carry this off, infants should suck the first milk of
their mother, if they give suck; otherwise they should

Of Disorders from Cordivenes and Wind.

If after some time the excrements become hard, with
cordivenes and a retention of wind, they will cause the
symptoms abovementioned. In this the same remedies
may be used, till the child's belly is open, and the acid
or corrupted milk should be corrected with absorbent
and tafaceous powders; whereof half a scruple is a dose.
Harris believes an acid to be so predominant in infants,
as to cause all their diseases. Boerhaave affirms, if ab-
portants are useful at any time, they must be in these cafes,
and orders vij grains of the tafaceous powders three times
a day.

The nurse must forbear to feed upon any thing that is
four or acid.

Of Watching, or Want of Sleep.

Want of sleep proceeds from the gripes, or coddive-
ens, and wind and pain occasioned thereby: we judge of
the health of children by their sleeping quietly, and of their
ilness by their watching, crying, and screaming. Watch-
ing may proceed from the milk being corrupted in the flo-
ach, or from cordivenes, or from wind.

In this disorder the body should be always kept open,
first by a clyster, and then a purge; and the absorbents
are to be given, and carminatives, particularly powder of
anifeed; and the belly is to be anointed with carminative
oil. Soon after the purge, give two drams of oil of al-
monds. The nurses should avoid acid and flatulent things,
and catching cold. Opiates, diascordium, and theriaca,
must never be used, unless in cafes of extreme necessity.

Of the Aphthae, or Thrush.

The aphthae are little whitish ulcers affecting the whole
superficies of the mouth, that is, the lips, gums, checks,
tongue, palate, and fauces; nay, they even descend through
the oesophagus to the stomach and intestines, and to the
anus; but then they are very dangerous, and commonly
put a period to the infant's life.

Boerhaave says, if the aphthae are of a pearl-colour,
pellucid, white, few in number, superficial, soft, and
fall off easily, apt to return in part, they are of the best
sort; but if they are white or opaque, like bacon, yellow,
brown, black, thick, denfe, running together, hard, te-
nacious, constantly restored, corrosive, they are bad.

Harris believes gargles to be of little service, because
infants cannot use them, inasmuch as they swallow every
thing that is put into their mouths. He therefore relies
for a cure on the tafaceous powders, and the moth gentle
cathartics, and believes them sufficient.

Allen says the decoction of elm-bark is the best gar-
garmin for the cure of the aphthae.
This disease often attacks adults in acute diseases and inflammation of the viscera. Boerhaave observes they are most common among the northern people, that inhabit low marshy places, and often attend a continual purrid fever, or an intermittent becoming continual; and that they are ushered in with a diarrhoea, or a dysentery, a nauseae, vomiting, loss of appetite, great anxiety about the precordia often returning, some great evacuation of the fluids, a fluxor and dulness, illeoptics, a perpetual complaint of weight about the stomach.

If it wheezy, hot, diluting, resolvent, and detergent medicines must be given, that the crust may be dispossed to fall off easily.

Huxham advises, when the aphthae supervene in fevers, to use gargles frequently of emollients and detergents, made with fuke, hydromel, decoction of turnips, &c. To give rhubarb inwardly, chiefly if the patient is gripped and loofe, adding an aromatic astringent with absorbents.

Of the Stoppage of the Nose.

There is often an excoriation of the parts near the pudenda, chiefly of the groin and scrotum; in the wrinkles of the neck, under the arms, and in other places, proceeding from the acrimony of the urine and sweat. From this proceed itching pains, crying, watching, and redness.

To remedy this, the parts affected may be washed often with warm water, and sprinkled with drying powders, such as chalk, burnt hartshorn; but especially tutty, and cerufs, which may be tied closely in a rag, and the powders shook out on the disordered places.

If the parts affected are more sore, and tend to a real ulceration, it will be proper to add a little faccharum sanitatum to the powders. Likewise a little white vitriol dissolved in spring water, and daubed upon the part, will dry and heal it very powerfully.

Of the Stoppage of the Nose.

The nostrils of infants are often plugged up with a greasemucus, infomuch that they can scarce breathe, or suck, or swallow; which renders them very unquiet and uneasy. To cure it, after a suitable purge, diffuse two or three grains of white vitriol in half an ounce of molarium water; then filter it, and apply it now and then to the nostrils with a linen rag.

Or you may apply oil of sweet almonds, impregnated with the oil of molarium, to the bottom and sides of the nostrils, which will resolve the filth, and render the respiration free.

Of the Scabby Eruptions and Crusta Lactea.

The heads of children are often troubled with aches or scabby eruptions; and if the face is affected with them, they are called crusta lactea. These are expelled by the benefit of nature; and, before the eruption, the infant is often troubled with epileptic fits from the irritation of the morbid matter.

If the humours strike in, either spontaneously or by improper applications, or if the exanthemata are of a blackish colour, they are very dangerous, and the infant generally falls into an asthma or a fatal epilepsy.

In the cure, externals, and especially such as are repelling, should be avoided; and things should be given inwardly which correct and temperate the blood, and expel the noxious matter by a diaphoresis. After the prime one is purged, both the nurse and child should take alexipharmics in the morning, and the tallow powders with calx of antimony, amber, and cinnabar, in the afternoon.

Externally, nothing of sulphur or mercury should be applied, or repelling lotions, or any thing cold. To mollify the febfs, fresh butter, or calves marrow, or cream, are sufficient. This case often proves obstinate; and then the nurse should observe a strict regimen, take sweeteners of the blood, and purgatives now and then.

Of a Diarrhoea and Vomiting.

The diarrhœa of infants is not to be stopped, either with astringents or narcotics; for astringents turn the flux of sharp humours towards the noble parts, and endanger the life of the child; and, though narcotics appease the ferocity of the turbulent humour for a time, yet they afterwards break out with greater force. Besides, opiates are too powerful for the tender constitution of infants, and must not be given at all, or with the utmost caution. In slight cases, diacordium may be ventured upon, to five or six grains; but, if there is a fever, it cannot be given without danger.

Therefore the best way is to give chalk, coral, pearls, and the like, of which about half a scruple is a dose; which will abate the orgasm of the humours, without kindling any new heat; after which the cure may be completed with rhubarb, from five grains to half a scruple, in solutive syrup of roses.

With regard to Vomiting, if there is great plenty of febrous and noxious humours in the stomach, infomuch that the stomac can retain nothing, if the child is a year or two old, he may safely take some grains of ipecacuanha; Harris says xv: but surely a third part of that quantity, nay, one or two grains, may be sufficient; for this does not require the swallowing of much liquor after it as some others; and yet clears the stomach of crudities, viscidities, and other bad humours.

Of Difficult Breeding the Teeth.

Among all the disorders which afflict children, there are none that generate such grievous symptoms as difficult dentition. About five or six months after birth, the teeth generally begin to make their appearance; first the incisors, or fore-teeth; next the canini, or dog-teeth; and lastly, the molares, or grinders. About the seventh year there comes a new set; and at twenty-one the two inner grinders, called dentes sapientise.

At the time of cutting their teeth, they flavor very much, and have a diarrhoea, which is no bad sign; but when it is difficult, especially when the canine teeth begin to be in motion, and to make their out-way out through the gums, the child has startings in his sleep, tumours of the gums, ulcers, inquietude, watchings; a loozeness of joints, greenish flops, the throat, fever, difficult breathing, suffocating catarrhs, convulsions, epilepsies, which often end in death.
It shews dентition is like to be bad, if the child is perpetually crying, thrusts his fingers into his mouth, and bites the nurse’s nipples; if unequal tubercles are perceived in the gums, both by the sight and touch, where the teeth are expected to appear; if there is heat in the mouth and the whole body; if they start without a cause, especially in sleep. These do not come on without great swelling, and sometimes a diarrhoea, as was mentioned above.

Morgan affirms in this case, it will be best to abate the cervecence of the blood with diluters; to appease the pain with gentle opiates; to open the body with purges and clysters; to draw off the fermented serum by blistering; to promote the cutting of the teeth by cooling, relaxing, and opening the gums; for this purpose diascinum is good; or a strong decoction of marsh-mallows and poppy heads, in thick milk, cream, or nears-foot oil: These take off the heat, and allage the pain.

**Of the Rickets.**

Children are seldom attacked with rickets before they are nine months, and after they are two years old; but it frequently happens in the intermediate space between these two periods. It may proceed originally from the disorders of the parents, and may be increased by those of the nurse.

It is likewise promoted by feeding the child with aqueous and mucous substances: crude summer-fruits, fish; by unleavened farinaceous aliment, and too great a quantity of sweet things; by an intermittent tumultuous ague, or other chronic or acute disorders; by a striking in of the itch or herpes; by the suppression or injudicious cure of ulcers; by being enervated with baths, fomentations, ointments, or moif vapours; by continual rest in a perforated chair, with his coats up.

The disorder is known, in those who cannot walk, from the caufes preceding; from his brothers or sisters having the same disease; from a fiabcul tumour of the head and face; from a flabby loose skin; from a swelling of the abdomen; from a falling awa y of the reft of the parts, espec ially of the muscles; from protuberances of the epiphyses of the joints, such as the wrists, ankles, knees, elbows, &c.; from the magnitude of the jugular veins and arteries, while the rest decrease. The legs grow crooked.

In those that have begun to walk, besides the former signs, there is a crawling, deility, and tottering in his motion; which soon proceeds to a constant desire of sitting, and afterwards changes to lying down: insomuch that nothing at laft is moveable, but the neck and head. Add to these, an early wit, an underftimulating which exceeds his age, while the appetite and digestion continue unhurt.

As he grows older, his head is enlarged, with ample futures; his thorax is comprimedit on the sides; and his sternum rises up sharp, while the extremities of the ribs are knotty. The abdomen is protuberant, and the teeth black and carious. These disorders sensibly increasing, are the cause ever after of pernicious diseases of the same kind; principally a spina ventosa, and a caries of the bone.

In the mean while a low feverish disorder preys upon the whole body, till the time of death; and then all the fibres, vessels, and viscera appear to be soft, flabby, and the fluids dissolved and mucous.

The cure is to be attempted with light, nourishing, dry aliment, not fat, but seasoned, and taken often: With a little found drink, such as beer, not stale, but well boiled and fine: With a dry warm air, and dry warm woolen clothing: With being carried about in the arms, and often shook, swung, and put in motion: With being driven in a vehicle over the stones: With repeated friffions with warm dry flannel, sprinkled with aromatics; especially the abdomen and spine of the back: With prudently repeated blistering, with strengthening purges, for several days successively: As also by the continued use of strengthening, drying, antiscorbous remedies, and such as raise the spirits.

Particularly for food, the bread should be biscuit, with a little saffron and spices. The flesh should be pigeons, pullets, veal, rabbets, mutton, gently roasted, minced, and mixed with biscuit, falt, a little parsley, thyme, nutmeg, or the like.

Likewise rice, miller, pearl barley, boiled with raisins; to which add a little wine and spice. The drink may be generous French red wine, of which give an ounce three or four times a-day.

**Pocket-Medicines.** In surgery, those which a surgeon ought to carry always about him, in a box or convenient case.

Thofe, according to Heifler, are the common digestive ointment, and the bronc or Egyptian ointment, for cleansing and digelling foul ulcers, and some vulnerary balsams, as the linimentum arcei, or the balm of Peru, of Gilead or Capivi, or the Samaritan balm: to these must also be added a platter or two, as the

Vol. III. No. 76.
MEDINA, a city of Arabia Deferta, situated two hundred miles north-west of Mecca; in E. long. 40° 3'.

This is called the city of the prophet, on account of Mahomet's being received and protected by the inhabitant's on his flight hither from Mecca, where the Mahometan era commences.

MEDITERRANEAN sea, extends from the straits of Gibraltar to the coasts of Syria and Palestine, being upwards of 2000 miles in length, but of a very unequal breadth; the west-part of it separates Europe from Africa; and the Levant or east-part of it divides Asia from Africa.

MEDITULLUM, is used by anatomists for that spongy substance between the two plates of the cranium, and in the interstices of all laminated bones.

MEDIUM, in logic, the mean or middle term of an syllogism, being an argument, reason, or consideration for which we affirm or deny any thing: or, it is the cause why the greater extreme is affirmed or denied of the less in the conclusion.

MEDIUM, in arithmetic, or arithmetical medium, or mean, that which is equally distant from each extreme, or which exceeds the lefser extreme as much as it is exceeded by the greater, in respect of quantity not of proportion: thus 9 is a medium between 6 and 12.

MEDIUM, in philosophy, that space or region through which a body in motion passes to any point; as thus air, is the medium wherein bodies move near our earth; water, the medium wherein fishes live and move; and glass is also a medium of light, as it affords it a free passage. That density or consistence in the parts of the medium, whereby the motion of bodies in it is retarded, is called the refitance of the medium; which together with the force of gravity, is the cause of the evacuation of the motion of projectiles.

Subtile or aetherial Medium. See ETHER.

MEDLAR, in botany. See MELEUS.

MEDULLA, in anatomy. See ANATOMY, p. 147.

MEDULLA OBLONGATA. See ANATOMY, p. 287.

MEDULLA SPINALIS. See ANATOMY, p. 288.

MEDUSA, in zoology, a genus of insects belonging to the order of molucca. The body is gelatinous, roundish, and depressed; and the mouth is in the centre of the under part of the body. There are twelve species, all natives of the sea.

MEDWAY, a river which rises in Ashdon forest in Suffolk; and running through Kent, is divided into two branches by the Isle of Sheppy, one of which is called East Swale, and the other West Swale.

MEISSEN, once the capital of the marquisate of Mißen or Missia, in Upper Saxony, on the river Elbe, ten miles north of Dresden.

MELOPODIUM, in botany, a genus of the dicotyledonous monoecious clafs. The calyx has four segments; the petals are five; and the stamens are usually placed in a single whorl, and the pistil has one or two ovules.

MELOANCHOLY, in medicine, a kind of delirium, attended with gloomy thoughts, heaviness, and sorrow. See MEDICINE.

MELANE, in natural history, a very beautiful fossil of a dense, compact, and regular texture, and of an extremely bright pale yellow, resembling nothing so much as the purest gold; it is remarkably heavy, and is usually found in little irregular masses of the bigness of a pigeon's egg, which are broken with a slight blow: but it is usually met with in the form of a fine gold-coloured efflorescence or vitriolic and pyritical bodies; or in loose, shatterly, and friable masses of a more dusky yellow; in which latter state it so much resembles a native sulphur, that it is frequently mistaken for one; however, it is not inflammable; but calcines in the fire to a greyish powder, which, by burning longer changes to a deep and fine purple.

The Greeks used it externally, as a gentle emollient and a styptic: they made it an ingredient in their ointments for old ulcers, and used to sprinkle the powder of it on fresh wounds to stop the hemorrhage.

MELANTHERIA, in botany, a genus of the monogynia class. The corolla consists of six petals; and the filaments are composed of the long unguis of the corolla: there are three species, none of them natives of Britain.

MELANURUS, in ichthyology. See SPARUS.

MELASTOMA, in botany, a genus of the decandria monogyne class. The calyx is bell-shaped, and has four segments; the petals are five, inserted into the calyx; and the berry has five cells. There are twelve species, none of them natives of Britain.

MELCHITES, in church-history, the name given to the Syriac, Egyptian, and other Christians of the Levant. The Melchites, excepting some few points of little or no importance, which relate only to ceremonies and ecclesiastical discipline, are in every respect protected.
MELCHISEDCHIANS, in church history, a sect which arose about the beginning of the third century, and affirmed, that Melchisedek was not a man, but a heavenly power, superior to Jesus Christ: for Melchisedek, they said, was the intercessor and mediator of the angels; but Jesus Christ was so only for men, and his priesthood only a copy of that of Melchisedek.

MELEAGRIS, the turkey, in ornithology. The pavo, or North American turkey of Ray, has a caruncle both on the head and throat; and the breast of the male is bearded. He lives upon grain and insects. When the cock struts, he blows up his breast, spreads and erects his feathers, relaxes the caruncle on the forhead, and the naked parts of the face and neck become intensely red. The calyx is smaller. There are three species, viz. 1. The gallo-pavo, or North American turkey of Ray, has a caruncle both on the head and throat; and the breast of the male is bearded. He lives upon grain and insects. When the cock struts, he blows up his breast, spreads and erects his feathers, relaxes the caruncle on the forhead, and the naked parts of the face and neck become intensely red. 2. The crista, or Brainalian pheasant of Ray, has an erect crest of feathers on the head, and violet-coloured temples: it has a caruncle on the throat, but none on the head. 3. The fatra, or Swallow-tailed pheasant of Edwards, has two blue horns behind the eyes, a red body spotted with black and white.

MELEAGRIS, the turkey, in ornithology. The pavo, or North American turkey of Ray, has a caruncle both on the head and throat; and the breast of the male is bearded. He lives upon grain and insects. When the cock struts, he blows up his breast, spreads and erects his feathers, relaxes the caruncle on the forhead, and the naked parts of the face and neck become intensely red. 2. The crista, or Brainalian pheasant of Ray, has an erect crest of feathers on the head, and violet-coloured temples: it has a caruncle on the throat, but none on the head. 3. The fatra, or Swallow-tailed pheasant of Edwards, has two blue horns behind the eyes, a red body spotted with black and white.

MELON, in botany. See Cucumis.

MELODY, in music, the agreeable effect of different sounds, ranged and disposed in succession; so that melody is the effect of a single voice or instrument, by which it is distinguished from harmony.

MELOE, in zoology, a genus of insects of the order of Coleoptera. The antennae are jointed, the larva jointed, the bract is roundish; the elytra are arched and flexible; and the head is inflected and gibbous. There are 16 species, principally distinguished by their color. The vesicatorius, or cantharis of the hops, when bruised, is universally used as a blistering plaster.

MELON, in botany. See Cucumis.

MEMBRA, in architecture, denotes any part of a building; as, a frieze, cornice, or the like. This word is also sometimes used for the moulding. See Moulding.

MEMBER of parliament. See Parliament.

MEMBERED, in heraldry, is where the legs or feet of an eagle, griffin, or other bird, are of a different colour from the rest of the body.

MEMBRANE, in anatomy, a pliable texture of fibres interspersed together in the same plane. See Anatomy, part I and II.

MEMECYLON, in botany, a genus of the Odontacae clausa. The calyx is above the fruit, and the corolla is monopetalous and bell-shaped; and the berry has one cell, containing many seeds. In Canada, Virginia, and Jamaica, where this fruit commonly grows, it is pickled for the table.

MELTING cone, in assaying. See Chemistry, p. 113.

MEMBER, in architecture, denotes any part of a building; as, a frieze, cornice, or the like. This word is also sometimes used for the moulding. See Moulding.

MEMBERED, in heraldry, is where the legs or feet of an eagle, griffin, or other bird, are of a different colour from the rest of the body.

MEMBRANE, in anatomy, a pliable texture of fibres interspersed together in the same plane. See Anatomy, part I and II.

MEMECEYLON, in botany, a genus of the Odontacae clausa. The calyx is above the fruit, and has an entire margin; the corolla consists of one petal; and the berry is crowned with a cylindrical calyx. There is but one species, native of Ceylon.

MEMOIRS, in matters of literature, a species of history, written by persons who had some share in the transactions they relate; answering to what the Romans called Commentarii.

MEMORY, a faculty of the human mind, whereby it retains and recalls the ideas it has once perceived. See Metaphysics.

MEMPHIS, once the capital of Egypt, stood on the west side of the Nile, almost opposite to Grand Cairo.

MENDICANTS, or begging friars, several orders of religious in Popish countries, who, having no settled revenues, are supported by the charitable contributions they receive from others.

MENGRELIA, a province of Asiatic Turkey, situated on the north-east part of the Euxine sea, between Georgia and Circassia, where the Turks purchase boys and young women for their seragios.

MENIALS, domestic or household servants, who live under their lord or master's roof.

MENINGES, or Meninges, in anatomy, a name given to the dura and pia mater of the brain.

MENISCUS, in optics, a lens convex on one side, and concave on the other. See Optics.

MENISPEMUM, in botany, a genus of the Dicata dioecia clausa. The calyx consists of five segments, and the corolla of five petals. It has three berries, containing each a kidney-shaped seed. There are seven species, none of them natives of Britain.

MENNISTITES, a sect of baptists in Holland, called from Mennon Simonis of Friesland, who lived in the sixteenth century. This sect believe, that the New Testament is the only rule of faith; that the terms Person and Trinity are not to be used in speaking of the Father, Son, and Holy Ghost; that the first man was not created perfect; that it is unlawful to swear, or to wage war upon any occasion; that infants are not the proper subjects of baptism; and that ministers of the gospel ought to receive no salary.

MENOLOGY, the Greek calendar, in which the lives of the saints in short, or barely their names, are cited; answering nearly to the martyrology of the Latin church. See Martyrology.

MENSA, in law-books; a term that includes in it all patrimony, and necessaries for livelihood.

MENSALS, in church-history, such livings as were formerly united to the tables of religious houses, and hence called mensal benefices.

MENSES, Flours, Courses, Catamenia, in medicine, the monthly evacuations from the uterus of women not with child and not giving suck. See Medicine.

MENNONITES, a sect of baptists in Holland, called from Mennon Simonis of Friesland, who lived in the sixteenth century. This sect believe, that the New Testament is the only rule of faith; that the terms Person and Trinity are not to be used in speaking of the Father, Son, and Holy Ghost; that the first man was not created perfect; that it is unlawful to swear, or to wage war upon any occasion; that infants are not the proper subjects of baptism; and that ministers of the gospel ought to receive no salary.

MERCHANT, a person who buys and sells commodities in grofs, or deals in exchanges; or that traffics in the way of commerce, either by importation or exportation. See Commerce.

MERCURY, in botany, a genus of the dioecia ericacearum class. The calyx of both male and female consists of three segments; neither of them have any corolla; the stamens are from nine to twelve; the anthers are globular and didymous; the female has two stigmas; and the capsule has two cells, and one seed in each. There are four species, two of them natives of Britain, viz. the perennis, or dogs mercury; and the annua, or French mercury.

MERCURY, in natural history. See Chemistry, p. 85, and 137.

MERCURY, ⊗, in astronomy. See Astronomy, p. 436.

MERCURY, in heraldry, a term used in blazoning by planets, for the purple colour in the arms of sovereign princes.

MERCURY, in ornithology. See Propitia cupiditas.

MERCURY, ⊗, in astronomy. See Propitia cupiditas.

MERCURY, in botany, a genus of the dicotyledonous class. The calyx of both male and female consists of three segments; neither of them have any corolla; the stamens are from nine to twelve; the anthers are globular and didymous; the female has two stigmas; and the capsule has two cells, and one seed in each. There are four species, two of them natives of Britain, viz. the perennis, or dogs mercury; and the annua, or French mercury.

MESIPPI, or Meschipsi, a country of North America, bounded by Canada on the north, the British plantations on the east, the gulf of Mexico on the south, and the province of New Mexico on the west.

MESSENGERS, are certain officers chiefly employed under the direction of the secretaries of state, and always in readiness to be sent with all kinds of dispatches foreign and domestic. They also, by virtue of the secretaries warrants, take up persons for high treason, or other offences against the state.

MESSIAS, in botany, a genus of the icofandria class. The calyx consists of five segments, and the corolla of numerous linear petals; and the capsule is fleshly below the flower, and contains many seeds. There are 45 species, none of them natives of Britain.

MESTERY, in anatomy. See Anatomy, p. 262.

MIDIAN, in astronomy. See Geography, and Astronomy.

METAPHYSICS is that part of philosophy which considers the nature and properties of thinking beings.

Aristotle, after treating on physics, begins his next book, (in which he pretends to elevate the mind above corporeal objects, to fix it in the contemplation of God, of angels, and of things spiritual, and to enable it to judge of the principles of sciences by abstraction,) with the Greek words μετα τω φυσικων, φυλο ψυχικων, 1. e. after metaphysics. His disciples, and succeeding philosophers, have formed, of these two, one word, METAPHYSICS, by which they mean that science of which we have just now given the definition.

Metaphysics is divided, according to the objects that it considers, into six principal parts, which are called, 1. Ontology: 2. Cosmology: 3. Anthropology: 4. Psychology: 5. PneumatoLOGY: and, 6. Theodicy, or metaphorical theology.

1. The doctrine that is named Ontology, is that part of metaphysics which investigates, and explains, the nature and general essence of all beings, as well as the qualities and attributes that essentially appertain to them, and which we ought to assign them by abstraction, as considering them a priori. Hence it appears, that this doctrine should proceed in its operations from the most simple ideas; such as do not admit of any other qualities of which they may be compounded. These simple ideas are, for example, those of being, of essence, of substance, of mode, of existence as well with regard to time as place, of a necessary cause, of unity, the idea of negation, the difference between a being that is simple or compound, necessary or accidental, finite or infinite; the idea of efficient and abstractive properties, as of the greatness, perfection, and goodness of beings; and so of the rest. The business therefore of ontology, is to make us acquainted with every kind of being in its essence and abstractive qualities, and such as are distinct from all other beings. This knowledge being once established on simple principles, just conclusions may from thence be drawn, and those things proved after which metaphysics inquires, and which is its business to prove.

It is easy to conceive, that even a clear knowledge of beings, and their essential properties, would be still defective and useless to man, if he did not know how to determine and fix his ideas by proper denominations, and consequently to communicate his perceptions to those whom he would instruct, or against whom he is obliged to dispute, as they would not have the same perceptions that he has. It is, by the way, perhaps one of the greatest advantages that we have over other animals, to be able so to determine our ideas by signs or denominations, either of writing or speech, as to refer each particular perception to its general idea, and each general perception to its particular idea. To render therefore our ideas intelligible to others, we must have determinate words or denominations for each kind; and ontology teaches us those terms which are so necessary to fix our ideas, and to give them the requisite
requisite perplicity and precision, that we may not dis- 5. The fifth part of metaphysics is called Pneumatol- pute about words when we endeavour to extend the sphere ogy. It is not a very long time since this term has been of our knowledge, or when we debate concerning the invented, and that metaphysicians have made of it a definite doctrine. By this they mean the knowledge of all essence of an object, or endeavour to make it more evident. spirits, angels, &c. It is easy to conceive that infinite art is It is for this reason that ontology was formerly regarded necessary to give an account of what we do not absolutely as a barren science, that consulted of technical terms only; as a materia lmentology: whereas the best modern philosophicks make it a more substantial science, by annexing as a mere terminology: whereas the best modern determinate ideas to those words, and the examination of philosophers make it a more substantial science, by of those objects themselves that these terms imply. But the annexing determinate ideas to those words, and the examination of misfortune is, to speak the truth, that in this ontologic determination there is still much uncertainty and sophi- those words, and the examination of those objects themselves that these terms imply. But the fulty. For, in the first place, we yet know of no metaphysics where all the definitions are jule; and in the misfortune is, to speak the truth, that in this ontologic second place, the words that are employed in these definitions determination there is still much uncertainty and sophi- have always something equivocal in their meaning, and try. For, in the first place, we yet know of no metaphysics have consequently themselves need of definitions; and in and the examination of those objects themselves that these terms imply. But the in this manner we may recede to infinity, unless we recur misfortune is, to speak the truth, that in this ontologic to the first impressions that the simple words have made in determination there is still much uncertainty and sophi- our minds, and the primitive ideas which they there fty. The words man, love, coach, &c. say more, and make a stronger impression than all the definitions we can give of them; by ontologic explications they are always covered with a dark cloud.

2 Metaphysics, after having, in as solid a manner as possible, explained and established the principles above mentioned, continues its inquiries to the second part, that is called Cosmology, and examines into the essence of the world, and all that it contains; its eternal laws; of the nature of matter; of motion; of the nature of tangible bodies, of their attributes and essential qualities, and of all that can be known by abstraction, and sometimes also by adding the lights that man acquires concerning them by the experience of his senses. It is also in cosmology that we examine the Leibnitizian system; that is, whether God, in creating the world, must necessarily have created the best world; and if this world be in effect. And in this manner they purse the argument from consequence to consequence to its last resort. All philosophers, however, do not go equally deep. Each mind has its dofe of penetration. Due care should be likewise taken, that sibility, in this chain of reasoning, carried beyond the general bounds of the human mind, do not prejudice either the perplicity or the truth of ideas: seeing that error here too nearly approaches the truth; and that every idea, which cannot be rendered intelligible, is in effect equal to a falfe idea.

3 Anthrophology, or the knowledge of man, forms the third branch of metaphysics. It is subdivided into two parts. The first, which consists in the knowledge of the exterior parts of the human frame, does not belong to this science: anatomy and physiology teach that. The business here is only a metaphysical examination of man, his existence, his essence, his essential qualities and necessary attributes, all considered a priori; and this exam- en leads at the same time to

4 Psychology, which is the fourth part of metaphysics, and consists in the knowledge of the soul in general, and of the soul of man in particular; concerning which, the most profound, the most subtle and abstract researches have been made, that the human reason is capable of producing; and concerning the substance of which, in spite of all these efforts, it is yet extremely difficult to assert any thing that is rational, and still less any thing that is positive and well supported.

6 Metaphysical Theology, which M. Leibnitz and some others call Theodicy, is the sixth and last doctrine of metaphysics. It teaches us the knowledge of the existence of God; to make the most rational suppositions concerning his divine essence, and to form a just idea of his qualities and perfections, and to demonstrate them by abstract reasoning a priori. Theodicy differs from natural theology, in as much as this last borrows, in fact, from theodicy, proofs and demonstrations to confirm the existence of a Supreme Being; but after having boldly established that great truth, by extending its consequences, natural theology teaches us what are the relations and connections that subsist between that Supreme Being and man, and what are the moral duties that result from that connexion. As pneumatology is a science highly infidious and chimerical, so is metaphysical theology susceptible of found argument and demonstration; to the great comfort of mankind, the whole of whose happiness is founded on the certainty of this science. If the effects and operations of spirits in the universe were as evident as the effects and operations of the Deity, and their necessary existence as capable of being proved a priori, pneumatology would be a doctrine of equal certainty with theodicy: but as neither one nor the other can be proved, with regard to spirits in general, whilst God manifests himself in every part of nature, we have only to de- fend from the most simple and abstract ideas, to those that are the most compound; and from thence to reaffect, by a chain of reaffectings, from the creature up to the Author of the creature and of all nature: We shall find, that the refult of all these operations of the mind will constantly be, The necessity of the existence of a God; and we may at all times determine, though very imperfectly, from the weaknesses of our discernment, what that Supreme Being must be, by positively determining what he cannot be. Everything that can concur to furnish new proofs on this subject, or to elucidate and establish those which are already known, is therefore of insensible value to mankind: and though this was the only object of metaphysics, it would highly merit the attention of those of the most refined and most exalted genius.

After giving this general view of the subject, we shall proceed.
proceed to give the substance of what Mr Locke has delivered upon it.

Of ideas in general, and their original.

By the term idea, as defined by Mr Locke, is meant whatever is the object of the understanding when a man thinks, or whatever it is which the mind can be employed about in thinking.

In order to trace the manner by which we acquire these ideas, let us suppose the mind to be, as we say, unripe paper, void of all characters, without any ideas: how comes it to be furnished? whence has it all the materials of reason and knowledge? From experience and observation. This, when employed about external sensible objects, we may call sensation: by this we have the ideas of bitter, sweet, yellow, hard, &c. which are commonly called sensible qualities, because conveyed into the mind by the senses. The same experience, when employed about the internal operations of the mind, perceived and reflected on by us, we may call reflection: hence we have the ideas of perception, thinking, doubting, willing, reasoning, &c.

These two, viz. external material things as the objects of sensation, and the operations of our own minds as the objects of reflection, are the only originals from whence all our ideas take their beginnings: the understanding seems not to have the least glimmering of ideas, which it doth not receive from one of these two sources. These, when we have taken a full survey of them, and their several modes and compositions, we shall find to contain our whole stock of ideas: and that we have nothing in our minds which did not come in one of these two ways.

It is evident, that children come by degrees to be furnished with ideas from the objects they are conversant with: they are so surrounded with bodies that perpetually and diversely affect them, that some ideas will (whether they will or no) be imprinted on their minds. Lights and colours, sounds and tangible qualities, do continually solicit their proper senses, and force an entrance into the mind. It is late, commonly, before children come to have ideas of the operations of their minds; and some men have not any very clear or perfect ideas of the greatest part of them all their lives: because, though they pass there continually, yet, like floating visions, they make not deep impressions enough to leave in the mind clear and lasting ideas, till the understanding turns inward upon itself, and reflects on its own operation, and makes them the objects of its own contemplation.

When a man first perceives, then he may be said to have ideas: having ideas, and perception, signifying the same thing.

Of simple ideas.

Of ideas, some are simple, others complex. A simple idea is one uniform appearance or conception in the mind, which is not distinguishable into different ideas. Such are the ideas of sensible qualities, which though they are in the things themselves so united and blended, that there is no separation, no distance between them, yet the ideas they produce in the mind enter by the senses simple and unmixed. Thus, though the hand feels softness and warmth in the same piece of wax, yet the simple ideas thus united in the same subject are as perfectly distinguishable as those that come in by different senses.

These simple ideas are suggested no other way than from the two ways above mentioned, viz. sensation and reflection.

The mind being once flooded with the simple ideas, has the power to repeat, compare, and unite them to an infinite variety; and so can make, at pleasure, new complex ideas. But the most enlarged understanding cannot frame one new simple idea; nor by any force destroy them that are there.

Of ideas of one sense.

Ideas, with reference to the different ways wherein they approach the mind, are of four sorts.

First, There are some which come into our minds by one sense only.

Secondly, There are others conveyed into the mind by more senses than one.

Thirdly, Others that are had from reflection only.

Fourthly, There are some suggested to the mind by all the ways of sensation and reflection.

First, some enter into the mind only by one sense peculiarly adapted to receive them. Thus colours, sounds, smells, &c. come in only by the eyes, ears, and nose. And if these organs are any of them so disordered as not to perform their functions, they have no other way to bring themselves in view, and be perceived by the understanding.

We shall here mention one, which we receive by our touch, because it is one of the chief ingredients in many of our complex ideas; and that is, the idea of solidity: it arises from the resistance one body makes to the entrance of another body into the place it possesseth, till it has left it. There is no idea which we more constantly receive from sensation than this. In whatever posture we are, we feel somewhat that supports us, and hinders us from sinking downwards: and the bodies we daily handle, make us perceive, that while they remain between them, they do, by an unassailable force, hinder the approach of the parts of our hands that press them. This seems to be the most essential property of body, and that whereby we conceive it to fill space: the idea of which is, that where we imagine any space taken up by a solid substance, we conceive it so to possess it, that it excludes all other solid substances. This resistance is so great, that no force can surmount it. All the bodies in the world pressing a drop of water on all sides, will never be able to overcome the resistance it makes to their approaching one another, till it be removed out of their way.

The idea of solidity is distinguished from that of pure space, in as much as this latter is neither capable of resistance nor motion: it is distinguished from hardness, in as much as hardness is a firm cohesion of the solid parts of matter making up masses of a sensible bulk, so that the whole doth not easily change its figure. Indeed, hard and soft, as commonly apprehended by us, are but relative to the constitutions of our bodies: that being called hard which will put us to pain sooner than change its figure by the pressure of any part of our bodies; and that soft, which
which changes the situation of its parts upon an easy and unpainful touch.

This difficulty of changing situation among the parts, gives no more solidity to the hardest body, than to the softest; nor is an adamant one jot more solid than water, he that shall fill a yielding soft body well with air or water, will quickly find its resistance. By this we may distinguish the idea of the extension of body, from the idea of the extension of space: That of body, is the cohesion or continuity of solid, separable, and moveable parts; that of space, the continuity of unsolid, inseparable, and immoveable parts. Upon the solidity of bodies depends their mutual impulse, resistance, and protrusion.

Of simple ideas of different senses.

Some ideas we get into the mind by more than one sense; as space, extension, figure, refl., and motion. These are perceivable by the eyes and touch.

Of simple ideas of reflection.

Some ideas are had from reflection only: Such are the ideas we have of the operations of our minds; of which the two principal are, perception, or thinking; and volition, or willing. The powers of producing these operations are called faculties; which are, the understanding, and will. The several modes of thinking, &c. belong to this head.

Of simple ideas of sensation and reflection.

There are some simple ideas conveyed into the mind by all the ways of sensation and reflection; such are pleasure, pain, power, existence, unity, succession. Pleasure or delight, pain or uneasiness, accompany almost every impression on our senses, and every action or thought of the mind.

The Author of our beings having given a power to our minds, in several inftances, to chuse amongst its ideas which it will think on; to excite us to these actions of thinking and motion, he has joined to several thoughts and sensations a perception of delight; without this we should have no reason to prefer one thought or action to another.

Pain has the same efficacy to set us on work that pleasure has; since we are as ready to avoid that, as to pursue this. This is worth our consideration, that pain is often produced by the same objects and ideas that produce pleasure in us. This their near conjunction gives us new occasion of admiring the wisdom and goodness of our Maker; who, designing the preservation of our being, has annexed pain to the application of many things to our bodies, to warn us of the harm they will do us, and as advices to withdraw us from them. But he not designing our preservation barely, but the preservation of every part and organ in its perfection, hath in many cases annexed pain to those very ideas which delight us. Thus heat, that is very agreeable to us in one degree, by a little greater increafe of it proves no ordinary torment: Which is wisely ordered by nature, that when any object does by the vehemence of its operation disorder the instruments of sensation, whose structures cannot but be very delicate, we might by the pain be warn-

ed to withdraw before the organ be quite put out of order. That this is the end of pain, appears from this consideration; that though great light is insufferable to the eyes, yet the highest degree of darkness does not at all distress them; because that causes no disorderly motion in that curious organ the eye. But excess of cold, as well as heat, pains us; because it is equally destructive to the temper which is necessary to the preservation of life.

Existence and unity are two other ideas suggested by every object without, and every idea within. When ideas are in our minds, we consider them as being actually there, as well as we consider things to be actually without us; which is, that they exist, or have existence; And whatever we consider as one thing, whether a real being, or idea, suggests the idea of unity.

Power is another idea derived from these sources: For finding in ourselves that we can think, and move several parts of our bodies at pleasure, and observing the effects that natural bodies produce in one another; by both these ways we get the idea of power.

Succession is another idea suggested by our senses, and by reflection on what passes in our minds: For if we look into ourselves, we shall find our ideas always, whilst we are awake, or have any thought, passing in train, one going and another coming, without intermission.

Some further considerations concerning simple ideas.

Whatever is able, by affecting our senses, to cause any perception in the mind, both thereby produce in the understanding a simple idea; which, whatever be the cause of it, is looked upon as a real positive idea in the understanding. Thus the ideas of heat and cold, light and darkness, motion and rest, &c. are equally positive in the mind, though some of their causes may be more private.

That a privative cause may produce a positive idea, appears from shadows; which (though nothing but the absence of light) are discernible, and cause clear and positive ideas. We have indeed some negative names which stand not directly for positive ideas, but for their absence; such as insipid, silence, which denote positive ideas, viz. taste and sound, with a signification of their absence.

It will be useful to distinguish ideas as they are perceptions in our minds, from what they are in the bodies that cause such perceptions in us; for we are not to think the former exact images and resemblances of something inherent in the subject, most of those of sensation being, in the mind, no more the likenesses of something existing without us, than the names that stand for them are the likenesses of our ideas, which yet, upon hearing, they excite in us.

Whatever the mind perceives in itself, or is the immediate object of perception, thought, or understanding, is an idea; And the power to produce any idea in our mind, is the quality of the subject wherein that power exists. Thus a snow ball having the power to produce in us the ideas of white, cold, and round; those powers, as they are in the snow-ball, are called qualities; and as they are sensations or perceptions in our understandings, they are called ideas. These qualities are of two sorts; First, original, or primary; such are solidity, ex-

Y y tension,
Perception is the first idea we receive from reflection: It is by some called thinking in general: Though thinking, in the propriety of the English tongue, signifies that sort of operation of the mind about its ideas, where in the mind is active; where it considers any thing with some degree of voluntary attention: For in bare perception the mind is, for the most part, only passive; and what it perceives, it cannot avoid perceiving. What this is, we cannot otherwise know, than by reflecting on what palls in our minds when we see, feel, hear, &c.

Impressions made on the outward parts, if they are not taken notice of within, cause no perception; as we fee in those whose minds are intently buried in the contemplation of certain objects.

We may observe that the ideas we receive from sensation, are often in grown people altered by the judgment, without our taking notice of it. Thus a globe of any uniform colour, (as of gold, or jet,) being set before our eyes, the idea thereby imprinted is of a flat circle variously shadowed: But being accustomed to perceive what kind of appearance convex bodies are wont to make in us, the judgment alters the appearances into their caues; and, from that variety of shadow or colour, frames to itself the perception of a convex figure of one uniform colour. This in many cases, by a settled habit, is performed so readily, that we take that for the perception of our sensation, which is but an idea formed by the judgment; so that one serves only to excite the other, and is scarce taken notice of itself: As a man who reads or hears with attention, takes little notice of the characters or sounds, but of the ideas that are excited in him by them.

Perception is also the first step and degree towards knowledge, is called retention; which is the keeping of those ideas it has received. Which is done two ways:

First. By keeping the idea which is brought into the mind for some time actually in view; which is called contemplation.

Secondly, By reviving those ideas in our minds which have disappeared, and have been, as it were, laid out of sight: And this is memory; which is, as it were, the storehouse of our ideas; for the narrow mind of men being nothing but a repository to lay up those ideas, which at another time it may have use of. But our ideas being nothing but actual perceptions in the mind, which cease to be any thing when there is no perception of them, this lying up of our ideas in the repository of the memory signifies no more but this, that the mind has a power, in many cases, to revive perceptions it has once had, with this additional perception annexed to them, that it has had them before. And it is by the assistance of this faculty, that we are said to have all those ideas in our understandings which we can bring in view, and make the objects of our thoughts, without the help of those sensible qualities which first impressed them there.

Those ideas that are often refreshed by a frequent return of the objects or actions that produce them, fix themselves fast in the memory, and remain longest there: Such are the original qualities of bodies, viz. Solidity, Extension, Figure, Motion, &c. These and the like are seldom or ever loit while the mind retains any ideas at all.
Of discerning, and other operations of the mind.

Another faculty of the mind, is that of discerning between its ideas. On this depends the evidence and certainty of several general propositions. In being able nicely to distinguish one thing from another, where there is the least difference, consists, in a great measure, that exactness of judgment and clearness of reason which is to be observed in one man above another.

To the well distinguishing our ideas, it chiefly contributes that they be clear and determinate; and when they are so, it will not breed any confusion or mistake about them, though the senses should convey them from the same object differently on several occasions.

The composing of our ideas one with another in respect of extent, degree, time, place, or any other circumstances, is another operation of the mind about its ideas which is the ground of relations. Brutes seem not to have this faculty in any great degree. They have probably several ideas distinct enough; but cannot compare them farther than some sensible circumstances annexed to the objects themselves.

Composition is another operation of the mind, whereby it combines several of its simple ideas into complex ones: Under which operation we may reckon that of enlarging; wherein we put several ideas together of the same kind, as several units to make a dozen.

Abstraction is another operation of the mind, whereby the mind forms general ideas from such as it received from particular objects; which it does by considering them, as they are in the mind such appearances separate from the circumstances of real existence, as time, place, &c. These become general representatives of all of the same kind, and their names applicable to whatever exists comparable to such abstract ideas. Thus the colour received from chalk, snow, and milk, is made a representative of all of that kind; and has a name given it (whiteness,) which signifies the same quality, wherever to be found or imagined. And thus universals, both ideas and terms, are made.

Of complex ideas.

In the reception of simple ideas the mind is only passive, having no power to frame any one to itself, nor having any idea which does not wholly consist of them. But about these simple ideas it exercises several acts of its own, whereby out of them, as the materials and foundations of the rest, the other are framed: The acts of the mind, wherein it exercises its power over its simple ideas, are chiefly these three: First, It combines several simple ideas into one compound one; and thus all complex ideas are made. Secondly, It brings together, whether simple or complex, ideas, and fuses them by one another, so as to take a view of them at once, without uniting them into one; by which way it gets all its ideas of relations. Thirdly, It separates them from all other ideas that accompany them in their real existence: And thus all its general ideas are made. As simple ideas are observed to exist in several combinations united together, so the mind may consider them as united, not only as they are really united in external objects, but as itself has joined them ideas thus made up of several ones put together, are called complex; as man, army, beauty, gratitude, &c. By this faculty of repeating and uniting together its ideas, the mind has great power in varying and multiplying the objects of its thoughts. But it is still confined to those simple ideas which it received from the two sources of sensation and reflection. It can have no other ideas of sensible qualities, than what come from without by the senses, nor any other ideas of the operations of a thinking subsistence than what it finds in itself; but having once got these simple ideas, it can by its own power put them together, and make new complex ones, which it never received so united.

Complex ideas, however compounded and decomposed, though their number be infinite, and their variety endless, may all be reduced under these three heads: 1st, Modes; 2dly, Substances; 3dly, Relations.

1st, Modes are such complex ideas as contain not the supposition of subsisting by themselves, but are considered as dependences on, and affections of substances; as triangle, gratitude, murder, &c. These modes are of two sorts: First, Simple, which are combinations of the same simple idea; as a dozen, score, &c. which are but the ideas of so many distinct units put together. Secondly, Mixed, which are compounded of simple ideas of several kinds; as beauty, which consists in a certain composition of colour and figure, causing delight in the beholder; theft, which is the concealed change of the possession of any thing, without the consent of the proprietors. These visibly contain a combination of ideas of several kinds.

2dly, Substances. The ideas of substances are all such combinations of simple ideas, as are taken to represent distinct particular things subsisting by themselves, in which the confused idea of substance is always the chief. Thus a combination of the ideas of a certain figure, with the powers of motion, thought, and reasoning, joined to subsistence, make the ordinary idea of man.

These again are either of single substances, as man, stone; or of collective, or several put together, as army, heap. Ideas of several substances thus put together, are as much each of them one simple idea, as that of a man or an unit.

3dly, Relations; which consist in the consideration and comparing of one idea with another. Of these several kinds we shall treat in their order.

Of simple modes: And, first, of the simple modes of space.

Concerning simple modes we may observe, that the modifications of any simple ideas are as perfectly different and distinct ideas in the mind, as those of the greatest distance or contrariety: Thus two is as distinct from three, as blueens from best.

Space is a simple idea which we get both by our fight and touch. When we consider it barely in length between two bodies it is called distance: when in length, breadth, and thickness, it may be called capacity. When considered between the extremities of matter, which fills the capacity of space with something solid, tangible, and moveable, it is called extension. And thus extension will be an idea belonging to body; but space may be conceived without it.

Each
Each different distance is a different modification of space; and each idea of any different space is a simple mode of this idea. Such are an inch, foot, yard, &c. When these ideas are made familiar to men's thoughts, they can in their minds repeat them as often as they will, without joining to them the idea of body, and frame to themselves the ideas of feet, yards, or fathoms, beyond the utmost bounds of all bodies; and, by adding these till one to another, enlarge their idea of space as much as they please. From this power of repeating any idea of distance, without ever being able to come to an end, we come by the idea of immensity.

Another modification of space is taken from the relation of the parts of the termination of extension or circumference space amongst themselves; and this is what we call figure. This the touch discovers in sensible bodies, whose extremities come within our reach; and the eye takes both from bodies and colours, whose boundaries are within its view; where observing how the extremities terminate either in straight lines, which meet at discernible angles, or in crooked lines, wherein no angles can be perceived; by considering these as they relate to one another in all parts of the extremities of any body or space, it has that idea we call figure: which affords to the mind infinite variety.

Another mode belong to this head, is that of place. Our idea of place is nothing but the relative position of any thing with reference to its distance from some fixed and certain points. Whence we say, that a thing has or has not changed place, when its distance either is or is not altered with respect to those bodies which which we have occasion to compare it. That this is so, we may easily gather from hence, that we can have no idea of the place of the universe, though we can of all its parts. To say that the world is somewhere, means no more than that it does exist. The word place is sometimes taken to signify that space which any body takes up; and so the universe may be conceived in a place.

Of duration, and its simple modes.

There is another sort of distance, the idea of which we get from the fleeting and perpetually perishing parts of succession, which we call duration. The simple modes of it are any different lengths of it whereof we have distinct ideas; as hours, days, years, &c. time, and eternity.

The idea of succession is got by reflecting on that train of ideas which constantly follow one another in our minds as long as we are awake. The distance between any parts of this succession, is what we call duration; and the continuance of the existence of ourselves, or any thing else, common to the succession of any ideas in our minds, is what we call our own duration, or that of another thing co-existing with our thinking. That this is so, appears from hence, that we have no perception of succession or duration, when that succession of our ideas ceases, as in sleep; the moment that we sleep, and awake, how distant ever, seems to be joined and connected. And possibly it would be so to a waking man, could he fix upon one idea without variation and the succession of others. And we see that they whose thoughts are very intent upon one thing, let slip out of their account a good part of that duration, and think that time shorter than it is. But if a man, during his sleep, dream, and a variety of ideas make themselves perceptible in his mind one after another, he hath then, during such dreaming, a sense of duration, and of the length of it.

A man having once got this idea of duration, can apply it to things which exist while he does not think: and thus we measure the time of our sleep, as well as that wherein we are awake.

Duration, as marked by certain periods and measures, is what we most properly call time, which we measure by the diurnal and annual revolutions of the sun, as being constant, regular, and universally observable by all mankind, and supposed equal to one another.

The mind having once got such a measure of time, as the annual revolution of the sun, can easily apply it to duration, wherein that measure itself did not exist; and the idea of duration equal to an annual revolution of the sun, is as easily applicable in our thoughts to duration where no sun nor motion was, as the idea of a foot or yard to distances beyond the confines of the world.

By the same means, and from the same original that we come to have the idea of time, we have also that idea which we call eternity: for having got the ideas of certain lengths of duration, we can in our thoughts add them to another, as off we please, without ever coming to an end.

And thus it is plain, that from the two fountains of all knowledge before mentioned, viz. sensation and reflection, we get the ideas of duration, and the several measures of it.

Of numbers.

The complex ideas of number are formed by adding several units together. The simple modes of it are each several combinations, as two, three, &c. These are of all others most distinct, the nearest being as clearly different from each other as the most remote: two being as distinct from one, as two hundred. But it is hard to form distinct ideas of every the least excess in extension. Hence demonstrations in numbers are more general in their use, and more determinate in their application, than those of extension.

Simple modes of numbers being in our minds but so many combinations of units, which have no variety but more or less; names for each distinct combination seem more necessary than in any other sort of ideas: For without a name, or mark, to distinguish that precise collection, it will hardly be kept from being a heap of confusion. Hence some Americans have no distinct idea of any number beyond twenty; so that when they are dispersed with of greater numbers, they shew the hairs of their head. So that to reckon right, two things are required: First, That the mind distinguish carefully two ideas which are different one from another only by the addition or subtration of one unit.

Secondly, That it retain in memory the names or marks of the several combinations, from an unit to that number; and that in exact order, as they follow one another. In either

iTRY,
e0(3-
Shewing the manner in which natural bodies, confidered in a chemical view, may be divided into classes; With their several subdivisions; their properdes defined; and the manner in which they are obtained, pointed out.

Aucides. There are di-
Inflammables, or volatile fluids, emitting noxious fumes when in a concentrated state. The non-acidic fluids in the following table are divided into simple and compound.

Simples, are those which are not decomposed by the chemist; and are of two sorts, viz.

Constitute, or compound fluids, formed of chemical elements.

1. SOLVENTS. Their are soluble in water, and not inflammable. They are divided into

Acids. They are di-
Solvent fluids, or those which can be no

Compounds, consisting of two or more

Nitrates, or Arsenic. A volatile fluid of a reddish colour, emitting noxious fumes when in a concentrated state.

Nitrous, or Aquafortis. A volatile fluid of a beautiful yellow colour, inferior in power to the former. Obtained from saltpetre.

Mercuric, or quick-silver. A powerful fluid, emitting noxious and inflammable fumes when in a concentrated state.

Platina. A white semimetal, resembling silver in its lustre; nearly of the same specific gravity and fixity with gold, and resisting the effects which have usually been applied for discovering the purity of gold, supposed from the elution of waters impregnated with saline substances; the diversity of which is exceeding great; but they all agree in having an acid joined with them.

Lime-stone, or marble. This is of infinite variety of colours and texture. Marble is the hardest and finest. Those kinds of lime-stone which feel asperous to the touch are generally impregnated with or

Common clay, is of many different colours, but chiefly red or yellow or white. The purest clay is that which burns white in the fire. This is probably nothing else than lime-stone calcaneus. Clay of any kind may, by a particular process, be converted into quick-lime. This is probably nothing else than lime-stone calcaneus.

Lapis nephriticus, or steatite, is an indurated clay, found in various parts. These are at first soft, and readily cut; but turn extremely hard in the air. Many other varieties of these earths might be

Salt, or as is called in the antique language. The earth of animals, dye. This is obtained by the calcination of animal-substances.

Chalk. A soft, friable, white substance. This is much freer of any heterogeneous mixture than any lime-stone, and is easily calcined into quick-lime. This is probably nothing else than lime-stone calcaneus.

Earth of vegetables, or black-stone. A consolidated earth, found in many places impregnated with saline substan-

Earth of animals, or caffeine. Obtained from the allies of burnt vegetables. A deliquescent salt.

Acid of borax, or sediment salt. Obtained from borax, in a solid form and friable-like form.

Acid of oxalic, or adipic acid. Obtained from all animal-substances in dissillation.

Acids. The finest form of acids is that of a very slight fluid, which is the finest form of acids in water.

Acid of saltpetre. Obtained from all vegetable acids are much less corrosive, and is powerful as a solvent.
A TABLE showing the several combinations that THE SIMPLE CHEMICAL ELEMENTS admit of with one another; the compound resulting from that mixture; and the manner in which the union is effected: With some account of the principal offices to which these are applied in arts or manufactures.

| N. B. | This mark *, put above any word, declares that there is some difficulty in the passage, or that the union is not very complete. |

### ALCOHOL.

**Sulphur.** Here there is no proper union of substances: but if sulphur is boiled in this acid, it becomes less inflammable and more fixed than any ordinary sulphur. It is not volatile so far as common sulphur is, but is easily distilled after its being added by the addition of water. Since water and alcohol are two fluids, the mixture is very combustible. By solution. By boiling the heat after the other has risen. By boiling until the solution becomes very volatile. A medicine much celebrated by Hoffman. By solution, sublating the alcohol. Boil. By a substance reduced like alcohol. A thick fluid. By solution after precipitation from the liquor in solution. This mixture has no name, nor is it applied to any remarkable use in arts.

### ACIDS.

**Nitrous acid.** By solution from the nitrous acid by alkalis. When once precipitated, it is again precipitated by a very strong solution.

### SEMI-METALS.

**Tin.** By solution from the nitrous acid by alkalis. The solutions which arise from the nitrous acid by alcohol.

### EARTHS.

**Clay.** By solution in boiling heat, and repeated corrosions with fresh acid, when evaporated.

### OILS.

**Sulphur.** By nufhmg* the heat after the oil comes over. It is to be observed that this is produced in every combination of this acid with inflammable or combustible bodies.

### METALS.

**Gold.** Imperfectly. By a particular process after being separated from aqua regia. Stannous chloride. By boiling the gold with the nitrous acid by alcohol. The forms which arise in this solution are inflammable.

### ALKALIS.

**Ammonium.** By boiling in the nitrous acid by alcohol. A more violent heat is generated upon the mixture of these acids with any other, and with many of them mutual fluids are produced. Applied to no particular use.

### MEALS.

**Alcohol.** By the ordinary method of dissolving copper from gold by the nitrous acid. It forms a profound liquid.

### SULPHUR.

**A.** By solution after precipitation from the nitrous acid.

### NITRIC ACID.

**Gold.** By solution after precipitation from the nitrous acid by alkalis. The fumes which arise in this solution are inflammable.

### VITRIC-ACID.

**Gold.** By solution after precipitation from a very dilute solution of chalk in the nitrous acid by alcohol. The solutions which arise from the nitrous acid by alcohol.

### VEGETABLE.

**Vegetable.** By the ordinary method of dissolving copper from gold by the nitrous acid. It forms a profound liquid.

### ALKALIS.

**Ammonium.** By boiling in the nitrous acid by alcohol. A more violent heat is generated upon the mixture of these acids with any other, and with many of them mutual fluids are produced. Applied to no particular use.

### ACIDS.

**Nitrous acid.** By solution from the nitrous acid by alkalis. When once precipitated, it is again precipitated by a very strong solution.

### SEMI-METALS.

**Tin.** By solution from the nitrous acid by alkalis. The solutions which arise from the nitrous acid by alcohol.
The content of the image appears to be a page from a book or a document discussing various acids, alkalis, and metals, along with their properties and uses. The text includes detailed descriptions of each substance, their reactions, and their applications. The page seems to be part of a larger discussion on chemistry, focusing on the interactions between different substances and their characteristics.

For example, the text mentions acids such as Vitriolic, Nitrous, Muriatic, Vegetable, and acid of Urine, of Amber, of Ants, of Borax, and others. These acids are paired with alkalis, metals, and other substances, highlighting their combinations and reactions. The page also includes a table with various substances and their properties, indicating a structured approach to the subject matter.

The document is rich in scientific detail, suitable for students or individuals with a strong interest in chemistry or related fields. It aims to provide a comprehensive overview of the topic, covering a wide range of substances and their interactions.

**Iron (Fe)**

- **Iron** appears as a metal that can be combined with various acids, bases, and solvents to form different compounds.
- **Antimony** is mentioned as a base that can be combined with iron.

**Semi-Metals**

- **Semi-metals** such as Antimony, Bismuth, Arsenic, and Cobalt are also listed with their associated phenomena and methods of preparation.

**Vitreous Earths**

- Vitreous earths are described as forming a glassy substance when heated.

**Absorbent Earths**

- Absorbent earths are noted for their ability to absorb certain substances.

**Platinum**

- Platinum is noted for its particular qualities that make it suitable for certain applications.

**Magnificent Earth**

- Magnificent earth is described as having a distinctive luster and color.

**Explanations of the Tables**

The tables provided offer various chemical combinations and their results. Each entry includes information on how to prepare the substance, its properties, and its reactions with different elements.
Each different space; and each mode of this is.

either of which if it fails, the whole business of numbering will be disturbed; and there will remain only the confused idea of multitude; but the ideas necessary to distinct numeration will not be attained to.

Of infinity.

The idea signified by the name infinity, is best examined, by considering what infinity is by the mind attributed, and then how it frames it. Finite and infinite, then, are looked upon as the modes of quantity, and attributed primarily to things that have parts, and are capable of increase or diminution by the addition or subtraction of any the least part. Such are the ideas of space, duration, and number.

When we apply this idea to the Supreme Being, we do it primarily, in respect of his duration and ubiquity; more figuratively, when to his wisdom, power, goodness, and other attributes, which are properly inexhaustible and incomprehensible: For when we call infinite, we have no other idea of this infinity, but what carries with it some reflection on the number or the extent of the acts or objects of God's power and wisdom, which can never be suppos'd so great, or so many, that these attributes will not always abound and exceed, though we multiply them in our thoughts with the infinity of endless number.

The next thing to be considered, is, how we come by the idea of infinity. Every one that has any idea of any flated lengths of space, as a foot, yard, &c. finds that he can repeat that idea, and join it to another, to a third, and so on without ever coming to an end of his additions. From this power of enlarging his idea of space, he takes the idea of infinite space, or immensity. By the same power of repeating the idea of any length of duration we have in our minds, with all the endless addition of number, we come by the idea of eternity.

If our idea of infinity be got by repeating without end our own ideas; why do we not attribute it to other ideas, as well as those of space and duration; since they may be as edifying and as often repeated in our minds, as the other? Yet no body ever thinks of infinite sweetness or whiteness, though he can repeat the idea of sweet or white as frequently as those of yard or day. But those ideas that have parts, and are capable of increase by the addition of any parts, afford us, by their repetition, an idea of infinity; because with the endless repetition there is continued an enlargement, of which there is no end. But it is not so in other ideas: For if to the perfect idea I have of white, I add another of equal whiteness; it enlarges not my idea at all. Those ideas that consist not of parts, cannot be augmented to what proportion men please, or be stretched beyond what they have received by their senses: But space, duration, and number, being capable of increase by repetition, leave in the mind an idea of an endless room for more; and so these ideas alone lead the mind towards the thought of infinity.

Of the modes of thinking.

When the mind turns its view inwards upon itself, thinking is the first idea that occurs: Wherein it observes a great variety of modifications; and thereof frames to

Of the modes of pleasure and pain.

Pleasure and pain are simple ideas, which we receive both from sensation and reflection. There are thoughts of the mind, as well as sensations, accompanied with pleasure or pain. Their causes are termed good or evil. Pleasure and pain, and their causes good and evil, are the hinges upon which our passions turn; by reflecting on the various modifications or tempers of mind, and the internal sensations which pleasure and pain, good and evil, produce in us, we may thence form to ourselves the ideas of our passions. Thus by reflecting upon the thought we have of the delight which any thing is apt to produce in us, we have an idea we call love: And on the contrary, the thought of the pain which any thing present or absent produces in us, is what we call hatred. Desire is that uneasiness which a man finds in himself upon the absence of any thing the present enjoyment of which carries the idea of delight with it. Joy is a delight of the mind arising from the present or aspired approaching possession of a good. Sorrow is an uneasiness of the mind, upon the thought of a good lost, or the sense of a present evil. Hope is a pleasure in the mind, upon the thought of a probable future enjoyment of a thing which is apt to delight. Fear is an uneasiness of the mind, upon the thought of a future evil likely to befall us. Anger is a discomposure of mind, upon the receipt of injury, with a present purpose of revenge. Disgust is the thought of the unattainableness of any good. Envy is an uneasiness of mind, caused by the consideration of a good we desire, obtained by one we think should not have had it before us.

It is to be considered, that in reference to the passions, the removal or lessening of a pain, is considered as a pleasure; and the loss or diminishing of a pleasure, as a pain. And farther, that the passions in most persons operate on the body, and cause various changes in it; but these being not always sensible, do not make a necessary part of the idea of each passion.

Of power.

The mind being every day informed by the senses of the alteration of those simple ideas, it observes in things without, reflecting also on what passes within itself, and

Vol. III. No. 67.
observing a constant change of its ideas, sometimes by the impressions of outward objects upon the senses, and sometimes by the determination of its own choice; and concluding, from what it has so constantly observed to have been, that the like changes will for the future be made in the same things, by the same agents, and by the like ways, considers in one thing the possibility of having any of its simple ideas changed, and in another the possibility of making that change, and so comes by that idea which we call power. Thus we say fire has a power to melt gold, and make it fluid; and gold has a power to be melted.

Power thus considered, is twofold, viz. as able to make, or as able to receive any change: the one may be called active, the other passive power. Of passive power all sensible things abundantly furnish us with ideas, whose sensible qualities and beings we find to be in a continual flux. Nor have we of active power fewer instances; since whatever change is observed, the mind must collect a power somewhere able to make that change. But yet, if we will consider it attentively, bodies by their senses do not afford us so clear and distinct an idea of active power as we have from reflection on the operations of our minds. For all power relating to action, and being but two sorts of action, viz. thinking and motion, let us consider whence we have the clearest ideas of the powers which produce these actions.

Of thinking, body affords us no idea at all: It is only from reflection that we have that; neither have we from body any idea of the beginning of motion. A body at rest, affords us no idea of any active power to move; and when it is set in motion itself, that motion is rather a passion than an action in it. The idea of the beginning of motion, we have only by reflection on what passes in ourselves; where we find by experience, that barely by willing it, we can move the parts of our bodies which were before at rest.

We find in ourselves a power to begin or forbear, continue or end, several actions of our minds, and motions of our bodies, barely by a thought, or preference of the mind. This power which the mind has thus to order the consideration of any idea, or the forbearing to consider it; or to prefer the motion of any part of the body to its rest, and vice versa, in any particular instance, is that we call the will; the actual exercise of that power is what we call volition, or willing. The forbearance or performance of that action, consequent to such order or command of the mind, is called voluntary; and whatsoever action is performed without such a thought of the mind, is called involuntary.

The power of perception is that we call the understanding. Perception, which we make the act of the understanding, is of three sorts: 1. The perception of ideas in our minds, 2. The reception of signs, 3. The perception of the agreement or disagreement of any distinct ideas. These powers of the mind, viz. of perceiving and preferring, are usually called by another name; and the ordinary way of speaking is, that the understanding and will are two faculties of the mind.

From the consideration of the extent of the power of the mind over the actions of the man, which every one finds in himself, arise the idea of liberty and necessity: so far as a man has a power to think or not to think, to move or not to move, according to the preference or direction of his own mind, so far is a man free. Whenever any performance or forbearance are not equally in a man's power; where-ever doing, or not doing, will not equally follow upon the preference of his mind; there he is not free, though perhaps the action may be voluntary. So that the idea of liberty, is the idea of a power in any agent to do or forbear any action, according to the determination or thought of the mind whereby either of them is preferred to the other. Where either of them is not in the power of the agent to be produced by him, according to his volition, there he is not at liberty; that agent is under necessity. So that liberty cannot be where there is no thought, no volition, no will; but there may be thought, there may be will, there may be volition, where there is no liberty. Thus a tennis-ball, whether in motion by the stroke of a racket, or lying still at rest, is not by any one taken to be a free agent. So a man striking himself or his friend by a convulsive motion of his arm, which it is not in his power by volition or the direction of his mind to stop or forbear; no body thinks he has in this liberty: every one pities him, as acting by necessity and constraint. Again, suppose a man be carried whilft fast asleep into a room, where is a person he longs to see, and be there locked fast in, beyond his power to get out; he awakes, and is glad to see himself in so desirable company; which he flays willingly in, that is, prefers his staying to going away. Is not this stay voluntary? no body will doubt it; and yet being locked fast in, he is not at liberty to stay, he has not freedom to be gone. So that liberty is not an idea belonging to volition or preferring, but to the person having the power of doing, or forbearing to do, according as the mind shall chuse or direct.

As it is in the motions of the body, so it is in the thoughts of our minds: where any one is such, that we have power to take it up, or lay it by, according to the preference of the mind, there we are at liberty. A waking man is not at liberty to think, or not to think, no more than he is at liberty whether his body shall touch any other or no: But whether he will remove his contemplation from one idea to another, is many times in his choice. And then he is, in respect of his ideas, as much at liberty, as he is in respect of bodies he rests on. He can at pleasure remove himself from one to another: but yet some ideas to the mind, like some motions to the body, are such, as in certain circumstances it cannot avoid, nor obtain their absence by the utmost effort it can use. Thus a man on the rack is not at liberty to lay by the idea of pain, and entertain other contemplations.

Where ever thought is wholly wanting, or the power to act or forbear according to the direction of thought, there necessity takes place. This in an agent capable of volition, when the beginning or continuance of any action is contrary to the preference of his mind, is called compulsion: when the hindering or stopping any action is contrary to his volition, it is called restraint: Agents that have no thought, no volition at all, are in every thing necessary agents.
Mixed modes are combinations of simple ideas of different kinds. The mind being once furnished with simple ideas, can put them together in several compositions, without examining whether they exist fo together in nature. And hence it is, that these ideas are called notions, as if they had their original and constant existence more in the thoughts of men, than in the reality of things: and to form such ideas, it sufficed that the mind put the parts of them together, and that they were constant in the understanding, without considering whether they had any real being. There are three ways whereby we get these complex ideas of mixed modes.

1st, By experience, and observation of things themselves: Thus by seeing two men wrestle, we get the idea of wrestling.

2dly, By invention, or voluntary putting together of several simple ideas in our own minds: So he that first invented printing, had an idea of it first in his mind before it ever evinced.

3dly, By explaining the names of actions we never saw, or nations we cannot see; and by enumerating all those ideas which go to the making them up. Thus the mixed mode, which the word lie stands for, is made up of these simple ideas: 1st, Articulate sounds. 2dly, Certain ideas in the mind of the speaker. 3dly, Those words, the signs of those ideas. 4thly, Those signs put together, by affirmation or negation, otherwise than the ideas they stand for are in the mind of the speaker. Since languages are made, complex ideas are usually got by the explanation of those terms that stand for them: for since they consist of simple ideas combined, they may, by words standing for those simple ideas, be represented to the mind of one who understands those words; though that combination of simple ideas was never offered to his mind by the real existence of things.

Mixed modes have their unity from an act of the mind, combining those several simple ideas together, and considering them as one complex one: the mark of this union is a certain name given to that combination. Men seldom reckon any number of ideas to make one complex one: but such collections as there be names for. Thus the killing of an old man, is as fit to be united into one complex idea, as that of a father; yet there being no name for it, it is not taken for a particular complex idea, nor a distinct species of action from that of killing any other man.

Those collections of ideas have names generally affixed, which are of frequent use in conversation: in which calls men endeavor to communicate their thoughts to one another with all possible dispatch. Those others, which they have seldom occasion to mention, they tie not together, nor give them names.

This gives the reason, why there are words in every language, which cannot be rendered by any one single word of another. For the fashions and customs of one nation make several combinations of ideas familiar in one, which another had never any occasion to make. Such were οργανικὰς among the Greeks, proscriptio among the Romans. This also occasions the constant change of languages; because the change of custom and opinions brings with it new combinations of ideas, which, to avoid long descriptions, have new names annexed to them, and so they become new species of mixed modes.

Of all our simple ideas, those that have had most mixed modes made out of them, are thinking, and motion; which comprehend in them all action; and power, from whence these actions are conceived to flow. For actions being the great business of mankind, it is no wonder, if the several modes of thinking and motion should be taken notice of, the ideas of them observed and laid up in memory, and have names assigned them. For without such complex ideas with names to them, men could not easily hold any communication about them. Of this kind are the modes of actions distinguished by their causes, means, objects, ends, instruments, time, place, and other circumstances; as also of the powers fitted for those actions: thus boldness is the power to do or speak what we intend, without fear or disorder; which power of doing anything, when it has been acquired by the frequent doing the same thing, is that idea we call habit; when forward, and ready upon every occasion, to break into action, we call it disposition; thus testimony is a disposition or aptness to be angry.

Power being the source of all action, the substances wherein these powers are, when they exert this power, are called causes; and the substances thereupon produced, or the simple ideas introduced into any subject, effects. The efficacy whereby the new substance or idea is produced, is called, in the subject exerting that power, action; in the subject, wherein any simple idea is changed, or produced, passion: Which efficacy, in intellectual agents, we can conceive to be nothing else but powers of thinking and willing; in corporeal agents, nothing else but modifications of motion.

Of our complex ideas of substances.

The mind observing several simple ideas to go constantly together, which being presumed to belong to one thing, are called, in united in one subject, by one name, which we are apt afterward to talk of and consider as one simple idea, which indeed is a composition of many ideas together. We imagine not these simple ideas to subsist by themselves; but suppose some substratum whereon they subsist, which we call substance. The idea of pure substance is nothing but the supposed (but unknown) support of those qualities, which are capable of producing simple ideas in us.

The ideas of particular circumstances are composed out of this obscure and general idea of substance, together with such combinations of simple ideas as are observed to exist together, and supposed to flow from the internal constitution and unknown essence of that substance. Thus we come by the idea of man, horse, gold, &c. Thus the sensible qualities of iron, or a diamond, make the complex idea of those substances, which a smith or a jeweller commonly knows better than a philosopher.

The same happens concerning the operations of the mind, viz. thinking, reasoning, &c. which we concluding not to subsist by themselves, nor apprehending how they can belong to body, or be produced by it, we think
them the actions of some other substance, which we call spirit; of whose substance or nature we have as clear a notion as of that of body; the one being but the supposed substratum of the simple ideas we have from without, as the other of those operations which we experiment in ourselves within: So that the idea of corporeal substance in matter, is as remote from our conceptions as that of spiritual substance.

Hence we may conclude, that he has the perfect idea of any particular substance, who has collected most of the simple ideas which do exist in it; among which he is to reckon its active powers and passive capacities, though not frivolously simple ideas.

Secondary qualities, for the most part, serve to distinguish substances. For our senses fail us in the discovery of the bulk, figure, texture, &c. of the minute parts of bodies, on which their real constitutions and differences depend; and secondary qualities are nothing but powers, with relation to our senses. The ideas that make our complex ones of corporeal substances, are of three sorts: First, The ideas of primary qualities of things, which are discovered by our senses; such are bulk, figure, motion, &c. Secondly, The sensible secondary qualities; which are nothing but powers to produce several ideas in us by our senses. Thirdly, Tha aptness we consider in the juxta-position of discernible parts, we call kingdom and unking and subject to the view from the comparison of one thing with another. Thus when we give men names, we agree in that of father.

There is no idea of any kind, which is not capable of an almost infinite number of considerations, in reference to other things; and therefore this makes no small part of mens words and thoughts. Thus one single man may at once sustain the relations of father, brother, son, husband, friend, subject, master, servant, bigger, less. And as to an almost infinite number; he being capable of as many relations, as there may be occasions of comparing him to other things in any manner of agreement, disagreement, or respect whatsoever.

Of cause and effect, and other relations.

Of cause and effect we get from our observation of the vicissitude of things, while we perceive some qualities or substances begin to exist, and that they receive their existence from the due application and operation of other beings: That which produces, is the cause; that which is produced, the effect. Thus fluidity in wax is the effect of a certain degree of heat, which we observe to be constantly produced by the application of such heat.

We distinguish the originals of things into two sorts. First, When the thing is wholly made new, so that no part thereof did ever exist before, as when a new particle of matter doth begin to exist which had before no being, it is called creation.

Secondly, When a thing is made up of particles which did all of them before exist, but the thing so constituted of pre-existing particles, which all together make up such a collection of simple ideas, had not any existence before, as this man, this egg, this rose, &c. this, when referred to a substance produced in the ordinary course of nature by an internal principle, but first on work by some external agent, and working by insensible ways which we perceive not, is called generation. When the cause is extrinsic, and the effect produced by a sensible separation, or juxta-position of discernible parts, we call it making; and such are all artificial things. When any simple idea is produced,
The denominations of things taken from time, are for the most part only relations. Thus when it is said that Queen Elizabeth lived sixty-nine, and reigned forty-five years, no more is meant, than that the duration of her existence was equal to sixty-nine, and of her government to forty-five annual revolutions of the sun.

Young and old, and other words of time, that are thought to stand for positive ideas, are indeed relative; and intimate a relation to a certain length of duration, whereof we have the idea in our minds. Thus we call a man young or old, that has lived little or much of that time that men usually attain to. This is evident from our application of these names to other things; for a man is called young at twenty, but a horse old, &c. The fun and stars we call not old at all, because we know not what period God has set to that sort of beings.

There are other ideas, that are truly relative, which we signify by names that are thought positive and absolute; such as great and little, strong and weak. The things thus denominated, are referred to some standards, with which we compare them. Thus we call an apple great, that is bigger than the ordinary sort of wholesome we have used to; and a man weak, that has not so much strength of power to move, as men usually have.

Of identity and diversity.

Another occasion the mind takes of comparing, is the very being of things. When considering a thing as existing at any certain time, or place, and comparing it with itself as existing at any other time, &c. it forms the idea of identity and diversity. When we fix any thing in any certain time and place, we are sure it is that very thing, and can be no other, how like forever it may be in all other respects.

We conceiving it impossible that two things of the same kind should exist together in the same place, we conclude, that whatever exists any where at the same time, excludes all of the same kind, and is there itself alone. When therefore we demand whether any thing be the same, or no, it refers always to something that existed such a time, in such a place, which it was certain at that instant was the same with itself and no other.

We have ideas of three sorts of substances: 1st, Of God; 2dly, Finite intelligent beings; 3dly, Bodies.

Firstly, God being eternal, unalterable, and everywhere, concerning his identity there can be no doubt.

Secondly, Finite spirits having had their determinate time and place of beginning to exist, the relation to that time and place will always determine to each its identity, as long as it exists.

Thirdly, The same will hold of every particle of matter to which no addition or subtraction is made. These three exclude not one another out of the same place, yet each exclude those of the same kind out of the same place.

The identity and diversity of modes and relations are determined after the same manner that substances are; only the actions of finite beings, as motion and thought, consisting in succession, they cannot exist in different times and places as permanent beings: for no motion or thought, considered as at different times, can be the same, each part thereof having a different beginning of existence.

From whence it is plain, that existence itself is the principium individuationis, which determinates a being to a particular time and place incommunicable to two beings of the same kind. Thus, suppose an atom existing in a determined time and place; it is evident that, considered in any instant, it is the same with itself, and will be so long as its existence continues. The name may be said of two, or more, or any number of particles, whilst they continue together. The mass will be the same, however jumbled; but if one atom be taken away, it is not the same mass.

In vegetables, the identity depends not on the same mass, and is not applied to the same thing. The reason of this, is the difference between an animate body and mass of matter; this being only the cohesion of particles any how united; the other, such a disposition, an organization of parts, as is fit to receive and distribute nourishment, so as to continue and frame the wood, bark, leaves, &c. (of an oak, for instance) in which consists the vegetable life. That therefore which has such an organization of parts partaking of one common life, continues to be the same plant, though that life be communicated to new particles of matter, vitally united to the living plant.

The case is not so much different in brutes, but that any one may hence see what makes an animal, and continues it the same.

The identity of the same man likewise consists in a participation of the same continued life in succeeding particles of matter vitally united to the same organized body.

To understand identity aright, we must consider what idea the word is applied to stands for; it being one thing to be the same substance, another the same man, and a third the same person.

An animal is a living organized body; and the same animal is the same continued life communicated to different particles of matter, as they happen successively to be united to that organized living body; and our notion of man is but of a particular sort of animal.

Person stands for an intelligent being, that reasons and reflects, and can consider itself the same thing in different times and places; which it doth by that consciousness that is inseparable from thinking. By this every one is to himself what he calls self, without considering whether that self be continued in the same or divers substances. In this consists personal identity, or the sameness of a rational being; and so far as this consciousness extends backward to any past action or thought, so far reaches the identity of that person. It is the same self now, it was then: And it is by the same self, with this present one that now reflects on it, that that action was done.

Self is that conscious thinking thing, whatever subsistence it matters not, which is conscious of pleasure or pain, capable of happiness or misery; and is concerned for itself as far as that consciousness extends. That with which the consciousness of this present thinking thing can join itself, makes the same person, and is one self with it; and so attributes to itself and owns all the actions of that thing as its own, as far as that consciousness reaches.
This personal identity is the subject of reward and punishment, being that by which every one is concerned for himself. If the consciousness went along with the little finger, when that was cut off, it would be the same self that was just before concerned for the whole body.

If the same Socrates, waking and sleeping, did not partake of the same consciousness, they would not be the same person. Socrates waking, could not be in justice accountable for what Socrates sleeping did. Now no more than one twin for what his brother twin did because their outsides were so like that they could not be distinguished.

But suppose I wholly lose the memory of some parts of my life, beyond a possibility of retrieving them, so that I shall never be conscious of them again: Am I not the same person that did those actions, though I have now forgotten them? I answer, that we must here take notice what the word I is applied to, which in this case is the man only: And the same man being presumed to be the same person, I is easily here supposed to stand also for the same performer. But if it be possible for the same man to have different incommunicable consciousness at different times, it is past doubt the same man would, at different times, make different persons. Which we see is the sense of mankind in the solemn declaration of their opinions, human laws not punishing the mad man for the sober man's actions, nor the sober man for what the mad man did; thereby making them two persons. Thus we say in English, such a one is not himself, or is beside himself; in which phrase it is inculcated, that self is changed, and the self-same person is no longer in that man.

But is not a man drunk or sober the same person? Why else is he punished for the same fact he commits when drunk, though he be never afterwards conscious of it? Just as much the same person, as a man that walks and does other things in his sleep is the same person, and is as answerable for any mischief he shall do in it. Human laws punish both with a justice suitable to their way of knowledge: Because in these cases they cannot distinguish certainly what is real, and what is counterfeit. And so the ignorance in drunkenness or sleep, is not admitted as a plea: For though punishment be annexed to personality, and personality to consciousness; and the drunkard, perhaps, is not conscious of what he did; yet human judges justly punish him, because the fact is proved against him, but want of consciousness cannot be proved for him.

To conclude: Whatever substance begins to exist, it must during its existence be the same. Whatever compositions of substances begin to exist, during the union of those substances, the concrete must be the same. Whatever mode begins to exist, during its existence it is the same. And so if the composition be of different substances, and different modes, the same rule holds.

Of other relations.

All simple ideas, wherein are parts or degrees, afford an occasion of comparing the subjects wherein they are to one another, in respect of those simple ideas. As

habiter, sweeter, more, left, &c. These depending on the equality and excess of the same simple ideas, in several subjects, may be called proportional relations.

Another occasion of comparing things is taken from the circumstances of their origin, as father, son, brother, &c. These may be called natural relations.

Sometimes the foundation of considering things, is some act whereby any one comes by a moral right, power, or obligation to do something: Such are general, captain, burgber; these are instituted and voluntary relations, and may be distinguished from the natural, in that they are alterable and separable from the persons to whom they sometimes belonged, though neither of the substances so related be destroyed: But natural relations are not alterable, but are as lasting as their subjects.

Another relation is the conformity or disagreement of men voluntary actions to a rule to which they are referred, and by which they are judged off: These may be called moral relations. It is this conformity or disagreement of our actions to some law (whereby good or evil is drawn on us from the will and power of the law-maker, and is what we call reward or punishment) that renders our actions morally good or evil.

Of these moral rules or laws, there seem to be three sorts, with their different enforcements: First, The divine law; secondly, Civil law; thirdly, The law of opinion or reputation. By their relation to the first, our actions are either sins or duties; to the second, criminal or innocent; to the third, virtues or vices.

Firstly, The divine law, is that law which God has set down to the actions of men, whether promulgated to them by the light of nature, or the voice of revelation.

That God has given a law to mankind, seems undeniable; since he has, first, A right to do it; we are his creatures. Secondly, Goodness and wisdom, to direct our actions to what is best. Thirdly, Power to enforce it by reward, and punishment: of infinite weight and duration. This is the only true touch-stone of moral rectitude; and by which men judge of the most considerable moral good or evil of their actions; that is, whether, as duties or sins, they are like to procure to them happiness or misery from the hands of the Almighty.

Secondly, The civil law is the rule fet by the commonwealth to the actions of those that belong to it. This law nobody over-looks; the rewards and punishments being ready at hand to enforce it, extending to the protecting or taking away of the life, liberty, and estate of those who observe or disobey it.

Thirdly, The law of opinion, or reputation. Virtue and vice are names supposed every where to stand for actions in their own nature right and wrong. As far as they are really so applied, they so far are coincident with the divine law. But it is visible that these names in the particular instances of their application, through the several nations and societies of men, are constantly attributed only to such actions as in each country and society are in reputation or disrepute. So that the measure of what is everywhere called and esteemed virtue and vice, is the approbation or disapprobation, or dislike, praise or blame, which by a tacit consent establishes itself in the societies and tribes of men in the world;
world; whereby several actions come to find credit or disgrace among them, according to the judgment, maxims, or fashions of the place.

That this is so, appears hence: That though that passes for virtue in one place, which is elsewhere accounted vice, yet every where virtue and praise, vice and blame, go together: Virtue is every where that which is thought praise worthy; and nothing else but that which has the allowance of public esteem, is called virtue. These have so close an alliance, that they are often called by the same name.

It is true, virtue and vice do, in a great measure, everywhere correspond with the unchangeable rule of right and wrong, which the laws of God have established; because the observance of these laws visibly secures and advances the general good of mankind, and the neglect of them breeds mischief and confusion: And therefore men, without renouncing all sense and reason, and their own interest, could not generally mistake in placing their commendation and blame on that side that deferred it not.

They who think commendation and disgrace not sufficient motives to engage men to accommodate themselves to the opinions and rules of those with whom they converse, seem little skilled in the history of mankind; the greatest part of which govern themselves chiefly by this law of fashion.

The penalties that attend the breach of God's laws are seldom seriously reflected on; and those that do reflect on them entertain thoughts of future reconciliation; and for the punishment due from the laws of the commonwealth, men flatter themselves with the hopes of impunity: But no man escapes censure and dislike, who offends against fashion; nor is there one of a thousand stiff and infensible enough, to bear up under the constant dislike and condemnation of his own club.

Morality then is nothing but a relation to these laws or rules: And these rules being nothing but a collection of several simple ideas, the conformity thereto is but so ordering the action, that the simple ideas belonging to it may correspond to those which the law requires. By which we see, how moral beings and notions are found on, and terminated in the simple ideas of sensation and reflection. For example; let us consider the complex idea signified by the word murder. First, from reflection, we have the ideas of willing, considering, purposing, malice, &c. all of life, perception, and self-motion. Secondly, from sensation, we have the ideas of man, and of some action whereby we put an end to that perception and motion in the man; All which simple ideas are comprehended in the word murder.

This collection of simple ideas being found to agree or disagree with the esteem of the country I have been bred in, and to be held worthy of praise or blame, I call the action virtuous or vicious. If I have the will of a supreme invisible Law maker for my rule; then as I suppose the action commanded or forbidden by God, I call it good or evil, fit or duty: If a compare it with the civil law of my country, I call it lawful or unlawful, a crime or no crime.

Moral actions may be considered two ways:
First, As they are in themselves a collection of simple ideas; in which sense, they are positive absolute ideas.
Secondly, As good or bad, or indifferent: In this respect they are relative, it being their conformity or disagreement with some rule that makes them so. We ought carefully to distinguish between the positive idea of the action, and the reference it has to a rule: Both which are commonly comprehended under one name, which often occasions confusion, and misleads the judgment.

Thus the taking from another what is his, without his consent, is properly called stealing: But that name being commonly understood to signify also the moral pravity of the action, men are apt to condemn whatever they hear called stealing as an ill action disagreeing with the rule of right. And yet the private taking away his sword from a madman, to prevent his doing mischief, though it be properly denominated stealing, as the name of such a mixed mode, yet when compared to the law of God, it is no sin or transgression, though the name stealing ordinarily carries such an intimation with it.

Of real and fantastical ideas.

Our ideas, in reference to things from whence they are taken, or which they may be supposed to represent, come under a threefold distinction; and are, first, either real or fantastical; secondly, adequate, or inadequate; thirdly, true or false.

Real ideas are such as have a foundation in nature, such as have a conformity with the real being and existence of things, or with their archetypes.

Fantastical are such as have no foundation in nature, nor any conformity with that reality of being to which they are referred as to their archetypes. By examining the several sorts of ideas we shall find, that, first, our simple ideas are all real; not that they are images or representations of what does exist, but as they are the certain effects of powers in things without us, ordained by our Maker to produce in us such sensations: They are real ideas in us, whereby we distinguish the qualities that are really in things themselves.

Their reality lies in the steady correspondence they have with the distinct constitutions of real beings. But whether they answer to those constitutions as to causes or patterns, it matters not; it suffices, that they are constantly produced by them.

Complex ideas being arbitrary combinations of simple ideas put together, and united under one general name, in forming of which the mind ues its liberty, we must inquire which of these are real, and which imaginary combinations.

First, Mixed modes and relations having no other reality than what they have in the minds of men, nothing else is required to make them real, but a possibility of existing conformable to them. These ideas being themselves archetypes, cannot differ from their archetypes, and so cannot be chimerical; unless any one will jumble together in them inconsistent ideas. Those indeed that have names assigned them in any language, must have a conformity to the ordinary signification of the name that is given.
M E T A P H Y S I C S.

given them, that they may not be thought fantastical.

Secondly, Our complex ideas of substances being made, in reference to things existing without us, whose representations they are thought are no farther real, than as they are such combinations of simple ideas as are really united, and co-exist in things without us: those are fancifical which are made up of several ideas that never were found united, as Centaur, &c.

Of ideas adequate or inadequate.

Real ideas are either adequate or inadequate. First, adequate; which perfectly represent those archetypes which the mind supposes them taken from, and which it makes them to stand for. Secondly, Inadequate; which are such as do but partially or incompletely represent those archetypes to which they are referred. Whence it appears,

First, That all our simple ideas are adequate; for they being the effects of certain powers in things fitted and ordained by God to produce such sensations in us, they cannot but be correspondent and adequate to such powers, and we are sure they agree to the reality of things.

Secondly, Our complex ideas of modes being voluntary collections of simple ideas, which the mind puts together without reference to any real archetypes, cannot but be adequate ideas. They are referred to no other pattern, nor made by any original, but the good-loving and will of him that makes the combination. If indeed one would conform his ideas to those which are formed by another person, they may be wrong or inadequate, because they agree not to that to which the mind designs to be their archetype and pattern; in which respect only any ideas of modes can be wrong, imperfect, or inadequate.

Thirdly, Our ideas of substances have in the mind a double reference: First, They are sometimes referred to a supposed real essence, of each species of things; Secondly, They are designed for representations in the mind, of things that do exist, by ideas discoverable in them: In both which respects they are inadequate.

First, If the names of substances stand for things, as supposed to have certain real essences, whereby they are of this or that species, of which real essences men are wholly ignorant; it follows, that the ideas they have in their minds, being referred to real essences as archetypes which are unknown, they must be so far from being adequate, that they cannot be supposed to be any representation of them at all. Our complex ideas of substances are nothing but certain collections of simple ideas that have been observed or supposed constantly to exist together. But such a complex idea cannot be the real essence of any substance: For then the properties we discover in it would be deducible from it, and their necessity connection with it be known; as all the properties of a triangle depend on and are deducible from the complex idea of three lines including a space: But it is certain, that in our complex ideas of substances are not contained such ideas on which all other qualities that are to be found in them depend.

Secondly, Those that take their ideas of substances from their sensible qualities, cannot form adequate ideas of them: Because their qualities and powers are so various, that no man's complex idea can contain them all. Most of our simple ideas, whereas of complex ones of substances do consist, are powers, which being relations to other substances, we cannot be sure we know all the powers, till we have tried what changes they are fitted to give and receive from other substances in their several ways of application; which being not possible to be tried upon one body, much less upon all, it is impossible we should have adequate ideas of any substance made of a collection of all its properties.

Of true and false ideas.

Truth and falsehood, in propriety of speech, belong only to propositions; and when ideas are termed true or false, there is some secret or tacit proposition which is the foundation of that denomination. Our ideas being nothing but appearances, or perceptions in the mind, can, in strictness of speech, no more be said to be true or false, than single names of things can be said to be true or false. The idea of Centaur has no more falsehood in it when it appears in our minds, than the name Centaur when it is pronounced or written on paper. For truth or falsehood lying always in some affirmation or negation, our ideas are not capable, any of them, of being false, till the mind passes some judgment on them, that is, affirms or denies something of them. In a metaphysical sense, they may be said to be true, that is, to be really such as they exist; though in things called true, even in that sense, there is perhaps a secret reference to our ideas, looked upon as the standards of that truth; which amounts to a mental proposition.

When the mind refers any of its ideas to any thing extraneous to it, they are then capable of being true or false: because in such a reference, the mind makes a tacit supposition of their conformity to that thing; which supposition, as it is true or false, so the ideas themselves come to be denominated. This happens in these cases:

1d. When the mind supposes its idea conformable to that in other men's minds, called by the same name, such as that of justice, virtue, &c.

2d. When the mind supposes any idea conformable to some real existence. Thus, that of Man is true, that of Centaur false; the one having a conformity to what has really existed, the other not.

3d. When the mind refers any of its ideas to that real constitution and essence of any thing whereon all its properties depend: and thus the greatest part, if not all our ideas of substances are false.

As to the first, when we judge of our ideas by their conformity to those of other men, they may be any of them false; but simple ideas are least liable to be mistaken. We seldom mistake green for blue, or bitter for sweet; much less do we confound the names belonging to different senses, and call a colour by the name of a taze. Complex ideas are much more liable to falshood in this particular; and those of mixed modes more than substances: because in substances, their sensible qualities serve, for the most part, to distinguish them clearly; but in mixed modes we are more uncertain, and we may call that justice which ought to be called by another name. The reason
referred to the real existence of things, none can be termed false but our complex ideas of substances: for our simple ideas being nothing but perceptions in us answerable to certain powers in external objects, their truth consists in nothing but such appearances as are produced in us suitable to those powers: neither do they become liable to the imputation of falseness, whether we judge these ideas to be in the things themselves, or no: for God having set them as marks of distinguishing things, that we may be able to discern one thing from another, and thereby chuse them as we have occasion, it alters not the nature of our simple ideas, whether we think the idea of blue (for instance) to be in the violet itself, or in the mind only: and it is equally from that appearance to be denominated blue, whether it be that real colour, or only a peculiar texture in it, that causes us to call it blue: since the name blue notes properly nothing but that mark of distinction that is in a violet, discernible only by our eyes, whatever it consists in.

Neither would our simple ideas be false, if by the different structure of our organs it were so ordered, that the same object should produce in several mens minds different ideas: for this could never be known, since objects would operate constantly after the same manner. It is most probable, nevertheless, that the ideas produced by the same objects in different mens minds, are very near and indistinguishably like. Names of simple ideas may be misapplied: as a man, ignorant in the English tongue, may call purple, scarlet: but this makes no falsehood in the idea. Complex ideas of modes cannot be false, in reference to the essence of any thing really existing; because they have no reference to any pattern existing, or made by nature.

Our complex ideas of substances, being all referred to patterns in things themselves, may be false. They are so, if by way of representations of the unknown essences of things: 2dly, When they put together simple ideas which in the real existence of things have no union; as in centaur. 3dly, When from any collection of simple ideas, that do always exist together, there is separated, by a direct negation, any one simple idea which is constantly joined with them. Thus, if from extension, solidity, fixedness, malleableness, fusibility, &c. we remove the colour observed in gold: If this idea be only left out of the complex one of gold, it is to be looked on as an inadequate and imperfect, rather than a false one; since though it contains not all the simple ideas that are united in nature, yet it puts none together but what do really exist together.

Upon the whole, our ideas, as they are considered by the mind, either in reference to the proper significations of their names, or in reference to the reality of things, may more properly be called right or wrong ideas, according as they agree or disagree to those patterns to which they are referred. The ideas that are in mens minds, simply considered, cannot be wrong, unless complex ideas, wherein inconsistent parts are jumbled together. All other ideas are in themselves right, and the knowledge about them right and true knowledge. But when we come to refer them to any patterns, or archetypes, then they are capable of being wrong, as far as they disagree with such archetypes.

Of the association of ideas.

Some of our ideas have a natural correspondence and connection one with another: It is the office and excellency of our reason to trace these, and hold them together in that union and correspondence which is founded in their peculiar beings. Besides this, there is another connection of ideas wholly owing to chance or custom: Ideas that in themselves are not at all of kin, come to be so united in some mens minds, that it is very hard to separate them; they always keep company, and the one no sooner comes into the understanding, but its associate appears with it; and if they are more than two, the whole gang always inseparably shew themselves together. This strong combination of ideas, not allied by nature, the mind makes in itself either voluntarily, or by chance: And hence it comes in different mens minds to be very different, according to their different inclinations, education, interests, &c.

Custom fettes habits of thinking in the understanding, as well as of determining in the will, and of motions in the body; all which seem to be but trains of motion in the animal spirits, which, once set a going, continue on in the same steps they have been used to; which by oftentirely become easy, and, as it were, natural. As far as we can comprehend thinking, thus ideas seem to be produced in our minds; or if they are not, this may serve to explain their following one another in an habitual train, when once they are put into that tract, as well as it does to explain such motions of the body.

This connection in our minds of ideas, in themselves loose and independent one of another, is of so great force to fet us awry in our actions, as well moral as natural, passions, reasonings, and notions themselves, that perhaps there is not any one thing that deserves more to be looked after. Thus the ideas of goblins and spirits have really no more to do with darkness than light; yet let but a foolish child inculcate these often on the mind of a child, and raise them there together, possibly he shall never be able to separate them again so long as he lives, but darkness shall ever afterwards bring with it those frightful ideas. A man has suffered pain or sickness in any place; he saw his friend die in such a room; though these have in nature nothing to do one with another, yet when the idea of the place occurs to his mind, it brings that of the pain and displeasure with it; he confounds him in his mind, and can as little bear the one as the other.

Intellectual habits and defects this way contradicted, are not less frequent and powerful, though less observed. Let the ideas of being and matter be strongly joined either by education or much thought, whilst these are still combined in the mind, what notions, what reasonings will
there be about separate spirits? Let custom from the very
culhhood have joined figure and shape to the idea of God,
and what absurdities will that mind be liable to about
the Deity? Let the idea of infallibility be joined to any
person, and these two constantly together possefs the
mind; and then one body in two places at once shall be
swallowed for a certain truth, whenever that imagined in-
fallible person dilates, and demands assent without in-
quity.

Some such wrong combinations of ideas will be found to
establish the irreconcilable opposition between different
sects of philosophy and religion: for we cannot imagine
every one of their followers to impose wilfully on himself,
and what absurdities will that mind be liable to about
persons, and these two constantly together possess the
Deity? Let the idea of infallibility be joined to any
person, and these two constantly together possess the
mind; and then one body in two places at once shall be
swallowed for a certain truth, whenever that imagined in-
sfallible person dilates, and demands assent without in-
quity.

Some such wrong combinations of ideas will be found to
establish the irreconcilable opposition between different
sects of philosophy and religion: for we cannot imagine
every one of their followers to impose wilfully on himself,
and what absurdities will that mind be liable to about
persons, and these two constantly together possess the
Deity? Let the idea of infallibility be joined to any
person, and these two constantly together possess the
mind; and then one body in two places at once shall be
swallowed for a certain truth, whenever that imagined in-
sfallible person dilates, and demands assent without in-
quity.

2. The next fort of agreement or disagreement the
mind perceives in any of its ideas, may be called relative,
and is nothing but the perception of the relation between
any two ideas of what kind forever; that is, their agree-
ment or disagreement one with another in several ways
the mind takes of comparing them.

3. The third fort of agreement or disagreement to be
found in our ideas, is, coexistence or non-coexistence in
the fame subject; and this belongs particularly to substan-
ces. Thus when we pronounce concerning gold, that it
is fixed, it amounts to no more but this, that fixedness,
or a power to remain in the fire unconsumed, is an idea
that always accompanies that particular fort of yellowness,
weight, fusibility, &c. which make our complex idea
signified by the word gold.

4. The fourth fort, is that of actual and real exis-
tence agreeing to any idea. Within these four forts
of agreement or disagreement, is contained all the
knowledge we have, or are capable of. For all that we
know or can affirm concerning any idea, is, That it is, or
is not the fame with some other; as, that blue is not yel-
low; That it does, or does not coexist with another in
the fame subject; as, that iron is susceptible of magnet-
ical impressions; That it has that or this relation to fome
other ideas; as, That two triangles, upon equal bases be-
tween two parallels, are equal: or, that it has a real
existence without the mind; as, that God is.

There are several ways wherein the mind is possessed
of truth, each of which is called knowledge. First,
there is actual knowledge, when the mind has a present
view of the agreement or disagreement of any of its ideas,
or of the relation they have with another. Second-
ly, A man is said to know any proposition, when having
once evidently perceived the agreement or disagreement
of the ideas whereof it consists, and so lodged it in his
memory, that whenever it comes to be reflected on again,
the mind affents to it without doubt or hesitation, and is
certain of the truth of it. And this may be called habi-
tual knowledge. And thus a man may be said to know
all those truths which are lodged in his memory by a fore-
gone, clear, and full perception.

Of habitual knowledge there are two forts: the one
is of such truths laid up in the memory, as whenever they
occur to the mind, it actually perceives the relation that is
between those ideas. And this is in all those truths,
where the ideas themselves, by an immediate view, dis-
cover their agreement or disagreement one with another.
The other is of such truths, whereof the mind having
been convinced, it retains the memory of the conviction,
without the proofs. Thus a man that remembers cer-
tainly, that he once perceived the demonstration, that the
three angles of a triangle are equal to two right ones,
knows it to be true, when that demonstration is gone out

ideas to disagree. This it does without any pains or de-
duction, by its natural power of perception and dilution.
This is what men of art have reduced to those general
rules, viz. what is, is; and it is impossible for the same
thing to be and not to be. But no maxim can make a
man know it clearer, that round is not flat, than the
bare perception of those two ideas, which the mind at
first sight perceives to disagree.

Of knowledge in general.

Since the mind, in all its thoughts and reasonings, has
no other immediate object but its own ideas, which alone
does or can contemplate, it is evident that our know-
ledge is only converfant about them. Knowledge then
seems to be nothing but the perception of the connection
and agreement, or disagreement and repugnancy of any
of our ideas: where this perception is, there is know-
lledge; and where it is not, there, though we fancy,
guess, or believe, yet we always come short of know-
lledge. Where we know that white is not black, what do
we but perceive that these two ideas do not agree? Or
that the three angles of a triangle, are equal to two right
ones; what do we more but perceive that equality to two
right ones does necessarily agree to, and is inseparable
from the three angles of a triangle? But to understand
a little more distinctly wherein this agreement or disagree-
ment consists, we may reduce it all to these four forts:

1st. Identity or diversity; 2dly, Relation; 3dly, Co-
existence; 4thly, Real existence.

1. Identity or diversity. It is the first act of the
mind, to perceive its ideas; and so far as it perceives
them, to know each what it is, and thereby to perceive
their difference, that is, the one not to be the other:
by this the mind clearly perceives each idea to
agree with itself, and to be what it is; and all distinct

ideas to disagree. This it does without any pains or de-
duction, by its natural power of perception and dilution.
This is what men of art have reduced to those general
rules, viz. what is, is; and it is impossible for the same
thing to be and not to be. But no maxim can make a
man know it clearer, that round is not flat, than the
bare perception of those two ideas, which the mind at
first sight perceives to disagree.
of his mind, and possibly cannot be recollected: But he
knows it in a different way from what he did before,
namely, not by the intervention of those intermediate
ideas, whereby the agreement or disagreement of those in
the proposition was at first perceived, but by remembering,
<i.e.</i> knowing that he was once certain of the truth of
this proposition, that the three angles of a triangle are
equal to two right ones. The immutability of the same
relations between the same immutable things, is now the
idea that shews him, that if the three angles of a triangle
were once equal to two right ones, they will always be
do. And hence he comes to be certain, that what was
once true, is always true; what ideas once agreed, will
always agree; and consequently, what he once knew to
be true, he will always know to be true, as long as he
can remember that he once knew it.

Of the degrees of our knowledge.

All our knowledge consisting in the view the mind has
of its own ideas, which is the utmost light and greatest
certainty we are capable of, the different clearness of our
knowledge seems to lie in the different way of perception
the mind has of the agreement or disagreement of any of
its ideas.

When the mind perceives this agreement or disagree-
ment of two ideas immediately by themselves, without
the intervention of any other, we may call it intuitive
knowledge; in which cases the mind perceives truth,
as the eye does light, only by being directed towards it.
Thus the mind perceives, that white is not black; that three
are more than two; and equal to one and two. This part
of knowledge is irreducible, and, like the bright fun-shine,
forces itself immediately to be perceived as soon as ever
the mind turns its view that way. It is on this intuition
that depends all the certainty and evidence of our other
knowledge; which certainty every one finds to be so
great, that he cannot imagine, and therefore not require
a greater.

The next degree of knowledge, is, where the mind
perceives not this agreement or disagreement immediate-
ly, or by the <i>juxta-position</i>, as it were, of the ideas, be-
cause those ideas concerning whose agreement or disagree-
ment the inquiry is made, cannot by the mind be so put
together, as to shew it. In this case the mind is fond to
discover the agreement or disagreement which it searches,
by the intervention of other ideas: And this is that which
we call reasoning. And thus, if we would know the agree-
ment or disagreement in bigness, between the three
angles of a triangle, and two right angles, we cannot by
an immediate view and comparing them do it; because
the three angles of a triangle cannot be brought at once,
and be compared with any other one or two angles. And
so of this the mind has no immediate or intuitive know-
ledge. But we must find out some other angles, to which
the three angles of a triangle have equality; and finding
those equal to two right ones, we come to know the equality
of these three angles to two right ones. Those intervening
ideas which serve to shew the agreement of any two others,
are called proofs; and where the agreement or disagree-
ment is by this means plainly and clearly perceived, it is
called demonstration. A quickness in the mind to find
those proofs, and to apply them right, is that which is
called sagacity.

This knowledge, though it be certain, is not so clear
and evident as intuitive knowledge. It requires pains
and attention, andsteady application of mind, to discover
the agreement or disagreement of the ideas it considers;
and there must be a progression by steps and degrees,
before the mind can in this way arrive at certainty. Before
demonstration there was a doubt, which, in intuitive
knowledge, cannot happen to the mind that has its facul-	y of perception left to a degree capable of distinct ideas,
no more than it can be a doubt to the eye (that can dif-
tinctly see white and black) whether this ink and paper
be all of a colour.

Now, in every step that reason makes in demonstrative
knowledge, there is an intuitive knowledge of that agree-
ment or disagreement it seeks with the next intermediate
idea, which it uses as a proof; for if it were not so, that
yet would need a proof; since without the perception of
such agreement or disagreement, there is no knowledge
produced. By which it is evident, that every step in rea-
soning, that produces knowledge, has intuitive certainty:
which when the mind perceives, there is no more requi-
red but to remember it, to make the agreement or disa-
greement of the ideas concerning which we inquire visible
and certain. This intuitive perception of the agreement
or disagreement of the intermediate ideas in each step and
progression of the demonstration, must also be exactly
carried in the mind; and a man must be sure that no part
is left out; which because in long deductions the mem-
ory cannot easily retain, this knowledge becomes more
imperfect than intuitive, and men often embrace falfes-
hoods for demonstrations.

It has been generally taken for granted, that mathema-
tics alone are capable of demonstrative certainty. But
to have such an agreement or disagreement as may be in-
tuitively perceived, being not the privilege of the ideas of
number, extension, and figure alone, it may possibly be
the want of due method and application in us, and not of
sufficient evidence in things, that demonstration has been
thought to have so little to do in other parts of knowledge:
For in whatever ideas the mind can perceive the agree-
ment or disagreement immediately, there it is capable of
intuitive knowledge: And where it can perceive the agree-
ment or disagreement of any two ideas, by an intuitive
perception of the agreement or disagreement they
have with any intermediate ideas, there the mind is capa-
bile of demonstration which is not limited to the ideas of
figure, number, extension, or their modes. The rea-
son why it has been generally supposed to belong to them
only, is, because in comparing their equality or excess the
modes of numbers have every the least difference very
clear and perceivable: And in extension, though every
the least excess is not so perceptible, yet the mind has
found out ways to discover the just equality of two angles,
extensions, or figures: and both, that is, numbers and
figures, can be set down by visible and lasting marks.

But in other simple ideas, whose modes and differences
are made and counted by degrees, and not quantity, we
have not so nice and accurate a distinction of their differ-
ences, as to perceive or find ways to measure their just
equality,
equality, or the least differences: For tho"se other simple ideas being appearances or sensations produced in us by the size, figure, motion, &c. of minute corporscles singly inelensible, their different degrees also depend on the variation of some, or all of those causes; which since it cannot be observed by us in particles of matter, whereof each is too subtle to be perceived, it is impossible for us to have any exact measures of the different degrees of those simple ideas. Thus, for instance, not knowing what number of particles, nor what motion of them, is fit to produce a precise degree of whiteness, we cannot demonstrate the certain equality of any two degrees of whiteness, because we have no certain standard to measure them by, nor means to distinguish every the least difference; the only help we have been from our senses, which in this point fail us.

But where the difference is so great as to produce in the mind ideas clearly distinct, there ideas of colours, as we see in different kinds, blue and red, (for instance,) are as capable of demonstration as ideas of number and extension. What is here said of colours, holds true in all secondary qualities. These two then, intuition and demonstration, are the degrees of our knowledge; whatever comes short of one of these, is but faith or opinion, not knowledge, at least, in all general truths. There is, indeed, another perception of the mind employed about the particular existence of finite beings without us; which going beyond probability, but not reaching to either of the foregoing degrees of certainty, passes under the name of knowledge.

Nothing can be more certain, than that the idea we receive from an external object is in our minds: This is intuitive knowledge; but whether we can thence certainly infer the existence of anything without us, corresponding to that idea, is that whereof some men think there may be a question made, because men may have such an idea in their minds, when no such things exist, no such object affects their senses. But its evident that we are invincibly conscious to ourselves of a different perception, when we look upon the sun in the day, and think on it by night; when we actually taste wormwood, or smell a rose, or only think on that flavour or odour. So that we may add to the two former sorts of knowledge, this also of the existence of particular external objects, by that perception and consciousness we have of the actual entrance of ideas from them, and allow these three degrees of knowledge, viz. intuitive, demonstrative, and sensitive.

But since our knowledge is founded on, and employed about our ideas only, will it follow thence that it must be conformable to our ideas; and that where our ideas are clear and distinct, obscure and confused, there our knowledge will be so too? No. For our knowledge consisting in the perception of the agreement or disagreement of any two ideas, its clearness or obscurity consists in the clearness or obscurity of that perception, and not in the clearness or obscurity of the ideas themselves. A man (for instance) that has a clear idea of the angles of a triangle, and of equality to two right ones, may yet have but an obscure perception of their agreement; and so have but a very obscure knowledge of it. But obscure and confused ideas can never produce any clear or distinct knowledge; because, as far as any ideas are obscure or confused, so far the mind can never perceive clearly whether they agree or disagree.

Of the extent of human knowledge.

From what has been said concerning knowledge, it follows, First, That we can have no knowledge farther than we have ideas.

Secondly, That we have no knowledge farther than we can have perception of that agreement or disagreement of our ideas, either by intuition, demonstration, or sensation.

Thirdly, We cannot have an intuitive knowledge that shall extend itself to our ideas, and all that we would know about them, because we cannot examine and perceive all the relations they have one to another, by juxtaposition, or an immediate comparison one with another. Thus we cannot intuitively perceive the equality of two extentions, the difference of whole figures makes their parts incapable of an exact immediate application.

Fourthly, Our rational knowledge cannot reach to the whole extent of our ideas; because between two different ideas we would examine, we cannot always find such proofs as we can connect one to another, with an intuitive knowledge in all the parts of the deduction.

Fifthly, Sensitive knowledge reaching no farther than the existence of things actually present to our senses, is yet much narrower than either of the former.

Sixthly, From all which it is evident, that the extent of our knowledge, comes not only short of the reality of things, but even of the extent of our own ideas. We have the ideas of a square, a circle, and equality; and yet, perhaps, shall never be able to find a circle equal to a square.

The affirmations or negations we make concerning the ideas we have, being reduced to the four sorts above mentioned, viz. identity, coexistence, relation, and real existence, we shall examine how far our knowledge extends in each of these.

First, As to identity and diversity, our intuitive knowledge is as far extended as our ideas themselves; and there can be no idea in the mind, which it does not presently, by an intuitive knowledge, perceived to be what it is, and to be different from any other.

Secondly, As to the agreement or disagreement of our ideas in coexistence: In this our knowledge is very short; though in this consists the greatest and most material part of our knowledge, concerning substances. For our ideas of substances being nothing but certain collections of simple ideas, coexisting in one subject, (our idea of flame, for instance, is a body hot, luminous, and moving upward;) when we would know any thing farther concerning this, or any other sort of substance, what do we but inquire what other qualities or powers these substances have, or have not? Which is nothing else but to know what other simple ideas do or do not coexist with those that make up that complex idea. The reason of this, is because the simple ideas which make up our complex ideas of substances, have no visible necessary con-
metaphysics.

The ideas of a Supreme Being, infinite in power, goodness, and wisdom, whose workmanship we are, and on whom we depend; and the idea of ourselves, as understanding rational creatures; would, if duly considered, afford such foundations of our duty, and rules of action, as might place morality among the sciences capable of demonstration. The relations of other modes may certainly be perceived, as well as those of number and extension. Where there is no property, there is no injustice, is a proposition as certain as any demonstration in Euclid: for the idea of property being a right to any thing; and the idea of injustice being the violation of that right; it is evident, that these ideas being thus established, and these names annexed to them, we can as certainly know this proposition to be true, as that a triangle has three angles equal to two right ones. Again, No government allows absolute liberty. The idea of government being the establishment of society upon certain rules or laws which require conformity to them, and the idea of absolute liberty being for any one to do whatever he pleases, we are as capable of being certain of the truth of this proposition, as of any in mathematics.

What has given the advantage to the ideas of quality, and made them thought more capable of certainty and demonstration, is,

First, That they can be represented by sensible marks which have a nearer correspondence with them than any words or sounds. Diagrams drawn on paper are copies of the ideas, and not liable to the uncertainty that words carry in their signification: But we have no sensible marks that resembie our moral ideas; and nothing but words to express them by; which though when written they remain the same, yet the ideas they stand for may change in the same man; and it is very seldom that they are not different in different persons.

Secondly, Moral ideas are commonly more complex than figures. Whence these two inconveniences follow:

First, That their names are of more uncertain signification; the precise collection of simple ideas they stand for not being so easily agreed on, and so the sign that is used for them in communication always, and in thinking often, does not readily carry with it the same idea. Secondly, The mind cannot easily retain those precise combinations so exactly and perfectly as is necessary; in the examination of the habits and correspondencies, agreements or disagreements of several of them one with another, especially where it is to be judged off by long deductions, and the intervention of several other complex ideas, to shew the agreement or disagreement of two remote ones.

vol. iii. numb. 77.
Now one part of these disadvantages in moral ideas, which has made them be thought not capable of demonstration, may in a good measure be remedied by definitions, setting down that collection of simple ideas which every term shall stand for, and then using the terms declaratively and constantly for that precise collection.

As to the fourth sort of knowledge, viz. of the real actual existence of things, we have an intuitive knowledge of our own existence; a demonstrative knowledge of the existence of God; and a sensitive knowledge of the objects that present themselves to our sensae.

From what has been said, we may discover the causes of our ignorance: which are chiefly these three: First, Want of ideas; Secondly, Want of a discoverable connection between the ideas we have; Thirdly, Want of tracing and examining our ideas.

First, There are some things we are ignorant of for want of ideas. All the simple ideas we have are confined to the observances of our senses, and the operations of our own minds that we are conscious of in ourselves. What other ideas it is possible other creatures may have, by the assistance of other senses and faculties more or perfecter than we have, or different from ours, it is not for us to determine; but to lay or think there are no such, because we conceive nothing of them, is no better an argument, than if a blind man should be positive in it, that there was no such thing as light and colours, because we know not. This we know, and certainly find, that we have no other views of them, besides those we have, to make discoveries of them more perfect. The intellectual and sensible world are in this perfectly alike, that the parts which we see of either of them, hold no proportion with that we see not; and whatsoever we can reach with our eyes or our thoughts of either of them, is but a point almost in comparison of the real.

Another great cause of ignorance, is the want of ideas that we are capable of. This keeps us in ignorance of things we conceive capable of being known. Bulk, figure, and motion we have ideas of; yet not knowing what is the particular bulk, motion, and figure of the greatest part of the bodies of the universe, we are ignorant of the several powers, efficacies, and ways of operation, whereby the effects we daily see are produced. These are hid from us in some things, by being too remote; in others, by being too minute.

When we consider the vast distance of the known and visible parts of the world, and the reasons we have to think that what lies within our ken is but a small part of the immense universe, we shall then discover an huge abyss of ignorance. What are the particular fabricks of the great masses of matter, which make up the whole suspension of corporeal beings; how far they are extended; and what is their motion, and how continued; and what influence they have upon one another; are contemplations, that at first glimpse our thoughts lose themselves in. If we confine our thoughts to this little system of our fun, and the greater masses of matter that visibly move about it; what several sorts of vegetable, animals, and intellectual corporeal beings, infinitely different from those of our little spot of earth, may probably be in other planets, to the knowledge of which, even of their outward figures and parts, we can no way attain, whilst we are confined to this earth, there being no natural means, either by sensation or reflection, to convey their certain ideas into our minds?

There are other bodies in the universe, no less concealed from us by their minuteness. These inensible corpulces being the active parts of matter, and the great instruments of nature on which depend all their secondary qualities and operations, our want of precise distinct ideas of their primary qualities keeps us in incurable ignorance of what we desire to know about them. Did we know the mechanical affections of rhubarb and opium, we might as easily account for their operations of purging or causing sleep, as a watchmaker can for the motions of his watch. The dissolving of silver in aqua regia, or gold in aqua regia, and not vice versa, would be then, perhaps, no more difficult to know, than it is to a smith to understand why the turning of one key will open a lock, and not the turning of another. But whilst we are destitute of fufceptible acute enough to discover the minute particles of bodies, and to give us ideas of their mechanical affections, we must be content to be ignorant of their properties and operations: Nor can we be assured about them any farther than some few trials we make are able to reach; but whether they will succeed another time, we cannot be certain. This hinders our certain knowledge of universal truths concerning natural bodies; and our reason carries us herein very little beyond particular matters of fact. And therefore, how far forever human industry may advance useful and experimental philosophy, in physical things, yet scientific will still be out of our reach; because we want perfect and adequate ideas of those very bodies which are nearest to us, and most under our command.

This, at first sight, shews us how disproportionate our knowledge is to the whole extent, even of material beings; to which if we add the consideration of that infinite number of spirits that may be, and probably are, which are yet more remote from our knowledge, whereof we have no cognizance; we shall find this cause of ignorance conceal from us, in an impenetrable obscurity, almost the whole intellectual world, a greater certainly, and a more beautiful world than the material: For being some very few ideas of spirit we get from our own mind by reflection, and from thence the belt we can collect of the Father of all spirits, the Author of them and us and all things, we have no certain information so much as of the existence of other spirits but by revelation; much less have we distinct ideas of their different natures, states, powers, and several constitutions, wherein they agree or differ from one another, and from us: And therefore in what concerns their different species and properties, we are under an absolute ignorance.

The second cause of ignorance, is the want of discoverable connection between those ideas we have: Where we want that, we are utterly incapable of universal and certain knowledge: and are, as in the former case, left only to observation and experiment. Thus the mechanical
...al affections of bodies having no affinity at all with the ideas they produce in us, we can have no distinct knowledge of such operations beyond our experience; and can reason no otherwise about them, than as the effects or, appearance of an infinitely wise agent, which perfectly surpasses our comprehensions.

The operation of our minds upon our bodies, is as inconceivable. How any thought should produce a motion in body, is as remote from the nature of our ideas, as how any body should produce any thought in the mind. That it is so, if experience did not convince us, the consideration of the things themselves would never be able in the least to discover to us.

In some of our ideas there are certain relations, habits, and connections, so visibly included in the nature of the ideas themselves, that we cannot conceive them separable from them by any power whatsoever: In these only we are capable of certain and universal knowledge. Thus the idea of a right lined triangle, necessarily carries with it an equality of its angles to two right ones. But the coherence and continuity of the parts of matter, the production of sensation in us of colours and sounds, &c. by impulse and motion, being such wherein we can discover no natural connection with any ideas we have, we cannot but ascribe them to the arbitrary will and good pleasure of the wise Architect.

The things that we observe constantly to proceed regularly, we may conclude to be by a law set them; but yet by a law that we know not; whereby, though causes work feability, and effects coherently flow from them, yet their connections and dependencies being not discoverable in our ideas, we can have but an experimental knowledge of them.

The third cause of ignorance, is our want of tracing those ideas we have or may have, and finding out those intermediate ideas which may shew us what habitude of agreement or disaffreement they may have one with another: And thus many are ignorant of mathematical truths, for want of application in inquiring, examining, and by due ways comparing those ideas.

Hitherto we have examined the extent of our knowledge, in respect of the several forts of beings that are: There is another extent of it, in respect of univerfality, which will also deserve to be considered; and in this regard our knowledge follows the nature of our ideas. If the ideas are abstract, whose agreement or disaffreement we perceive, our knowledge is universal. For what is known of such general ideas, will be true of every particular thing in which that essence, that is, abstract idea, is to be found: And what is once known of such ideas, will be perpetually, and for ever true. So that, as to all general knowledge, we must search and find it only in our own minds: And it is only the examining of our own ideas that furnishes us with that. Truths belonging to essences of things, (that is, to abstract ideas), are external, and are to be found out by the contemplation only of those essences, as the existence of things is to be known only from experience.

Of the reality of our knowledge.

This reader by this time may be ready to object, If it be true, that all knowledge lies only in the perception of the agreement or disaffreement of our own ideas, the visions of an enthusiast, and the reasonings of a fool-man, will be equally certain: It is no matter how things are, so a man observe but the agreement of his own imaginations, and talk conformably; it is all truth, all certainty.

To this it is answered, that if our knowledge of our ideas should terminate in them, and reach no farther, where there is something farther intended, our most fee-rious thoughts would be of little more use than the reveries of a crazy brain. But it is evident, that this way of certainty, by the knowledge of our own ideas, goes a little farther than bare imagination: and that all the certainty of general truths is a manias, lies in nothing else but this knowledge of our ideas.

It is evident, that the mind knows not things immediately, but by the intervention of the ideas it has of them. Our knowledge therefore is real, only so far as there is a conformity between our ideas and the reality of things. But how shall we know when our ideas agree with things themselves? There are two sorts of ideas, that we may be assured agree with things: These are,

First, Simple ideas; which since the mind can by no means make to itself, must be the effect of things occurring upon the mind in a natural way, and producing therein those perceptions, which, by the will of our Maker, they are ordained and adapted to. Hence it follows, that simple ideas are not fictions of our fancies, but the natural and regular productions of things without us, really operating upon us; which carry with them all the conformity our finite requires, which is to represent things under those appearances they are fitted to produce in us. Thus the idea of whiteness, as it is in the mind, exactly answers that power which is in any body to produce it there. And this conformity between our simple ideas, and the existence of things, is sufficient for real knowledge.

Secondly, All our complex ideas, except those of substances, being archetypes of the mind's own making, and not referred to the existence of things as to their originals, cannot want any conformity necessary to real knowledge: For that which is not designed to represent any thing but itself, can never be capable of a wrong representation. Here the ideas themselves are considered as archetypes, and things no otherwise regarded than as they are conformable to them. Thus the mathematician considers the truth and properties belonging to a rectangle, or circle, only as they are ideas in his own mind, which possibly he never found existing mathematically, that is, precisely true; yet his knowledge is not only certain, but real; because real things are no farther concerned, nor intended to be meant by any fuch propositions, than as things really agree to those archetypes in his mind. It is true of the idea of a triangle, that its three angles are equal to two right ones: It is true also of a triangle, wherever it exists: What is true of those figures, that have barely an ideal existence in his mind, will hold true of them also when they come to have a real existence in matter.

Hence it follows, that moral knowledge is as capable of real certainty as mathematics: For certainty being nothing
nothing but the perception of the agreement or disagreement of our ideas, and demonstration nothing but the perception of such agreement by the intervention of other ideas, our moral ideas, as well as mathematical, being archetypes themselves, and so adequate or complete ideas, all the agreement or disagreement we shall find in them will produce real knowledge, as well as in mathematical figures. That which is requisite to make our knowledge certain, is the clearness of our ideas; and that which is required to make it real, is, that they answer their archetypes.

Thirdly, But the complex ideas, which we refer to archetypes without us, may differ from them, and so our knowledge about them may come short of being real; and such are our ideas of substances. These must be taken from something that does or has existed, and not be made up of anything that does or has existed, and not be made up of such ample ones as have been discovered to coexist in nature. And our ideas being thus true, their agreement we find they have with others will be knowledge. Whatever ideas we have, we have, the agreement we find they have with others will be knowledge. If those ideas be abstract, it will be general knowledge. But to make it real concerning substances, the ideas must be taken from the real existence of things. Wherever, therefore, we perceive the existence or disagreement of our ideas, there is certain knowledge: And wherever we are sure those ideas agree with the reality of things, there is certain real knowledge.

Of truth in general.

Truth, in the proper import of the word, signifies the joining or separating of signs, as the things signified by them do agree or disagree one with another. The joining or separating of signs, is what we call propositions: So that truth properly belongs only to propositions. Whereof there are two sorts, mental and verbal; as there are two sorts of signs commonly made use of, ideas and words.

It is difficult to treat of mental propositions without verbal; because, in speaking of mental, we must make use of words, and then they become verbal. Again, men commonly in their thoughts and reasonings use words instead of ideas; especially if the subject of their meditation contains in it complex ideas. If we have occasion to form mental propositions about white, black, circle, &c. we can, and often do, frame in our minds the ideas themselves, without reflecting on the names: But when we would consider, or make propositions about the more complex ideas, as of a man, vitriol, fortitude, glory, &c. we usually put the name for the idea; because the idea of these names stand for being for the most part confused, imperfect, and undetermined, we reflect on the names themselves, as being more clear, certain, and distinct, and reader to occur to our thoughts, than pure ideas; and so we make use of these words instead of the ideas themselves, even when we would meditate and reason within ourselves, and make tacit mental propositions.

We must then observe two sorts of propositions that we are capable of making: First, Mental propositions, wherein the ideas in our understandings are put together or separated by the mind perceiving or judging of their agreement or disagreement. Secondly, Verbal propositions; which are words put together or separated in affirmative or negative sentences: So that proposition consists in joining or separating signs; and truth consists in putting together or separating those signs, according as the things they stand for agree or disagree.

Truth, as well as knowledge, may well come under the distinction of verbal and real; that being only verbal truth, wherein terms are joined according to the agreement or disagreement of the ideas they stand for, without regarding whether our ideas are such as really have or are capable of having an existence in nature. But then it is they contain real truth, when these signs are joined as our ideas agree, and when our ideas are such as, we know, are capable of having an existence in nature; which in substances we cannot know, but by knowing that such have existed. Truth is the marking down in words the agreement or disagreement of ideas as it is: Falsity is the marking down in words the agreement or disagreement of ideas otherwise than it is; and so for as these ideas, thus marked by sounds, agree to their archetypes, so far only is the truth real. The knowledge of this truth consists in knowing what ideas the words stand for, and the perception of the agreement or disagreement of those ideas, according as it is marked by those words.

Besides truth taken in the strict sense before mentioned, there are other sorts of truths: As, first, Moral truth; which is speaking things according to the persuasion of our own minds. Secondly, Metaphysical truth; which is nothing but the real existence of things conformable to the ideas to which we have annexed their names.

These considerations of truth either having been before taken notice of, or not being much to our present purpose, it may suffice here only to have mentioned them.

Of our knowledge of existence.

Hitherto we have only considered the essence of things; which being only abstract ideas, and thereby removed in our thoughts from particular existence, give us no knowledge of existence at all. We proceed now to inquire concerning our knowledge of the existence of things, and how we come by it.

We have the knowledge of our own existence by intuition; of the existence of God, by demonstration; and of other things, by sensation. As for our own existence, we perceive it so plainly, that it neither needs, nor is capable of any proof. I think, I reason, I feel pleasure and pain: can any of these be more evident to me than my own existence? If I doubt of all other things, that very doubt makes me perceive my own existence, and will not suffer me to doubt of that. If I know I doubt, I have as certain a perception of the thing doubting, as of that thought which I call doubt. Experience then convinces us, that we have an intuitive knowledge of our own existence; and an internal infallible perception that we are. In every act of sensation, reasoning, or thinking, we are conscious to ourselves of our own being; and
and in this matter come not short of the highest degree of certainty.

Of our knowledge of the existence of a God.

Though God has given us no innate ideas of himself, yet having furnished us with those faculties our minds are endowed with, he hath not left himself without a witness, since we have sense, perception, and reason, and cannot want a clear proof of him as long as we carry ourselves about us. Nor can we justly complain of our ignorance in this great point, since he has so plentifully provided us with means to discover and know him, so far as is necessary to the end of our being, and the great concernment of our happiness. But though this be the most obvious truth that reason discovers, yet it requires thought and attention; and the mind must apply itself to a regular deduction of it, from some part of our intuitive knowledge; or else we shall be as ignorant of this, as of other propositions which are in themselves capable of clear demonstration. To shew, therefore, that we are capable of knowing, that is, being certain, that there is a God, and how we may come by this certainty, we need go no farther than ourselves, and that undoubted knowledge we have of our own existence. It is beyond question, that man has a clear perception of his own being: He knows certainly that he exists, and that he is something. In the next place, man knows by an intuitive certainty, that bare nothing can no more produce any real being, than it can be equal to two right angles. If therefore, we know there is some real being, it is an evident demonstration, that from eternity there has been something; since what was not from eternity had a beginning; and what had a beginning, must be produced by something else. Next, it is evident, that, what has its being from another, must also have all that which is in and belongs to its being from another too: All the powers it has, must be owing to, and received from the same source. This eternal source then of all being must be also the source and original of all power; and so this eternal Being must be also the most powerful.

Again, man finds in himself perception and knowledge: We are certain, then, that there is not only some being, but some knowing intelligent being in the world. There was a time, then, when there was no knowing being, or else there has been a knowing being from eternity. If it be said, there was a time when that eternal being had no knowledge; the reply is, that then it is impossible there should have ever been any knowledge; it being as impossible that things wholly void of knowledge, and operating blindly, and without any perception, should produce a knowing being, as it is that a triangle should make itself three angles bigger than two right ones.

Thus from the consideration of ourselves, and what we infallibly find in our own constitutions, our reason leads us to the knowledge of this certain and evident truth, that there is an eternal, most powerful, and knowing being; and from this idea duly considered, will easily be deduced all those other attributes we ought to ascribe to this eternal being.

From what has been said, it is plain, we have a more certain knowledge of the existence of a God, than of any

Vol. III. No. 77.
mind does sufficiently lead us into the knowledge of God. For it will hence follow, that all other knowing beings that have a beginning must depend on him, and have no other ways of knowledge or extent of power than what he gives them; and therefore if he made those, he made also the less excellent pieces of this universal, all insensible bodies, whereby his omniscience, power, and providence, will be established; and from thence all his other attributes necessarily follow.

Of our knowledge of the existence of other things.

The knowledge of our own being we have by intuition: The existence of a God, reason clearly makes known to us. The knowledge of the existence of any other thing, we can have only by sensation; for there being no necessary connection of real existence with any idea a man hath in his memory, nor of any other existence, but that of God, with the existence of any particular man; no particular man can know the existence of any other being, but only when, by actually operating upon him, it makes itself be perceived by him. The having the idea of any thing in our mind, no more proves the existence of that thing, than the picture of a man evidences his being in the world, or the visions of a dream make thereby a true history. It is therefore the actual receiving of ideas from without, that gives us notice of the existence of other things, and makes us know that something doth exist at that time without us, which caueth that idea in us, though perhaps we neither know nor consider how it doeth; for it takes not from the certainty of our history. It is therefore the actual receiving of ideas from without, that gives us notice of the existence of other things or our knowledge of any thing, let him consider that the certainty of things existing in rerum natura, when we have the testimony of our senses for it, is not only as great as our frame can attain to, but as our condition needs. For our faculties being not suited to the full extent of being, nor a clear comprehensive knowledge of all things, but to the preservation of us in whom they are, and accommodated to the use of life; they serve our purpose well enough, if they will but give us certain notice of those things that are convenient or inconvenient to us: For he that sees a candle burning, and has experimented the force of the flame, by putting his finger in it, will little doubt that this is something existing without him which does him harm, and puts him to pain; which is assurance enough; when no man requires greater certainty to govern his actions by, than what is as certain as his actions themselves: So that this evidence is as great as we can desire, being as certain to us as our pleasure or pain, that is, happiness or misery; beyond which we have no concernment either of knowing or being.

In fine, when our senses doth actually convey into our understandings any idea, we are assured that there is something at that time really existing without us. But this knowledge extends only as far as the present testimony of our senses, employed about particular objects, that do then affect them, and no farther. My seeing a man a minute since, is no certain argument of his present existence.

As when our senses are actually employed about any object, we know that it does exist: so by our memory we may be assured, that heretofore things that affected our senses have existed: And thus we have the knowledge of the past existence of several things, whereas our senses having informed us, our memories still retain the ideas; and of this we are past all doubt, so long as we remember well.

As to the existence of spirits, our having ideas of them does not make us know that any such things do exist without
without us, or that there are any finite spirits, or any other spiritual beings but the eternal God. We have ground from revelation, and several other reasons, to believe with assurance, that there are such creatures: But our senses not being able to discover them, we want the means of knowing their particular existence; for we can no more know that there are such spirits really existing, by the ideas we have of such beings, than by the ideas any one has of fairies, or centaurs, he can come to know, that things answering those ideas do really exist.

Hence we may gather, that there are two sorts of propositions: One concerning the existence of any thing answerable to such an idea, as that of an elephant, phœnix, motion, or angel, viz. whether such a thing does anywhere exist: And this knowledge is only of particulars, and not to be had of any thing without us, but only of God, any other way than by our senses.

Another sort of proposition is, wherein is expressed the agreement or disagreement of our abstract ideas, and their dependance one on another. And these may be universal and certain: so having the idea of God and my self, of fear and obedience, I cannot but be sure that God is to be feared and obeyed by me: and this proposition will be certain concerning man in general, if I have made an abstract idea of such a species, whereof I am one particular. But such a proposition, how certain soever, proves not to me the existence of men in the world; but will be true of all such creatures, whenever they do exist: which certainty of such general propositions, depends on the agreement or disagreement discernible in those abstract ideas. In the former case, our knowledge is the consequence of the existence of things producing ideas in our minds by our senses: in the latter, the consequences of the ideas that are in our minds, and producing those general propositions, many whereof are called eternal veritates: and all of them indeed are so; not from being written all or any of them in the minds of all men, or that they were any of them propositions in any one's mind, till he, having got the abstract ideas, joined or separated them by affirmation or negation; but wherever we can suppose such a creature as man is, endowed with such faculties, and thereby furnished with such ideas as we have, we must conclude he must needs, when he applies his thoughts to the consideration of his ideas, know the truth of certain propositions, many whereof are called eternal veritates.

Of judgment.

The understanding faculties being given to man, not barely for speculation, but also for the conduct of his life, a man would be at a great loss, if he had nothing to direct him but what has the certainty of true knowledge. He that will not eat till he has demonstration that it will nourish him, nor stir till he is infallibly assured of success in his business, will have little else to do but sit still, and perish.

Therefore as God hath sent some things in broad daylight; as he has given us some certain knowledge, though limited to a few things, in comparison, (probably as a taste of what intellectual creatures are capable of, to excite us a desire and endeavour after a better state;) so in the greatest part of our concernment, he has afforded us only the twilight of probability, suitable to that state of mediocrity and probationship he has been pleased to place us in here.

The faculty which God has given man to enlighten him, next to certain knowledge, is judgment; whereby the mind takes its ideas to agree or disagree, without perceiving a demonstrative evidence in the proofs. The mind exercises this judgment sometimes out of necessity, where demonstrative proofs and certain knowledge are not to be had; and sometimes out of listening, unskilfulness, or haste, even where they are to be had.

This faculty of the mind, when it is exercised immediately about things, is called judgment; when about truths delivered in words, is most commonly called assent or dissent. Thus the mind has two faculties convergent about truth and falsehood: First, Knowledge; whereby it certainly perceives, and is undoubtedly satisfied of the agreement or disagreement of any ideas. Secondly, Judgment, which is the putting ideas together, or separating them from one another in the mind, when their certain agreement or disagreement is not perceived, but presumed to be so. And if it fo unites or separates them as in reality things are, it is right judgment.

Of probability.

Probability is nothing but the appearance of the agreement or disagreement of two ideas, by the intervention of proofs, whose connection is not constant and immutable; or is not perceived to be so; but is or appears for the most part to be so; and is enough to induce the mind to judge the proposition to be true or false, rather than the contrary.

Of probability there are degrees, from the neighbourhood of certainty and demonstration, quite down to improbability and unlikelihood, even to the confines of impossibility: And also degrees of assent from certain knowledge, and what is next it, full assurance and confidence, quite down to conjecture, doubt, distrust, and disbelief. That proposition then is probable, for which there are arguments or proofs to make it pass or be received for true: The entertainment the mind gives to this sort of propositions, is called belief, assent, or opinion. Probability then being to supply the defect of our knowledge, is always conversant about propositions whereof we have no certainty, but only some inducements to receive them for true. The grounds of it are, in short, these two following.

First, The conformity of any thing with our own knowledge, experience, or observation.

Secondly, The testimony of others, vouching their observation and experience. In the testimony of others is
to be considered, *First*, The number; *Secondly*, The integrity; *Thirdly*, The skill of the witneses; *Fourthly*, The design of the author, if it be a testimony cited out of a book; *Fifthly*, The consistence of the parts and circumstances of the relation; *Sixthly*, Contrary testimonies.

The mind, before it rationally affents or disaffents to any probable proposition, ought to examine all the grounds of probability, and see how they make, more or less, for or against it; and upon a due balancing of the whole, reject or receive it, with a more or less firm assent, according to the preponderancy of the greater grounds of probability on one side, or the other.

**Of the degrees of assent.**

The grounds of probability, laid down in the foregoing section, as they are the foundations on which our assent is built, so are they also the measure whereby its several degrees are (or ought to be) regulated. Only we are to take notice, that no grounds of probability operate any farther on the mind, which searches after truth, and endeavours to judge right, than they appear, at least, in the first judgment or search that the mind makes. It is indeed in many cases impossible, and in most very hard, even for those who have admirable memories, to retain all the proofs which, upon a due examination, made them embrace that side of the question. It suffices, that they have once, with care and fairness, sifted the matter as far as they could; and having once found on which side the probability appeared to them, they lay up the conclusion in their memories, as a truth they have discovered; and for the future remain satisfied with the testimony of their memories, that this is the opinion, that, by the proofs they have once seen of it, deserves a degree of their assent as they afford it.

It is unavoidable then that the memory be relied on in this case, and that men be persuaded of several opinions, whereof the proofs are not actually in their thoughts, nay, which perhaps they are not able actually to recall: Without this the greatest part of men must be either sceptics, or change every moment, when any one offers them arguments which for want of memory, they are not presently able to answer.

It must be owned, that men flocking to past judgments, is often the cause of great obstinacy in error and mistake: For the fault is not that they rely on their memories for what they have before well judged, but because they judged before they had well examined. Who almost is there that hath the leisure, patience, and means, to collect together all the proofs concerning most of the opinions he has, so as safely to conclude, that he has a clear and full view, and that there is no more to be alleged for his better information? And yet we are forced to determine ourselves on one side, or other: The conduct of our lives, and the management of our great concerns, will not bear delay: For those depend, for the most part, on the determination of our judgment in points, wherein we are not capable of certain knowledge, and wherein it is necessary for us to embrace one side or the other.

The propositions we receive upon inducements of probability, are of two sorts: *First*, Concerning some particular existence, or matter of fact, which falling under our observation, is capable of human testimony; *Secondly*, Concerning things which, being beyond the discovery of our senses, are not capable of human testimony.

Concerning the first of these, viz. **Particular matter of fact**.

*First*, Where any particular thing, connotant to the connotant observation of ourselves, and others, in the like case, comes attested with the concurrent reports of all that mention it, we receive it as easily, and build as firmly upon it, as if it were certain knowledge. Thus, if all Englishmen, who have occasion to mention it, should report, that it froze in England last winter, or the like, a man would as little doubt of it, as that seven and four are eleven.

The first and highest degree of probability is, when the general consent of all men, in all ages, as far as can be known, concurs with a man's own concomitant experience in the like cases, to confirm the truth of any particular matter of fact, attested by fair witnesses: Such are the stated constitutions and properties of bodies, and the regular proceedings of causes and effects in the ordinary course of nature. This we call an argument from the nature of things themselves: For what we and others always observe to be after the same manner, we conclude with reason to be the effects of steady and regular causes, though they come not within the reach of our knowledge; as that fire warmed a man, or made lead fluid; that iron sunk in water, swam in quicksilver. A relation affirming any such thing to have been, or a predication that it will happen again in the same manner, is received without doubt or hesitation; and our belief thus grounded, rises to assurance.

*Secondly*, The next degree of probability, is when by my own experience, and the agreement of all others that mention it, a thing is found to be for the most part so; and that the particular instance of it is attested by many and undoubted witnesses. Thus history giving us such an account of men in all ages, and my own experience confirming it, that most men prefer their own private advantage to the public; if all historians that write of Tiberius, say that he did so, it is extremely probable: And in this case, our assent rises to a degree which we may call confidence.

*Thirdly*, In matters happening indifferently, as that a bird should fly this or that way; when any particular matter of fact comes attested by the concurrent testimony of unsuspected witneses, there our assent is also unavoidable. Thus, that there is in Italy such a city as Rome; that about one thousand and seven hundred years ago there lived such a man in it as Julius Caesar, &c. a man can as little doubt of this, and the like, as he does of the being and actions of his own acquaintance, whereof he himself is a witness.

**Probability**, on these grounds, carries so much evidence with it, that it leaves us as little liberty to believe or disbelieve, as demonstration does, whether we will know or be ignorant. But the difficulty is, when testimonies contradict common experience, and the reports of witneses clash with the ordinary course of nature, or with one another; here diligence, attention, and exactness, is required.
agitation of the imperceptible minute parts of the burning
jecture, guesses, doubt, wavering, distrust, &c. matter. This sort of probability, which is the best con-
duc of rational experiments, and the rise of hypothesis has also its use and influence. And a wary reasoning from
in analogy leads us often into the discovery of truths and
useful deductions, which would otherwise be concealed.

Though the common experience, and the ordinary course
of things, have a mighty influence on the minds of men,
to make them give or refuse credit to any thing proposed
to their belief; yet there is one case wherein the strange-
ness of the fact lessens not the agent to a fair testimony
given of it. For where such supernatural events are suit-
able to ends aimed at by Him who has the power to change
the course of nature, there, under such circumstances, they
may be the fitter to procure belief, by how much the more
they are beyond or contrary to ordinary observation. This
is the proper case of miracles; which, well attested, do
not only find credit themselves, but give it also to other
truths.

There are propositions that challenge the highest de-
gree of our assent upon bare testimony, whether the thing
proposed agree or disagree with common experience and
the ordinary course of things or no: The reason where-
of is, because the testimony is of such an one as cannot
deceive nor be deceived; and that is God himself. This
becomes with it, certainty beyond doubt, evidence beyond
exception. This is called by a peculiar name, revelation,
and our assent to it, faith, which has as much certainty
in it as our knowledge itself; and we may as well doubt
of our own being, as we can whether any revelation from
God be true. So that faith is a settled and sure princi-
ple of assent and assurance, and leaves no manner of
room for doubt or hesitation; only we must be sure, that
it be a divine revelation, and that we understand it
right, else we shall expose ourselves to all the extra-
-gancy of enthusiasm, and all the error of wrong principles,
if we have faith and assurance in what is not divine re-
velation.

Of reason.

The word reason, in English, has different signifi-
cations. Sometimes it is taken for true and clear prin-
ciples; sometimes for clear and fair deductions from those
principles; sometimes for the cause, and particularly for
the final cause: But the consideration we shall have of it
here, is as it stands for a faculty whereby man is suppos-
ed to be distinguished from beasts, and wherein it is evi-

dent he much surpasses them.

Reason is necessary, both for the enlargement of our
knowledge, and regulating our assent; for it hath to do
both in knowledge and opinion, and is necessary and af-

tilling to all our other intellectual faculties; and indeed
contains two of them, viz. first, Sagacity, whereby it
finds intermediate ideas; secondly, Ilation, whereby it
orders and disposes of them, as to discover what
connection there is in each link of the chain, whereby
the extremes are held together, and thereby, as it were,
to draw into view the truth sought for; which is that we
call Ilation, or inference, and consists in nothing but the
perception of the connection there is between the ideas
in each step of the deduction; whereby the mind comes to
see either the certain agreement or disagreement of any

Vol. III. No. 77.
two ideas, as in demonstration, in which it arrives at
knowledge; or their probable connection, on which it
gives or with-holds its assent, as in opinion.

Sense and intuition reach but a little way: The great-
est part of our knowledge depends upon deductions and
intermediate ideas. In those cases where we must take
propositions for true, without being certain of their being
so, we have need to find out, examine, and compare the
grounds of their probability: In both cases, the faculty
which finds out the means, and rightly applies them to
discover certainty in the one, and probability in the other,
is that which we call reason: So that in reason we may
consider these four degrees; first, The discovering and
finding out of proofs; secondly, The regular and methodi-
cal disposition of them, and laying them in such order
as their connection may be plainly perceived; thirdly, The
perceiving their connection; fourthly, The making a right
conclusion.

There is one thing more which deserves to be considered
concerning reason; and that is, whether syllogism, as is
generally thought, be the proper instrument of it; and the
usefulest way of exercising this faculty. The causers to
doubt of it, are these:

First, Because syllogism serves our reason but in one
only of the formentioned parts of it; and that is, to shew
the connection of the proofs of any one instance, and no
more: But in this it is of no great use, since the mind
can perceive such connection, where it really is, as easil-
y, nay perhaps better, without it. We may observe, that
there are many men that reason exceeding clear and right-
y, who know not how to make a syllogism: And scarce
any one make syllogisms in reasoning within himself. In-
deed, sometimes they may serve to discover a fallacy, hid
in a rhetorical flourish; or by stripping an abdardity of the
cover of wit and good language, shew it in its naked de-
formity: But the weakness or fallacy of such a loose dis-
course it shews, by the artificial form it is put into, only
to those who have throughly studied mode and figure, and
have fo examined the many ways that three propositions
may be put together, as to know which of them does cer-
tainly conclude right, and which not, and upon what
grounds it is that they do so: But they who have not so
far looked into those forms, are not sure, by virtue of
syllogism, that the conclusion certainly follows from the
premises; the mind is not taught to reason by these rules;
it has a native faculty to perceive the coherence or inco-
herence of its ideas, and can range them right without
any such perplexing repetitions.

And to shew the weaknesses of an argument, there needs
no more but to strip it of the superfluous ideas, which,
blanded and confounded with those on which the infe-
rence depends, to shew a connection where there is
none, or at least do hinder the discovery of the want of
it; and then to lay the naked ideas, on which the force
of the argumentation depends, in their due order; in which
position the mind, taking a view of them, sees what con-
nection they have, and so is able to judge of the inference
without any need of syllogism at all.

Secondly, Because syllogisms are not less liable to fal-
lacies than the plainer ways of argumentation. And for
this we appeal to common observation, which has always
found these artificial methods of reasoning more adapted
to catch and entangle the mind, than to instruct and in-
form the understanding. And if it be certain that fallacy
can be couched in syllogisms, as it cannot be denied, it
must be something else, and not syllogism, that must dis-
cover them: But if men skilled in and used to syllogism,
find them affixing to their reason in the discovery of truth,
we think they ought to make use of them. All that we aim
at is, that they should not ascribe more to these forms
than belongs to them; and think that men have no ufe, or not
so full a ufe, of their reasoning faculty without them.

But however it be in knowledge, it is of far less, or no
ufe at all in probabilities: For the aften there being to
be determined by the preponderancy, after a due weight-
ing of all the proofs on both sides, nothing is so unfit to
affix the mind in that as syllogism; which running away
with one assumed probability, pursues that till it has led
the mind quite out of fight of the thing under considera-
don. But let it help us (as perhaps may be said) incorne-
menc of their errors or mistakes; yet full it fails our rea-
son in that part, which if not its highest perfection, is yet
certainly its hardest talk, and which that we most need its
help in; and that is, the finding out of proofs, and making
new discoveries. This way of reasoning discovers no new
proofs, but is the art of marshalling and arranging the old
ones we have already. A man knows first, and then he
is able to prove syllogically; so that syllogism comes af-
ter knowledge; and then a man has little or no need of it.
But it is chiefly by the finding out these ideas that shew
the connection of distant ones, that our flock of know-
lledge is increased, and that useful arts and sciences are
advanced.

Reason, though of a very large extent, fails us in se-
veral instances; as, first, Where our ideas fail. Second-
ly, It is often at a loss, because of the obscurity, confu-
nion, or imperfection of the ideas it is employed about.
Thus having no perfect idea of the least extent of
matter, or of infinity, we are at a loss about the divisibil-
ity of matter. Thirdly, Our reason is often at a stand,
because it perceives not thue ideas, which would serve to
shew the certain or probable agreement or disagreement
of any two other ideas. Fourthly, Our reason is often
engaged in absurdities and difficulties, by proceeding up-
on false principles, which being followed, lead men into
contradictions to themselves, and inconsistency in their
own thoughts. Fifthly, Dubious words, and uncertain
signs, often puzzle mens reason, and bring them to a
nonplus.

Though the deducing one proposition from another, be
a great part of reason, and that which it is usually em-
ployed about; yet the principal art of ratiocination, is
the finding the agreement or disagreement of two ideas
one with another, by the intervention of a third; as a
man, by a yard, finds two houses to be of the same length,
which could not be brought together to measure their e-
quality by juxtaposition: Words have their consequences
as the signs of such ideas; and things agree or dis-
agree, as really they are; but we observe it only by our
ideas.
METAPHYSICS.

In reasoning, men ordinarily use four sorts of arguments.

The first is to allege the opinions of men, whose parts, learning, eminency, power, or some other cause, has gained a name, and settled their reputation in the common esteem with some kind of authority: This may be called argumentum ad verecundiam.

Secondly, Another way is, to require the adversary to admit what they allege as a proof, or to affign a better: This is called argumentum ad hominem.

A third way, is to press a man with consequences drawn from his own principles or concessions: This is known under the name of argumentum ad hominem.

Fourthly, The using of proofs drawn from any of the foundations of knowledge or probability: This is called argumentum ad judicium. This alone, of all the four, brings true instruction with it, and advances us in our way to knowledge: For, first, It argues not another man’s opinion to be right, because I, out of respect, or any other consideration but that of conviction, will not contradict him. Secondly, It proves not another man to be in the right way, nor that I ought to take the same with him, because I know not a better. Thirdly, Nor does it follow, that another man is in the right way, because he has shewn me that I am in the wrong: This may dispose me, perhaps, for the reception of truth, but helps me not to it: That must come from proofs and arguments, and light arising from the nature of things themselves; not from my shame-facedness, ignorance, or error.

METAPLASTUS, in grammar, a transmutation or change made in a word, by adding, retrenching, or altering a letter or syllable thereof.

METASTASIS, in medicine, a transposition or settlement of some humour or disease on some other part; and sometimes it signifies such an alteration of a difeafe as is succeeded by a solution.

METATHESIS, in grammar, a figura whereby the letters or syllables of a word are transposed, or shifted out of their usual situation, as pilfris for prifris.

METEMPSYCHOSIS, the doctrine of transmigration, which supposes that human souls, upon leaving the body, become the souls of such kind of brutes as they must resemble in their manners.

This was the doctrine of Pythagoras and his followers; who, held that the souls of vicious men were imprisoned in the bodies of miserable beings; there to do penance for several ages, at the expiration whereof they returned again to animate men; but if they had lived virtuously, some happier brute, or even a human creature, was to be their lot. What led Pythagoras to this opinion was that soul was not of a perishable nature; whereas he concluded, that it must move into some other body upon its abandoning this. Lucan thinks this doctrine was contrived to mitigate the apprehension of death, by persuading men that they only changed their lodgings, and ceased to live only to begin a new life.

METEMPTOSIS, a term in chronology, expressing the solar equation, necessary to prevent the new moon from happening a day too late; by which it is opposed to premptos, which signifies the lunar equation necessary to prevent the new moon from happening a day too soon.

METEOR, in physiology, an imperfect, changeable, and mixt body, or the resemblance of a body appearing in the atmosphere, and formed by the action of the heavenly bodies, out of the common elements.

Metereors are of three kinds; fiery, airy, and watery. Fiery meteors consist of a fat sulphureous smoke set on fire; such as falling stars, draco volans, the ignis fatuus, and other phenomena, appearing in the air. Airy meteors consist of flatulent and spiritual exhalations, such as winds, &c. Watery meteors are composed of vapours, or watery particles, variously modified by heat and cold, such as clouds, rain, hail, snow and dew.

METEGLIN, a drink prepared of honey, one of the most pleasant and general drinks the northern parts of Europe afford. It is, according to Bailey, made as follows: Put as much raw honey naturally running from the comb, into spring water, as that, when the honey is thoroughly dissolved, an egg will not sink to the bottom, but be just suspended in it. Then boil the liquor for
for an hour or more, till such time as the egg swim above the fire; then take it off the fire, and let it cool. When very cool, next morning, it may be barreled up; and adding to it half an ounce of ginger, as much of cloves, as much of mace, and a quarter of an ounce of cinnamon. All gably poured, a spoonful of yeast may be added also at the bung to increase its fermentation. When it has done working, it may be closely stopped up; and after it has stood a month, it may be drawn off into bottles.

**METHOD.** the arrangement of our ideas in such a regular order, that their mutual connection and dependence may be readily comprehended.

**METHODISTS.** a name first given to a society of religious young men at Oxford, and now applied to all those who adhere to the doctrine of the church of England as taught by Whitefield, Wesley, &c. They are said to be, in general, plain well-meaning people, who do not differ from the established church; but profess to live with great purity, according to her articles. At their first appearance their teachers were charged, in the heat of their zeal, with several irregularities, and many expressions in their preaching which were not altogether unexceptionable; but as the civil government, with a moderation and wisdom peculiar to the present time, thought fit to overlook their behaviour, they have since honestly acknowledged wherein they were mistaken; and, in consequence of the perfect liberty of conscience they enjoy, have found into a more regular and peaceable conduct, agreeable to the genuine spirit of Christianity.

**METODISTS.** Methodici, is also an appellation given to a sect of ancient physicians, who reduced the whole healing art to a few common principles or appearances.

**METONYMY.** in rhetoric, is a trope in which one name is put for another, on account of the near relation there is between them. By this trope any of the most significant circumstances of a thing are put for the thing itself. The metonymy is used with most advantage in the following cases. 1. When the narration stands for the action, and what the poet or historian describes he is said to do; which is a lively manner of expression, exceeding the common, as much as action goes beyond description, or life excels painting. 2. When the name of any relation is put for the duty it requires, and the benevolence and tendernefs that may be expected from it. Thus Anacreon says, that through money there is no longer any such thing as brethren or parents in the world. 3. When the word which is used for a proper name, is either taken from the person’s country, family, profession, personal circumstance, or resemblance to some other; thus, as Sardanapalus was a monster of debauchery, and Nero of cruelty, to call any debauched person a Sardalapalus, and a cruel one Nero, brands them much deeper than to call one debauched, and the other cruel.

**METOP.** in architecture, is the interval, or square space between the triglyphs of the doric frieze, which among the ancients used to be painted or adorned with carved work, representing the heads of oxen, or utensils used in sacrifices.

**METOPES.** in architecture, is the interval, or square above the liquor; then take it off the fire, and let it cool. When very cool, next morning, it may be barreled up; and adding to it half an ounce of ginger, as much of cloves, as much of mace, and a quarter of an ounce of cinnamon. All gably poured, a spoonful of yeast may be added also at the bung to increase its fermentation. When it has done working, it may be closely stopped up; and after it has stood a month, it may be drawn off into bottles.

**METOPOGRAPHY.** the pretended art of knowing a person’s disposition and manners, by viewing the traces and lines in the face.

**METRE.** in poetry, a system of feet of a just length.

The different metres in poetry, are the different manners of ordering and combining the quantities, or the long and short syllables; thus hexameter, pentameter, iambic, sapphic verses, &c. consist of different metres, or measures.

In English verses, the metres are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleases. The most usual are the heroic, generally consisting of five long and five short syllables, and verses of four feet, and of three feet and a half, or single syllable.

**METRETES.** an ancient measure of capacity, containing a little more than nine gallons.

**METROPOLIS.** the capital or principal city of a country or province.

The term metropolis is also applied to archiepiscopal churches, and sometimes to the principal or mother church of a city.

**METZ.** a city of Germany, in the duchy of Lorraine, capital of the bishopric of Metz, situated thirty miles north of Nancy.

**MEXICO.** the metropolis of New Spain at present, and formerly of the empire of Mexico, situated in W. long. 103°, N. lat. 20°.

This province of New Spain in America is now divided into Old and New Mexico.

**Old Mexico,** situated between 83 and 116 degrees of W. long. and between 8 and 28 degrees N. lat. is bounded by New Mexico, or Granada, on the north; by the gulf of Mexico, on the north-east; by Terra-firma, on the south-east; and by the Pacific Ocean, on the south-west.

**New Mexico,** including California, situated between 100 and 140 degrees of W. long. and between the Tropic of Cancer and 48 degrees of N. lat. is bounded by unknown lands on the north, by Florida on the east, by Old Mexico on the south, and by the Pacific Ocean on the west.

**MEZZOTINTO.** a particular manner of representing figures on copper, so as to form prints in imitation of painting in Indian ink.

The manner of making mezzotintos is very different from all other kinds of engraving and etching, since instead of forming the figures with lines and scratches made with the point of a graver, or by means of aquafortis, they are wholly formed by scraping and burnishing. Mezzotintos are made in the following manner: take a well-polished copper-plate, and beginning at the corner, rake or burnish the surface all over with a knife or instrument made for the purpose, first one way, and then the other, till the whole is of a regular roughness, without the least smooth part to be seen; in which state, if a paper was to be worked off from it at the copper-plate press, it would be all over black. When this is done, the plate is rubbed over with charcoal, black chalk, or black lead, and then the design is drawn with white chalk; after which the cut-lines are traced out.
MIDWIFERY is the art of assisting nature in bringing forth a perfect foetus, or child, from the womb of the mother.

The knowledge of this art depends greatly on an intimate acquaintance with the anatomy of the parts of generation in women, both internal and external. But, as those have already been fully described under the article Anatomy, we must refer to the different parts of that science upon which the knowledge of midwifery depends.

For the Bones of the Pelvis, see Anatomy, p. 171, &c.

For the Parts of Generation in Females, both external and internal, see Anatomy, p. 274, &c.

For the different theories of Conception, see Generation.

Of the Increase of the Uterus after Conception.

It is supposed, that the ovum swims in a fluid, which absorbs so as to increase gradually in magnitude, till it comes in contact with all the inner surface of the fundus uteri; and this being diffused in proportion to the augmentation of its contents, the upper part of the neck begins also to be stretched.

About the third month of gestation, the ovum in big- nes equals a goose egg; and then nearly one fourth of the neck, at its upper part, is diffused equal with the fundus. At the fifth month, the fundus is increased to a much greater magnitude, and rises upwards to the middle space between the upper part of the pubes and the navel; and at that period, one half of the neck is extended. At the seventh month, the fundus reaches as high as the navel; and at the eighth month, it is advanced midway between the navel and febrochis cordis; and in the ninth month, is raised quite up to this last mentioned part, the neck of the womb being then altogether diffused. See Plate CXI, fig. 1, 2, 3.

2

Fig. 1.

MICROCOSM, a Greek term, signifying the little world; used by some for man, as being supposed an epitome of the universe or great world.

MICROGRAPHY, the description of objects too minute to be viewed without the assistance of a microscope. See Microscope.

MICROMETER, a machine, which, by means of a screw, serves to measure extremely small distances to a great degree of accuracy.

MICROPUS, in botany, a genus of the syngenesia polygamy class. The receptacle is palleaceous; it has no pappus; and the corolla have no radii. There are two species, none of them natives of Britain.

MICROSOPHCS, a genus of the polyandria class. The calix consists of eight segments, and the corolla of eight petals; and the berries contain many seeds. There is but one species, a native of India.

MICROCOS, in botany, a genus of the polyandria mogyinia class. The calix consists of five leaves, and the corolla of five petals. There are two species, both natives of India.

MICROSOPE, an optical instrument, by means whereof the univerfe or great world.

MICROSOPHCS, a genus of the polyandria class. The calix consists of five leaves, and the corolla of five petals. There are two species, both natives of India.

MICROSCOPE, an optical instrument, by means whereof very minute objects are represented. See Optics.
Fig. 1. Gives a front-view of the uterus in situ suspended in the vagina; the anterior parts of the os ilium, with the os pubis, pudenda, perineum, and anus, being removed in order to shew the internal parts.

A, The last vertebra of the loins.
BB, The os ilium.
CC, The acetabula.
DD, The inferior and posterior parts of the os ilium.
E, The part covering the extremity of the coccyx.
F, The inferior part of the rectum.
GG, The vagina cut open longitudinally, and stretched on each side of the collum uteri, to shew in what manner the uterus is suspended in the same.
HH, Part of the vesica urinaria stretched on each side of the vagina, and inferior part of the fundus uteri.
I, The collum uteri.
K, The fundus uteri.
LL, The tubi Fallopiani and fimbrine.
MM, The ovaria.
NN, The ligamenta lata and rotunda.
OO, The superior part of the rectum.

Fig. 2. Gives a front-view of the uterus in the beginning of the first month of pregnancy; the anterior part being removed that the embryo might appear through the amnios, the chorion being detached off.

A, The fundus uteri.
B, The collum uteri, with a view of the rugous canal that leads to the cavity of the fundus.
C, The os uteri.

Fig. 3. In the same view and section of the parts as in fig. 1. shews the uterus as it appears in the second or third month of pregnancy.

A, The fundus uteri.
B, The collum uteri, with a view of the rugous canal that leads to the cavity of the fundus.
C, The os uteri.
D, The anus.
G, The vagina, with its plicae.
HH, The posterior and inferior part of the urinary bladder extended on each side; the anterior and superior part being removed.
II, The mouth and neck of the womb, as raised up when examining the same by the touch, with one of the fingers in the vagina.
KK, The uterus as stretched in the second or third month, containing the embryo, with the placenta adhering to the fundus.

Now that the whole substance of the uterus is stretched, the neck and os internum, which were at first the strongest, become the weakest part of the womb, and the stretching force being still continued by the increase of the fetus and fecundines, which are extended by the enclosed waters in a globular form, the os uteri begins gradually to give way. In the beginning of its dilatation, the nervous fibres in this place, being more sensible than any other part of the uterus, are irritated, and yield an uneasy sensation; to alleviate which, the woman squeezes her uterus, by contracting the abdominal muscles, and at the same time filling the lungs with air, by which the diaphragm is kept down; the pain being rather increased than abated by this straining, is communicated to all the neighbouring parts, to which the ligaments and vessels are attached, such as the back, loins, and inside of the thighs; and by this compression of the uterus, the waters and membranes are pressed against the os uteri, which is, of consequence, a little more opened. See fig. 4, 5, 6. of Plate-CXI.

Fig. 4. In the same view and section of the parts with the former figures, represents the uterus in the eighth or ninth month of pregnancy.

A, The uterus as stretched to near its full extent, with the waters, and containing the fetus entangled in the funis, the head presenting at the upper part of the pelvis.
BB, The superior part of the os ilium.
CC, The acetabula.
DD, The remaining posterior parts of the os ilium.
E, The coccyx.
F, The inferior part of the rectum.
GGG, The vagina stretched on each side.
H, The os uteri, the neck being stretched to its full extent or entirely obliterated.
II, Part of the vesica urinaria.
KK, The placenta, at the superior and posterior part of the uterus.
LL, The membranes.
M, The funis umbilicalis.

Fig. 5. Gives a front view of twins in utero in the beginning of labour.

A, The uterus as stretched, with the membranes and waters.
BB, The superior parts of the os ilium.
CC, The acetabula.
DD, The os ilium.
E, The coccyx.
F, The inferior part of the rectum.
GG, The vagina.
H, The os internum stretched open about a finger-breadth, with the membranes and waters in time of labour-pains.
II, The inferior part of the uterus, stretched with the waters, which are below the head of the child that presents.

KK, The two placentas adhering to the posterior part of the uterus, the two fetus's lying before them, one with its head in a proper position at the inferior part of the uterus, and the other situated preternaturally with the head to the fundus; the bodies of each are here entangled in their proper funis, which frequently happens in the natural as well as preternatural positions.

LLL, The membranes belonging to each placenta.

Fig. 6. Shews, in a lateral view and longitudinal division of the parts, the gravid uterus when labour is somewhat advanced.

A, The lowest vertebra of the back; the distance from which to the last mentioned vertebra is here shown by dotted lines.
CC, The usual thickness and figure of the uterus when extended by the waters at the latter end of pregnancy.
M I D W I F E R Y.

D, The same contracted and grown thicker after the waters are evacuated.
EE, The figure of the uterus when pendulous.
FF, The figure of the uterus when stretched higher than usual, which generally occasions vomitings and difficulty of breathing.
G, The os pubis of the left side.
HH, The os internum.
I, The vagina.
K, The left nympha.
L, The labium pudendi of the same side.
M, The remaining portion of the bladder.
N, The anus.
OP, The left hip and thigh.
The woman being unable to continue this effort, for any length of time, from the violence of the pain it occasions, and the strength of the muscles being thereby a little exhausted and impaired, the contracting force abates; the tension of the os times being taken off, it becomes more soft, and contracts a little; so that the nervous fibres are relaxed. This remission of pain the patient enjoys for some time, until the fame increasing force renews the stretching pains, irritation, and something like a tearing of the os uteri; the compression of the womb again takes place, and the internal mouth is a little more dilated, either by the pressure of the waters and membranes, or when the fluid is in small quantity, by the child's head forced down by the contraction of the uterus, which in that case is in contact with the body of the fetus. See Plate CXI. where

Fig. 7. Shews the forehead of the fetus turned backwards to the os facrum, and the occupit below the pubes, by which means the narrow part of the head is to the narrow part of the pelvis, that is, between the inferior parts of the os sacrum.
A, The uterus contracted closely to the fetus after the waters are evacuated.
BCCD, The vertebrae of the loins, os sacrum, and coccyx.
E, The anus.
F, The left hip.
G, The perineum.
H, The es externum beginning to dilate.
I, The os pubis of the left side.
K, The remaining portion of the bladder.
L, The posterior part of the os uteri.
In this manner the labour pains begin, and continue to return periodically, growing stronger and more frequent, until the os uteri is fully dilated, and the membranes are depressed and broke; so that the waters are discharged, the uterus contracts, and, with the assistance of the muscles, the child is forced along and delivered.

Of Abortions.
A miscarriage that happens before the tenth day, was formerly called an efflux, because the embryo and fecundines are not then formed, and nothing but the liquid conception, or genitura, is discharged. From the tenth day to the third month it was known by the term expulsion, the embryo and fecundines being still so small, that the woman is in no great danger from violent flooding.

If she parted with her burden betwixt that period and the seventh month, she was said to suffer an abortion; in which case she underwent greater danger, and was delivered with more difficulty than before; because the uterus and vessels being more distended, a larger quantity of blood was lost in a shorter time, the fetus was increased in bulk, and the neck of the womb is not yet fully stretched: besides, should the child be born alive, it will be so small and tender that it will not suck, and scarce receive any sort of nourishment.

When delivery happens between the seventh month and full time, the woman is said to be in labour: but, instead of these distinctions, if she loses her burden at any time from conception to the seventh or eighth, or even in the ninth month, we now lay indiscriminately, she has miscarried.

The common term of pregnancy is limited to nine solar months, reckoning from the last discharge of the catamenia: yet in some, though very few, uterine delivery exceeds that period.

Of false Conceptions and Moles.
It was formerly supposed, that if the parts of the embryo and fecundines were not separated and distinctly formed from the mixture of the male and female semen, they formed a mass, which, when discharged before the fourth month, was called a false conception; if it continued longer in the uterus, so as to increase in magnitude, it went under the denomination of a mole. But these things are now to be accounted for in a more probable and certain manner. Should the embryo die (suppose in the first or second month,) some days before it is discharged, it will sometimes be entirely dissolved; so that, when the fecundines are delivered, there is nothing else to be seen. In the first month, the embryo is so small and tender, that this dissolution will be performed in twelve hours: in the second month, two, three, or four days will suffice for this purpose; and even in the third month, it will be dissolved in fourteen or fifteen: besides the blood frequently forms thick lamina round the ovum, to the surface of which they adhere so strongly, that it is very difficult to distinguish what part is placenta, and what membrane. Even after the embryo and placenta are discharged, in the second or third month, the mouth and neck of the womb are often so closely contracted, that the fibrous part of the blood is retained in the fundus, sometimes to the fifth or seventh day; and when it comes off, exhibits the appearance of an ovum, the external surface, by the strong preffure of the uterus, resembling a membrane; so that the whole is mistaken for a false conception.

This substance, in bigness, commonly equals a pigeon or hen egg; or if it exceeds that size, and is longer retained, is distinguished by the appellation of mole: but this last generally happens in women betwixt the age of forty-five and fifty, or later, when their menses begin to disappear; sometimes from internal or external accidents that may produce continued floodings. If the catamenia have
have ceased to flow for some time in elderly women, and return with pain, such a symptom is frequently the forerunner of a cancer; before or after this happens, sometimes a large fluid-like substance will be discharged with great pain, resembling that of labour; and upon examination, appears to be no more than the fibrous part of the blood, which assumes that form by being long pressed in the uterus or vagina.

In this place, it will not be amiss to observe, that the glands of the uterus and vagina will sometimes increase, and differ the adjacent parts to a surprising degree; if (for example) one of the glands of the uterus be so obstructed as that there is a pressure on the returning vein and excretory duct, the arterial blood will gradually stretch the smaller vessels, and consequently increase the size of the gland, which will grow larger and larger, as long as the force of the impelled fluid is greater than the resistance of the vessels that contain it; by which means, a very small gland will be enlarged to a great bulk, and the uterus gradually stretched as in uterine gestation, though the progress may be so slow as to be protracted for years instead of months. Nevertheless, the os internum will be dilated, and the gland (if not too large to pass) will be squeezed into the vagina, provided it adheres to the uterus, by a small neck; nay, it will lengthen more and more, so as to appear on the outside of the os externum; in which case, it may be easily separated by a ligature. This disease will be the sooner known and easier remedied, the lower its origin in the uterus is. But should the gland take its rise in the vagina, hard by the mouth of the womb, it will swell itself still sooner, and a ligature may be easily introduced, provided the tumour is not so large as to fill up the cavity and hinder the neck of it from being commodiously felt. Though the greatest difficulty occurs, when the gland is confined to the uterus, being too much enlarged to pass through the os internum.

Sometimes all, or most of the glands in the uterus are thus affected, and augment the womb to such a degree, that it will weigh a great many pounds, and the woman is destroyed by its pressure upon the surrounding parts: but, should this indolent state of the tumour be altered by any accident that will produce irritation and inflammation, the parts will grow chilurous, and a cancer ensue.

This misfortune, for the most part, happens to women, when their menstrual evacuations leave them; and sometimes (though seldom) to child-bearing women, in consequence of severe labour.

Of the Placenta.

The ovum is formed of the placenta with the chorion and amnion, which are globularly distended by the incrusted waters that surround the child. The placenta is commonly of a round figure, somewhat resembling an oatcake, about six inches in diameter, and one inch thick in the middle, growing a little thinner towards the circumference; it is composed of veins and arteries, which are divided into an infinite number of small branches, the venous parts of which unite in one large tube, called the umbilical vein, which brings back the blood, and is supposed to carry along the nutritive fluid from the vessels of the chorion and placenta, to the child, whose belly it perforates at the navel; from thence passing into the liver, where it communicates with the vena portarum and cava. It is furnished with two arteries, which arise from the internal iliacs of the child, and running up on each side of the bladder, perforates the belly where the umbilical vein entered; then they proceed to the placenta, in a spiral line, twining round the vein, in conjunction with which they form the funiculus umbilicalis, which is commonly four or five hand breadths in length, sometimes only two or three, and sometimes it extends to the length of eight or ten. The two arteries, on their arrival at the inner surface of the placenta, are divided and subdivided into minute branches, which at last end in small capillaries that inoculate with the veins of the same order. These arteries, together with the umbilical vein, are supposed to do the same office in the placenta which is afterwards performed in the lungs by the pulmonary artery and vein, until the child is delivered and begins to breathe; and this opinion seems to be confirmed by the following experiments. If the child and placenta are both delivered suddenly, or the last immediately after the first; and if the child, though alive, does not yet breathe; the blood may be felt circulating, sometimes slowly, at other times with great force, through the arteries of the funis to the placenta, and from thence back again to the child, along the umbilical vein. When the vessels are slightly pressed, the arteries swell between the pressure and the child, while the vein grows turgid between that and the placenta, from the surface of which no blood is observed to flow, although it be lying in a bason, among warm water. As the child begins to breathe, the circulation, though it was weak before, immediately grows stronger and stronger, and then in a few minutes the pulsation in the navel-string becomes more languid, and at last entirely flops. If, after the child is delivered, and the navel-string cut, provided the placenta adheres firmly to the uterus, which is thereby kept extended; or, if the womb is still distended by another child; no more blood flows from the umbilical vessels, than what seemed to be contained in them at the instant of cutting; and this, in common cases, does not exceed the quantity of two or three ounces; and finally, when, in consequence of violent floodings, the mother expires, either in time of delivery, or soon after it, the child is sometimes found alive and vigorous, especially if the placenta is found; but if loose, then the child will lose blood as well as the mother.

The external surface of the placenta is divided into several lobes, that it may yield and conform itself more commodiously to the inner surface of the uterus, to which it adheres, so as to prevent its being separated by any shock or blows upon the abdomen, unless when violent. These groups of veins and arteries which enter into the composition of the placenta receive external coats from the chorion, which is the outward membrane of the ovum, thick and strong, and forms three fourths of the external globe that contains the waters and the child; the remaining part being covered by the placenta; so that these two in conjunction constitute the whole external surface of the ovum. Some indeed allege, that these are enveloped with a cribriform or cellular substance, by which
which they seem to adhere by contact only, to the uterus; and that the inner membrane of the womb is full of little glands, whose excretory ducts opening into the fundus and neck, secrete a soft thin mucus, to lubricate the whole cavity of the uterus, which beginning to stretch in time of gestation, the vessels that compose these glands are also diffused; consequently, a greater quantity of this mucus is separated and retained in this cribriform and cellular substance, the absorbing vessels of which take it in, and convey it along the veins, for the nourishment of the child. The womb being therefore diffused in proportion to the increase of the child, those glands are also proportionably enlarged; by which means, a larger quantity of the fluid is separated, because the nourishment of the child must be augmented in proportion to the progress of its growth; and this liquor undergoes an alteration in quality as well as in quantity, being changed from a clear thin fluid into the more viscous consistence of milk. In some cases this mucus hath been discharged from the uterus in time of pregnancy, and both mother and child weakened by the evacuation, which may be occasioned by the chorion's adhering too loosely, or being in one part actually separated from the womb.

Formerly, it was taken for granted by many, that the placenta always adhered to the fundus uteri; but this notion is refuted by certain observations, in consequence of which we find it as often flicking to the sides, back and fore parts, and sometimes as far down as the inside of the os uteri. See Plate CXXI.

When the placenta is delivered, and no other part of the membrane tore except that through which the child passed, the opening is near the edge or side of the placenta, and seldom in the middle of the membranes; and a hog's bladder being introduced at this opening, and inflated, when lying in water, will shew the shape and size of the inner surface of the womb, and plainly discover the part to which the placenta adhered.

The chorion is, on the inside, lined with the amnion, which is a thin transparent membrane, without any vessels so large as to admit the red globules of blood; it adheres to the chorion by contact, and seems to form the external coat of the funis umbilicalis.

This membrane contains the ferum, in which the child swims; which fluid is supposed to be furnished by lymphatic vessels that open into the inner surface of the amnion. If this liquid be neither absorbed into the body of the foetus, nor taken into the stomoch by suction at the mouth, there must be absorbing vessels in this membrane, in the same manner as in the abdomen and other cavities of the body, where there is a constant renovation of humidity.

The quantity of this fluid, in proportion to the weight of the foetus, is much greater in the first than in the last month of gestation, being in the one perhaps ten times the weight of the embryo; whereas, in the other, it is commonly in the proportion of one to two: for, six pounds of water surrounding a foetus that weighs twelve pounds, is reckoned a large proportion, the quantity being often much less; nay, sometimes there is very little or none at all.

In most animals of the brute species, there is a third membrane called allantois, which resembles a long and wide blind-gut, and contains the urine of the foetus: it is situated between the chorion and amnion, and communicates with the urachus that rises from the fundus of the bladder, and runs along with the umbilical vessels, depositing the urine in this reser voir, which is attached to its other extremity. This bag hath not yet been certainly discovered in the human foetus, the urachus of which, though plainly perceivable, seems hitherto to be quite imperforated.

From the foregoing observations upon nutrition, it seems probable, that the foetus is rather nourished by the absorption of the nutritive fluid into the vessels of the placenta and chorion, than from the red blood circulated in full stream from the arteries of the uterus to the veins of the placenta, and returned by the arteries of the left to the veins of the right, in order to be renewed, refined, and made arterial blood in the lungs of the mother.

Of the Child's situation in the Uterus.

The embryo or foetus, as it lies in the uterus, is nearly of a circular or rather oval figure, which is calculated to take up as little space as possible: the chin rests upon the breast, the thighs are pressed along the belly, the heels applied to the breech, the face being placed between the knees, while the arms cross each other round the legs. The head, for the most part, is down to the lower part of the uterus; and the child being contracted into an oval form, the greatest length is from head to breech: but the distance from one side to the other is much less than that from the fore to the back part; because the thighs and legs are doubled along the belly and stomoch, and the head bended forwards on the breast.

The uterus being confined by the vertebrae of the loins, the distance from the back to the fore-part of it must be less than from side to side; so that, in all probability, one side of the foetus is turned towards the back, and the other to the fore-part of the womb; but, as the back part of the uterus forms a little longitudinal cavity on each side of the vertebræ, the fore-parts of the foetus may therefore for the most part tilt more backwards than forwards.

It has been generally supposed, that the head is turned up to the fundus, and the breech to the os uteri, with the fore-parts towards the mother's belly; and that it remains in this situation till labour begins, when the head comes downwards, and the face is turned to the back of the mother. Some allege, that the head precipitates about the end of the eighth or beginning of the ninth month, by becoming specifically heavier than the rest of the body. Others affirm, that as the child increases in bulk, especially during the two last months, the proportion of surrounding water must be diminished, so that it is confined in its motion, and, in struggling to alter its position, the head is moved to the os tunicæ, where it remains till delivery. The particulars of this and other theories may be found in Mauriceau, Le Motte, Simpson, and Old. But, from the following observations, it seems more probable, that the head is, for the most part, turned down to the lower part of the uterus from conception to delivery.

In the first month, according to some writers, the embryo
bryo exhibits the figure of a tadpole, with a large head and small body or tail, which gradually increases in magnitude, till the arms and thighs begin to bud or strut out, like small nipples, from the shoulders and breech: two black specks appear on each side of the head, with a little hole or opening between them, which in the second month are easily distinguished to be the eyes and mouth. See Plate CXI. fig. 2. The legs and arms are gradually formed, while the body turns larger; but the fingers are not separated or distinct, till the latter end of the second or beginning of the third month. See Plate CXI. fig. 3. This is commonly the case; but sometimes the bulk and appearance differ considerably in different embryos of the same age. The younger the embryo, the larger and heavier is the head in proportion to the rest of the body; and this is the case in all the different gradations of the fetus; so that when dropped or suspended by the navel string in water, the head must sink lowermost of course. Besides, when women miscarry in the fourth, fifth, sixth, and seventh months, the head for the most part presents itself, and is first delivered. See Plate CXI. fig. 3. By the touch in the vagina, the head is frequently felt in the seventh, sometimes in the sixth, but more frequently in the eighth month; and if the same women are thus examined, from time to time, till the labour begins, the head will always be felt of a round firm substance at the fore-part of the brim of the pelvis, betwixt the os internum and pubes, through the substance of the vagina and uterus. See Plate CXI. fig. 4. But all these opinions are liable to objections. If the descent of the head proceeded from its specific gravity, we would always find it at the os internum, because this reason would always prevail; but it was owing to a diminution of water, why should we often find the breek presented, even when there is a quantity of that fluid large enough to give the head free liberty to rise again towards the fundus, or (according to the other opinion) to sink down by its specific gravity to the os internum? Some, indeed, suppose, that the head always presents itself, except when it is hindered by the funis umbilicalis twisting round the neck and body, so as to impede the natural progress: but, were this supposition just, when we turn and deliver by the feet those children that presented in a preternatural way, we should always find them more or less circumscribed by the navel string: the funis is as often found twirled round the neck and body when the head presents as in any other case. That the head is downwards all the time of gestation, seems, on the whole, to be the most reasonable opinion, though it be liable to the objection already mentioned, and seems contradictory to the observation of some authors, who allege, that in opening women that died in the fifth, sixth, or seventh month, they have found the child's head towards the fundus uteri. But as it lies as easly in one posture as in another, till the birth, this dispute is of less consequence in the practice of midwifery. It may be useful to suggest, that the wrong posture of the child in the uterus may proceed,

1. From circumvolutions in the funis umbilicalis. See Plate CXIII. fig. 1, which represents, in a front view of the pelvis, the breech of the fetus presenting, and dilating the os internum, the membranes being too soon broke. The fore-parts of the child are to the posterior part of the uterus; and the funis, with a knot upon it, surrounds the neck, arms, and body.

Or, 2. When there is little or no water surrounding the child, it may move into a wrong position, and be confined there by the structure of the uterus. See Plate CXIII. fig. 2, 3, 4.

Fig. 2. is the reverse of fig. 1, the fore-parts of the child being to the fore-part of the uterus.

Fig. 3. represents, in a front view of the pelvis, the fetus comprized, by the contraction of the uterus, into a round form, the fore-parts of the former being towards the inferior part of the latter, and one foot and hand fallen down into the vagina. In this figure, the anterior part of the pelvis is removed, by a longitudinal section through the middle of the foramen magnum.

D, The inferior and posterior part of the os externum.
EEEE, The remaining parts of the olla pubis and ischium.
FFFF, The membrana adiposa.

Fig. 4. represents, in the same view with fig. 3, the fetus in the contrary position; the breech and fore-parts being towards the fundus uteri, the left arm in the vagina, and the fore arm without the os externum, the shoulder being likewise forced into the os uteri.

Or, lastly, The wrong position of the child may be the effect of a pendulous belly or narrow pelvis, when the head lies forward over the pubis. See Plate CXI. fig. 6. See also Plate CXII. fig. 6 and 7.

Fig. 6. gives a lateral internal view of a distended pelvis, divided longitudinally, with the head of a fetus of the seventh month passing the same.

E, The tuberolithy of the os ischihialm of the same side.
F, The processus acutus.
G, The foramen magnum.

OF TOUCHING.

Touching is performed by introducing the fore-finger lubricated with pomatum into the vagina, in order to feel the os internum and neck of the uterus; and sometimes into the rectum, to discover the stretching of the fundus. By some, we are advised to touch with the middle finger, as being the longest; and by others, to employ both that and the first: but the middle is too much encumbered by that on each side, to answer the purpose fully,
fully; and when two are introduced together, the patient never fails to complain. The design of touching is to be informed whether the woman is, or is not with child; to know how far she is advanced in her pregnancy; if she is in danger of miscarriage; if the os uteri be dilated; and in time of labour to form a right judgment of the cafe, from the opening of the os internum, and the pressing down of the membranes with their waters; and lastly, to distinguish what part of the child is presented.

It is generally impracticable to discover, by a touch in the vagina, whether or not the uterus is impregnated, till after the fourth month: then the best time for examination is the morning, when the woman is fasting, after the contents of the bladder and rectum have been discharged; and the surgeon, if necessary, to submit to the inquiry in a standing posture; because, in that case, the uterus hangs lower down in the vagina, and the weight is more sensible to the touch than when she lies reclined. One principal reason of our uncertainty is, when we try to feel the neck, the womb rises up against the vagina, at the side of the os internum, (see Plate CXI. fig. 3.) and in some, the vagina feels very tense; but, when the fundus uteri is advanced near the navel, the pressure from above keeps down the os internum so much, that you can generally feel both the neck, and above that, the stretching of the under part of the uterus. See Plate CXI. fig. 3.

There is no considerable variation to be felt in the figure of the os internum, except in the latter end of pregnancy, when it sometimes grows larger and fatter, (see Plate CXI. fig. 4.) nor do the lips seem to be more closed in a woman with child than in another, especially in the beginning of pregnancy: but, in both cases the os uteri is felt like the mouth of a young puppy or tench. In some the lips are very small; in others, large; and sometimes, though seldom, smoothened over or pointed. In many women, who have formerly had children and difficult labours, the lips are large, and so much separated, as to admit the tip of an ordinary finger; but a little higher up, the neck seems to be quite closed.

In the first four months, the neck of the womb may be felt hanging down in the vagina, by pulling up the finger by the side of the os internum; but the stretching of the uterus and upper part of the neck cannot be perceived till the fifth, and sometimes the sixth month; and even then, the uterus must be kept down by a strong pressure upon the belly.

The stretching of the fundus is sometimes felt by the finger introduced into the rectum, before it can be perceived in the vagina; because, in this last method, the uterus recedes from the touch, and rises too high to be accurately distinguished; whereas the finger being introduced into the rectum, passes along the back of the womb almost to the upper part of the fundus, and in a unimpregnated state, is felt flat on the back part, and jutting out at the sides; but the impregnated uterus is perceived like a large round tumour.

About the fifth or sixth month, the upper part of the uterus is so much stretched, as to rise three or four inches above the os pubis, or to the middle space between that and the navel; so that, by pressing the hand on the belly, especially of lean women, it is frequently perceived; and if, at the same time, the index of the other hand be introduced in the vagina, the neck will seem shortened, particularly at the front part and sides, and the weight will be sensibly felt; but, if the parts of the abdomen are stretched after eating, one may be deceived by the pressure of the stomach, because weight and pressure are the same. But all these signs are more perceptible towards the latter end of pregnancy; and in some women the os internum is felt a little open some weeks before the full time, though generally it is not opened till a few days before labour begins.

From the fifth to the ninth month, the neck of the uterus becomes shorter and shorter, and the stretching of the womb grows more and more perceptible. In the seventh month, the fundus rises as high as the navel; in the eighth month, to the middle space between the navel and the scrobiculus cordis; and in the ninth, even to the scrobiculus, except in pendulous bellies; See Plate CXI. fig. 4. But all these marks may vary in different women, for when the belly is pendulous, the parts below the navel are much more stretched than those above, and hang over the os pubis; the fundus will then be only equal to, or a little higher than the navel; at other times, the uterus will rise in the latter end of the seventh or eighth month to the scrobiculus cordis. The neck of the womb will, in some, be felt as long in the eighth, as in others in the sixth or seventh month. This variation sometimes makes the examination of the abdomen more certain than the touch of the vagina; and so vice versa. At other times we must judge by both. See Plate CXI. fig. 6.

Of the signs of Conception, and the equivocal signs of pregnant and obstructed women.

The signs of pregnancy are to be distinguished from those that belong to obstructions, by the touch in the vagina and motion of the child, in the fifth or sixth month; sometimes, by the touch in the rectum, before and after the fifth month, when the tumour of the abdomen is plainly perceived.

Most women, a day or two before the irritation of the catamenia, labour under complaints proceeding from a plethora; such as stretching pains in the back and loins, in the thighs, breast and head; a stickiness and oppression at the stomach, and a fullness of all the visceras of the abdomen; and all these symptoms abate, and gradually vanish, when the discharge begins and continues to flow. But, if the woman be obstructed by any accident or error in the non-naturals, all these complaints continue and increase, and are hardly distinguishable from the symptoms of pregnancy, till the end of the fourth month; at which period, women with child grow better, and all the complaints of fullness gradually wear off; whereas, those, who are only obstructed, grow worse and worse.

The fundus uteri, in the obstructed patient, is not stretched; the disorder in the stomach is not so violent as in a pregnant woman, and seldom accompanied with reachings; while the women with child are afflicted with a reaching every morning, and subject to longings before the first labours under a fulness of the vessels; the last, over and above this complaint, suffers an additional one from the
the division of the uterus by the impregnated ovum. Obstiruptions and pregnancy are both accompanied by a stretching of the uterus in the breasts; but in the last only, it may be perceived the areola, or brown ring, round the nipples, from which, in the last month, a thin film diffils; but this circle is not always to be discernible as in the first pregnancy, and even then is uncertain as well as the others.

About the fifth or sixth month, the circumfered tumour or stretching of the uterus is felt above the os pubis; and, by this circumfered and confident, easily distinguished from the alicites, or dropsy of the abdomen: it is also rounder and firmer than those swellings that accompany obstiruptions, which proceed from a general fullness of the vessels belonging to the ligaments and neighbouring viscer.

On the whole, the difficulty of distinguishing between obstiruptions and pregnancy in the first months, is so great, that we ought to be cautious in giving our opinion; and never prescribe such remedies as may endanger the fruit of the womb; but rather endeavour to palliate the complaints, until time shall discover the nature of the case; and always judge on the charitable side, when life or reputation is at stake.

In the fifth or sixth month of uterine gestation, by the touch in the vagina, we perceive the neck of the womb considerably shortened, and the stretching of the lower part of the uterus is then feebly felt between the mouth of the womb and the pubes, and on each side of the neck. This is the only moment when the head can possibly be felt against the lower part of the uterus; but rather endeavour to palliate the complaints, until time shall discover the nature of the case; and always judge on the charitable side, when life or reputation is at stake. See Plate CXI. fig. 3.

In the seventh month, the head of the child is frequently felt resting against the lower part of the uterus, between the pubes and os internum; and being pushed upwards towards the fundus, sinks down again by its own gravity. All these difficulties are more plain and certain, the nearer the patient approaches to the time of delivery.

Sometimes, the head is not felt till the eighth or ninth month; and in some few cases, not till after the membranes are broke, when it is forced down by the contraction of the uterus, and strong labour-pains. This circumstance may be owing to the head's resting above the basin, especially in a narrow pelvis; or to the diffusion of its belly with air after death, by which the fetus being rendered specifically lighter than the surrounding waters, the body floats up to the fundus, if there is a large quantity of fluid in the membranes; nor is the body always felt when the child lies across the uterus.

How to distinguish the false labour from the true, and the means to be used on that occasion.

If the os uteri remains close shut, it may be taken for granted that the woman is not yet in labour, notwithstanding the pains she may suffer: with regard to which, an accurate inquiry is to be made; and if her complaints proceed from an over stretching fullness of the uterus or vessels belonging to the neighbouring parts, bleeding in the arm or ankle, to the quantity of six or eight ounces, ought to be prescribed, and repeated occasionally. If the pains are occasioned by a looseness or diarrhea, it must be immediately restrained with opiates. Cholic pains are distinguished from those of labour, by being chiefly confined to the belly, without going off and returning by distinct intervals; they are for the most part produced by feces too long retained in the colon, or by such ingesta as occasion a rarefaction or expansion of air in the intestines; by which they are violently stretched and vellicated. This complaint must be removed by opening the bowels, to empty the guts of their noxious contents; and this evacuation being performed, opiates may be administered to allay the pains; either by being injected by the anus, taken by the mouth, or applied externally in form of pithem or embrocation.

Sometimes, the os internum may be a little dilated, and yet it may be difficult to judge whether or not the patient be in labour; the case, however, may be ascertained, after some attendance, by these considerations: if the woman is not arrived at her full time; if no soft or glary mucus hath been discharged from the vagina; if the pains are limited to the region of the belly, without extending to the back and sides of the thighs; if they are slight, and continue without intermission or increase; if, nay, if they have long intervals, and recur without force sufficient to push down the waters and membranes, or child's head, to open the os internum; if this part be felt thick and rigid, instead of being soft, thin, and yielding; we may safely pronounce, that labour is not yet begun; and those alarms are to be removed as we have directed in the case of false or cholick pains. Besides, if the pulse be quick and strong, and the patient attacked by fitches in the sides, back, or head, blooding will be likewise necessary. See Plate CXI, fig. 4.

The division of Labours.

A natural labour is when the head presents, and the woman is delivered by her pains and the assistance commonly given: but, should the case be tedious and lingering, that we are obliged to use extraordinary force, in stretching the parts, extracting with the forceps, or (to save the mother's life) in opening the head and delivering with the crotchit, it is distinguished by the appellation of laborious: and the pretternatural comprehends all those cases in which the child is brought by the feet, or the body delivered before the head. Neither do we mind how the child presents, so much as the way in which it is delivered: for there are cases in which the head presents, and for several hours we expect the child will be delivered in the natural way; but if the woman has not strength enough to force down the child's head into the pelvis, or in floodings, we are at length obliged to turn and bring it by the feet, because it is so high that the forceps cannot be applied; and if the child is not large, nor the pelvis narrow, it were pity to destroy the hopes of the parents, by opening the skull and extracting with the crotchit. In this case, therefore, although the child presents in a natural way, we are obliged to turn and deliver it in the same manner as if the shoulder, breast, or back, had presented; and generally, this operation is more difficult than in either of those cases, because, if the waters are all discharged, and the uterus close contracted round the fetus, it is more difficult to raise the head to the fundus. When the breech presents, we are frequently
ly obliged to push it up, and search for the leg; which
being found, we proceed to deliver the body, and lastly
the head. If the head is large, or the pelvis narrow, and
the waters not discharged, we ought, if possible, to turn
the child into the natural position.

For a further illustration, and to inform young prac-
titioners that difficult cases do not frequently occur, sup-
pose, of three thousand women in one town or village,
one thousand shall be delivered in the space of one year,
and in nine hundred and ninety of these births, the child
shall be born without any other than common assistance:
fifty children of this number shall offer with the fore-
head turned to one side, at the lower part of the pelvis,
where it will flop for some time; ten shall come with
the forehead towards the groin, or middle of the pubes
five shall present with the breech; two or three with the
face, and one or two with the ear; yet, all these shall
be safely delivered, and the calf be more or less lingering
and laborious, according to the size of the pelvis and child,
or strength of the woman of the remaining ten that
make up the thousand, shall present with the head
differently turned and two with the breech; and these
cannot be faced without stretching the parts, using the
forceps or crotchets, or pulling up the child in order to
bring it by the feet; this necessity proceeding either from
the weakness of the woman, the rigidity of the parts, a
narrow pelvis, or a large child, etc. the other two should
lie acrogs, and neither head nor breech, but some other
part of the body, present, so that the child must be turned
and delivered by the feet. Next year, let us suppose
another thousand women delivered in the same place; not
above three, six, or eight, shall want extraordinary as-
sistance; nay, sometimes, though seldom, when the child
is young, or unusually small, and the mother has strong
pains and a large pelvis, it shall be delivered even in the
very worst position, without any other help than that of
the labour-pains.

As the head, therefore, presents right in nine hundred
and twenty of a thousand labours, all such are to be ac-
counted natural; those of the other seventy, that require
assistance, may be deemed laborious; and the other ten
to be denominated laborious or preternatural, as they are
delivered by the head or feet.

In order, therefore, to render this treatise as distinct as
possible, for the sake of the reader’s memory, as well as
of the dependance and connection of the different labours,
they are divided in the following manner: that is ac-
counted natural, in which the head presents, and the
woman is delivered without extraordinary help; those
births are called laborious or nonnatural, when the head
comes along with difficulty, and must be assisted either
with the hand in opening the parts, or with the filet or
forceps, or even when there is a necessity for opening and
extracting it with the crotchets; and those in which the
child is brought by the breech or feet, are denominated
preternatural, because the delivery is performed in a pre-
ternatural way.

Of the different positions of women in labour.

In almost all countries, the woman is allowed either
to sit, walk about, or rest upon a bed, until the os uteri
is pretty much dilated by the gravitation of the waters,
or (when they are in small quantity) by the head of the
foetus, so that delivery is soon expected; when the is put
into such position as is judged more safe, easy, and conve-
nient for that purpose: but the patient may be put upon
labour too prematurely, and bad consequences will attend
such mistakes.

Among the Egyptians, Greeks, and Romans, the
woman was placed upon an high stool; in Germany and
Holland they use the chair which is described by Deventer
and Heister; and for hot climates the stool is perfectly
well adapted; in northern countries, and cold weather,
such a position must endanger the patient’s health.

In the West Indies, and some parts of Britain, the
woman is seated on a stool made in form of a semicircle:
in other places she is placed on a woman’s lap; and some,
kneeling on a large cushion, are delivered backwards.

In France the position is chiefly that of half sitting
and half lying, on the side or end of a bed; or the woman
being in naked bed, is raised up with pillows or a bed-
chair.

The London method is very convenient in natural and
easy labours; the patient lies in bed upon one side, the
knees being contracted to the belly, and a pillow put
between them to keep them asunder. But the most com-
mofions method is to prepare a bed and a couch in the
same room; a piece of oiled cloth or dressed sheep skin
is laid across the middle of each; over the under-sheet, and
above this, are spread several folds of linen, pinned or tied
with tape to each side of the bed and couch; these are
designed to frap up the moisture in time of labour and af-
ter delivery, while the oiled cloths or sheep skins below
preserve the feather bed from being wetted or spoiled:
for this purpose, some people lay besides upon the bed
several under-sheets over one another, so that by sliding
out the uppermost every day, they can keep the bed dry
and comfortable.

The couch must be no more than three feet wide, and
provided with castors; and the woman without any other
dress than that of a short or half shift, a linen skirt or pet-
ticoat open before, and a bed-gown, ought to lie down
upon it, and be covered with cloaths according to the fea-
on of the year. She is commonly laid on the left side,
but in that particular she is to consult her own ease; and
a large sheet being doubled four times or more, one end
must be flapt in below her breech, while the other hangs
over the side of the couch, to be spread upon the knee of
of the accoucheur or midwife, who sits behind her on a
low seat. As soon as she is delivered, this sheet must be
removed, a soft warm cloth applied to the os externum,
and the pillow taken from betwixt her knees; the theft
must be shifted with a clean, warm, half shift, linen skirt,
and bed-gown, and her belly kept firm with the broad
head-band of the filet, the ends of which are to be pin-
and tied together in the form of a bow. These measures being
taken, the couch must be run close to the bed side, and the patient
gently moved from one to another; but, if there is no
room, the bed must be furnished with the same apparatus.
Some, again, are laid across the foot of the bed, to the
head of which the cloaths are previously turned up till after
delivery, when the woman’s posture is adapted, and then

they are rolled down again to cover and keep her warm; by this expidient, the place of a couch is supplied, and the upper part of the bed preferred soft and clean; whereas those who are laid above the cloaths must be taken up and shifted while the bed is put to rights; in which case, they are subject to fainting; and to such as are very much enfeebled, this fatigue is often fatal.

Women are most easily touched, least fatigued, and kept warmest, when they lie on one side: but if the labour should prove tedious, the Parifian method seems most eligible; because when the patient half lies, half sits, the brim of the pelvis is horizontal, a perpendicular line falling from the middle space between the iliacus cords and navel, would pass exactly through the middle of the basin. In this position, therefore, the weight of the waters, and, after the membranes are broke, of the child's head, will gravitate downwards, and affist in opening the parts; while the contracting force of the abdominal muscles and uterus, is more free, strong, and equal in this than in any other attitude. Wherefore, in all natural cafes, when the labour is lingering or tedious, this or any other position, such as standing or kneeling, ought to be tried, which by an additional force, may help to push along the head, and alter its direction when it does not advance in the right way. Nevertheless, the patient must by no means be too much fatigued.

When the woman lies on the left side, the right hand must be used in touching, and vice versa, unless she is laid across the bed; in which case, either hand will equally answer the same purpose: but, if she lies athwart, with the breech towards the bed's foot, it will be most convenient to touch with the left hand when she is upon the left side, and with the right when in the opposite position. And here it will not be amiss to observe, that in the description of all the laborious and preternatural deliveries treated of in this performance, the reader must suppose the woman lying on her back, except when another posture is prescribed; and that in natural and laborious labours, whether she be upon her side or back, the head and shoulders are a little raised into a reclining posture, so that, if she may breathe easily, and assist the pains.

But in preternatural labours, when there is a necessity for using great force in turning the child, the head and shoulders must lie lower than the breech, which being close to the side or foot of the bed, ought to be raised higher than either, because when the pelvis is in this situation, the hand and arm are easily pushed up in a right line, along the back part of the uterus, even to its fundus. Sometimes, however, when the feet of the child are towards the belly of the mother, they are more easily felt and managed when she lies on her side. At other times, placing the woman on her knees and elbows on a low couch, according to Daventer's method, will succeed better, by diminishing in part the strong resistance from the pressure and weight of the uterus and child, by which the feet will sometimes be easier found and delivered; but then it is safer for the child, and easier to the operator and mother, to turn her to her back before you deliver the body and head.

Of the management of women in a Natural Labour.

In a woman come to full time, labour commonly begins and proceeds in the following manner.

The os uteri is felt soft, and a little opened; the circumference being sometimes thick, but chiefly thin: from this aperture is discharged a thick mucus, which lubricates the parts, and prepares them for stretching. This discharge usually begins some days before, and is accounted the forerunner of real labour; at the same time, the woman is seized at intervals with slight pains that gradually stretch the os uteri, fitting it for a larger dilatation; and when labour actually begins, the pains become more frequent, strong, and lasting.

At every pain, the uterus is strongly compressed by the same effort which expels the contents of the rectum at stool, namely the inflation of the lungs, and the contraction of the abdominal muscles.

If the child be surrounded with a large quantity of waters, (see Plate CXI. fig. 4. and 6.) the uterus cannot come in contact with the body of it, but at every pain the membranes are pushed down by the fluid they contain, and the mouth of the womb being sufficiently opened by this gradual and repeated dilatation, they are forced into the middle of the vagina; then the uterus contracts and comes in contact with the body of the child, and, if it be small, the head is propelled with the waters. Here the membranes usually break; but, if that is not the case, they are pushed along towards the os externum, which they also gradually open, and appear on the outside, in the form of a large round bag. Mean while, the head advances, and the os externum being by this time fully dilated, is also protruded; when, if the membranes, instead of burbling in the middle of the pouting, are torn all round at the os externum, the child's head is covered with some part of them, which goes under the name of the caul, or king's hood. If the placenta is, at the same time, separated from the uterus, and the membranes remain unbroken, the fecondaries, waters, and child, are delivered together; but, if the placenta adheres, they must of course give way: and should they be tore all around from the placenta, the greatest part of the body as well as the head of the child will be enveloped by them, from which it must be immediately disengaged, that the air may have a free passage into the lungs.

When the head is large, so that it does not descend immediately into the pelvis, the membranes are forced down by themselves; and being stretched thinner and thinner, give way; when all the waters which are farther advanced than the head, run out; then the uterus coming in contact with the body of the child, the head is squeezed down into the mouth of the womb, which it plucks up so as to detain the rest of the waters. See Plate CXI. fig. 6.

Sometimes, when the quantity of waters is very small, and the uterus embraces the body of the child, the head, covered with the membranes, is forced downwards, and gradually opens the os internum; but, at its arrival in the middle of the pelvis and vagina, part of the waters will be pushed down before it; sometimes in a large, and sometimes in a small proportion, towards the back part of the pelvis. At other times, when the waters are in small quantity, no part of them are to be distinguished farther than the head, which descending lower and lower, the attenuated membranes are split upon it; while, at the same time, it fills up the mouth of the womb and upper
The sagittal future, and the bones are a little separated of the pelvis: this is the place where the coronal crosses the sagittal future, and the bones are a little separated from each other, yielding a softness to the touch, by which may be distinguished four futures, or rather one crossing another. These may be plainly perceived, even before the membranes are broke; yet the examination must not be made during a pain, when the membranes are stretched down and filled with waters; but only when the pain begins to remit, and the membranes to be relaxed; otherwise they may be broke too soon, before the os internum be sufficiently dilated, and the head properly advanced.

When the vertex is come lower down, the sagittal future only is to be felt; because, as the hindhead descends in the pelvis, the fontanelle is turned more backwards, to the side, or towards the concavity of the sacrum: but, after it has arrived below the under part of the os pubis, the lambdoidal may be felt crossing the end of the sagittal future, the occiput making a more obtuse angle than that of the parietal bones, at the place where the three are joined together. But all these circumstances are more easily distinguished after the membranes are broke, or when the head is so compressed that the bones ride over one another, provided the hairy scalp be not excessively swelled. See Plate CXI. fig. 7.—See also Plate CXII. fig. 2, which shews in what manner the head of the foetus is helped along with the forceps, as artificial hands, when it is necessary for the safety of either mother or child.

How and when to break the Membranes.

If the child be surrounded with a large quantity of waters, the uterus cannot come in contact with the body so as to press down the head, until the membranes are pushed a considerable way before it into the vagina; nor even then, until they are broke, and the fluid diminished in such a manner as will allow the womb to contract, and with the assistance of the pains, force along the child. When the membranes therefore are strong or unadvanced, and continue so long unbrooke that the delivery is retarded, provided the os internum be sufficiently dilated, they ought to be broke without further delay; especially if the woman hath been much fatigued or exhausted with labour, or is seized with a violent flooding: in which case, the rupture of the membranes hastens delivery, and the hemorrhage is diminished by the contraction of the uterus, which

---

**MIDWIFERY.** 215
which lessens the mouths of the vessels that are also compressed by the body of the child.

The common method of breaking the membranes is by thrusting the finger against them when they are protruded with the waters during the pain, or by pinching them with the finger and thumb; but if they are detained too high to be managed in either of these methods, the hand may be introduced into the vagina, if the os externum is so lax as to admit it easily: and if this cannot be done without giving much pain, the fore and middle fingers being pushed into the vagina with the other hand, let a probe or pair of pointed scissors be directed along and between them, and thrust through the membranes, when they are pushed with the waters below the head. This operation must be cautiously performed, lest the head should be wounded in the attempt; and as for the membranes, let the opening be never so small, the waters are discharged with force sufficient to tear them asunder.

If the vertex, instead of resting at the side of the brim of the pelvis, or at the os pubis, is forced further down to the os internum, and the waters happen to be in small quantity, the head is pushed forwards, and gradually opens the mouth of the womb without any sensible interruption of the waters: then it advances by degrees into the vagina, and the membranes being split or tore, little or nothing is discharged until the body of the child is delivered: and in this case, the hair of the head being plainly felt, will be a sufficient indication that the membranes are broke. If no hair is to be felt, but a smooth body presents itself to the touch; and the woman has undergone many strong pains, even after the mouth of the womb hath been largely dilated, and the head forced into the middle of the pelvis; you may conclude, that delivery is retarded by the rigidity of the membranes; that there is but a small quantity of waters; and that, if the containing sacs were broke, the head would come along without further hesitation.

Sometimes, no waters can be felt while the head is no farther advanced than the upper part of the pelvis, because it plugs up the passage and keeps them from descending; but, as it advances downwards, the uterus contracts, and they are forced down in a small quantity towards the back part: from thence, as the head descends, or even though it should flick in that situation, they are pushed farther down, and the membranes may be easily broke; but the task is more difficult when no waters come down, and the membranes are contiguous to the head. In this case, they must be scratched a little during every pain, with the nail of a finger, which, though short and smooth, will, by degrees, wear them thinner and thinner, until they split upon the head by the force of labour. Yet this expedient ought never to be used until you are certain that delivery is retarded by their rigidity; for, if that be not the hindrance, the difficulty must proceed from the weakness of the woman, a large head, or narrow pelvis: in which case, the delivery is a work of time, and will be obstructed by the premature discharge of the waters, which by gradually passing by the head, ought to keep the parts moist and slippery, in order to facilitate the birth: for when the membranes are not broke until the head is forced into the middle of the pelvis, the largest part of it being then past the upper part of the sacrum, is commonly squeezed along, opens the os externum, and is delivered before all the waters are discharged from the uterus; so that what remains, by moistening and lubricating the parts, help the shoulders and body to pass with more ease. When the membranes are too soon broke, the under part of the uterus contracts sometimes so strongly before the shoulders, that it makes the resistance still greater.

In most natural labours, the space between the fore and back fontanelles, viz. the vertex, presents to the os internum, and the forehead is turned to the side of the pelvis, because the basin at the brim is widest from side to side; and frequently, before the head is pushed in and fast wedged among the bones, the child (after a pain) is felt to move and turn it to that side or situation in which it is least pressed and hurt, if it was not presenting in that position before: but this position of the head may alter, viz. in those where it is as wide, or wider, from the back part to the fore part of the brim, than from side to side, the forehead may be turned backwards or forwards. But this form of the pelvis seldom happens.

This posture is always observed in a narrow pelvis, when the upper part of the sacrum juts forward to the pubes; but, as the child is forced lower down, the forehead turns into the hollow at the inferior part of the sacrum, because the vertex and occiput find less resistance at the lower part of the os pubis than at the ifchium, to which it was before turned; the pelvis being at the pubes, as formerly described, no more than two inches in depth, whereas at the ifchium it amounts to four. If, therefore, the forehead sticks in its former situation, without turning into the hollow, it may be assisted by introducing some fingers, or the whole hand, into the vagina, during a pain, and moving it in the right position.

When the head of the fetus presents, and is forced along in any of those positions, the labour is accounted natural; and little else is to be done, but to encourage the woman to bear down with all her strength in every pain, and to rest quietly during each interval: if the parts are rigid, dry, or inflamed, they ought to be lubricated with pomatum, hog’s lard, butter, or ung. alb.: the two first are most proper for the external parts; and the the two last (as being harder and not so easily melted) ought to be put up into the vagina, to lubricate that and the os internum.

The mouth of the womb and os externum, for the most part, open with greater difficulty in the first than in the succeeding labours, more especially in women turned of thirty. In these cases, the os externum must be gradually dilated in every pain, by introducing the fingers in form of a cone, and turning them round, so as to stretch the parts by gentle degrees; and the whole hand being admitted into the vagina, it will be sometimes found necessary to insinuate the fingers with the flat of the hand between the head and os internum: for, when this precaution is not taken in time, the os uteri is frequently pushed before the head (especially that part of it next the pubes) even through the os externum; or if the head passes the mouth of the womb, it will protrude the parts at the os externum, and will endanger a laceration in the perineum.
perineum. This dilatation, however, ought to be cautiously performed, and never attempted except when it is absolutely necessary; even then it must be effected slowly, and in time of a pain, when the woman is least sensible of the dilating force.

When the labour happens to be lingering, though every thing be in a right posture, if the aidants be clamorous, and the woman herself too anxious and impatient to wait the requisite time without complaining, the labour will be actually retarded by her uneasiness, which we must endeavour to surmount by arguments and gentle persuasion; but if she is not to be satisfied, and strongly impressed with an opinion that certain medicines might be administered to hasten delivery, it will be convenient to prescribe some innocuous medicine, that the may take between whiles, to beguile the time and please her immanation: but, if she is actually weak and exhausted, it will be necessary to order something that will quicken the circulating fluids, such as preparations of anlber, caflor, myrrh, volatile spirits, the pulv. myrrh. composit. of the London, or pulv. ad partum of the Edinburgh Pharmacopoeia, with every thing in point of diet and drink that nourishes and strengthens the body. If the patient is of a plethoric habit, with a quick strong pulse, the contrary method is to be used, such as yamfection, antiphlogistic medicines, and plentiful draughts of weak diluting fluids.

How to behave when the birth is obstructed by the navel-string or shoulders of the child, or a narrow pelvis.

Although the head is pushed down into the pelvis, and the vertex employed in opening the os externum, the forehead being lodged in the concavity formed by the coccyx and lower part of the sacrum; yet frequently after the labour-pain is abated, the head gets is withdrawn by the navel-string happening to be twilled round the neck; or when the shoulders, instead of advancing, are retarded at the brim of the pelvis, one refting over the offa pubis, while the other is fixed at the sacrum; or when (the waters having been long evacuated) the under-part of the uterus contracts round the neck and before the shoulders, keeping up the body of the child.

When the head is therefore drawn back by any of these obstacles, and the delivery hath been retarded during several pains, one or two fingers being introduced into the rectum before the pain goes off, ought to press upon the forehead of the child at the root of the nose, great care should be taken to avoid the eyes: this pressure detains the head till the return of another pain, which will squeeze it farther down, while the fingers pushing slowly and gradually, turn the forehead half round forwards and half round upwards. By this assistance, and the help of strong pains, the child will be forced along, although the neck be entangled in the navel-string; for, as the child advances, the uterus contracts, and consequently the placenta is moved lower: the funis umbilicus will also fretch a little, without obstructing the circulation.

The head being thus kept down, the shoulders too are pressed in every suceeding pain until they are forced into the pelvis, when the whole comes along without further difficulty. And this expedient will, moreover, an-
The child being born, the funis umbilicalis must be divided, and the placenta delivered, according to the directions that will occur in the sequel.

How to manage the Child after Delivery.

The child being delivered, ought to be kept warm beneath the beds-cloaths, or immediately covered with a warmed flannel or linen cloth; if it cries and breathes, the umbilical cord may be tied and cut, and the child delivered to the nurse without delay; but, if the air does not immediately rush into the lungs, and the circulation continues between it and the placenta, the operation of tying and cutting must be delayed, and every thing tried to stimulate, and sometimes to give pain. If the circulation is languid, respiration begins with difficulty, and proceeds with long intervals; and if it be entirely stopped in the funis; the child, if alive, is not easily recovered; sometimes, a great many minutes are elapsed before it begins to breathe. Whatever augments the circulating force, promotes respiration; and as this increases, the circulation grows stronger, so that they mutually afflict each other. In order to promote the one and the other, the child is kept warm, moved, shaken, whipt; the head, temples, and breast rubbed with spirits, garlic, onion, or mustard applied to the mouth and nose; and the child has been sometimes recovered by blowing into the mouth with a silver canula, so as to expand the lungs.

When the placenta is itself delivered, immediately or soon after the child, by the continuance of the labours, or hath been extricated by the operator, that the uterus may contract, so as to restrain too great a flooding; in this case, if the child has not yet breathed, and a pulsation is felt in the ves sels, some people (with good reason) order the placenta, and as much as possible of the navel-string, to be thrown into a basin of warm wine or water, in order to promote the circulation between them and the child; others advise us to lay the placenta on the child’s belly, covered with a warm cloth; and a third fet order it to be thrown upon hot ashes: but, of these, the warm water seems the most innocent and effectual expedient. Nevertheless, if the placenta is still retained in the uterus, and no dangerous flooding ensues, it cannot be in a place of more equal warmth, while the operator endeavours, by the methods above described, to bring the child to life.

In lingering labours, when the head of the child hath been long lodged in the pelvis, so that the bones ride over one another, and the shape is preternaturally lengthened, the brain is frequently so much compressed, that violent convulsions ensue before or soon after the delivery, to the danger and oft-times the destruction of the child. This disorder is frequently relieved and carried off, and the bad consequences of the long compression prevented, by cutting the navel-string before the ligature is made, or tying it so lightly as to allow two, three, or four large spoonfuls to be discharged.

If the child has been dead one or two days before delivery, the lips and genitals (especially the forcaum in boys) are of a livid hue; if it hath lain dead in the uterus two or three days longer, the skin may be easily stripped from every part of the body, and the navel-strings appears of the same colour with the lips and genitals; in ten or fourteen days, the body is much more livid and mortified, and the hairy scalp may be seared with ease; and indeed, any part of the child which hath been strongly pressed into the pelvis, and retained in that situation for any length of time, will adopt the same mortified appearance.

How to tie the Funis Umbilicalis.

Different practitioners have used different methods of performing this operation; some proposing to tie and separate the funis before the placenta is delivered; to apply one ligature close to the belly of the child, with a view to prevent a rupture of the navel; and making another two inches above the former, to divide the rope between the two tyings: by the second ligature, they mean to prevent a dangerous hemorrhage from the woman, provided the placenta adheres to the uterus. But all these precautions are founded upon mistaken notions, and the following seems to be that which is safest and best: if the placenta is not immediately delivered by the pains, and no flooding obliges you to hasten the extraction, the woman may be allowed to rest a little, and the child to recover; if it does not breathe, or the respiration is weak, let the methods above prescribed be put in practice, with a view to stimulate the circulation; but if the child is lively, and cries with vigour, the funis may be immediately tied in this manner: having provided a ligature or two, composed of sandy threads waxed together, so as to equal the diameter of a pack-thread, being seven inches in length, and knotted at each end, tie the navel-string about two fingers breadth from the belly of the child, by making at first one turn, if the funis be small, and securing it with two knots; but if the cord be thick, make two more turns, and another double knot; then cut the funis with a pair of sharp scissors one finger’s breadth from the ligature towards the placenta; and in cutting run the scissors as near as possible to the root of the blades, else the funis will be apt to slip from the edge, and you will be obliged to make several snips before you can effect a separation: at the same time, guard the points of the scissors with your other hand. The child being washed, a linen rag is wrapped round the tied funis; which being doubled up along the belly, a square compress is laid over it, and kept firm or moderately tight with what the nurses call a belly-band, or roller round the body.

This portion of the funis soon shrinks, turns frizz livid, then black, and about the fifth day falls off close to the belly; and let the navel-string be tied in any part, or at any distance whatsoever from the belly, it will always drop off at the same place: so that ruptures in the navel seldom or never depend upon the tying of the funis, but may happen when the compress and belly band are not kept sufficiently firm, and continued some time after the separation of the withered portion, especially in those children that cry much: the bandage ought always to be applied so firmly as not to affect respiration.

The ligature upon the funis must always be drawn so tight as to shut up the mouths of the vessels: therefore, if they continue to pour out their contents, another ligature must be applied below the former; for if this precaution...
Of delivering the Placenta.

The funis being separated, and the child committed to the nurse, the next care is to deliver the placenta and membranes, if they are not already forced down by the labour-pains. We have already observed, that if there is no danger from a flooding, the woman may be allowed to rest a little, in order to recover from the fatigue she has undergone; and that the uterus may, in contracting, have time to squeeze and separate the placenta from its inner surface: during which pause also, about one, two or three tea-cups full of blood is discharged through the funis, from the vessels of the placenta, which is thus diminished in bulk, so that the womb may be the more contracted; and this is the reason for applying one ligature only upon the cord. In order to deliver the placenta, take hold of the navel-string with the left hand, turning it round the fore and middle fingers, or wrapping it in a cloth, that it may not slip from your grasp; then pull gently from side to side, and direct the woman to assist your endeavour, by straining as if your knees were at stool, blowing forcibly into her hand, or provoking herself to reach by thrusting her finger into her throat. If by these methods the placenta cannot be brought away, introduce your hand slowly into the vagina, and feel for the edge of the cake, which when you have found, pull it gradually along; as it comes out at the os externum, take hold of it with both hands and deliver it, bringing away, at the same time, all the membranes, which, if they adhere, must be pulled along with leisure and caution.

When the funis takes its origin towards the edge of the placenta, which is frequently the case, the cake comes easier off by pulling, than when the navel-string is inserted in the middle, unless it be uncommonly retained by its adhesion to the womb, or by the strong contraction of the os internum. If the funis is attached to the middle of the placenta, and that part presents to the os internum or externum, the whole mass will be too bulky to come along in that position: in this case you must introduce two fingers within the os externum, and bring it down with its edge foremost.

When the placenta is separated by the contraction of the uterus, in consequence of its weight and bulk, it is pulled down before the membranes, and both are brought away inverted.

When part of the placenta hath passed the os internum, and the rest of it cannot be brought along by easy pulling, because the os uteri is close contracted round the middle of it, or part of it still adheres to the womb, slide the flat of your hand below the placenta through the os internum; and having dilated the uterus, slip down your hand to the edge of the cake, and bring it along: but, if it adheres to the uterus, pull up your hand agio, and having separated it cautiously, deliver it as before.

If, instead of finding the edge or middle of the placenta, presenting to the os externum or internum, you feel the mouth of the womb closely contracted, you must take hold of the navel-string as above directed, and slide your other hand along the funis into the vagina; then slowly push your fingers and thumb, joined in form of a cone, through the os uteri, along the same cord, to the place of its insertion in the placenta: here let your hand rest, and feel with your fingers to what part of the uterus the cake adheres: if it be loose at the lower edge, try to bring it along; but if it adheres, begin and separate it slowly, the back of your hand being turned to the uterus, and the fore part of your fingers towards the placenta: and for this operation the nails ought to be cut short and smooth. In separating, press the ends of your fingers more against the placenta than the uterus; and if you cannot distinguish which is which, because both feel soft (though the uterus is firmer than the placenta, and this last more solid than coagulated blood,) in this case, slide down your fingers to its edge, and conduct them by the separated part, pressing it gently from the uterus, until the whole is disengaged. Sometimes, when part of it is separated, the rest will loosen and come along, if you pull gently at the detached portion; but, if this is not effected with ease, let the whole of it be separated in the most cautious manner: sometimes, also, by grasping the inside of the placenta with your hand, the whole will be loosened without further trouble. As the placenta comes along, slide down your hand and take hold of the lower edge, by which it must be extracted, because it is too bulky to be brought away altogether in a heap; and let it be delivered as whole as possible, keeping your thumb or fingers fixed upon the navel-string, by which means laceration is often prevented.

When the woman lies on her back, and the placenta adheres to the left side of the uterus, it will be most commodious to separate the cake with the right hand; whereas the left hand is most conveniently used when the placenta adheres to the right side of the womb; but when it is attached to the forepart, back, or fundus, either hand will answer the purpose.

That part of the uterus to which the placenta adheres, is kept still dilated, while all the rest of it is contracted.

The nearer the adhesion is to the os internum, the easier is the placenta separated, and vice versa: because it is difficult to reach up to the fundus, on account of the contraction of the os internum, and lower part of the womb, which are not stretched again without great force after they have been contracted for any length of time.

When therefore the placenta adheres to the fundus, and all the lower part of the womb is strongly contracted, the hand must be forced up in form of a cone into the vagina, and then gradually dilate the os internum and inferior part of the uterus. If great force is required, exert it slowly, resting between whiles, that the hand may not be
be cramped, nor the vagina in danger of being tore from the womb; for in this case, the vagina will lengthen considerably upwards.

While you are thus employed, let an assitant press with both hands on the woman's belly; or while you push with one hand, press with the other, in order to keep down the uterus, else it will rise high up, and roll about like a large ball, below the lax perties of the abdomen, so as to hinder you from effecting the necessary dilatation.

When you have overcome this contraction, and introduced your hand into the fundus, separate and bring the placenta along, as above directed; and should the uterus be contracted in the middle like a hour-glass, a circumstance that sometimes, though rarely happens, the same method must be practised.

In every case, and especially when the placenta hath been delivered with difficulty, introduce your your hand after its extraction, in order to examine if any part of the uterus be pulled down and inverted; and if that be the case, push it up and reduce it without los of time; then clear it of the coagulated blood, which otherwise may occasion violent after-pains.

For the most part, in ten, fifteen, or twenty minutes, more or less, the placenta will come away of itself; and though some portion of it, or of the membranes, be left in the uterus, provided no great flooding ensues, it is commonly discharged in a day or two, without any detriment to the woman: but at any rate, if possible, all the fecundines ought to be extracted at once, and before you leave your patient, in order to avoid reflections.

**OF LABORIOUS LABOURS.**

**How LABORIOUS LABOURS are occasioned.**

All those cases in which the head presents, and cannot be delivered in the natural way, are accounted more or less laborious, according to the different circumstances from which the difficulty arises; and these commonly are, first, Great weakens, proceeding from loss of appetite and bad digestion; frequent vomitings, diarrhées, or dyfenteries, flooding, or any other disease that may exhaust the patient; as also the fatigue she may have undergone by unskilful treatment in the beginning of labour.

Secondly, From excessive grief and anxiety of mind, occasioned by the unfeaneful news of sudden misfortune in time of labour; which often affect her so, as to carry off the pains, and endanger her sinking under the shock.

Thirdly, From the rigidity of the os uteri, vagina, and external parts, which commonly happens to women in the first birth, especially to those who are about the age of forty: though it may be also owing to large calolities, produced from laceration or ulceration of the parts; or to glands and scirrous tumours that block up the vagina.

Fourthly, When the under-part of the uterus is contracted before the shoulders, or the body entangled in the navel-string.

Fifthly, From the wrong presentation of the child's head; that is, when the forehead is towards the groin or middle of the os pubis; when the face presents with the chin to the os pubis, internum, or sacrum; when the crown of the head rolls above the os pubis, and the forehead or face is pressed into the hollow of the sacrum; and lastly, when one of the ears presents.

Sixthly, From the extraordinary ossification of the child's head; by which the bones of the skull are hindered from yielding, as they are forced into the pelvis; and form a hydrocephalus or dropsy, distending the head to such a degree, that it cannot pass along until the water is discharged.

Seventhly, From a too small or distorted pelvis, which often occurs in very little women, or such as have been rickety in their childhood. See Plate CXII. fig. 6. 7.

In all these cases, except when the pelvis is too narrow and the head too large, provided the head lies at the upper-part of the brim, or (though pressed into the pelvis) can be easily pushed back into the uterus, the best method is, to turn the child and deliver by the feet; but, if the head is pressed into the middle or lower part of the pelvis, and the uterus strongly contracted round the child, delivery ought to be performed with the forceps; and in all the seven cases, if the woman is in danger, and if you can neither turn, nor deliver with the forceps, the head must be opened and delivered with crotchets. Laborious cases, from some of the above recited causes, happen much oftener than those we call preternatural; but, those which proceed from a narrow pelvis, or a large head, are of the worst consequence. These cases demand greater judgment in the operator than those in which the child's head does not present; because in these last we know, that the best and safest method is to deliver by the feet; whereas in laborious births, we must maturely consider the cause that retards the head from coming along, together with the necessary assistance required; we must determine when we ought to wait patiently for the efforts of nature, and when it is absolutely necessary to come to her aid. If we attempt to succour her too soon, and use much force in the operation, so that the child and mother, or one of the two, are lost, we will be apt to reproach ourselves for having acted prematurely; upon the supposition, that if we had waited a little longer, the pains might have, by degrees, delivered the child; or at least, forced the head fo low, as that we might have extracted it with more safety, by the assistance of the forceps. On the other hand, when we leave it to nature, perhaps by the strong pressire upon the head and brain, the child is dead when delivered, and the woman so exhausted with tedious labour, that her life is in imminent danger: in this case, we blame ourselves for delaying our help too long, reflecting that bad we delivered the patient sooner, without paying such ferupulous regard to the life of the child, the woman might have recovered without having run such a dangerous risk. Doubtless it is our duty to save both mother and child, if possible; but, if that is impracticable, to pay our chief regard to the parent; and in all dubious cases, to act cautiously and circumspectly, to the beft of our judgment and skill.

If the head is advanced into the pelvis, and the uterus strongly contracted round the child, great force is required to pull it back into the womb, because the effort must be sufficient
sufficient to stretch the uterus, so as to re-admit the head, together with your hand and arm; and even then the child will be turned with great difficulty.

Should you turn when the head is too large, you may bring down the body of the child, but the head will stick fast above, and cannot be extracted without the help of forceps or crotchets; (see explanation of Plate CXIII. fig. 5, below:) yet the case is still worse in a narrow pelvis, even though the head be of an ordinary size. When things are so situated, you should not attempt to turn, because if so doing you may give the woman a great deal of pain, and yourself much unnecessary fatigue: you ought therefore to try the forceps, and if they do not succeed, diminish the size of the head, and extract it, as shall be afterwards shown.

Plate CXIII. fig. 5. represents, in a lateral view of the pelvis, the method of extracting, with the assistance of a curved crotchet, the head of the fetus, when left in the uterus, after the body is delivered and separated from it; either by its being too large, or the pelvis too narrow.

ABC, The os facrum and coccyx.
D, The os pelvis of the left side.
EE, The uterus.
F, The locking part of the crotchet.
g.h.i. The point of the crotchet on the inside of the cranium.

Of the Fillets and Forceps.

We have already observed, that the greatest number of difficult and lingering labours proceed from the head's sticking fast in the pelvis, which situation is occasioned by one of the seven causes recited above: when formerly this was the case, the child was generally left, unless it could be turned and delivered by the feet; or if it could be extracted alive, either died soon after delivery, or recovered with great difficulty from the long and severe compression of the head, while the life of the mother was endangered from the same cause as above described: for, the pressure being reciprocal, the fibres and vessels of the soft parts contained in the pelvis are bruised by the child's head, and the circulation of the fluids obstructed; so that a violent inflammation, and sometimes a sudden mortification, ensues. If the child could not be turned, the method practised in these cases, was to open the head and extract with the crotchet; and this expedient produced a general clamour among the women, who observed, that when recourse was had to the assistance of a man-midwife, either the mother or child, or both, were lost. This censure, which could not fail of being a great discouragement to male practitioners, stimulated the ingenuity of several gentlemen of the profession, in order to contrive some gentler method of bringing along the head, so as to save the child, without any prejudice to the mother.

Their endeavours have not been without success: a more safe and certain expedient for this purpose hath been invented, and of late brought to greater perfection in this than in any other kingdom; so that if we are called in before the child is dead, or the parts of the woman in danger of a mortification, both the fetus and mother may frequently be happily saved. This fortunate contrivance is no other than the forceps, which was, as is alluded, first used here by the Chamberlains, by whom it was kept as a secret, and after their decease conveyed imperfectly known, as to be seldom applied with success; so that different practitioners had recourse to different kinds of fillets or crotchets. Blunt hooks also of various make were invented in England, France, and other parts. The forceps, since the time of Dr Chamberlain, have undergone several alterations, particularly in the joining, handles, form, and composition.

The common way of using them formerly, was by introducing each blade at random, taking hold of the head any how, pulling it straight along, and delivering with downright force and violence; by which means, both os internum and externum were often tore, and the child's head much bruised. On account of these bad consequences, they had been altogether disused by many practitioners; some of whom endeavoured, in lieu of them, to introduce divers kinds of fillets over the child's head; but none of them can be so easily used, or have near so many advantages, as the forceps, when rightly applied and conducted.

For my own part, says Dr Smellie, finding in practice that, by the directions of Chapman, Giffard, and Gregoire at Paris, I frequently could not move the head along without contusing it, and tearing the parts of the woman; for they directed us to introduce the blades of the forceps where they will easiest pass, and taking hold of the head in any part of it, to extract with more or less force, according to the resistance; I began to consider the whole in a mechanical view, and reduce the extraction of the child to the rules of moving bodies in different directions: in consequence of this plan, I more accurately surveyed the dimensions and form of the pelvis, together with the figure of the child's head, and the manner in which it passed along in natural labours: and from the knowledge of these things, I not only delivered with greater ease and safety than before, but also had the satisfaction to find in teaching, that I could convey a more distinct idea of the art in this mechanical light than in any other; and particularly, give more precise and solid directions for applying the forceps, even to the conviction of many old practitioners, when they reflected on the uncertainty attending the old method of application. From this knowledge, too, joined with experience, and hints which have occurred and been communicated to me, I have been led to alter the form and dimensions of the forceps, so as to avoid the inconveniences that attended the use of the former kinds. See Plate CXIII. fig. 6.

A, The straight forceps, in the exact proportion as to the width between the blades, and length from the points to the locking part; the first being two and a half inches, and the second six inches; which, with three inches and a half, (the length of the handles), make in all eleven inches and a half.

B represents the posterior part of a single blade, in order to shew the width and length of the open part of the same, and the form and dimensions of the whole.

C, The blunt hook, which is used for three purposes:

To assist the extraction of the head, after the cranium is opened with the scissors, by introducing the
the small end along the ear on the outside of the head to above the under-jaw, where the point is to be fixed; the other extremity of the hook being held with one hand, whilst two fingers of the other are to be introduced into the foresaid opening, by which holds the head is to be gradually extracted.

2. The small end is useful in abortions, in any of the first four or five months, to hook down the second ones, when lying loose in the uterus, when they cannot be extracted by the fingers, or labour-pains, and when the patient is much weakened by bleedings.

3. The large hook at the other end is useful to assist the traction of the body, when the breech presents; but should be used with great caution, to avoid the dislocation or fracture of the thigh.

The lacks or fillets are of different kinds, of which the most simple is a noose made on the end of a fillet or lime garter; but this can only be applied, before the head is fast jammed in the pelvis, or when it can be pushed up and raised above the brim. The os externum and internum having been gradually dilated, this noose must be conveyed on the ends of the fingers, and slipped over the fore and hind head. There are also other kinds differently introduced upon various blunt instruments, too tedious either to describe or use: but the most useful of all these contrivances, is a fillet made in form of a sheath, mounted upon a piece of slender whale bone, about two feet in length, which is easier applied than any other expedient of the same kind. See Plate CXIII. fig. 7.

A represents the whale-bone fillet, which may be sometimes useful in laborious cases, when the operator is not provided with the forceps, in sudden and unexpected exigencies.

BB, Two views of a pessary for the prolabus uteri. After the uterus is reduced, the large end of the pessary is to be introduced into the vagina, and the os uteri retained in the concave part, where there are three holes to prevent the stagnation of any moisture. The small end without the os externum has two tapes drawn through the two holes, which are tied to four other tapes, that hang down from a belt that surrounds the woman's body, and by this means keeps up the pessary. This pessary may be taken out by the patient when she goes to bed, and introduced again in the morning; but as this sometimes rubs the os externum, so as to make its use uneasy, the round kind, marked C, are of more general use. They are made of wood, ivory, or cork, (the last covered with cloth and dipt in wax;) The pessary is to be lubricated with pomatum, the edge forced through the passage into the vagina, and a finger introduced in the hole in the middle lays it across within the os externum. They ought to be larger or smaller, according to the wideness or narrowness of the passage, to prevent their being forced out by any extraordinary straining.

DD gives two views of a female catheter, to shew its degree of curvature and different parts.

When the head is high up in the pelvis, if the woman has been long in labour, and the waters discharged for a considerable time, the uterus being strongly contracted, so as that the head and shoulders cannot be raised, or the child turned to be delivered by the feet, while the mother is enfeebled, and the pains so weak, that, unless assisted, she is in danger of her life: also, when the os internum, vagina, and labia pudendi, are inflamed, and tumefied; or when there is a violent discharge of blood from the uterus, provided the pelvis is not too narrow, nor the head too large, this fillet may be successfully used; in which case, if the os externum and internum are not already sufficiently open, they must be gradually dilated as much as possible, by the hand, which, at the same time must be introduced and passed along the side of the head, in order to ascertain the position thereof. This being known, let the other hand introduce the double of the whale-bone and fillet over the face and chin, where you can have the best purchase, and where it will be least apt to slip and lose its hold. This application being effected, let the hand be brought down, and the whale-bone drawn from the sheath of the fillet, which (after the ends of it are tied together) must be pulled during every pain, pressing at the same time with the other hand, upon the opposite part of the head, and using more or less force according to the resistance.

The disadvantage attending all fillets, is the difficulty in introducing and fixing them; and though this last is easier applied than the others; yet when the vertex presents, the child's chin is so pressed to the breast, that it is often impracticable to intumesc the fillet between them; and if it is fixed upon the face or hind head, it frequently slips off, in pulling: but, granting it commodiously fixed, when the head is large, or the pelvis narrow; so that we are obliged to pull with great force, the fillet will gall, and even cut the soft parts to the very bone; and if the child comes out of a sudden, in consequence of violent pulling, the external parts of the woman are in great danger of sudden laceration: but, if the head is small, and comes along with a moderate force, the child may be delivered by this contrivance, without any bad consequence; though in this case, we find by experience, that unless the woman has some very dangerous symptom, the head will in time slide gradually down into the pelvis, even when it is too large to be extracted with the fillet or forceps, and the child be safely delivered by the labour-pains, although slow and lingering, and the mother seems weak and exhausted, provided the be supported with nourishing and strengthening cordials.

As the head in the 6th and 7th cases is forced along the pelvis, commonly in these laborious cases, the bones of the cranium are so compressed, that they ride over one another, so that the bulk of the whole is diminished, and the head, as it is pushed forward, is, from a round, altered into an oblong figure: when therefore it is advanced into the pelvis, where it flicks fast for a considerable time, and cannot be delivered by the labour-pains, the forceps may be introduced with great ease and safety, like a pair of artificial hands, by which the head is very little (if at all) marked, and the woman very seldom torn. But if the head is detained above the brim of the pelvis, or if a small portion of it only farther advanced, and it appears, that the one being too narrow, or the other too large, the woman cannot be delivered by the strongest labour-pains;
in that case, the child cannot be fixed either by turning and bringing it by the feet, or delivered by the application of fillet or forceps; but the operator must unavoidably use the disagreeable method of extracting with the crotcher. Nevertheless, in all these cases, the forceps ought first to be tried; and sometimes they will succeed beyond expectation, provided the birth is retarded by the weakness of the woman, and the second, third, fourth, or fifth obstructions: but they cannot be depended upon even when the vertex presents, with the forehead to the side or back part of the pelvis, and (though the woman has had strong pains for many hours after the membranes are broke) the head is not forced down into the pelvis, or at least, but an inconsiderable part of it, resembling the small end of a fugar-loaf. For, from these circumstances, you may conclude, that the largest part of it is still above the brim, and that either the head is too large, or the pelvis too narrow. Even in these cases, indeed, the left fillet or a long pair of forceps may take such firm hold, that, with great force and the strong purchase, the head will be delivered: but such violence is commonly fatal to the woman, by causing such an inflammation, and perhaps laceration of the parts, as is attended with mortification.

When the head is high, the forceps may be locked in the middle of the pelvis; but in that case, great care must be taken in feeling with the fingers all round, that no part of the vagina be included in the locking. Sometimes, when the head refts, or is pressed too much on the forepart or side of the pelvis, either at the brim or lower down, by introducing one blade, it may be moved farther down, provided the labour-pains are strong, and the operation assisted by the fingers of the other hand applied to the opposite side of the head; but if the fingers cannot reach high enough, the best method is to turn or move the blade towards the ear of the child, and introduce the other along the opposite side.

General rules for using the Forceps.

The farther the head is advanced in the pelvis, the easier it is delivered with the forceps; because then, if in the 6th or 7th case, it is changed from a round to an oblong figure, by being forced along by the labour-pains; on the contrary, when the head remains high up, retting upon the brim of the pelvis, the forceps are used with greater difficulty and uncertainty.

The os externum must be gradually opened by introducing the fingers one after another, in form of a cone, after they have been lubricated with pomatum, moving and turning them in a semicircular motion, as they are pushed up. If the head is so low down that the hand cannot be introduced high up in this form, let the parts be dilated by the fingers turned in the direction of the coccyx, the back of the hand being upwards, next to the child’s head: the external parts being sufficiently opened to admit all the fingers, let the back of the hand be turned to the perineum, while the fingers and thumb being flattened, will slide along between the head and the os sacrum. If the right hand be used, let it be turned a little to the left side of the pelvis, because the broad ligament and membrane that fill up the space between the sacrum and ischia, will yield and allow more room for the fingers to advance; for the same reason, when the left hand is introduced, it must be turned a little to the right side. Having gained your point so far, continue to pull up, until your fingers pass the os internum; at the same time, with the palm of your hand, raise or scoop up the head; by which means, you will be more at liberty to reach higher, dilate the internal parts, and distinguish the situation and size of the head, together with the dimensions of the pelvis: from which investigation, you will be able to judge, whether the child ought to be turned and brought by the feet, or delivered with the forceps; or, if the labour-pains are strong, and the head presents tolerably fair, without being jammed in the pelvis, you will resolve to wait some time, in hope of seeing the child delivered by the labour-pains, especially when the woman is in no immediate danger, and the chief obstacle is the rigidity of the parts.

The position of the head is distinguished by feeling for one of the ears, the fore or smooth part of which is towards the face of the child; if it cannot be ascertained by this mark, the hand and fingers must be pulled farther up, to feel for the face or back part of the neck; but, if the head cannot be traced, the observation must be taken from the fontanelle, or that part of the cranium where the lambdoidal crosses the end of the sagittal future. When the ears of the child are towards the sides of the pelvis, or diagonal, the forehead being either to the sacrum or pubes, the patient must lie on her back, with her breech a little over the bed. If one ear is to the sacrum, and the other to the pubes, she must be laid on one side, with her breech over the bed, as before, her knees being pulled up to her belly, and a pillow placed between them; except when the upper part of the sacrum juts too much forward; in which case, the must lie upon her back, as above described.

The blades of the forceps ought always, if possible, to be introduced along the ears; by which means, they approach nearer to each other, gain a firmer hold, and hurt the head less than in any other direction; frequently, indeed, not the least mark of their application is to be perceived; whereas, if the blades are applied along the forehead and occiput, they are at a greater distance from each other; require more room, frequently at their points press in the bones of the skull, and endanger a laceration in the os externum of the woman. See Plate CXII. fig. 2.

The woman being laid in a right position for the application of the forceps, the blades ought to be privately conveyed between the feather-bed and the clothes, at a small distance from one another, or on each side of the patient: that this conveyance may be the more easily effected, the legs of the instrument ought to be kept in the operator’s side-pockets. Thus provided, when he sits down to deliver, let him spread the sheet that hangs over the bed, upon his lap, and under that cover, take out and dispose the blades on each side of the patient; by which means, he will often be able to deliver with the forceps, without their being perceived by the woman herself, or any other of the attendants. Some people pin a sheet to each shoulder, and throw the other end over the bed,
bed, that they may be the more effectually concealed from the view of those who are present: but this method is apt to confuse and embarras the operator. At any rate, as women are commonly frightened at the very name of an instrument, it is advisable to conceal them as much as possible, until the character of the operator is fully established.

The different ways of using the Forceps.

When the Head is down to the Os Externum.

When the head presents fair, with the forehead to the sacrum, the occiput to the pubes, and the ears to the sides of the pelvis, or a little diagonal; in this case, the head is commonly pretty well advanced in the bason, and the operator seldom miscarries in the use of the forceps. Things being thus situated, let the patient be laid on her back, her head and shoulders being somewhat raised, and the breech advanced a little over the side or foot of the bed; while the attendants fitting on each side support her legs, at the same time keeping her knees duly separated and raised up to the belly, and her lower parts always covered with the bed cloaths, that she may not be frightened, and the breech advanced a little over the side or foot of the bed; while the attendants fitting on each side support her legs, at the same time keeping her knees duly separated and raised up to the belly, and her lower parts always covered with the bed cloaths, that she may not be apt to catch cold. In order to avoid this inconvenience, if the bed is at a great distance from the fire, the weather cold and the woman of a delicate constitution, it is advisable to hide her face, and cover it with a low chair, and having lubricated with pomatum the blades of the forceps, and also his right hand and fingers, slide first the hand gently into the vagina, pushing it a long in a flattened form, between that and the child's head, until the fingers have passed the os internum; then, with his other hand, let him take one of the blades of the forceps from the place where it was deposited, and introduce it between his right hand and the head; if the point or extremity of it should flick at the ear, let it be flipp backward a little, and then guided forwards with a slow and delicate motion; when it shall have passed the os uteri, let it be advanced still farther up, until the rent at which the blades lock into each other be close to the lower part of the head, or at least within an inch thereof.

Having in this manner introduced one blade, let him withdraw his right hand, and intimate his left in the same direction, along the other side of the head, until his fingers shall have passed the os internum; then taking out the other blade from the place of concealment, with the hand that is difengaged, let it be applied to the other side of the child's head, by the same means employed in introducing the first; then the left hand must be withdrawn, and the head being embraced between the blades, let them be locked in each other. Having thus secured them, he must take a firm hold with both hands, and, when the pain comes on, begin to pull the head along from side to side, continuing this operation during every pain until the vertex appears through the os externum, and the neck of the child can be felt with the finger below the os pubis; at which time, the forehead pushes out the perineum like a large tumour: then let him stand up, and raising the handles of the forceps, pull the head upwards also, that the forehead being turned half round upwards, the perineum and lower parts of the os externum may not be tore.

In stretching the os externum or internum, we ought to imitate nature: for in practice we find, that when they are opened slowly, and at intervals, by the membranes with the waters, or the child's head, the parts are seldom inflamed or lacerated: but in all natural labours, when these parts are suddenly opened, and the child delivered by strong and violent pains, without much intermission, this misfortune sometimes happens, and the woman is afterwards in great pain and danger.

We ought therefore, when obliged to dilate those parts, to proceed in that slow, deliberate manner; and though upon the first trial, they feel so rigid, that one would imagine they could never yield or extend; yet, by stretching with the hand, and retting by intervals, we can frequently overcome the greatest resistance. We must also, in such cases, be very cautious, pulling slowly, with intermissions, in order to prevent the same laceration: for which purpose too, we ought to lubricate the perineum with pomatum, during those short intervals, and keep the palm of one hand close prefixed to it and the neighbouring parts, while with the other we pull at the extremity of the handles of the forceps; by which means, we preferre the parts, and know how much we may venture to pull at a time. When the head is almost delivered, the parts, thus stretched, must be flipp over the forehead and face of the child, while the operator pulls upwards with the other hand, turning the handles of the forceps to the abdomen of the woman.

This method of pulling upwards, raises the child's head from the perineum, and the half round turn to the abdomen of the mother brings out the forehead and face from below; for, when that part of the hind-head which is joined to the neck, rests at the under-part of the os pubis, the head turns upon it, as upon an axis. In preternatural cases also, the body being delivered, mul in the same manner be raised up over the belly of the mother, and at the same time the perineum flipp over the face and forehead of the child.

In the introduction of the forceps, let each blade be pushed up in an imaginary line from the os externum, to the middle space betwixt the navel and forobicular cordis of the woman; or, in other words, the handles of the forceps are to be held as far back as the perineum will allow. The introduction of the other hand to the opposite side, will, by pressing the child's head against the first blade, detain it in its proper place till the other can be applied; or, if this pressure should not seem sufficient, it may be supported by the operator's knee.

When the head is come low down, and cannot be brought farther, because one of the shoulders rests above the os pubis, and the other upon the upper-part of the sacrum, let the head be strongly grasped with the forceps, and pulled up as far as possible, moving from blade to blade as you pull up, that the shoulders may be the more easily moved to the sides of the pelvis, by turning the face or forehead a little towards one of them; then, the forehead must be brought back again into the hollow of the sacrum, and another effort made to deliver: but, should
should the difficulty remain, let the head be pushed up again, and turned to the other side; because it is uncertain which of the shoulders rests on the os pubis, or sacrum. Suppose, for example, the right shoulder of the child sticks above the os pubis, the forehead being in the hollow of the sacrum; in this case, if the forehead be turned to the right-hand side of the woman, the shoulder will not move; whereas, if it be turned to the left, and the head at the same time pushed a little upwards, so as to raise and disengage the parts that were fixed, the right shoulder being towards the right-hand side, and the other to the left side of the brim of the pelvis, when the forehead is turned back again into the hollow of the sacrum, the obstacle will be removed, and the head be more easily delivered. This being performed, let the forceps be unlocked, and the blades disposed cautiously under the cloaths so as not to be discovered; then proceed to the delivery of the child, which, when the navel-string is cut and tied, may be committed to the nurse. The next care is to wipe the blades of the forceps, singly, under the cloaths, slide them warily into your pockets, and deliver the placenta.

When the forehead is to the Os Pubis.

When the forehead, instead of being towards the sacrum, is turned forwards to the os pubis, the woman must be laid in the same position as in the former case; because here also, the ears of the child are towards the sides of the pelvis, or a little diagonally situated, provided the forehead is towards one of the groins. The blades of the forceps being introduced along the ears, or as near them as possible, according to the foregoing directions, the head must be pushed up a little, and the forehead turned to one side of the pelvis; thus let it be brought along, until the hindhead arrives at the lower part of the ilium; when the forehead must be turned backward, into the hollow of the sacrum, and even a quarter or more to the contrary side, in order to prevent the shoulders from hitching on the upper part of the os pubis, or sacrum, so that they may be still towards the sides of the pelvis; then let the quarter turn be reversed, and the forehead being replaced in the hollow of the sacrum, the head may be extracted as above. In performing these different turns, let the head be pushed up or pulled down occasionally, as it meets with least resistance. In this case, when the head is small, it will come along as it presents; but if large, the chin will be so much pressed against the breast, that it cannot be brought up with the half-round turn, and the woman will be tore if it comes along. See Plate CXII, where

**Fig. 3.** Shews the head of the fetus, by strong labour-pains, squeezed into a longish form, with a tumour on the vertex, from a long compression of the head in the pelvis.

L, The forceps.

M, The vesica urinaria much distended, with a large quantity of urine from the long pressure of the head against the urethra.

N, The under part of the uterus.

OO, The os uteri.

When the forehead and face of the child are turned to the side of the pelvis, (in which case it is higher than in the first situation,) it will be difficult, if the woman lies on her back, to introduce the forceps so as to grasp the head with a blade over each ear; because the head is often pressed so hard against the bones, in this position, that there is no room to separate the fingers between the ear and the os pubis. So as to introduce the blades safely, on the inside of the os internum, or push one of them up between the fingers and the child's head. When things are so situated, the belt posture for the woman is that of lying on one side, as formerly directed, because the bones will yield a little, and the forceps (of consequence) may be the more easily introduced.

Suppose her lying on her left side, and the forehead of the child turned to the same side of the pelvis; let the fingers of the operator's right hand be introduced along the ear, between the head and the os pubis, until they pass the os internum: if the head is immovably fixed in the pelvis, that there is no passage between them, let his left hand be pushed up between the sacrum and the child's head, which being raised as high as possible, above the brim of the pelvis, he will have room sufficient for his fingers and forceps; then let him slide up one of the blades, with the right hand, remembering to press the handle backwards to the perineum, that the point may humour the turn of the sacrum and child's head; this being effected, let him withdraw his left hand, with which he may hold the handle of the blade, already introduced, while he insinuates the fingers of his right hand at the os pubis, as before directed, and pushes up the other blade, slowly and gently, that he may run no risk of hurting the os internum or bladder; and here also keep the handle of it as far backwards as the perineum will allow: when the point has passed the os internum, let him slide it up farther, and join the legs by locking them together, keeping them still in a line with the middle space between the navel and scrobiculus cordis. Then let him pull along the head, moving it from side to side, or from one ear of the child to the other; when it is sufficiently advanced, let him move the forehead into the hollow of the sacrum, and a quarter-turn farther, then bring it back into the same cavity; but, if the head will not easily come along, let the woman be turned on her back after the forceps have been fixed, and the handles firmly tied with a garter or fillet; let the hindhead be pulled half round forwards, from below the os pubis, and the instrument and child managed as before.

When the head cannot be raised above the brim of the pelvis, or the fingers introduced within the os internum, to guide the points of the forceps along the ears, especially at the os pubis, ischium, or sacrum; let the fingers and hand be pushed up as far as they will go, along the open space between the sacrum and ischium; then one of the blades may be introduced, moved to, and fixed over the ear, the situation of which is already known: the other hand may be introduced, and the other blade conducted in the same manner, on the opposite side of the pelvis; but, before they...
they are locked together, care must be taken that they are exactly opposite to each other, and both sufficiently introduced. In this case, if the operator finds the upper part of the facrum jetting, in so much that the point of the forceps cannot pass it, let him try with his hand to turn the forehead a little backwards, so that one ear will be towards the groin, and the other towards the side of that prominence; consequently, there will be more room from the blades to pass along the ears: but if the forehead should remain immovable, or though moved return to its former place, let one blade be introduced behind one ear, and its fellow before the other, in which case the introduction is sometimes more easily performed when the woman lies on her back, than when she is laid on one side. See Plate CXII. fig. 2.

When the Face presents.

When the face presents, resting on the upper part of the pelvis, the head ought to be pushed up to the fundus uteri, the child turned and brought by the feet, because the hind head is turned back on the shoulders, and, unless very small, cannot be pulled along with the forceps; but should it advance pretty fast in the pelvis, it will be sometimes delivered alive, without any resistance. But, if it defends slowly, or, after it is low down, flicks for a considerable time, the long pressure on the brain frequently destroys the child, if not relieved in time, by turning or extracting with the forceps.

When the head is detained very high up, and no signs of its descending appear, and the operator having stretched the parts with a view to turn, discovers that the pelvis is narrow, and the head large, he must not proceed with turning, because after this hath been performed, perhaps with great difficulty, the head cannot be delivered without the assistance of the crotchet. No doubt it would be a great advantage in all cases where the face or forehead presents, if we could raise the head so as to alter the bad position, and move it so, with our hand, as to bring the crown of the head to present: and indeed this should always be tried, and more especially, when the pelvis is too narrow, or the head too large; and when we are dubious of saving the child by turning: but frequently this is impossible to be done, when the waters are evacuated, the uterus strongly contracted on the child, and the upper part of the head so slippery as to elude our hold; inomuch that, even when the pressure is not great, we seldom succeed, unless the head is small, and then we can save the child by turning. If you succeed, and the woman is strong, go on as in natural labour; but, if this fails, then it will be more advisable to wait with patience for the descent of the head, so as that it may be delivered with the forceps; and consequently the child may be saved; but, if it still remains in its high situation, and the woman is weak and exhausted, the forceps may be tried; and, should they fail, recourse must be had to the crotchet; because the mother’s life is always to be more regarded than the safety of the child.

When the face of the child is come down, and flicks at the os externum, the greatest part of the head is then squeezed down into the pelvis, and if not speedily delivered, the child is frequently lost by the violent contraction of the brain: besides, when it is so low down, it seldom can be returned, on account of the great contraction of the uterus. In this case, when the chin is turned towards the os pubis, at the lower part of that bone, the woman must be laid on her back, the forceps introduced, as formerly directed in the first case, and when the chin is brought out from under the os pubis, the head must be pulled half round upwards; by which means the fore and hind head will be raised from the perineum, and the under part of the os externum prevented from being tore.

If the chin points to either side of the pelvis, the woman must be laid on her side, the blades of the forceps introduced along the ears, one at the os pubis, and the other at the facrum; and the chin, when brought lower down, turned to the pubis, and delivered: for the pelvis being only two inches in depth at this place, the chin is easily brought from under it, and then the head is at liberty to be turned half round upwards; because the chin being disengaged from this bone, can be pulled up over it externally; by which means, two inches of room, at least, will be gained, for the more easy delivery of the fore and hind head, which are now pressed against the perineum. When the chin is towards the facrum, the hind head pressed back between the shoulders, so that the face is kept from rising up below the os pubis, the head must be pulled up with the hand, to the upper part of the pelvis, and the forceps introduced and fixed on the ears; the hindhead must be turned to one side of the pelvis, while the chin is moved to the other side, and, if possible, to the lower part of the ilium; then the hind head must be brought into the hollow of the facrum, with the chin below the os pubis, and delivered as above directed. If this cannot be done, let the operator try, with the forceps, to pull down the hind-head below the os pubis, and at the same time, with the fingers of the other hand, push the face and forehead backwards and upwards into the hollow of the facrum.

For when the chin points to the back part of the pelvis, the forehead is squeezed against the os pubis, while the hind-head is pressed upon the back, between the shoulders; so that the head cannot be delivered unless the occiput can be brought out from below the os pubis, as formerly described. See Plate CXII. fig. 4. and 5.

Fig. 4. shews, in the lateral view the face of the child presenting and forced down into the lower part of the pelvis, the chin being below the pubes, and the vertex in the concavity of the os facrum: The water being likewise all discharged, the uterus appears closely joined to the body of the child.

Fig. 5. shews, in a lateral view, the head of the child in the same position as in the former figure.

AB, The vertebrae of the loins, os facrum, and coccyx.
C, The os pubis of the left side.
D, The inferior part of the rectum.
E, The perineum.
F, The left labium pudendi.
GGG, The uterus.

The sum of all that has been said on this head, may be comprehended in the following general maxims.

Young practitioners are often at a loss to know and judge
judge by the touch in the vagina, when the head is far enough down in the back for using the forceps. If we were to take our observations from what we feel of the head at the os pubis, we should be frequently deceived; because in that place the pelvis is only two inches in depth, and the head will seem lower down than it really is; but if, in examining backwards, we find little or no part of it towards the sacrum, we may be certain that all the head is above the brim: if we find it down as far as the middle of the sacrum, one third of it is advanced; if as far down as the lower part, one half; and in this case, the largest part is equal with the brim. When it is in this situation, we may be almost certain of succeeding with the forceps; and when the head is so low as to protrude the external parts, they never fail. But these things will differ according to different circumstances, that may occasion a tedious delivery.

Let the operator acquire an accurate knowledge of the figure, shape, and dimensions of the pelvis, together with the shape, size, and position of the child’s head.

Let the breech of the woman be always brought forwards, a little over the bed, and her thighs pulled up to her belly, whether she lies on her side or back, to give room to apply, and to move the forceps up or down, or from side to side.

Let the parts be opened and the fingers pass the os internum; in order to which, if it cannot be otherwise accomplished, let the head be raised two or three inches, that the fingers may have more room; if the head can be raised above the brim, your hand is not confined by the bones; for, as we have already observed, the pelvis is wider from side to side, at the brim, than at the lower part; if the fingers are not past the os uteri, it is in danger of being included between the forceps and the child’s head.

The forceps, if possible, should pass along the ears, because, in that case, they seldom or never hurt or mark the head.

They ought to be pushed up in an imaginary line, towards the middle space between the navel and scrobiculus cordis, otherwise the ends will run against the sacrum.

The forehead ought always to be turned into the hollow of the sacrum, when it is not already in that situation. When the face presents, the chin must be turned to below the os pubis, and the hind-head into the hollow of the sacrum.

When the shoulders rest at the pubes, where they are detained, the head must be turned a large quarter to the opposite side, so as that they may lie towards the sides of the pelvis.

The head must always be brought out with an half round turn, over the outside of the os pubis, for the preservation of the perineum, which must at the same time be supported with the flat of the other hand, and slide gently backwards over the head.

When the head is so low as to protrude the parts, in form of a large tumour, and the vertex hath begun to dilate the os externum, but, instead of advancing, is long detained in that situation, from any of the forementioned causes of laborious cases, and the operator cannot exactly distinguish the position of the head, let him introduce a finger between the os pubis and the head, and he will frequently find the back part of the neck, or one ear, at the forehead, or towards the side of the pelvis: when the situation is known, he needs not stretch the os externum, and raise the head, as formerly directed; but he may introduce the forceps, and they being properly joined, and their handles tied, pull gently during every pain; or if the pains are gone, at the interval of four or five minutes, that the parts may be slowly dilated, as they are in the natural labour: but, when the situation cannot be known, the head ought to be raised. The same method may also be taken when the face presents, and is low in the pelvis, except when the chin is toward the back part: and in this case, the head ought to be raised likewise.

Almost all these directions are to be followed, except when the head is small, in which case it may be brought along by the force of pulling: but this only happens when the woman is reduced, and the labour-pains are not sufficient to deliver the child; for, the lower part of the uterus may be strongly contracted before the shoulders, and so close to the neck of the child, as to prevent its advancing, even when the head is so loose in the pelvis, that we can sometimes pull our fingers all round it: and this is oftentimes the occasion of preventing the head’s being delivered when low in the pelvis. The difficulty, when high up, is from the restraint at the brim; and when it passes that, the head is seldom retained in the lower part, unless the patient is weak. In this case, we need not wait, because we are commonly certain of relieving the woman immediately with the forceps, by which you prevent the danger that may happen both to the mother and child, by the head’s continuing to lodge there too long. This case should be a caution against breaking the membranes too soon, because the uterus may contract too forcibly and too long before the shoulders; when the head in this case is advanced one third or half way on the outside of the os externum, if the pains are strong, this last inconvenience is frequently remedied by introducing your two fingers into the rectum, as formerly directed: by these rules; delivery may (for the most part) be performed with ease and safety: nevertheless, the head is sometimes so squeezed and locked in the pelvis, and the hairy scalp so much swelled, that it is impracticable to raise up the head so as to come at the ears or os internum; or to distinguish the future of the skull, so as to know how the heads present. In this case, the forceps must be introduced at random, and the uncertainty of the position generally removed by remembering, that in those cases, where the head is squeezed down with great difficulty, the ears are for the most part towards the os pubis and sacrum; and that the forehead seldom turns into the hollow of the sacrum, before the occiput is come down to the lower part of the ischium; and then rises gradually towards the under part of the os pubis, and the perineum and anus are forced down before it, in form of a large tumour.

On such occasions, the woman being laid on her side, if one ear is to the sacrum and the other to the os pubis, the blades of the forceps are to be introduced; and if they meet with any resistance at the points, they must not be forcibly thrust up, lest they pass on the outside of the os uteri, and tear the vagina, which, together with the womb
womb, would be included in the instrument, and pulled along with the head; for this reason, if the blade does not easily pass, let it be withdrawn a little downwards, as before directed, and then pulled again, moving the point close to the head; if the ear obstructs its passage, let the point be brought a little outwards: and by these cautious efforts, it will at length pass without further resistance, and ought to be advanced a considerable way, in order to certify the operator that he is not on the outside of the os internum.

When the forceps are fixed, and the operator uncertain which way the forehead lies, let him pull slowly, and move the head with a quarter turn, first to one side and then to the other, until he shall have found the direction in which it comes most easily along.

If at any time we find the forceps begin to slip, we must reft, and pull them up again gently: but, if they are like to slip off at a side, un tie the handles, and move them so as to take a firmer hold, fix as before, and deliver. If we are obliged to hold with both hands, the parts may be supported by the firm application of an assistant's hand; for, without such cautious management, they will run a great risk of being lacerated; a misfortune which rarely happens, when the perinaeum is properly pressed back, and the head leisurely delivered. Sometimes, when the head is brought low down, you may take off the forceps, and help along with your fingers on each side of the coccyx, or in the rectum, as directed in the natural labour.

If the head is low down, the ears are commonly diagonal, or to the sides; and when the head is brought down one third, or one half, through the os externum, the operator can then certify himself, whether the forehead is turned to the coccyx or os pubis, by feeling with his finger for the back part of the neck or ear, between the os pubis and the head; and then move the head as above directed.

Let him try to alter with his hand every bad position of the head; and if it be detained high up in the pelvis, in consequence of the woman's weakness, the rigidity of the parts, the circumvolutions or shortness of the funis, or the contraction of the uterus over the shoulders of the child, the forceps will frequently succeed when the focus cannot be turned: but, if the head is large, or the pelvis narrow, the child is seldom saved either by turning or using the forceps, until the head shall be farther advanced. And here it will not be amiss to observe, that the blades of the forceps ought to be new covered with strips of washed leather after they have been used, especially in delivering a woman suspected of having an infectious disease.

The signs of a Dead Child.

When the head presents, and cannot be delivered by the labour-pains; when all the common methods have been used without success, the woman being exhausted, and all her efforts vain; and when the child cannot be delivered without such force as will endanger the life of the mother, because the head is too large or the pelvis too narrow; it then becomes absolutely necessary to open the head, and extract with the hand, forceps, or crotchet, Indeed this last method formerly was the common practice when the child could not be easily turned, and is still in use with those who do not know how to save the child by delivering with the forceps: for this reason, their chief care and study was to distinguish whether the focus was dead or alive; and as the signs were uncertain, the operation was often delayed until the woman was in the most imminent danger; or when it was performed sooner, the operator was frequently accused of rashness, on the supposition that the child might in time have been delivered alive by the labour-pains: perhaps he was sometimes conscious to himself of the justice of this imputation, although what he had done was with an upright intention.

The signs of a dead focus were, first, the child's ceasing to move and stir in the uterus. Secondly, The evacuation of meconium, though the breech is not pressed into the pelvis. Thirdly, No perceivable pulsation at the fontanelle and temporal arteries. Fourthly, A large swelling or tumour of the hairy scalp. Fifthly, An uncommon laxity of the bones of the cranium. Sixthly, The discharge of a fetid ichor from the vagina, the effluvia of which surround the woman and gave rise to the opinion that her breath conveyed a mortified smell. Seventhly, Want of motion in the tongue, when the face presents. Eighthly, No perceivable pulsation in the arteries of the funis umbilicalis, when it falls down below the head; nor at the wrist when the arm presents; and no motion of the fingers. Ninthly, The pale and livid countenance of the woman. Tenthly, A collapsing and flaccidity of the breast. Eleventhly, A coldness felt in the abdomen, and weight, from the child's falling like a heavy ball to the side on which the lies. Twelfthly, A separation of the hairy scalp on the slightest touch, and a distinct perception of the bare bones.

All or most of these signs are dubious and uncertain, except the last, which can only be observed after the focus hath been dead several days. One may also certainly pronounce the child's death, if no pulsation hath been felt in the navel string for the space of twenty or thirty minutes; but the same certainty is not to be acquired from the arm, unless the skin can be stripped off with ease.

When the Crotchett is to be used.

Midwifery is now so much improved, that the necessity of destroying the child does not occur so often as formerly: indeed it never should be done, except when it is impossible to turn, or to deliver with the forceps; and this is seldom the case but when the pelvis is too narrow, or the head too large to pass, and therefore rests above the brim: for this reason, it is not so necessary for the operator to puzzle himself about dubious signs; because in these two cases, there is no room for hesitation: for if the woman cannot possibly be delivered in any other way, and is in imminent danger of her life, the best practice is undoubtedly to have recourse to that method which alone can be used for her preservation, namely, to diminish the bulk of the head.

In this case, instead of destroying, you are really saving a life; for, if the operation be delayed, both mother and child are lost.
The method of using the Scissors, blunt Hook, and Crotchets.

When the head presents, and such is the case that the child can neither be delivered by turning, nor extracted with the forceps, and it is absolutely necessary to deliver the woman to save her life, this operation must then be performed in the following manner.

The operator must be provided with a pair of curved crotchets, made according to the improvements upon those proposed by Mefnard, together with a pair of scissors about nine inches long, with reeds near the middle of the blades, and the blunt hook.

Of the Woman's Posture.

The patient ought to be laid on her back or side in the same position directed in the use of the forceps; the operator must be seated on a low chair, and the instruments concealed and disposed in the same manner, and for the same reason mentioned in treating of the forceps. The parts of the woman have already, in all likelihood, been sufficiently dilated by his endeavours to turn or deliver with the forceps; or if no efforts of that kind have been used, because by the touch he had learned that no such endeavours would succeed, as in the case of a large hydrocephalus, when the bones of the cranium are often separated at a great distance from each other; or upon perceiving that the pelvis was extremely narrow: If, upon these considerations, he hath made no trials in which the parts were opened, let him gradually dilate the os externum and internum, as formerly directed.

The head is commonly kept down pretty firm, by the strong contraction of the uterus round the child; but should it yield to one side, let it be kept steady by the hand of an assistant, pressing upon the belly of the woman; let him introduce his hand, and press two fingers against one of the futures of the cranium; then take out his scissors from the place in which they were deposited, and guiding them by the hand and fingers till they reach the hairy scalp, push them gradually into it, until their progress is stopped by the reeds.

If the head slips aside, in such a manner, as that they cannot be pushed into the skull at the future, they will make their way through the solid bones, if they are moved in a semicircular turn, like the motion of boring, and this method continued till you find the point firmly fixed; for, if this is not observed, the points slide along the bones.

The scissors ought to be so sharp at the points, as to penetrate the interguments and bones when pushed with a moderate force; but not so keen as to cut the operator's fingers, or the vagina in introducing them.

The scissors being thus forced into the brain, as far as the reeds at the middle of the blades, let them be kept firm in that situation; and the hand that was in the vagina being withdrawn, the operator must take hold of the handles with each hand, and pull them a sufficient, that the blades may dilate and make a large opening in the skull; then they must be bent, turned, and again pulled aunder, so as to make the incision crucial; by which means the opening will be enlarged, and sufficient room made for the introduction of the fingers: let them be afterwards closed, and introduced even beyond the reeds; when they must again be opened, and turned half round from side to side, until the structure of the brain is effectively destroyed, that it can be evacuated with ease. This operation being performed, let the scissors be shut and withdrawn; but, if this instrument will not answer the last purpose, the business may be done by introducing the crotchets within the opening of the skull. The brain being thus destroyed, and the instrument withdrawn, let him introduce his right hand into the vagina, and two fingers into the opening which hath been made, that if any sharp splinters of the bones remain, they may be broken off and taken out; lest they should injure the woman's vagina, or the operator's own fingers.

If the case be an hydrocephalus, let him fix his fingers on the inside and his thumb on the outside of the opening, and endeavour to pull along the skull in time of a pain; but, if labour is weak, he must desire the woman to assist his endeavours by forcing down; and thus the child is frequently delivered; because, the water being evacuated, the head collapses of course.

But when the pelvis is narrow, the head requires much greater force to be brought along; unless the labour-pains are strong enough to press it down and diminish it, by squeezing out the cerebrum: in this case, let the operator withdraw his fingers from the opening, and, holding them along the head, press the os uteri; then, with his left hand, taking one of the crotchets from the place of its concealment, introduce it along his right hand, with the point towards the child's head, and fix it above the chin in the mouth, back part of the neck, or above the ears, or in any place where it will take firm hold; having fixed the instrument, let him withdraw his right hand, and with it take hold on the end or handle of the crotch; then introduce his left to seize the bones at the opening of the skull (as above directed) that the head may be kept steady, and pull along with both hands.

If the head is still detained by the uncommon narrowness of the pelvis, let him introduce his left hand along the opposite side, in order to guide the other crotch; which being also applied and locked or joined with its fellow, in the manner of the forceps, he must pull with sufficient force, moving from side to side, and as it advances, turn the fore head into the hollow of the sacrum, and extract as with the forceps, humouring the shape of the head and pelvis during the operation, which ought to be performed slowly, with great judgment and caution; and from hence it appears absolutely necessary to know how the head presents, in order to judge how the crotchets must be fixed, and the head brought along to the best advantage.

If, when the head is delivered in this manner, the body cannot be extracted, on account of its being much swelled, of a monstrous size, or (which is most commonly the case) the narrowness of the pelvis; let him descend from pulling, left the head should be separated from the body, and introducing one hand so as to reach with his fingers to the shoulder-blades or breast, conduct along it one of the crotchets, with the point towards the occiput, and fix it with a firm application; then withdrawing his hand, employ it in pulling the crotch, while the other
is exerted in the same manner upon the head and neck of the child; if the instrument begins to lose its hold, he must push it farther up, and fixing it again, repeat his efforts, applying it still higher and higher, until the body is extracted.

Of Preternatural Labours.

Preternatural labour happens, when, instead of the head, some other part of the body presents to the os uteri. Preternatural labours are more or less difficult according to the presentation of the child, and the contraction of the uterus round its body. The nearer the head and shoulders are the os internum or lower part of the uterus, the more difficult is the case; whereas, when the head is towards the fundus, and the feet or breech near the os internum, it is more easy to turn and deliver.

To begin with the easiest of these first, it may be proper to divide them into three classes. First, how to manage when the feet, breech, or lower parts present. Secondly, how to behave in violent floodings; and, when the child presents wrong before the membranes are broke, how to save the waters in the uterus, that the foetus may be the more easily turned: and what method to follow even after the membranes are broke, when all the waters are not evacuated. Thirdly, how to deliver when the uterus is strongly contracted; the child presenting either with the fore or back parts; and lying in a circular form, or with the shoulders, breech, neck, face, ear, or vertex, and lying in a longish form, with the feet and breech towards the fundus of the womb, which is contracted like a long sheath, close to the body of the foetus; and when the fore-parts of the child lie towards the side, fundus, fore or back part of the uterus.

The first class of Preternatural Labours. When the feet, breech, or lower parts of the foetus present, and the head, shoulders, and upper parts are towards the fundus.

These, for the most part, are accounted the easiest, even although the uterus should be strongly contracted round the body of the child, and all the waters discharged.

If the knees or feet of the child present to the os internum, which is not yet sufficiently dilated to allow them and the body to come farther down; or, if the woman is weak, wore out with long labour, or endangered by a flooding; let the operator introduce his hand into the vagina, push up and stretcher the os uteri, and bring along the feet; which being extracted, let him wrap a linen cloth round them, and pull until the breech appears on the outside of the os externum: if the face or fore-part of the foetus is already towards the back of the uterus, let him perfect in pulling in the same direction; but, if they are towards the os pubis, or to one side, they must be turned to the back-part of the uterus; and as the head does not move round equal with the body, he must make allowance for the difference in turning, by bringing the last one quarter farther than the place at which the head is to be placed; so that the face or forehead which was towards one of the groins will be forced to the side of the sacrum, where it joins with the ischium. This quarter turn of the body must be again undone, without affecting the position of the head; a cloth may be wrapped round the breech, for the convenience of holding it more firmly; then, placing a thumb along each side of the spine, and with his fingers grasping the belly, let him pull along the body from side to side, with more or less force, according to the resistance: when the child is delivered as far as the shoulders, let him slide his hand flattened (suppose the right, if the lies on her back) between its breast and the perineum, coccyx, and sacrum of the woman, and introduce the fore or middle finger (or both, if necessary) into the mouth of the foetus; by which means, the chin will be pulled to the breadth, and the forehead into the hollow of the sacrum. And this expedient will also raise upwards the hindhead, which rests at the os pubis.

When the forehead is come so low as to protrude the perineum, if the woman lies on her back, let the operator stand up, and pull the body and head of the child upwards, bringing the forehead with an half-round turn from the under part of the os externum, which will thus be defended from laceration. The application of the fingers in the child's mouth will contribute to bring the head out in this manner, prevent the os externum from hitherto on the chin, help along the head, and guard the neck from being overstrained; a misfortune which would infallibly happen, if the forehead should be detained at the upper part of the sacrum: nor is there any great force required to obviate this inconvenience, or the least danger of hurting the mouth, if the head is not larger for, if the head cannot be brought along with moderate force; and the operator is afraid of injuring or over-straining the lower jaw, let him push his fingers farther up, and press on each side of the nose, or on the inferior edges of the pockets of the eyes. If the legs are come out, and the breech pulled into the vagina, there is no occasion for pushing up to open, but only to pull along and manage as above directed; still remembering to raise the forehead flowly from the perineum, which may be pressed back with the fingers of his other hand.

In the case of a narrow pelvis, or large head, which cannot be brought along without the risk of over-straining the neck, let him slide up his fingers and hand into the vagina, and bring down one of the child's arms, at the same time pulling the body to the contrary side, by which means the shoulder will be brought lower down: let him run his fingers along the arm, until they reach the elbow; which must be pulled downwards with an half round turn to the other side, below the breast. This must not be done with a jerk, but flowly and cautiously, in order to prevent the dislocation, bending, or breaking of the child's arm.

Let him again guide his fingers into the child's mouth, and try if the head will come along: if this will not succeed, let the body be pulled to the other side, so as to bring down the other shoulder; then slide up his left hand, and, extracting the other arm, endeavour to deliver the head. If one finger of his right hand be fixed in the child's mouth, let the body rest on that arm; let him place the left hand above the shoulders, and put a finger on each side of the neck: if the forehead is towards one
fide at the upper part of the pelvis, let him pull it lower
down, and gradually turn it into the hollow of the fa-
crum; then stand up, and, in pulling, raise the body, so as to bring out the head in an half-round turn, as above
directed.

When the forehead is hindered from coming down in-
to the lower part of the facrum by an uncommon shape of
the head or pelvis, and we cannot extract it by bringing
it out with an half-round turn at the os pubis, we must
try to make this turn in the contrary direction; and in-
stead of introducing our fingers into the child’s mouth,
let the breadth of it rest on the palm of your left hand,
(the woman being on her back,) and placing the right on
its shoulders, with the fingers on each side of the neck,
press it downwards to the perineum. In consequence of
this pressure, the face and chin being within the perineum,
will move more upwards, and the head come out with an
half-round turn from below the os pubis: for this pur-
pose of motion is now where the fore-part of the neck presses
at the perineum; whereas, in the other method, the back
part of the neck is against the lower part of the os pubis,
on which the head turns.

If the forehead is not turned to one side, but flicks at
the upper part of the facrum, especifally when the pelvis
is narrow; let him endeavour, with his finger in the
mouth, to turn it to one side of the jetting in of the fa-
crum, because the pelvis is wider at the sides of the brim,
and bring it along as before.

If one of the child’s arms, instead of being placed a
long the sides of the head, is turned in between the face
and facrum, or between the hindhead and os pubis, the
same difficulty of extracting occurs as in a large head or
narrow pelvis; and this position frequently ensues, when
the fore-parts of the child’s body are turned from the os
pubis down to the facrum: if they are turned to the left
side of the woman, the left hand and arm are commonly
brought in before the face, and vice versa; but, in these
cases, the elbow is, for the most part, easily come at,
because it is low down in the vagina, and then there is a
necessity for bringing down one or both arms before the
head can be delivered: from whence we may conclude,
that those authors are sometimes in the wrong, who ex-
pressly forbid us to pull down the arms. Indeed, if the
pelvis is not narrow, nor the head very large, and the arms
lie along the sides of the head, there is seldom occasion
to pull them down; because, the pelvis is wider at the
sides, and the membranes and ligaments that fill up the
space between the facrum and ilia yield to the pres-
sure, and make room for the passage of the head: but
when they are squeezed between the head and the facrum,
ilia, or os pubis, and the head flicks in the pelvis, they
certainly ought to be brought down, or even when the
head comes along with difficulty. Neither is the al-
leged contraction of the os internum round the neck of
the child so frequent as hath been imagined; because,
for the most part, the contraction embraces the head and
not the neck: but, should the neck alone suffer, that in-
convenience may be removed by introducing the hand in-
to the vagina, and a finger or two into the child’s mouth,
or on each side of the nose: by which means also a suf-
ficient dilatation will be preferred in the os externum,
which frequently contracts on the neck, as soon as the
arms are brought out.

The diameter, from the face or forehead to the ver-
tex, being greater than that from the forehead to the
back part of the hindhead or neck, when the hindhead
rests at the os pubis, and the forehead at the upper part
of the facrum, the head can seldom be brought down,
except the operator, by introducing a finger into the mouth,
moves the same to the side, brings the chin to the breast,
and the forehead into the hollow of the facrum; by which
means, the hindhead is raised, and allowed to come along
with greater ease; and in pulling, half the force only is
applied to the neck, the other half being exerted upon the
head, by the finger which is fixed in the mouth; so that
the forehead is more easily brought out, by pulling up-
wards, with the half-round turn from the perineum.

When the operator, with his fingers in the child’s mouth,
cannot pull down the forehead into the hollow of the fa-
crum, let him pull the fore-finger of his left hand between
the neck and os pubis, in order to raise the hindhead up-
wards; which being done, the forehead will come down
with less difficulty, especially if he push up and pulls
down at the same time, or alternately.

If it be discovered by the touch, that the breech pre-
sents, that the membranes are not yet broke, the woman
in no danger, the os internum not yet sufficiently dilated,
and the labour-pains strong; the midwife ought to wait
until the membranes, with the waters, are pushed far-
ther down, as in the natural labour: for, as they come
down through the os uteri into the vagina, they stretch
open the parts contained in the pelvis; and the bulk within
the uterus being diminished, it contracts and comes in
contact with the body of the child; so that the breech is
pushed along by the mechanical force of the abdominal
muscles operating upon the womb.

The same consequence will follow even although the
membranes are broke; for the waters lubricate the parts
as they flow off; and the breech, if not too large, or the
pelvis narrow, is pushed down. In this case, when the
nates present equal and fair to the os uteri, so it is also
reasonable to conclude, that when the breech presents, it
lies in the same manner, but that the fore-parts of the
child are rather turned backwards to one side of the ver-
tex: of the loins: in this position, one hip will present,
and the other rest on the os pubis; but, when forced along
with pains, the last will be gradually moved more and
more to the groin of that side, and from hence slip down
at the side of the basin: the lower at the same time will
be forced to the other, and the hollow betwixt the thighs
will rest upon the jetting in of the os facrum, and come
down in that manner; the thighs on each side, and the
back and round part of the breech passing in below the
arch of the os pubis, which is the best position: but if the
back of the child is tilted backwards, then it will be for-
ced down in the contrary direction, and come along with
more difficulty, viz. the thighs to the os pubis, and back
to the facrum; when it is come down to the middle or
lower part of the pelvis, let the operator introduce the
fore-finger of each hand, along the outside, to the groins,
and, taking hold, pull gently along during a strong pain.

If the os externum is so contracted, that he cannot
take sufficient hold, let it be opened slowly, so as to al-
low his hands to be pushed up with ease; when he has
infiltrated a finger or two in each groin, let him place his
thumbs on the thighs, if they are towards the os pubis,
so as to obtain a firm hold; then pull along from side to
side, and, if the back of the child is to the os pubis, con-
tinue in that manner, until the body and head are
derived: the legs being commonly stretched up along
the belly and back, when the child is extracted as far as
the shoulders, they come out of themselves, or are easily
brought down; but, if the belly of the child is turned to
one side, or to the os pubis, in that case, when the breech
is delivered, he ought to turn the belly down to the fa-
crum, and the back to the os pubis; and that the face
may be also turned to the back of the mother, let him re-
member the quarter extraordinary, which must be again
reversed, and then he may pull along and deliver.

If the body cannot be turned until the thighs and legs
are brought down, either on account of the bulk, or be-
cause the hold on the breech is not sufficient, let him con-
tinue to pull along, until the hands appear on the outside
of the os externum; then seize one of the knees with his
finger and thumb, and extract that leg; and let the other
be brought down in the same manner. If he attempts to
pull out the legs, before the hands arrive at this place,
the thighs are always in danger of being bent or broke.

When the legs are delivered, let him wrap a cloth round
the breech of the child, and as the body was pulled down
almost as far as the breast, before the legs could be brought
out, it must be pulled up again to the navel, or above it;
because, without this precaution, the shoulders would be
so much engaged in the pelvis, that it would be imprac-
ticable to make the motions formerly directed, so as to
turn the face to the back of the mother: whereas, when
the body is pulled up, these turns can be effected with
greater ease, because the belly being in the pelvis, it
yields easier to the form of the basin. When the face
is turned properly down, let him proceed to deliver, as
above directed.

If the breech is detained above the pelvis, either by
its uncommon magnitude, or the narrowness of the basin;
or if one of the nates is pushed in, while the other recls
above the os pubis, facrum, or to either side; if the wo-
man is low and weak, the pains lingering and insufficient
to force the child along; or if (he is in danger from a vio-
let flooding: in any of these cases, let him (during e-
very pain) gradually open first the os externum, and then
the os internum, with his fingers and hand. Having thus
gained admission, let him push up the breech to the fore
or back part, or to one side of the uterus, that his hand
and arm may have room to slide along the fore-parts or
belly of the child, so as to feel the thighs, that will di-
rect him to the legs, which must be brought down with
his fingers, while, at the same time, he pushes up the
hams with his thumb, that in case the legs lie straight
up, they may be extracted with more ease by the flexion
of the knee, and run the legs risk of being bent, broke,
or oversize: for, if they are folded downward, they
are the more easily brought out.

If the breech be strongly pressed into the upper part of
the pelvis, let him also push it upwards and to one side,
that his hand and arm may have free passage; for the
higher the breech is raised out of his way, he will be at
more freedom to extract the legs.

If both legs cannot be easily brought down, he may
safely deliver with one, of which taking hold with a linen
cloth wrapped round it, let him slide his other hand into
the vagina, and a finger or two into the outside of
the groin which is bent: by these means, the hip will
come down the easier, and the leg, which is already ex-
tracted, will not be over-strained by involving the whole
force of pulling the body along.

If the legs lie towards the left side of the woman, who
is laid on her back, the right hand must be introduced
into the uterus; if they lie to her right side, the left
hand will better answer the purpose; and if they are to-
wards her back or belly, either hand may be indifferent-
ly used.

In all cases where the breech presents, the safest prac-
tice is always to pull up and bring down the legs, pro-
vided the os uteri is sufficiently dilated, and the waters
not wholly discharged. If the waters are evacuated, the
uterus strongly contracted around the child, the breech
low, so that it cannot be returned, or so small as to
come easily along, we ought then to deliver it accord-
gingly; but, if so large as neither to be pulled up or brought
along with the assistance of the fingers, let the operator
introduce the curved handle of the blunt crotchet into
one of the groins, his fingers into the other, and pull
evry cautiously, in order to prevent a fracture or dislo-
cation of the thigh bone, which might otherwise happen
from the use of this instrument, the blunt point of which
must be sufficiently past the groin. A fillet may also be
used for the same purpose.

In the foregoing cases the woman was supposed to be
laid on her back, her legs supported, and breech to the
bed-side; this being generally the best position for deli-
vering the body and head: indeed, when the child is
small, the may lie on her side, and the same methods be
used in delivering, provided the operator still remembers
that in this position the ilium and ischium of one side
are down, and the others up. Besides, when the breech
is pulled up, in order to bring down the legs, if they
lie forwards towards the fore part of the uterus, and the
belly is pendulous, he can reach them with the greatest
ease when lies on one side, or, if the resitance is
very great, turn her to her knees and elbows; but, when
the legs are delivered, if the child is large, or the pelvis
narrow, the ought to be turned upon her back, because
the body and head can be better and safer delivered by
pulling up and down; and in that posture she is also kept
more firm, and her thighs less in the operator's way, than
when she lies upon her side. See Plate CXIII. fig. 1. and 2.

The second class of Preternatural Labours.

When the membranes are broke, but the face, shoul-
der, or some other part of the child, being pushed into
the pelvis, locks up the os externum, so as that a small
quantity of the waters hath been discharged, the uterus
is kept from contracting strongly round the child, which
is therefore more easily turned than possibly can be when
they are all gone:

When
When, before the membranes are broke, the child is felt through them, preferring wrong, and at the same time the pains put them down so as to dilate the os internum more or less:

When the woman, at any time in the four last months, is seizes with a violent flooding that cannot be restrained, and unless speedily delivered must lose her life; if labour-pains cannot be brought on by stretching the parts, delivery must be forced; but, if she is in labour, and the membranes have been pulled down with the waters, they may be broke; by which means, the flooding is frequently diminished, and the child delivered by the labour-pains.

In these three different cases, if we can prevent the strong contraction of the uterus by keeping up the waters, we can also for the most part turn the child with great ease, even in the very worst positions.

In the first case, let the operator slowly introduce his hand into the vagina, and his fingers between that part of the child which is pushed down, and the os internum: if in so doing he perceives some of the waters coming along, he must run up his hand as quick as possible into the uterus, betwixt the inside of the membranes and the child's body; the lower part of his arm will then fill up the os externum like a plug, so that no more of the waters can pass; let him turn the child with its head and shoulders up to the fundus, the break down to the lower part of the uterus, and the fore-parts towards the mother's back; let the hand be pushed no farther up than the middle of the child's body, because, if it is advanced as high as the fundus, it must be withdrawn lower, before the child can be turned; and by these means the waters will be discharged, and the uterus of consequence contracted so as to render the turning more difficult.

In the second case, when the membranes are not broke, and we are certain that the child does not present fair; if the os internum is not sufficiently dilated, and the woman is in no danger, we may let the labour go on, until the parts are more stretched; lubricating and extending the os externum, by degrees, during every pain. Then introducing one hand into the vagina, we infinuate it in a flattened form, within the os internum, and push up between the membranes and the uterus, as far as the middle of the womb: having thus obtained admittance, we break the membranes by grasping and squeezing them with our fingers, slide our hand within them, without moving the arm lower down, then turn and deliver as formerly directed; but if, in any of these cases, you find the head is large or the pelvis narrow, bringing down the head into the natural position, and affist as directed in lingering or laborious cases.

If the woman (in the third case) is attacked with a violent flooding, occasioned by a separation of all or any part of the placenta from the uterus, during the last four months of pregnancy, and every method has in vain been tried to lessen and restrain the discharge, the operator ought to pronounce the case dangerous, and prudently declare to the relations of the patient, that unless she is speedily delivered, both she and the child must perish, observing at the same time, that by immediate delivery they may both be saved; let him also give the assistance and advice of some person eminent in the profession, for the satisfaction of her friends, and the support of his own reputation. Where there are no labour-pains, and the mouth of the womb is not dilated, it is sometimes very difficult to deliver, more especially if the os internum is not a little lax, but feels rigid.

If the os uteri is so much contracted, that the finger cannot be introduced, some authors have recommended a dilator, by which it may be gradually opened so as to admit a finger or two. Doubtless, some cases may happen, in which this may be necessary. If in stretching the os internum, labour-pains are brought on, let the operator slowly proceed and encourage them: when the mouth of the womb is opened, if the head presents and the pains are strong, by breaking the membranes the flooding will be diminished; but, if she floods to such a degree as to be in danger of her life, and the dilatation does not bring on labour, at least not enough for the occasion, she must be immediately delivered in the following manner: but in the first place let her friends be apprized of the danger, and the operator beware of promising to save either mother or child.

The operator having performed his duty in making the friends acquainted with the situation of the case, must gently open the os externum, by introducing his fingers gradually, turning them half round and pushing upward; then forming them, with the thumb, into the figure of a wedge or cone, continue to dilate slowly and by intervals, until his hand is admitted into the vagina: having thus far gained his point, let him introduce, in the same slow cautious manner, first one, then two fingers, into the os internum, which may be dilated so as to admit the other two and the thumb in the same conical form, which will gradually make way for sliding the hand along between the outside of the membranes and inside of the uterus; then he must manage as directed in the second case: if, upon sliding his hand upon the outside of the membranes, he feels the placenta adhering to that side of the womb, he must either withdraw that hand, and introduce the other on the opposite side, or break through the membranes at the lower edge of the placenta.

The greatest danger in this case frequently proceeds from the sudden emptying of the uterus and belly; for when labour comes on of itself, or is brought on in a regular manner, and the membranes are broke, the flooding is gradually diminished, and first the child, then the placenta, is delivered by the pains; so that the pressure or resistance is not all at once removed from the belly and uterus of the woman, which have time to contract by degrees; consequently, those fainting fits and convulsions are prevented which often proceed from a sudden removal of that compression under which the circulation was performed.

The younger the woman is with child, the greater is the difficulty in opening the os internum; and more so in the first child, especially if she is past the age of thirty-five.

We should never refuse to deliver in these dangerous cases, even although the patient seems expiring: for, immediately after delivery, the uterus contracts; the mouths of the vessels are shut up, so that the flooding ceases; and she may recover, if she lives five or six hours.
after the operation, and can be supported by frequent
draughts of broth, jelly, custard, weak cordial, and ano-
dye medicines, which maintain the circulation, and gra-
dually fill the empty vessels.

If, in time of flooding, the is seized with labour-pains,
or if, by every now and then stretching with your fingers
the os internum, you bring on labour, by which either
the membranes or head of the child is pulled down; and
opens the os internum, the membranes ought to be
broke; so that some of the waters discharging, the
uterus may contract and squeeze down the foetus. This
may be done sooner in those women who have had chil-
dren formerly. If, notwithstanding this expedient, the
flooding still continues, and the child is not like to be
soon delivered, it must be turned immediately; or, if the
head is in the pelvis, delivered with the forceps: but, if
neither of these two methods will succeed, on account of the
narrowness of the pelvis, or the bigness of the head, this
last must be opened and delivered with the crotchet. In
all these cases, let the parts be dilated slowly and by in-
tervals, in order to prevent laceration. See Plate CXI,
fig. 4. 5. 6.

The third class of Preternatural Labours.

We have already observed, that the principal difficulti-
ties in turning children and bringing them by the feet,
proceeded from the contraction of the uterus and bad
position of the foetus. If the child lies in a round form,
whether the fore-parts are towards the os internum, or
up to the fundus uteri, we can, for the most part, move
it with the hand, so as to turn the head and shoulders to
the upper part, and the breech and legs downwards; but
if the child lies lengthways, the womb being contracted
around it, like a long sheath, the task is more difficult;
especially, if the head and shoulders of the child are
down at the lowest part of the uterus, with the breech
and feet turned up to the fundus.

The hand of the operator being introduced into the ut-
terus, if he finds the breech below the head and shoul-
ders, let him search for the legs, and bring them down: but
if the breech be higher than the upper parts of the child,
or equal with them, he must try to turn the head and
shoulders to the fundus, and the breech downwards, by
pulling up the first, and pulling down the last; then pro-
ceed with delivery as before directed. This is commonly
executed with care, provided some part of the waters still
remain in the uterus; but, if the woman has been long
in labour, and the waters discharged, the contraction of the
womb is so strong, that the child cannot be turned
without the exertion of great force frequently repeated.
In this case, the easiest method both for the patient and
operator, is to pull up the hand gradually on that side to
which the legs and thighs are turned; and even after he
has reached them, if they are not very high up, let him
advance his hand as far as the fundus uteri; he will thus
remove the greatest obstacle, by enlarging the cavity of the
womb, so as more easily to feel and bring down the legs:
then he may pull up and pull down, as we have pre-
scribed above; but, if the head and shoulders still continue
to hinder the breech and body from coming along, and
the feet cannot be brought so low, as the outside of the
os externum, while they are yet in the vagina he may
apply a noose upon one or both; for unless the child is so
small that he can turn it round by grasping the body when
the head and shoulders are pushed up, and he endeavours
to bring down the other part, they will again return to the
same place, and retard delivery: whereas, if he gains a firm
hold of the feet, either without the os externum, or in the
vagina, by means of the noose fixed upon the ankles, he can
with the other hand pull up the head and shoulder, and be
able in that manner to bring down the breech. He must con-
tinue this method of pulling up and pulling down, until
the head and shoulder are raised to the fundus uteri; for
should he leave off too soon, and withdraw his hand, al-
though the child is extracted as far as the breech, the
head is sometimes so prefixed down and engaged with the
body in the passage, that it cannot be brought farther
down without being tore along with the crotchet; for the
breech and part of the body may block up the passage in
such a manner, as that the hand cannot be introduced to
raise the head.

Those cases are commonly the easiest in which the fore-
parts present, and the child lies in a round or oval form,
across the uterus, or diagonally, when the head or breech
is above and over the os pubis, with the legs, arms, and
navel-string, or one or all of them, at the upper or lower
part of the vagina, or on the outside of the os externum.
Those are more difficult in which, though the child lies
in the same round or contracted form, the back, shoul-
ders, belly, or breech, are over the os internum; because if
we cannot move the child round, so as to place the head
to the fundus, the legs are brought down with much more
difficulty than in the other cases: but if the shoulder,
breast, neck, ear, face, or crown of the head presents, and
the legs and breech are up to the fundus uteri, the case
is still more difficult; because, in the other two, the ut-
erus is contracted in a round form, so that the wrong
position of the child is more easily altered than in this,
when the womb is contracted in a long shape, and some-
times requires vast force to stretch it, so as that the head
may be raised to the fundus, and the legs and breech
brought down.

The crown of the head is the worst part that can pre-
cent, because in that case the feet and breech are higher,
and the uterus of a longer form than in any other. The
presentation of the face is, next to this, attended with the
greatest difficulty: but when the neck, shoulder, back, or
breech present, the head is turned upwards, and keeps the
lower part of the womb dilated: so that, upon stretch-
ing the upper part, the child's head is more easily raised
to the fundus.

When the fore-parts of the child present, if the feet,
hands, and navel-string are not detained above the os ut-
eri, some or all of them descend into the vagina, or ap-
ppear on the outside of the os externum. If one or more
of them come down, and the child at the same time lies
in a round form across the uterus, let the accoucheur in-
troduce his hand between them and the facrum. When it
is past the os internum, let it rest a little, while he feels
with his fingers the position of the focus: if the head
and shoulders lie higher than the breech, he must take
hold of the legs and bring them down without the os
internum:
internum: if the breech is detained above the brim of the pelvis, let him slide up the flat of his hand along the buttocks, and pull down the legs with the other hand, by which method the breech is disengaged and forced into the middle of the pelvis. See Plate CXIII. fig. 3.

In most of these cases where the child is pressed in an oval form, if neither the head or breech present, the head is to one side of the uterus, and the breech to the other; because it is wider from side to side, than from the back to the fore part; and if either the head or breech is over the os pubis, the other is turned off to the side: in moving the head or shoulders to the fundus, they are raised with greater ease along the side, than at the back or fore parts, for the same reasons.

If the head and shoulders lie lower down, so as to hinder the breech from coming along, and the legs from being extracted, let him pull up the head and shoulders to the fundus, and pull out the legs; then try to bring in the breech; and if it still sticks above, because the head and shoulders are again forced down by the contraction of the uterus, he must with one hand take hold of the legs that are now without the os externum, and, sliding the other into the uterus, pull the head and shoulders again up to the fundus, while, at the same time, he pulls the legs and breech along with the feet. If the legs cannot be brought farther down than the vagina, because the breech is high up, let him flip a noose over the feet round the ancles, as before observed; by which he may pull down the lower parts with one hand, while the other is employed in pushing up, as before. By this double purchase, the child may be turned even in the most difficult cases: but the operator, in pulling, must beware of overstraining the ligaments of the joints.

If the legs can be extracted through the os externum, let a single cloth, warmed, be wrapped round them, in order to yield a firmer hold to the accoucheur; but when they can be brought no lower than the neck of the uterus and vagina, he may use one of these following nooses.

Let him take a strong limber fillet, or soft garter half-worn, about one yard and a half in length, and moderately broad and thick; if thick, an eye may be made at one end of it, by doubling about two inches and sewing it strongly; and the other end passed through this doubling, in order to make the noose; which being mounted upon the thumb and fingers of his hand, must be introduced, and gently slipped over the toes and feet of the child so as to embrace the ancles, and thus applied it must be drawn tight with his other hand.

If the foot or feet should be too slippery, that his fingers cannot hold them, and work over the noose at the same time, it must be withdrawn and mounted round his hand or wrist; with which hand, when introduced, he may take firm hold on both feet, if they are as far down as the vagina; then with the fingers of his other hand, he can slide the noose along the hand and fingers that hold the feet, and fix it round the ancle: but if one foot remains within the uterus, the fingers of his other hand cannot pull up the noose far enough to slide it over the ancle; so that he must have recourse to a director, like that for polypules, mounted with the noose, which will pull it along the hand and fingers that hold the foot. The noose being thus slipped over the fingers upon the ancle, he must pull the extremity of the fillet which hath passed the eye at the upper end of the director, and after it is close drawn, bring down the instrument.

If the fillet or garter is too narrow or thin, let it be doubled in the middle, and the noose made by pulling the two ends through the doubling.

When the belly presents, and the head, shoulders, breech, thighs, and legs, are turned up over the back to the fundus uteri; when the back presents, and all these parts are upwards; when the side presents, with the head, shoulders, breech, thighs and legs turned to the side, back, or fore part of the uterus: in all these cases, when the child is pressed into a round, or (more properly) an oval figure, it may be, for the most part, moved round, with one hand introduced into the uterus, the head and shoulders pushed to the fundus, and the legs and breech to the os internum; which being effected, the legs are easily brought down. See Plate CXIII. fig. 4. But these cases are more or less difficult as the feet are farther up, or lower down, because the business is to bring them downwards.

When the breath, shoulders, neck, ear, or face presents to the os internum, the breech, thighs, and legs being towards the fundus, with the fore parts of the foetus turned either to the side, back, or fore-part of the woman's belly; and the whole lying in a longish form, the uterus being closely contracted around its body like a sheath; let the accoucheur introduce his hand into the vagina, and open the os internum by pulling up the fingers and hand flattened between the parts that present and the inside of the membranes; and rett his hand in that situation, until he can distinguish how the child lies, and form a right judgment how to turn and deliver; for, if these circumstances are not maturely considered, he will begin to work in a confused manner, fatigue himself and the patient, and find great difficulty in turning and extracting the child.

If the feet and legs of the foetus lie towards the back, sides, or fundus uteri, the woman ought to be laid on her back, with her breech raised and brought a little over the bed, as formerly observed; because, in that position he can more easily reach the feet than in any other.

If they lie towards the fore-part of the uterus, especially when the belly is pendulous, she ought to lie upon her side; because in the other posture, it is often difficult to turn the hand up to the fore-part of the womb; whereas, if she is laid on the left side, the right hand may be introduced at the upper part and left side of the brim of the pelvis, where it is widest, and then along the fore-part of the uterus, by which means the feet are more easily come at. If it is more convenient for the accoucheur to use his left hand, the patient may be turned on her right side. The only inconvenience attending these positions, is, that the woman cannot be kept so firm and steady, but will be apt to roll about and shrink from the operator: besides, there may be a necessity for turning her upon her back, after the body is delivered, before he can extract the head, especially if it be large, or the pelvis narrow.

The situation of the child being known, and the position of
of the uterus, and obtain a freer scope to bring them down to the lower part, and pass it up again on the outside of such incumbrance.

The hand being advanced as high as the fundus, let him, after some pause, feel for the breech, slide his fingers along the thighs in search of the legs and feet; of which taking hold with his whole hand, if possible, let him bring them down either in a straight line or with a half turn: or should the contraction of the uterus be so strong, that he cannot take hold of them in that manner, let him seize one or both ankles between his fingers, and pull them along; but if he cannot bring them down to the lower part of the uterus, fo as to apply the noose, he must try again to pull up the body, in order still more to stretch the uterus; for the presenting part cannot be raised up, or, though pulled upwards, immediately returns before the legs can be properly seized or brought down; the operator ought, in that case, to force up his hand slowly and gradually between the uterus and the child: if the resistance is great, let him ret a little, between whiles, in order to save the strength of his hand and arm, and then proceed with his efforts until he shall advance his hand as far as the feet; for the higher his hand is pulled, the more will the uterus be stretched, and the more room granted for bringing the legs along: and if, in pulling up his hand, the fingers should be entangled in the navel string or one of the arms, let him bring it a little lower, and pass it up again on the outside of such incumbrance. The hand being advanced as high as the fundus, let him, after some pause, feel for the breech, slide his fingers along the thighs in search of the legs and feet; of which taking hold with his whole hand, if possible, let him bring them down either in a straight line or with a half turn: or should the contraction of the uterus be so strong, that he cannot take hold of them in that manner, let him seize one or both ankles between his fingers, and pull them along; but if he cannot bring them down to the lower part of the uterus, fo as to apply the noose, he must try again to pull up the body, in order still more to stretch the uterus, and obtain a freer scope to bring them down to the lower part, and pass it up again on the outside of such incumbrance.

The hand being advanced as high as the fundus, let him, after some pause, feel for the breech, slide his fingers along the thighs in search of the legs and feet; of which taking hold with his whole hand, if possible, let him bring them down either in a straight line or with a half turn: or should the contraction of the uterus be so strong, that he cannot take hold of them in that manner, let him seize one or both ankles between his fingers, and pull them along; but if he cannot bring them down to the lower part of the uterus, fo as to apply the noose, he must try again to pull up the body, in order still more to stretch the uterus, and obtain a freer scope to bring them down to the lower part, and pass it up again on the outside of such incumbrance.

If one leg only can be brought down, the child being turned, and that member extracted through the os externum, let the accoucheur slide his hand up to fetch the other; but, if this cannot be done, he must fix a finger on the outside of the groin of that thigh which is folded along the belly, and bring along that buttock, as in the breech cafe, while he pulls with his other hand at the other leg; and the body being thus advanced, deliver as before directed.

When the shoulder presents, and the arm lies double in the vagina, let him pull them both up; but, if this cannot be done, and the hand is prevented from passing along, he must bring down the arm, and hold it with one hand, while the other hand is introduced; then let go and pull up the shoulder, and as the child is turned, and the feet brought down, the arm will for the most part return into the uterus: but, if the arm that is come down, be so much swelled, that it is impracticable to introduce the hand, fo as to turn and deliver the child, he must separate it at the joint of the shoulder, if it be so low down; or at the elbow, if he cannot reach the shoulder. If the limb be much mortified, it may be twisted off; otherwise, it may be snip and separated with the scissors.

If the shoulder, by the imprudence and ignorance of the unskilful, who pull, in expectation of delivering in that way, is forced into the vagina, and part of it appears on the outside of the os externum, a vast force is required to return it into the uterus; because, in this case, the shoulder, part of the ribs, breast, and side, are already pulled out of the uterus, which must be extended fo as not only to receive them again, but also to admit the hand and arm of the accoucheur. If this detention cannot possibly be effected, he must fix a crotchet above the sternum, and turn the child by pulling up the shoulder and pulling down with the crotchet; or slide his fingers to the neck of the child, and with the scissors divide the head from the body; then deliver first the separated head, or bring along the body by pulling at the arm, or, if need be, with the assistance of the crotchet.

When the forehead, face, or ear presents, and cannot be altered with the hand into the natural position; or is not advanced to the os externum, as that we can affist with the forceps; the head must be returned, and the child delivered by the feet: but if this cannot be done, and the woman is in imminent danger, recourse must be had to the crotchet.

If the navel-string comes down by the child's head, and the pulsation is felt in the arteries, there is a necessity for turning without loss of time; for unless the head advances fast, and the delivery is quick, the circulation in the vessels will be entirely obstructed, and the child consequently perish. If the head is low in the pelvis, the forceps may be successfully used.

No doubt, if the pelvis is very narrow, or the head too large, it would be wrong to turn: in that case, we ought to try if we can possibly raise the head, so as to reduce the funis above it, and after that let the labour go on: but, if the waters are all gone, and a large portion of the funis falls down, it is impossible to raise it, so as to keep it up, even although we could easily raise the head; because, as one part of the funis is pulled up with the fingers, another part falls down, and eradates the reduction; and to raise it up to the side, and not above the head, will be to no purpose; when a little only jets down at the side of the head, our endeavours will, for the most part, be useless.

The ancients, as well as some of the moderns, advise, in all cases when the upper parts, such as the shoulders, breast, neck, face, or ear of the child present, to pull them upwards, and bring in the head as in the natural way; observing, that the fetus ought never to be delivered by the feet, except in the presentation of the lower parts, such as the small of the back, belly, side, breech, or legs. Were it practicable at all times to bring the head into the right position, a great deal of fatigue would be saved to the operator, much pain to the woman, and imminent danger to the child: he therefore ought to attempt this method, and may succeed when he is called before the membranes are broke, and feels, by the touch, that the face, ear, or any of the upper parts, present; in that case, let him open the os externum slowly during every pain, and when the os internum is sufficiently dilated by the descent of the waters and membranes, let him introduce his hand into the uterus, as before directed, betwixt the womb and the membranes, which must be broke;
provided the thighs are strongly pressed against the funis by the feet. This we cannot promise after the head is brought in; and once the operator's hand is in the uterus, he ought not to run such risks. The child's head, which will, of consequence, come along with the parts that hindered the head from presenting are again forced down: besides, the head is so large and slippery, that he can obtain no firm hold. He might, indeed, by introducing a finger into the mouth, lay hold of the under jaw, and bring in the face, provided the child's head, upon the upper part of which the neck and shoulders, then pull along. The crotchets, if it be detained by the size of the belly, as to stop the circulation in the rope; as also when the child is detained by the head, after the body is delivered: in both cases, the danger must be obviated by an expeditious delivery; and if the body is delivered in the navel-string, it must be disengaged as well as possible, especially when the funis happens to be between the thighs. The legs and breech of the child being brought down, and the body properly turned with the fore-parts to the mother's back, let the accoucheur endeavour to bring it along; but, if it is detached by the fize of the belly, distended with air or water, (a case that frequently happens when the head has been dead for several days,) let the belly be opened, by forcing into it the points of his scissors; or, he may tear it open with the sharp crotchets.

The body of the child being delivered, the arms brought down, and every method hitherto directed unsuccessfully used for the extraction of the head, which is detained by being naturally too large, over ossified, or dropping, or from the narrowness and distorsion of the pelvis; if the belly was not opened, and the child is found to be alive by the motion of the heart, or pulsation of the arteries in the funis, the forceps ought to be tried; but, if he finds it impracticable to deliver the head, so as to save the life of the child, he must, according to some, force the points of the scissors through the lower part of the occipital bone, or through the foramen magnum; then dilate the blades, so as to enlarge the opening, and introduce a blunt or sharp hook. This operation rarely succeeds when the head is over-ossified; but may answer the purpose when the bones are soft and yielding; or in the case of an hydrocephalus: because, in the first, the aperture may sometimes be enlarged, and in the other the water will be evacuated so as to diminish the bulk of the head, which will, of consequence, come along with more ease.

If, notwithstanding these endeavours, the head cannot be extracted, let the operator introduce his hand along the head, and his fingers through the os uteri; then slide up one of the curved crotchets along the ear, between his hand and the child's head, upon the upper part of which it must be fixed; this being done, let him withdraw his hand, take hold of the instrument with one hand, turning the curve of it over the forehead, and with the other grasp the neck and shoulders, then pull along. The crotchets being thus fixed on the upper part, where the bones are thin and yielding, makes a large opening, through which the contents of the skull are emptied, the head collapsing is more certain extracted, and the instrument hath a firm hold to the last, at the forehead, os petrosum, and basin of the skull.

The excellency of Mesnard's contrivance is more conspicuous here than when the head presents; because the curvature of the crotchet allows the point to be fixed on the upper part of the skull, which is to be tore open; and in pulling, the contents are evacuated, and the head is leftened: by these means, the principal obstruction is removed. See Plate CXIII. fig. 8.

a, Reprefents a pair of curved crotchets locked together in the same manner as the forceps. The dotted lines along the inside of one of the blades represent a sheath contrived to guard the point till it is intro-

b, The child is often in danger, and sometimes lost, when the breech presents, and is low down in the pelvis, provided the thighs are strongly pressed against the funis
... practitioner, who not knowing how to turn the fore parts the fetus, destroys the structure of the brain, and ex-
man's belly with both hands, in order to keep the uterus
lock and join them together, and pull along, moving and
body is much mortified, even though he hath used all the
when the child hath been dead for many days, and the
hind. This may also happen to an expert accoucheur,
position, pull at random with all their strength; so that
or how to bring it along, although it presented in that
pelvis: let him direct an assistant to press upon the wo-
... of the head; then withdrawing the hand which was in-
the pelvis, and introducing two fingers into the mouth,
needed or size of the head, or the nar-
extraordinarily obstinate, or size of the head, or the nar-
less and distortion of the pelvis, after having used the
without success, he must separate the body from the
head with a bifurcated or pair of scissors; then pulling
up the head into the uterine, turn the face to the fundus,
and the vertex down to the os internum and brim of the
pelvis: let him direct an assistant to press upon the woman's belly with both hands, in order to keep the uterus
and head firm in that position; then open the skull with
wielding the scissors, destroy the structure of the brain, and ex-
tract with the crotchets.

The head is sometimes left in the uterus by those practitioners, who not knowing how to turn the fore parts
and face of the child towards the back part of the uterus,
or how to bring it along, although it preferred in that
position, pull at random with all their strength; so that
the neck is stretched and separated, and the head left behind. This may also happen to an expert accoucheur,
when the child hath been dead for many days, and the
body is much mortified, even though he hath used all the necessary precautions.

In such a case, provided the head is not very large,
or the pelvis narrow, and the forehead is towards the
facrum, let him slide up his hand along the back part
of the pelvis, and introducing two fingers into the mouth,
with the thumb below the chin, try to pull the head into the
hollow of the facrum: if it sticks at the setting-in of that bone, he must endeavour to move it, first to one
side, and then to the other. If the head is small, it will
come along; if any fragment of the neck remains, or any
part of the loose skin, he may lay hold on it, and assist
delivery, by pulling at it with his other hand; if the head
is low down, it may be extracted with the forceps.

Should all these methods fail, let him pull up his hand
along the side of the head, until it shall have passed the
os internum; with the other hand, let him introduce one
of the curved crotchets, and fix it upon the upper part
of the head; then withdrawing the hand which was intro-
duced, take hold on the instrument, and sliding the
fingers of the other hand into the mouth, he must pull
down with both, as above directed. If the head is not
over-offixed, the crotchets will tear open the skull; and
the bulk being of consequence diminished, the whole may
be brought along, even in a narrow pelvis: but if it can-
ot be moved, even by this expedient, he must introduce
the other crotchets along the other side of the head, and
fixing it upon the skull, lock them together; then in
pulling, turn the fore-head down into the hollow of the
facrum, and extract with an half round turn upwards, as
when delivering with the forceps.

If the forehead is towards the os pubis, and cannot be
brought into the right position, let him with his hand
push up the head into the uterus, turn the forehead from
the anterior to the side or back part of it, and try to ex-
tract as before. If the child hath been dead some time,
and is much mortified, he must pull cautiously at the un-
der jaw, because, should that give way, he will have no
other hold for pulling, or keeping the head steady when
he attempts to extract with one crotchets.

When the head is so large, or the pelvis so narrow,
that none of these methods will succeed, let him push up,
and turning the upper parts downwards, direct an assistant
to press the patient's belly with both hands, moving them
from side to side, and squeezing in such a direction as
will force the head towards the os internum, and retain
it firmly in that position; then it must be opened and ex-
tracted.

Although, by these means, you may succeed in a few
cases of this kind, yet as great difficulties may occur from
inflammations of the pudenda, contraction of the uterus,
flipperness or largeness of the head, and the narrowness
of the pelvis, it will not be improper to inform the reader
of other methods that appear to be useful. Let the
hand be introduced into the vagina, and if it cannot be
admitted within the uterus, the fingers being infinuated,
may move the head so as to raise the face and chin to the
fundus, the vertex being turned to the os internum, and
the forehead towards the side of the facrum. This being
effected, let the operator slide up along one ear a blade
of the long forceps, which are curved to the side; then
change hands, and fend up the other blade along the op-
opposite ear: when they are locked, and the handles secu-
red by a fillet, he must pull the head so low as it will
come; then putting them into the hands of an assistant,
who will keep them in that position, let him make a
large opening with the scissors, squeeze the head with
great force, and extract slowly and by degrees.

Having turned down the vertex, as above directed, let
Leveret's tire tête, with the three sides joined together,
be introduced along the accoucheur's hand to the upper
part of the head; then let the sides or blades be opened
with the other hand, so as to incline the head, moving
them circularly and lengthwise in a light and easy man-
ner, that they may pass over the inequalities of the scalp,
and avoid the refistance of the head and uterus: when
they are exactly placed at equal distances from one an-
other, let him join the handles, withdraw his hand, and
ty them together with a fillet, pull down, open, and
extract, as above directed; and let it be remembered,
that the farther the hand can be introduced into the uter-
us, the more easily will both instruments be managed.

When
When the pelvis is large, or the head small, (in which cases this misfortune seldom happens,) without doubt we might succeed with Mauriceau's broad fillet or sling, provided it could be properly applied.

When the head is small, or the pelvis large, dilating the foremen magnum with the scissors; and introducing the blunt hook, may be of use either to pull the head along, or keep it down until we can fix the forceps, curve crotchet, or Leveret's tire-tête.

Of Twins.

Twin's are supposed to be the effect of a double conception in one cirition, when two or more ova are impregnated with as many animalcula; which descending from the ovarium, through the Fallopian tube, into the fundus uteri, as they increase, come in contact with that part, and with one another, and are so prefixed as to form one globular figure, and stretch the womb into the same form which it assumes when distended by one ovum only; and that during the whole term of uterine gestation, it is impossible to distinguish twins, either by the figure and magnitude of the uterus, or by the motion of the different fetuses; for one child, when it is large, and surrounded with a great quantity of waters, will sometimes produce as large a prominence (or even larger) in the woman's belly, than is commonly observed when she is big with twins. One child will also, by moving its legs, arms, and other parts of its body, against different parts of the uterus, at the same instant, or by intervals, yield the same sensation to the mother, as may be observed in two or more children; for part of the motion in twins is employed on each other, as well as upon the uterus.

There is therefore no certain method of distinguishing in these cases, until the first child is delivered, and the accoucheur has examined if the placenta is coming along. If this comes of itself, and after its extraction the mouth of the womb be felt contracted, and the operator is unwilling to give unnecessary pain by introducing his hand into the uterus; let him lay his hand upon the woman's abdomen, and if nothing is left in the womb, he will generally feel it just above the os pubis, contracted into a firm round ball of the size of a child's head, or less: whereas, if there is another child left, the fize will be found much larger. If the placenta does not come down before the second child, which is frequently the case, upon examining, he will commonly feel the membranes with the waters pushed down through the os uteri; or, if they are broke, the head or some part of the body will be felt. If, therefore, the woman has strong pains, and is in no danger from flooding or weakness, provided the head presents fair, and seems to come along, she will be delivered of this also in the natural way.

If the membranes are not broke, if the head does not immediately follow, or if the child presents wrong, he ought to turn and bring it immediately by the feet; in order to save the patient the fatigue of a second labour, that may prove tedious, and even dangerous, by enfeeling her too much. Besides, as the parts are fully opened by the first delivery, he can introduce his hand with ease; and as the membranes are, for the most part, whole, the waters may be kept up, and the fetus easily turned; but, if the pelvis is narrow, the woman strong, and the head presents, he ought to leave it to the efforts of nature.

If the child presents wrong, and, in turning that, he finds another, he must beware of breaking the membranes of one, while he is at work upon the other: but, should they chance to be broke, and the legs of both entangled together, (though this is seldom the case, because they are commonly divided by two sets of membranes,) let the operator, when he has got hold on two legs, run up his fingers to the breech, and feel if they belong to the same body: and one child being delivered, let the other be turned and brought out in the same manner. If there are more than two, the same method must take place, in extracting one after another.

In case of twins, the placenta of the first child is delivered; but, as this does not always happen, he ought, as formerly directed, to certify himself that there is nothing left in the uterus, when the cake comes of itself. Both children being delivered, let him extract both placentas, if they come not of themselves; and if they form distinct cakes, separate first one, then the other; but if they are joined together, forming but one mass, they may be delivered at once.

When there are three or four children, (a case that rarely happens,) the placentas are sometimes distinct, and sometimes all together form but one round cake; but, when this is macerated in water for some days, they, with their several membranes, may be easily separated from one another; for they only adhere in consequence of their long pressure in the uterus, and seldom have any communication of vessels.

Twins for the most part lie diagonally in the uterus, one below the other; so that they seldom obstruct one another at the os internum. See Plate CXL. fig. 5.

Of Monsters.

Two children joined together by their bellies, (which is the most common cafe of monstrous births,) or by the sides, or when the belly of one adheres to the back of the other, having commonly but one funis, are comprehended in this class, and supposed to be the effect of two animalcula impregnating the same ovum, in which they grow together, and are nourished by one navel-string, originally belonging to the funis; because, the vessels pertaining to the coats of the vein and arteries, do not anastomose with the vessels belonging to the funus.

In such a case, where the children were small, the adhesion hath been known to stretch in pulling at the feet of one, so as to be delivered; and the other hath been afterwards brought along, in the same manner, without the necessity of a separation.

When the accoucheur is called to a case of this kind, if the children are large, and the woman come to her full time, let him first attempt to deliver them by that method; but if, after the legs and part of the body of the first are brought down, the reef will not follow, let him slip up his hand, and with his fingers examine the adhesion; then introducing the scissors between his hand and the body of the fetus, endeavour to separate them by snipping.
snipping through the juncture. Should this attempt fail, he must diminish the bulk in the best manner he can think of, and bring the body of the first, in different pieces, by pulling or cutting them asunder, as he extracts with the help of the crotchet.

No certain rules can be laid down in these cases, which seldom happen; and therefore a great deal must be left to the judgment and sagacity of the operator, who must regulate his conduct according to the circumstances of the case, and according to the directions given for delivering, when the pelvis is narrow and the children extraordinary large.

Of the CEASARIAN OPERATION.

When a woman cannot be delivered by any of the means hitherto described and recommended in laborious and preternatural labours, on account of the narrowness or distortion of the pelvis, into which it is sometimes impossible to introduce the hand; or from large excrescences and glandular swellings, that fill up the vagina, and cannot be removed; or from large cicatrices and adhesions in that part, and at the os uteri, which cannot be separated; in such emergencies, if the woman is strong, and of a good habit of body, the Cæsarian operation is certainly advisable, and ought to be performed; because the mother and child have no other chance to be saved, and it is better to have recourse to an operation which hath sometimes succeeded, than leave them both to inevitable death. Nevertheless, if the woman is weak, exhausted with fruitless labour, violent floodings, or any other evacuation, which renders her recovery doubtful, even if she were delivered in the natural way: in these circumstances it would be rashness and presumption to attempt an operation of this kind, which ought to be delayed until the woman expires, and then immediately performed, with a view to save the child.

The operation hath been performed both in this and the last century, and sometimes with such success, that the mother has recovered, and the child survived. The previous steps to be taken, are to strengthen the patient, if weak, with nourishing broths and cordials; to evacuate the indurated faces with repeated glycyfers; and, if the bladder is distended with urine, to draw it off with a catheter. These precautions being taken, she must be laid on her back, on a couch or bed, her side on which the incision is to be made being raised up by pillows placed below the opposite side: the operation may be performed on either side, though the left is commonly preferred to the right; because, in this last, the liver extends lower. The apparatus consists of a bistoury, probe-scissors, large needles threaded, sponges, warm water, pledgets, a large tent or doffil, compresses, and a bandage for the belly.

If the weather is cold, the patient must be kept warm, and no part of the belly uncovered, except that on which the incision is to be made: if the operator be a young practitioner, the place may be marked by drawing a line along the middle space between the navel and the os ilium, about six or seven inches in length, slanting forwards towards the left groin, and beginning as high as the navel.

According to this direction, let him hold the skin of the abdomen tense between the finger and thumb of one hand, and, with the bistoury in the other, make a longitudinal incision through the cutis, to the membranes adnalis, which, with the muscles, must be slowly dissected and separated, until he reaches the peritonæum, which must be divided very cautiously, for fear of wounding the intestines that frequently flap out at the sides, especially if the membranes are broke, the waters discharged, and the uterus contracted.

The peritonæum being laid bare, it may either be pinched up by the fingers, or slowly dissected with the bistoury, until an opening is made sufficient to admit the fore-finger, which must be introduced as a director for the bistoury or scissors in making an effectual dilatation. If the intestines push out, let them be pressed downwards, so as that the uterus may come in contact with the opening. If the womb is still distended with the waters, and at some distance from the child, the operator may make upon it a longitudinal incision at once; but if it is contracted close round the body of the fetus, he must pinch it up, and dilate in the same cautious manner practiced upon the peritonæum, taking care to avoid wounding the Fallopian tubes, ligaments, and bladder: then introducing his hand, he may take out the child and secundines.

If the woman is strong, the uterus immediately contracts, so as that the opening, which at first extended to about six or seven inches, is reduced to two, or less; and in consequence of this contraction, the vessels being shrunk up, a great effusion of blood is prevented.

The coagulated blood being removed, and what is still fluid spunged up, the incision in the abdomen must be stitched with the interrupted stitch, and sufficient room left between the last stitch and the lower end of the opening, for the discharge of the moisture and extravasated fluid. The wound may be dressed with dry pledgets or doffils dipped in some liquid balsam warmed, covered with compresses moistened with wine, and a bandage to keep on the dressings and axle the belly. Some authors observe, that the cuts and muscles only should be taken up in the future, left bad symptoms should arise from stitching the peritonæum.

The woman must be kept in bed, as quiet as possible, and every thing administered to promote the lochial, perspiration, and sleep: which will prevent a fever and other dangerous symptoms. If she hath lost a great quantity of blood from the wounds in the uterus and abdomen, so as to be in danger from inanition, broths, caudles, and wine, ought to be given in small quantities, and frequently repeated; and the Peruvian bark administered in powder, decoction, or extract, may be of great service in this case.

Of the management of women from the time of their delivery to the end of the month, with the several diseases to which they are subject during that period.

Of the EXTERNAL APPLICATION.

The woman being delivered of the child and placenta, let a soft linen cloth, warmed, be applied to the external parts; and if she complains much of a smarting fores, some pomatum may be spread upon it. The linen that
that was laid below her, to sponge up the discharges, must be removed, and replaced with others that are clean, dry, and warm. Let her lie on her back, with her legs extended close to each other; or upon her side, if she thinks she can lie easier in that position, until the recoveries from the fatigue: if she is spent and exhausted, let her take a little warm wine or caudle, or, according to the common custom, some nutmeg and sugar grated together dry, and a warm. Let her lie on her back, with her legs replaced with others that are clean, and not be removed; and replaced with others that are clean, press the vifeera and the relaxed parietes of the abdomen, pinned moderately tight over the cloth, in order to compress the vifeera and the relaxed parietes of the abdomen, or those applied in their room; and, if there be a large discharge from the uterus, let the wet linen below her be also shifted, that she may not run the risque of catching cold.

When the patient is either weak or faint, she ought not to be taken out of bed, or even raised up to have her head and body thitred, until she is a little recruited; otherwise it will be in danger of repeated faintings, attended with convulsions, which sometimes end in death.

To prevent these bad consequences, her skirt and petticoats ought to be loosed and pulled down over the legs, and replaced by another well warmed, with a broad headband to be flit in below, and brought upon her thighs and hips: a warm double cloth must be laid on the belly, which is to be surrounded by the head band of the skirt pinned moderately tight over the cloth, in order to compress the vifeera and the relaxed parietes of the abdomen, or more or less, as the woman can easily bear it; by which means the uterus is kept firm in the lower part of the abdomen, and prevented from rolling from side to side when the patient is turned: but the principal end of this compression, is to hinder too great a quantity of blood from rushing into the relaxed vessels of the abdominal contents; especially when the uterus is emptied all at once, in a quick delivery. The pressure being thus suddenly removed, the head is all at once robbed of its proportion of blood, and the immediate revolution precipitates the patient into dangerous lyphothymia.

Retention and Excretion, and the Passions of the Mind.

Although we cannot remove the patient immediately after delivery into another climate, we can qualify the air, so as to keep it in a moderate and salutary temper, by rendering it warm or cold, moist or dry, according to the circumstances of the occasion. With regard to dry, women in time of labour, and even till the ninth day after delivery, ought to eat little solid food, and none at all during the first five or seven: let them drink plentifully of warm diluting fluids, such as barley water, gruel, chicken water, and tea; caudles are also commonly used, composed of water gruel boiled up with mace and cinnamon, to which, when strained, is added a third or fourth part of white wine, or else, if the patient drinks plentifully, sweetened with sugar to their taste: this composition is termed white caudle; whereas, if ale is used instead of wine, it goes under the name of brown caudle. In some countries, eggs are added to both kinds; but, in that case, the woman is not permitted to eat meat or broths till after the fifth or seventh day: in this country, however, as eggs are no part of the ingredients, the patient is indulged with weak broth sooner, and sometimes allowed to eat a little boiled chicken. But all these different preparations are to be prescribed weaker or stronger, with regard to the spices, wine, or ale, according to the different constitutions and situations of different patients: for example, if she is low and weak, in consequence of an extraordinary discharge of any kind, either before or after delivery, or if the weather is cold, the caudles and broths may be made the stronger; but, if she is of a full habit of body, and has the least tendency to a fever, or if the season is excessively hot, these drinks ought to be of a very weak confidence, or the patient restricted to gruel, tea, barley and chicken water, and these varied according to the emergency of the case.

Her food must be light and easy of digestion, such as panada, biscuit, and fago; about the fifth or seventh day she may eat a little boiled chicken, or the lightest kind of young meat: but, these last may be given sooner or later, according to the circumstances of the case, and the appetite of the patient. In the regimen as to eating and drinking, we should rather err on the abstemious side, than indulge the woman with meat and strong fermented liquors, even if these last should be most agreeable to her palate: for we find by experience, that they are apt to increase or bring on fevers, and that the most nourishing and salutary diet is that which we have above prescribed.

Every thing that is difficult of digestion, or quickens the circulating fluids, must of necessity promote a fever; by which, the necessary discharges are obstructed, and the patient’s life endangered.

As to the article of sleeping and watching, the patient must be kept as free from noise as possible, by covering the doors and stairs with carpets and cloths, oiling the hinges of the doors, silencing the bells, tying up the knockers, and in noisy streets throwing the pavement with straw; if, notwithstanding these precautions, she is disturbed, her ears must be stuffed with cotton, and opiates administered to procure sleep: because watching makes her restless, prevents perspiration, and promotes a fever.

Motion and rest are another part of the nonnaturals to which we ought to pay particular regard. By toiling about, getting out of bed, or sitting up too long, the perspiration is discouraged and interrupted; and in this last
at a fever: for the prevention of these bad symptoms, the
patient must be kept quiet in bed till the fourth or
fifth day, and then be gently lifted up in the bed-clothes,
in a lying posture, until the bed can be adjusted, into which
she must be immediately re-conveyed, there to continue
for the most part, till the ninth day, after which period
women are not to be subject to fevers, as immediately after
delivery. Some there are, who, from the nature of their
complaints, or other accidents, recover more slowly;
and such are to be treated with the same caution after,
as before, the ninth day, as the case seems to indicate:
others get up, walk about, and recover, in a much shorter
time; but these may some time or other pay dearly for
their foolhardiness, by encouraging dangerous fevers: so
that we ought rather to err on the safe side, than run
any risk whatsoever.

What next comes under consideration, is the circum-
stance of retention and excretion. We have formerly ob-
served, that in time of labour, before the head of the
child is locked into the pelvis, if the woman has not had
easy passage in her belly that same day, the rectum and
colon ought to be emptied by a glyster, which will affist
the labour, prevent the disagreeable excretion of the fec-
uses before the child's head, and enable the patient to re-
maintain two or three days after, without the necessity of
going to stool. However, should this precaution be ne-
lected, and the patient very coltive after delivery, we
must beware of throwing up stimulating glysters, or ad-
ministering strong cathartic, lest they should bring on too
many loose stools, which, if they cannot be stopped, som-
times produce fatal consequences, by obstructing the per-
spiration and lochia, and exhausting the woman, so as
that she will die of a sudden catastrophe, which hath
frequently happened from this practice. Wherefore, if
it be necessary to empty the intestines, we ought to pre-
scribe nothing but emollient glysters, or some very gentle
poultice, such as mustard or Elest. Levitatum. But no
excretion is of more consequence to the patient's recov-
ery, than a free perspiration; which is so absolutely ne-
cessary, that unless she has a moisture continually on the
surface of her body, for some days after the birth, the
fekion recovers to advantage; her health, therefore, in a
great measure depends upon her enjoying undisturbed
refpite, and a constant breathing sweat, which prevents a
fever, by carrying off the fection, and affists the equal
diffcharge of the lochia: and when these are obstructed,
and a fever ensues with pain and restlessness, nothing re-
lieves the patient so effectually as rest and profuse sweat-
ing, procured by opiates and sudorifics at the beginning
of the complaints; yet these last must be more cautious-
ly prescribed in excessive hot than in cool weather.

The last of the nonnaturals to be considered are the
sensations of the mind, which also require particular atten-
tion. The patient's imagination must not be disturbed by
the news of any extraordinary accident which may have
happened to her family or friends: for such information
hath been known to carry off the labour-pains entirely,
after they were begun, and the woman has sunk under her
dejection of spirits: and even after delivery, these un-
seasonable communications have produced such anxiety as
produce all the necessary excretions, and brought on a
violent fever and convulsions, that ended in death.

Of violent Floodings.

All women, when the placenta separates, and after
it is delivered, lose more or less red blood, from the
quantities of half a pound, to that of one pound, or even
two; but should it exceed this proportion, and continue
to flow without diminution, the patient is in great danger
of her life: this hazardous hemorrhage is known by the
violence of the discharge, wetting fresh cloths as fast as
they can be applied; from the pulse becoming low and
weak, and the countenance turning pale; then the ex-
tremities grow cold, the lips into faintings, and, if the
discharge is not speedily stopped, or diminished, is seized
with convulsions, which often terminate in death.

This dangerous efflux is occasioned by every thing that
hinders the emptied uterus from contracting, such as great
weakness and latitude, in consequence of repeated flood-
ings before delivery; the sudden evacuation of the ute-
rus; sometimes, though seldom, it proceeds from part
of the placenta's being left in the womb; it may happen
when there is another child, or more, still undelivered;
when the womb is kept dilated with a large quantity
of coagulated blood; or when it is inverted, by pulling
too forcibly at the placenta.

In this case, as there is no time to be lost, and inter-
\n
nal medicines cannot act so suddenly as to answer the pur-
pose, we must have immediate recourse to external appli-
cation. If the disorder be owing to weakness, by which
the uterus is disabled from contracting itself, so that the
mouths of the vessels are left open; or, though contracted
a little, yet not enough to restrain the hemorrhage of the
thin blood; or if, in separating the placenta, the accou-
cheur has scratched or tore the inner surface or mem-
brane of the womb; in these cases, such things must be
used as will assist the contractile power of the uterus, and
hinder the blood from flowing so fast into it and the neigh-
bouring vessels; for this purpose, cloths dipped in any
cold astringent fluid, such as oxycræte, or red tart wine,
may be applied to the back and belly. Some prescribe
venesection in the arm, to the amount of five or six ounces,
with a view of making resolution: if the pulse is strong,
this may be proper; otherwise, it will do more harm
than good. Others order ligatures, for compressing the
returning veins at the hams, arms, and neck, to retain as
much blood as possible in the extremities and head. Besid-es
these applications, the vagina may be filled with tow or
linen rags, dipped in the above-mentioned liquids, in
which a little allum, or salt, hath been dissolved; nay, some practitioners inject proof-spirits warmed, or,
foaking them up in a rag or sponge, introduce and squeeze
them into the uterus, in order to constringe the vessels.

If the flooding proceeds from another child, the reten-
tion of the placenta, or coagulated blood, these ought
immediately to be extracted; and if there is an inversion
of the uterus, it must be speedily reduced. Should the
hemorrhage, by these methods abate a little, but still
continue to flow, though not in such a quantity as to
bring on sudden death, some red wine and jelly ought to
be
be prescribed for the patient, who should take it frequently, and a little at a time; but above all things, chicken or mutton broths, administered in the same manner, for fear of overloading the weakened stomach, and occasioning re-chaings: these repeated in small quantities, will gradually fill the exhausted vessels, and keep up the circulation. If the pulse continues strong, it will be proper to order repeated draughts of barley-water, acidulated with elixir vitrii: but if the circulation be weak and languid, extract of the bark, dissolved in agua sinanom- mi tenuis, and given in small draughts, or exhibited in any other form, will be serviceable: at the same time, lulling the patient to rest with opiates. These, indeed, when the first violence of the flood is abated, if properly and cautiously used, are generally more effectual than any other medicine.

Of the After-pains.

After-pains commonly happen when the fibrous part of the blood is retained in the uterus or vagina, and formed into large clots, which are detained by the sudden contraction of the os internum and externum, after the placenta is delivered: or, if these should be extruded, others will sometimes be formed, though not so large as the first, because the cavity of the womb is continually diminishing after the birth. The uterus, in contracting, presses down these coagulums to the os internum; which being again gradually stretched, produces a degree of labour pains, owing to the irritation of its nerves: in consequence of this uneasiness, the woman squeezes the womb as in real labour: the force being increased, the clots are puffed along, and when they are delivered, the grows easy. The larger the quantity is of the coagulated blood, the fierer are the pains, and the longer they continue.

Women in the first child seldom have after-pains; because, after delivery, the womb is supposed to contract, and push off the clots with greater force in the first than in the following labours: after-pains may also proceed from obstructions in the vessels, and irritations at the os internum. In order to prevent or remove these pains, as soon as the placenta is separated and delivered, the hand being introduced into the uterus, may clear it of all the coagula. When the womb is felt through the parietes of the abdomen larger than usual, it may be taken for gran-ted, that there is either another child, or a large quantity of this clotted blood; and which, forever may be, there is a necessity for its being extracted. If the placenta comes away of itself, and the after-pains are violent, they may be alleviated and carried off by an opiate: for, by sleeping and sweating plentifully, the irritation is re-moved, the evacuations are increased, the os uteri is en-sensibly relaxed, and the coagula slide easily along. When the discharge of the lochia is small, the after-pains, if moderate, ought not to be restrained; because the squeezing which they occasion, promotes the other evacuation, which is necessary for the recovery of the patient. After pains may also proceed from an obstruction in some of the vessels, occasioning a small inflammation of the os internum and ligaments; and the squeezing thereby occasioned, may not only help to propel the obstructing fluid, but al-so (if not too violent) contribute to the natural discharges.

Of the Lochia.

We have already observed, that the delivery of the child and placenta is followed by an efflux of more or less blood, discharged from the uterus, which, by the immediate evacuation of the larger vessels, is allowed to contract itself the more freely, without the danger of an inflammation, which would probably happen in the contracto, if the great vessels were not emptied at the same time, but, as the fluids in the smaller vessels cannot be so soon evacuated, or returned into the vena cava, it is necessary, that, after the great discharge is abated, a flow and gradual evacuation should continue, until the womb shall be contracted to near the same size which it had before pregnancy; and to this it attains about the eighteenth or twentieth day after delivery, though the period is different in different women.

When the large vessels are emptied immediately after delivery, the discharge frequently ceases for several hours, until the fluids in the smaller vessels are propelled into the larger, and then begins to flow again, of a paler colour.

The red colour of the lochia commonly continues till the fifth day, though it is always turning more and more ferior from the beginning; but, about the fifth day, it flows off a clear, or sometimes (though seldom) of a greenish tint; for, the mouths of the vessels growing gradually narrower, by the contraction of the uterus, at last allow the ferior part only to pass: as for the greenish hue, it is supposed to proceed from a dissolution of the cellular or cribriform membrane or mucus, that surrounded the surface of the placenta and chorion; part of which, being left in the uterus, becomes livid, decays, and, dissolving, mixes with and tinctures the discharge as it passes along.

Though the lochia, as we have already observed, commonly continue to the eighteenth or twentieth day, they are every day diminishing in quantity, and soonest ceases in those women who suckle their children, or have had an extraordinary discharge at first; but the colour, quantity, and duration, differ in different women: in some patients, the red colour disappears on the first, or second day; and in others, though rarely, it continues more or less to the end of the month: the evacuation in some is very small, in others excessive: in one woman it ceases very soon, in another flows during the whole month: yet, all of these patients shall do well.

Some alledge, that this discharge from the uterus is the same with that from a wound of a large surface: but it is more reasonable to suppose, that the change of colour and diminution of quantity proceed from the flow contraction of the vessels; because, previous to pus, there must have been lacerations or impollhumes, and in women who have suddenly died after delivery no wound or excoriation hath appeared upon the inner surface of the womb, which is sometimes found altogether smooth, and at other times rough and unequal on that part to which the placenta adhered. The space that is occupied before delivery, from being nine inches in diameter, or eighteen inches in circumference, will, soon after the birth, be contracted to one third or fourfth of these dimensions.
Of the Milk Fever.

About the fourth day, the breasts generally begin to grow turgid and painful. We have formerly observed, that, during the time of uterine gestation, the breasts in most women gradually increase till the delivery, growing softer as they are enlarged by the vessels being more and more filled with fluids; and by this gradual distention they are prepared for secreting the milk from the blood, after delivery. During the two or three first days after parturition, especially when the woman has undergone a large discharge, the breasts have been sometimes observed to subside and grow flaccid; and about the third or fourth day, when the lochia begin to decrease, the breasts swell again to their former size, and stretch more and more, until the milk, being secreted, is either sucked by the child, or frequently of itself runs out at the nipples.

Most of the complaints incident to women after delivery, proceed either from the obstruction of the lochia in the uterus, or of the milk in the breasts, occasioned by any thing that will produce a fever; such as catching cold, long and severe labour, eating food that is hard of digestion, and drinking fluids that quicken the circulation of the blood in the large vessels; by which means the smaller, with all the secretory and excretory ducts, are obstructed.

The discharge of the lochia being so different in women of different constitutions, and besides in some measure depending upon the method of management, and the way of life peculiar to the patient, we are not to judge of her situation from the colour, quantity, and duration of them, but from the other symptoms that attend the discharge; and if the woman seems hearty, and in a fair way of recovery, nothing ought to be done with a view to augment or diminish the evacuation. If the discharge be greater than the can bear, it will be attended with all the symptoms of inanition; but as the lochia seldom flow so violently as to destroy the patient of a sudden, the may be supported by a proper nourishing diet, aflicted with cordial and restorative medicines. Let her, for example, use broths, jellies, and alleys milk; if the pulse is languid and sunk, she may take repeated doses of the confect. cardiae, with mixtures composed of the cordial waters and volatile spirits; sublastrigents and opiates frequently administered, with the cort. Peruvian, in different forms, and auffere wines, are of great service.

On the other hand, when the discharge is too small, or bath ceased altogether, the symptoms are more dangerous, and require the contrary method of cure: for now the business is to remove a too great plenitude of the vessels in and about the uterus, occafloning tension, pain, and labour, in the circulating fluids; from whence proceed great heat in the part, restlesness, fever, a full, hard, quick pulse, pains in the head and back, nausea, and difficulty in breathing. These complaints, if not at first prevented, or removed by rest and plentiful sweating, must be treated with venesection and the antiphlogistic method.

When the obstruction is recent, let the patient lie quiet, and encourage a plentiful diaphoresis, by drinking frequently of warm, weak, diluting fluids, such as water-gruel, barley-water, tea, or weak chicken-broth.

Should these methods be used without success, and the patient, far from being relieved by rest, plentiful sweating, or a sufficient discharge of the obstructed lochia, labour under an hot dry skin, anxiety, and a quick, hard, and full pulse, the warm diaphoretics must be laid aside; because, if they fail of having the desired effect, they must necessarily increase the fever and obstruction, and recourse be had to bleeding at the arm or ancle to more or less quantity, according to the degree of fever and obstruction; and this evacuation must be repeated as there is occasion. When the obstruction is not total, it is suppos’d more proper to bleed at the ankle than at the arm; and, at this last, when the discharge is altogether stopped. Her ordinary drink ought to be impregnated with nitre.

If the is colicive, emollient and gently opening glyders may be occasionally injected; and her breasts must be fomented and sucked, either by the mouth or pipe-gadles.

If, by these means, the fever is abated, and the necessary discharges return, the patient commonly recovers; but, if the complaints continue, the antiphlogistic method must still be pursued. If, notwithstanding these efforts, the fever is not diminished or removed by a plentiful discharge of the lochia from the uterus, the milk from the breasts, or by a critical evacuation by sweat, urine, or stool, and the woman is every now and then attacked with cold shiverings; an abscess or abscesses will probably be formed in the uterus or neighbouring parts, or in the breasts; and sometimes, the matter will be translated to other situations, and the seat of it foretold from the parts being affected with violent pains: these abscesses are more or less dangerous, according to the place in which they happen, the largeness of the suppuration, and the good or bad constitution of the patient.

If when the pains in the epigastic region are violent, and the fever increased to a very high degree, the patient should all of a sudden enjoy a cessation from pain, without any previous discharge or critical emption, the physician may pronounce that a mortification is begun; especially if, at the same time, the pulse becomes low, quick, wavering, and intermitting: if the woman’s countenance, from being florid, turns dusky and pale, while the her herself, and all the attendants, conceive her much mended; in that case, she will grow delirious, and die in a very short time.

What we have said on this subject, regards that fever which proceeds from the obstructed lochia, and in which the breasts may likewise be affected: but the milk fever is that in which the breasts are originally concerned, and which may happen though the lochia continue to flow in sufficient quantity; nevertheless, they mutually promote each other, and both are to be treated in the manner already explained; namely, by opiates, diluents, and diaphoretics, in the beginning; and, these prescriptions failing, the obstructions must be resolved by the antiphlogistic method described above. The milk-fever alone, when the uterus is not concerned, is not so dangerous, and much more easily relieved. Women of an healthy constitution, who suckle their own children, have good samples,

The Englith statute-mile is fourfcore chains, or 

1760 yards; that is, 5280 feet.
MILFORD HAVEN, the most commodious harbour in Great Britain, situated in the south west part of Pembroke in Wales, at the north entrance of the Bristol channel.

MILIARY, in general, something resembling millet-seeds.

MILIARY FEVER. See Medicine, p. 73.

MILITANT, or CHURCH MILITANT, denotes the body of Christians while here on earth.

MILITARY, something belonging to the soldiery or militia.

MILITIA, in general, denotes the body of soldiers, or those who make profession of arms.

In a more restrained sense, militia denotes the trained bands of a town or country, who arm themselves, upon a short warning, for their own defence. So that, in this sense, militia is opposed to regular or abated troops.

For the direction and command of the militia, the king constitutes lords-lieutenants of each county.

MILL, a machine or engine for grinding corn, &c. of which there are several kinds, according to the various methods of applying the moving power; as water-mills, wind-mills, mills worked by horses, &c. See Mechanics.

MILLERIA, a genus of the fypgenefia polygamia class. See Oniscus.

MILLEPES. See Oniscus.

MILLET, in botany. See Milium.

MILLET, in botany, a genus of the triandria digynia class. The corolla consists of two valves including one flower. There are five species, only one of which, viz. the effufum, or millet-grass, is a native of Britain.

MILIUM, in botany, a genus of the triandria digynia class. The corolla is dimidiated. There are two species, both male and female. For milk is always prepared from chyle as well in men as in women, in virgins and barren women, in mothers and nurfes. Milk approaches nearer to an animal nature than chyle.

If milk be good, and suffered to rest in a clean vessel, it first appears uniformly white; then throws up a white, thick, unctuous cream to its surface, and remains somewhat bluish below. The milks of all the known animals have these properties alike. The human milk is very sweet and thin, the next is that of asses, then that of mares, then of goats, and lastly of cows: whence it is preferred in this order to consumptive persons of weak viscerum. The rennet prepared of the juices of such creatures as chew the cud being mixed with milk, coagulates it into an uniform mafs, which may be cut with a knife, and it thus spontaneously separates into whey and curds; if long boiled over the fire, it lofts its more fluid parts, and condenses into a butyrous and cheefy mafs.

MILK, a well known animal fluid, which nature predisposes in the breaft of women, and the udders of other animals, for the nourishment of their young. Milk is a liquor prepared from the aliment chewed in the mouth, digested in the stomach, perfected by the force and juices of the intestines, and elaborated by means of the melentery and its gland and juices, and the juices of the thoracic duct. It has undergone some actions of the veins, arteries, heart, lungs, and juices, and began to be assimilated; yet may still be had separate and discharged out of the body. And thus by those, who, in the primitive ages, believed that the saints will one day reign on earth with Jesus Christ a thousand years.

MILLIONS, or Chiliasts, a name given to those, who, in the primitive ages, believed that the saints will one day reign on earth with Jesus Christ a thousand years.

MILLEPES. See Oniscus.

MILLIONS, or Chiliasts, a name given to those, who, in the primitive ages, believed that the saints will one day reign on earth with Jesus Christ a thousand years.

MILLET, in botany. See Milium.

MILLING of cloth. See Fulling.

MILLION, in arithmetic, the number of ten hundred thousand, or a thousand times a thousand. See Arithmetic.

MILLREE, a Portuguese gold coin, value $1 7½ d.

MILT, or MELT, is a denomination by which some call the rows of fishes.

MILTON,
MILTON, the name of several market towns, as one
12 miles north east of Dorchester, and another
12 miles north east of Maidstone.

MILVEUS, in ornithology. See Falco.

MIME, in the ancient comedy, a person who acted any
character by mere gestures, and hence denominated
pantomime. See Pantomime.

MIMESIS, in rhetoric, the imitating the voice and ges-
tures of another person.

MIMOSA, the sensitive plant, in botany, a genus
of the polygama monoeica class. The calix of the
hermaphrodite consists of five teeth, and the corolla of
five segments; it has five or more stamens, one pistil-
lum, and the fruit is a pod; the calix, corolla, and
flamina of the male are the same with those of the
female. There are 43 species, all natives of the In-
dies.—The mimosa is called the sensitive plant from
its remarkable property of shrinking its leaves and
branches upon being touched by the hand or any thing
ele. This motion it performs by means of three distinct
articulations, viz. of a single leaf with its pedicle, of
the pedicle to its branch, and of the branch to the trunk or
main stem; the primary motion of all which is the closing
of the two halves of the leaf on its rib; then the rib
or pedicle itself closes; and if the motion whereat the
plant is moved be very strong, the very branches
have the sensation propagated to them, and apply
themselves to the main stem, as the simple leaves did
before to their ribs, and these ribs to their branches;
so that the whole plant, in this flate, forms itself,
from a very complexly branched figure, into a sort of
straight cylindrical one.

Many attempts have been made to account for the mo-
tion of this plant upon mechanical principles; but all
these attempts have hitherto proved unsatisfactory.

MIMUSOPS, in botany, a genus of the odandria mon-
gynia class. The calix consists of eight leaves, and
the corolla of eight petals; and the drupa is pointed.
There are two species, both natives of America.

MINDORA, one of the Philippine islands, lies feath-
west of Luconia, from which it is separated by a narrow
channel.

MINE, in natural history, a place under ground, where
metals, minerals, or even precious stones are dug up.

As, therefore, the matter dug out of mines is va-
rious, the mines themselves acquire various denomina-
tions, as gold mines, silver mines, copper mines, iron
mines, diamond mines, salt mines, mines of antiquity,
of alum, &c.

Mines, then, in general, are veins or cavities within
the earth, whose sides receding from, or approaching
together to each other, make them of unequal breadths
in different places, sometimes forming larger spaces
which are called holes: they are filled with substances,
which, whether metallic or of any other nature, are
called the loads; when the substances forming these
loads, are reducible to metal, the loads are by the
miners said to be alive, otherwise they are called dead
loads. In Cornwall and Devon, the loads always hold
their course from eastward to westward; though in
other parts of England, they frequently run from
north to south. The miners report, that the sides of
the load never bear in a perpendicular, but constantly
under-lay either to the north or to the south. The
load is frequently intercepted by the choking of a vein
of earth, or stone, or some different metallic substance;
in which case it generally happens that one part of the
load is moved a considerable distance to the one side.
This transient load is by the miners called flooking:
and the part of the lead which is to be moved, is said
to be heaved.

According to Dr. Nicol's observations upon mines,
they seem to be, or to have been, the channels thro'
which the waters pass within the earth, and, like ri-
vers, have their small branches opening into them, in
different directions. Most mines have streams of water running
through them; and when they are found dry, it seems
to be owing to the waters having changed their course,
as being obliged to it, either because the load has Hop-
ted up the ancient passages, or that some new and more
easy ones are made.

Mines, says Dr. Shaw, are liable to many contin-
gencies; being sometimes poor, sometimes so much
exhaustible, sometimes subject to be drowned, especially
when deep, and sometimes hard to trace; yet there are
many instances of mines proving highly advantageous
for hundreds of years: the mines of Potosi are to this
day worked with nearly the same success as at first;
the gold mines of Cremnitz have been worked almost
these thousand years; and our Cornish tin mines are
extremely ancient. The next profit of the silver alone,
dug in the Mifnian silver mines in Saxony, is still, in
the space of eight years, computed at a thousand fix
hundred and forty millions, besides seventy-three
tons of gold. Many mines have been discovered by
accident: a torrent first laid open a rich vein of the
silver mine at Friburg in Germany; sometimes a
violent

MINDELHEIM, a city of Germany, thirty-three miles
south east of Ulm. It is the capital of the principality
of Mindelheim, conferred on the duke of Morbrough,
by the emperor in 1704.

MINDEN, a city of Germany, the capital of a duchy
of the same name, situated forty miles west of Ha-
over.

MINDORA, one of the Philippine islands, lies south-
west of Luconia, from which it is separated by a narrow
channel.

MINE, in natural history, a place under ground, where
metals, minerals, or even precious stones are dug up.

As, therefore, the matter dug out of mines is va-
rious, the mines themselves acquire various denomina-
tions, as gold mines, silver mines, copper mines, iron
mines, diamond mines, salt mines, mines of antiquity,
of alum, &c.
violent wind, by blowing up trees, or overturning the
parts of rocks, has discovered a mine; the same has
happened by violent showers, earthquakes, thunder,
the firing of woods, or even the stroke of a plough-
share or horse's hoof.

But the art of mining does not wait for these favourable
accidents, but directly goes upon the search and
discovery of such mineral veins, ores, or sands, as
may be worth the working for metal. The principal
investigation and discovery of mines depend upon a par-
ticular sagacity, or acquired habit of judging from par-
icular signs, that metallic matters are contained in
certain parts of the earth, not far below its surface.
The principal signs of a latent metallic vein, seem re-
ducible to general heads; such as, 1. The discovery
of certain mineral waters. 2. The discolouration of
the trees or grass of a place. 3. The finding of pie-
ces of ore on the surface of the ground. 4. The rife
of warm exhalations. 5. The finding of metallic
sands, and the like. All which are so many encour-
agements for making a stricter search near the places
where anything of this kind appears; whence rules
of practice might be formed for reducing this art to a
greater certainty. But when no evident marks of a
mine appear, the skilful mineralist usually bores into
the earth, in such places as from some analogy of know-
ledge, gained by experience, or by observing the sit-
uation, course, or nature of other mines, he judges
may contain metal.

After the mine is found, the next thing to be con-
idered, is whether it may be dug to advantage. In
order to determine this, we are duly to weigh the na-
ture of the place, and its situation, as to wood, wa-
ter, carriage, healthiness, and the like; and compare
the result with the richness of the ore, the charge of
digging, fluxing, washing, and smelting.

Particularly the form and situation of the spot should
be well considered. A mine must either happen, 1.
In a mountain. 2. In a hill. 3. In a valley. Or,
4. In a flat. But mountains and hills are dug with
much greater ease and convenience, chiefly because
the drains and burrows, that is, the adits or avenues,
may be here readily cut, both to drain the water and
to form gang-ways for bringing out the lead, &c. In
all the four cases we are to look out for the veins which
the rains, or other accidental thing, may have laid
bare; and if such a vein be found, it may often be
proper to open the mine at that place, especially if the
vein prove tolerably large and rich: otherwise the most
commodeous place for situation is to be chose for the
purpose, viz. neither on a flat, nor on the tops of
mountains, but on the sides. The best situation for a
mine, is a mountainous, woody, wholesome spot; of
a safe easy ascent, and bordering on a navigable river.
The places abounding with mines are generally health-
ful, as standing high, and everywhere exposed to the air;
yet some places, where mines are found, prove
poisonous, and can, upon no account, be dug, though
ever so rich: the way of examining a suspected place
of this kind, is to make experiments upon brutes, by
exposing them to the effluvia or exhalations, to find the
effects.

Devonshire and Cornwall, where there are so many
tines of copper and tin, is a very mountainous
country, which gives an opportunity in many places
to make adits, or subterraneous drains, to some valley
at a distance, by which to carry off the water from the
mine, which otherwise would drown them out from
getting the ore. These adits are sometimes carried a
mile or two, and dug at a vast expense, as from 2000 l.
to 4000 l. especially where the ground is rocky; and yet
they find this cheaper than to draw up the water out
of the mine quite to the top, when the water runs in
plenty, and the mine is deep. Sometimes, indeed,
they cannot find a level near enough, to which an adit
may be carried from the very bottom of the mine;
yet they find it worth while to make an adit at half
the height to which the water is to be raised, thereby
saving half the expense.

The late Mr Collar, considering that sometimes from
small streams, and sometimes from little springs, or
collections of rain-water, one might have a pretty
deal of water above ground, though not a sufficient
quantity to turn an over-shot wheel, thought, that if a
sufficient fall might be had, this collection of water
might be made useful in raising the water in a mine to
the adit, where it may be carried off.

Mines, in the military art, denotes a subterraneous can-
al, or passage, dug under the wall or rampart of a
fortification, intended to be blown up by gun-powder.
The adit or passage of a mine is commonly about
four feet square; at the end of this is the chamber of
the mine, which is a cavity about five feet in width
and in length, and about six feet in height; and here
the gun-powder is fixed. The faffifice of the mine,
is the train, for which there is always a little aperture
left. There are various kinds of mines, which acquire
various names, as royal mines, ferripine-mines, fork-
ed mines, according as their passages are straight, ob-
lique, winding, &c.

MINEHEAD, a borough and port town of Somerset-
shire, which sends two members to parliament: W.
long, 3° 20', N. lat. 51° 18'.

MINERAL, in natural history, is used, in general, for
all fossil bodies, whether simple or compound, dug out
of a subterraneous mine, from which it takes its deno-
nination.

MINERAL Waters, in medicine, all those wherein any
medicinal virtues, besides those of common water, are
found.

These mineral waters are of various kinds, but they
are considered under the general titles of chalybeate,
purgative, and alterative. The most useful and com-
modious additions for examining these three kinds of
mineral waters, are, according to Dr Shaw, galls, fy-
rup of violets, and oil of tartar per deliquium. Galls
discover in them any small proportion of vitriol or dis-
olved iron, as having the property of immediately
striking a purple or black colour in all waters where
any such substance is lodged. Spirit of violet, in the
same
MINIATURE, a delicate kind of painting, distinguished by the
smallness of the figures, its being performed with dots or points instead of lines; by
the fineness of the colouring; its requiring to be viewed with great care: and by
its being usually done on vellum.

This is the nicest and most tedious of all kinds of
painting, being performed wholly with the point of the
pencil: for when the colours are laid on flat without dot-
ting, though the figures be small, and the ground either
to white or paper, it is not called painting in miniature, but
washed. There are some painters who never use any
white colour in painting in miniature, but make the ground
of the vellum serve to raise their figures; in which case
the lights appear bright in proportion to the depth and
strength of the colours of the figures. Others, before
they go to work, give the vellum a light wash with white
lead well prepared and purified. These colours that have
the least body, are the best and most commodious for
painting in miniature; as carmine, ultramarine, fine
lakes, and greens made of herbs and flowers; but besides
these, the following colours are also made use of, viz.
vermilion, black lead, brown red, mastic pale, yellow
mastic, indigo, ivory black, lamp black, Spanish
brown, umber, gall stone, brown ochre, French pink,
orpend, gamboge, Naples yellow, blander green, ver-
diter, sea-green, German althe, lake white, and white
lead. All terrestrial colours, and other gross substan-
ces, are too coarse for fine work, how well-soever they may
be ground: but the finest particles may be separated by
tempering the colour in a cup of fair water; and having
flirred it well with your finger, and the whole being
thoroughly mixed, let it be used for a while, and then
pour it by inclination into a cell that has been well
floured in hot water, and let it stand to dry. Yellow
ochre, brown red, umber, and ultramarine, purify by
fire; but if they are burnt in too fierce a fire, they change,
and the brown red turns yellow, the yellow ochre and
umber turn reddish, and so of the rest: so that if the fire is not
too fierce, it renders them softer and kinder than before,
so that the finest and purest ultramarine, burnt in a red
hot thovel, becomes much more brilliant than it was be-
fore it was burnt. Greens, blacks, greys, and yellows,
on being mixed with a little of the gall of the ox, orp,
or eel, especially of the last, acquire a luster and vivacity
not natural to them. You must take the galls of eels, and
hang them on a nail to dry; and when you use any such
paste it in brandy, and mingle some of it with the colour al-
ready tempered with gum water wherein is a little sugar-
candy. When you begin to paint, the colours must be
placed on a small ivory pallet of the size of your hand, in
the middle of which should be placed the white, well
spread out, and nearer it the lighter, and further off those
darker colours you are going to use.

Your vellum must be glued to a copper-plate, or a
piece of thin board, exactly of the same size with the in-
tended piece; in doing which, the fair side of the vel-
num should be moistened with a fine wet linen, and a piece
of white paper being put upon the back of it, it is to be
applied to the plate or board, and stretching it upon it
equally in all directions, the vellum, which ought to be
every way a finger's-breadth larger than what you glue
it to, in order to be doubled over and glued behind.
When your piece is sketched out upon the vellum with a
pencil, you must, with a little thin carmine, run over all the
strokes that may not be defaced in working; and this
done, clean your vellum with crumbs of bread. In laying
on the colours, begin with sketching or drawing with large,

MINHO, a great river of Spain, which taking its rise in
Gallicia, divides that province from Portugal, and falls
into the Atlantic at Caminha.

MINIATURE, a delicate kind of painting, distinguished
from all others by the smallness of the figures, its be-
ing performed with dots or points instead of lines; by
the fineness of the colouring: its requiring to be
viewed very near: and by its being usually done on
vellum.

MINERVALIA, in Roman antiquity, festivals celebra-
ted in honour of Minerva, in the month of March;
at which time the scholars had a vacation, and usu-
ally made a present to their masters, called, from this festi-
val, mineral.

MINERVA, a great river of Spain, which taking its rife in
Gallicia, divides that province from Portugal, and falls
into the Atlantic at Caminha.

MINIATURE, a delicate kind of painting, distinguished
from all others by the smallness of the figures, its be-
ing performed with dots or points instead of lines; by

Vol. III. No. 79.
MIN (250)

MIN, in music, a note equal to two crotchets, or half a semibreve. See Music.

MINIMUM, in the higher geometry, the least quantity attainable in a given case.

MINISTER, a person who preaches, performs religious worship in public, administers the sacraments, &c. Ministers, in Scots law. See Law, Tit. 5.

MINISTERS, in Scots law. See Law, Tit. 5.

MINISTER, a person sent into a foreign country, to manage the affairs of his province, or of the state to which he belongs. Of the’s there are two kinds; those of the first rank are embassadors and envoys extraordinary, who represent the persons of their sovereigns. The ministers of the second rank are the ordinary residents. See Embassador.

MINIUM, or red-lead. See Chemistry, p. 84. and 136.

MINOR, in Scots law. See Law, Tit. 7.

MINOR, in logic, the second proposition of a regular sylloplism. See Logic.

MINORCA, an island in the Mediterranean, about twenty miles east of Majorca, thirty miles long, and twelve broad. It is subject to Great Britain, and only valued for its capacious harbour of Port Mahon.

MINOTAUR, in antiquity, a fabulous monster much talked of by the poets, feigned to be half man and half bull.

The minotaur was brought forth by Pasiphae, wife of Minos, king of Crete. It was shut up in the labyrinth of that island, and at last killed by Theseus.

Servius gives the explanation of this fable: he says that a secretary of king Minos, named Taurus, bull, having an intrigue with the queen Pasiphae, in the chamber of Daedalus, she was at length delivered of twins; one of whom resembled Minos, and the other Taurus. This occasioned the production to be reputed monstrous.

MINTREL, an ancient term for a fiddler, or player on any other kind of musical instrument.

MINT, the place in which the king’s money is coined. See Coinage.

There were anciently mints in almost every country in England; but the only mint at present in the British dominions, is that in the Tower of London. The officers of the mint are, 1. The warden of the mint, who is chief; he oversees the other officers, and receives the bullion. 2. The master worker; who receives the bullion.
MINUTE is also used for a short memoir, or sketch of a
MIRABILIS, marvel of Peru, in botany, a genus of the tri-
MIN U ART IA, in botany, a genus of the triandria tri-
Minute, in architecture, usually denotes the sixtieth,
Minute of time, the fiftieth part of an hour.
MINUET, in music, a very graceful kind of dance,
MIRACLE, in law, signifies a heinous offence or fault, particularly in the execution of an office.
MISSIONARIES, such ecclesiastics as are sent by any
MISTAKES, valvules. See Anatomy, p. 279.

MINE, in botany, a genus of the pentandria mono-
MINUET, in music, a very graceful kind of dance,
Mixture, a compound, or assemblage of several different bodies in the same mass. See Chemistry.

Mixt, or mixt body, in chemistry, that which is composed of different elements or principles. See Chemistry.

Mixture, a compound, or assemblage of several different bodies in the same mass. See Chemistry.

Mode, in metaphysics, denotes the manner of a thing's existence. See Metaphysics, p. 179.

Mode, in music, is defined to be a particular manner of constituting the octave; or, it is the melodic constitution of the octave, as it consists of seven essential sounds, besides the key or fundamental.

Mode, then, is the particular order of the consecutive degrees of an octave; the fundamental note whereof may be called the key, as it signifies that principal note which regulates the rest.

Model, in a general sense, an original pattern, proposed for any one to copy or imitate. This word is particularly used, in building, for an artificial pattern made in wood, stone, plaster, or other matter, with all its parts and proportions, in order for the better constructing and executing some great work, and to give an idea of the effect it will have in large. In all great buildings, it is much the surest way to make a model in relief, and not to trust to a bare design or draught.

Modena, a duchy of Italy, bounded by Mantua on the north, by Romania on the east, by Tuscany and Lucca on the south, and by Parma and the territory of Genoa on the west.

Modena, the capital of the duchy of that name, situated in 15° 20' E. long. and 44° 45' N. lat.

Moderator, in the schools, the person who presides at a dispute, or in a public assembly; thus the president of the annual assembly of the church of Scotland, is styled moderator.

Modern, in a general sense, something new, or of our time, in opposition to what is antique or ancient.

Modica, a town of Sicily, in the province of Noto, twenty-five miles south of Syracuse.

Modification, in philosophy, that which modifies or changes a thing, or gives it this or that manner of being.

Quantity and quality are accidents which modify all bodies.

Decree of Modification, in Scots law, a decree affecting the extent of a minister's stipend, without proportioning it among the persons liable in payment. See Law, Tit. v. 13.

Modillions, in architecture, ornaments in the corbe or niche of the Ionic, Corinthian, and Composite columns. See Architecture.

Modius, in antiquity, a kind of dry measure, in use among the Romans, for several sorts of grain.

Modulation, in music, the art of keeping in, or changing the mode or key.

Module, in architecture, a certain measure or big in a system of building. Architects generally choose the semidiameter of the bottom of the column for their module, and this they subdivide into parts or minutes. See Architecture.

MOHAWK-COUNTRY, a part of North America, inhabited by one of the five nations of the Iroquois, situated between the province of New York and the lake Ontario or Frontignac.

MOHILA,
Mole, in midwifery, a mass of fleshy matter, of a shape and size which may be mistaken for the head of an infant, or the female parts of a child.

Mombaça, or Monbasa, an island and city on the east coast of Africa, opposite to the country of Mombasa, in Zanguebar; E. long. 40°, N. lat. 10°.

Mole, in geography, a river in Surrey, so called from the town of Molesey.

Mole Cricket. See Gryllus.

Molar Teeth, or dentes molares, in anatomy, the large teeth called in English grinders. See Anatomy, p. 165.

Moldavia, a province of European Turkey, separated from Poland by the river Neißer.

Mole, in zoology. See Talpa.

Mole Cricket. See Gryllus.

Mole, in midwifery, a mass of fleshy matter, of a spherical figure, generated in the uterus, or womb, and sometimes mistaken for the head of an infant, or the female parts of a child. See Midwifery.

Mole, in geography, a river in Surrey, so called from its running, for part of its course, underground.

Mole, is also a mass of large stones laid in the sea by means of cofferdams; extending before a port, either to defend the harbour from the impetuosity of the waves, or to prevent the passage of ships without leave.

Action of Molestation, in Scots law. See Law, Tit. xxx. 19.

Mollugo, in botany, a genus of the triandria trigynia class. The calyx consists of five leaves; the corolla is wanting; and the capsule has three cells and three valves. There are five species, none of them natives of Britain.

Molasses, in commerce, the thick fluid matter remaining after the sugar is made, resembling syrup. In Holland molasses are much used in the manufacture of tobacco, and by the poor people for fuel. A brandy is also distilled from them, but it is said to be unwholesome.

Molossus, in Greek and Latin poetry, a foot composed of three long syllables, as delectant.

Molucca-islands, five islands in the Indian ocean, the largest of which is scarcely thirty miles round; they are called Bacian, Machian, Motyr, Ternate, and Typhon; they produce sago, oranges, lemons, and some other fruits; but what is peculiar to these islands, is their producing cloves. They are subject to the Dutch, and are situated in 125° of east longitude, and between 15° south, and 20° north latitude.

Moluccella, in botany, a genus of the didymia gymnosperma class. The calyx is bell-shaped, and larger than the corolla. There are three species, none of them natives of Britain.

Molwitz, a town of Silesia in the kingdom of Bohemia; E. long. 16° 45', N. lat. 50° 26'.

Molybdenum, or Molybdenum, a metal, one of the compounds of the element molybdenum, occurring in the form of yellow crystals, or as a white powder, which is always equal to the quantity of matter multiplied into the velocity; or, which is the same thing, it may be considered as a rectangle under the quantity of matter and velocity.

Momordica, in botany, a genus of the monoeia monogynia class. The calyx of the male and female consists of five segments; the corolla of the male has five segments; and the filaments are three. The corolla of the female consists of five segments; and it has three styli. There are eight species, none of them natives of Britain.

Monad, in botany, a genus of the diandria monoandria class. The corolla is unequal, the superior lip being larger than the corolla. There are three species, none of them natives of Britain.

Monarch, in botany. See Botany, p. 635.

Monarchy, a government in which the supreme power is vested in a single person. See Government.

Monarchia, in botany. See Botany, p. 635.

Monarchy, a government in which the supreme power is vested in a single person. See Government.

Monarchia, in botany. See Botany, p. 635.

Monastery, a convent, or house built for the reception and entertainment of monks, mendicant friars, or nuns, whether it be an abbey, priory, &c.

Monasteries are governed by different rules, according to the different regulations prescribed by their founders. The first regular and perfect monasteries were founded by St. Pachomius, in Egypt; but St. Basil is generally considered as the great father and patriarch of the Eastern monks; since in the fourth century he prescribed rules for the government of the monasteries, to which the Anchoress and Convents, and the others ancient fathers of the deserts, submitted. In like manner St. Benedict was styled the patriarch of the Western monks. He appeared in Italy towards the latter end of the fifth century, and published his rule, which was universally received throughout the west. St. Augulfin being sent into England by St. Gregory the pope, in the year 596, to convert the English, he at the same time introduced the monastic state into this kingdom; which made such progress there, that within the space of two hundred years, there were thirty kings and queens who preferred the religious habit to their crowns, and founded slately monasteries, where they ended their days in solitude and retirement.

Monastic, something belonging to monks. See Mon.

Monastic, something belonging to monks. See Mon.

Monaco, a two of Spain, in the province of Arragon, fifty miles north-east of Saragossa.

Monday, the first day of the week, so called as being anciently sacred to the moon, q. d. moon-day.

Monegum, a country in the south of Africa, situated between Angola and Zanguebar.

Money, a piece of matter, commonly metal, to which public authority has annexed a certain value and weight to serve as a medium in commerce.
Of artificial or material money.

I. From the infancy of the world, at least as far back as our accounts of the transactions of mankind reach, we find they had adopted the precious metals, that is, silver and gold, as the common measure of value, and as the adequate equivalent for every thing alienable.

The metals are admirably adapted for this purpose: They are perfectly homogeneous: When pure, their malleable, or bulked, are exactly in proportion to their weights: No physical difference can be found between two pounds of gold, or silver, let them be the production of the mines of Europe, Asia, Africa, or America: They are perfectly malleable, fusible, and suffer the most exact division which human art is capable to give them: They are capable of being mixed with one another, as well as with metals of a bader, that is, of a less homogeneous nature, such as copper: By this mixture they spread themselves uniformly through the whole mass of the composed lump, so that every atom of it becomes proportionally part of this noble mixture; by which means the subdivision of the precious metals is rendered very extensive. Their physical qualities are invariant; they lose nothing by keeping; they are solid and durable; and though their parts are separated by friction, like every other thing, yet till they are of the number of those which suffer least by it.

If money, therefore, can be made of any thing, that is, if the proportional value of things vendible can be measured by any thing material, it may be measured by the metals.

II. The two metals being pitched upon as the most proper substances for realizing the ideal scale of money, those who undertake the operation of adjusting a standard must constantly keep in their eye the nature and qualities of a scale, as well as the principles upon which it is formed.

The unit of the scale must constantly be the same, although realized in the metals, or the whole operation fails in the most essential part. This realizing the unit is like adjusting a pair of compasses to a geometrical scale, where the smallest deviation from the exact opening once given must occasion an incorrect measure. The metals, therefore, are to money what a pair of compasses is, to a geometrical scale.

This operation of adjusting the metals to the money of account implies an exact and determinate proportion of both metals to the money unit, realized in all the species and denominations of coin, adjusted to that standard.

The smallest particle of either metal added to, or taken away from any coin, which represents certain determinate parts of the scale, overturns the whole system of monetary value. And if, notwithstanding such variation, these coins continue to bear the same denominations as before, this will as effectually destroy their usefulness in measuring the value of things, as it would overturn the usefulness of a pair of compasses, to suffer the opening to vary, after it is adjusted to the scale representing feet, toises, miles, or leagues, by which the distances up the plan are to be measured.

III. Debasing the standard is a good term; because it conveys a clear and distinct idea. It is diminishing the weight of the pure metal contained in that denomination by which a nation reckons, and which we have called the money unit. Raising the standard requires no farther definition, being the direct contrary.

IV. Altering the standard (that is, raising or debasing the value of the money-unit) is like altering the national measures or weights. This is best discovered by comparing the tinge altered with things of the same nature which have suffered no alteration. Thus if the foot of measure was altered at once over all England, by adding to it, or taking from it, any proportional part of its standard length, the alteration would be best discovered, by comparing the new foot with that of Paris, or of any other country, which had suffered no alteration. Just so, if the pound sterling, which is the English unit, shall be found any how changed, and if the variation it has met with be difficult to ascertain, because of a complication of circumstances, the best way to discover it, will be to compare the former and the present value of it with the money of other nations which has suffered no variation. This the course of exchange will perform with the greatest exactness.

V. Artists pretend, that the precious metals, when absolutely pure from any mixture, are not of sufficient hardnece to constitute a solid and lasting coin. They are found also in the mines mixed with other metals of a bader nature, and the bringing them to a state of perfect purity occasions an unnecessary expense. To avoid, therefore, the inconvenience of employing them in all their purity, people have adopted the expedient of mixing them with a determinate proportion of other metals, which hurts neither their fusibility, malleability, beauty, or lustre. This metal is called alloy; and, being considered only as a support to the principal metal, is accounted of no value in itself. So that eleven ounces of gold, when mixed with one ounce of silver, acquires, by that addition, no augmentation of value whatever.

This being the case, we shall, as much as possible, overlook the existence of alloy, in speaking of money, in order to render language less subject to ambiguity.

Incapacities of the metals to perform the office of an invariable measure of value.

I. Were there but one species of such a substance as we have reprefented gold and silver to be; were there but one metal possessing the qualities of purity, divisibility, and durability; the inconveniences in the use of it for money would be fewer by far than they are found to be as matters stand.

Such a metal might then, by an unlimited division into parts exactly equal, be made to serve as a tolerably leady and universal measure. But the rivallhip between the metals, and the perfect equality which is found between all their physical qualities, so far as regards purity and divisibility, render them so equally well adapted to serve as the common measure of value, that they are universally admitted to pass current as money.

What is the consequence of this? That the one measures the value of the other, as well as that of every other thing. Now the moment any measure begins to be measured...
fared by another, whose proportion to it is not physically, perpetually, and invariably the same, all the uselness of such a measure is lost. An example will make this plain.

A foot of measure is a determinate length. An English foot may be compared with the Paris foot, or with that of the Rhine; that is to say, it may be measured by them; and the proportion between their lengths may be expressed in numbers; which proportion will be the same perpetually. The measuring the one by the other will occasion no uncertainty; and we may speak of lengths by Paris feet, and perfectly well understand by others who are used to measure by the English foot, or by the foot of the Rhine.

But suppose that a youth of twelve years old takes it into his head to measure from time to time, as he advances in age, by the length of his own foot, and that he divides this growing foot into inches and decimals: what can be learned from his account of measures! As he increases in years, his foot, inches, and subdivisions, will be gradually lengthening; and were every man to follow his example, and measure by his own foot, then the foot of a measure now established would totally cease to be of any utility.

This is just the case with the two metals. There is no determinate invariable proportion between their value; and the consequence of this is, that when they are both taken for measuring the value of other things, the things to be measured, like lengths to be measured by the young man's foot, without changing their relative proportion between themselves, change however with respect to the denominations of both their measures. An example will make this plain.

Let us suppose an ox to be worth three thousand pounds weight of wheat, and the one and the other to be worth an ounce of gold, and an ounce of gold to be worth exactly fifteen ounces of silver: If the cafe should happen, that the proportional value between gold and silver should come to be as 14 is to 1, would not the ox, and consequently the wheat, be estimated at less in silver, and more in gold, than formerly? Further, would it be in the power of any state to prevent this variation, in the measure of the value of oxen and wheat, without putting into the unit of their money less silver and more gold than formerly.

If therefore any particular state should fix the standard of the unit of their money to one species of the metals, while in fact both the one and the other are actually employed in measuring value; does not such a state resemble the young man, who measures all by his growing foot? For if silver, for example, be retained as the standard, while it is gaining upon gold, one at least additional value; and if gold continue all the while to determine the value of things as well as silver, it is plain, that, to all intents and purposes, this silver-measure is lengthening daily, like the young man's foot, since the same weight of it must become every day equivalent to more and more of the same commodity; notwithstanding that we suppose the same proportion to subsist, without the least variation, between that commodity and every other species of things alienable.

Buying and selling are purely conventional, and no man is obliged to give his merchantize at what may be supposed to be the proportion of its worth. The use, therefore, of an universal measure, is to mark, not only the relative value of the things to which it is applied as a measure, but to discover in an infant the proportion between the value of those, and of every other commodity valued by a determinate measure in all the countries of the world.

Were pounds sterling, livres, florins, piastras, &c. which are all money of account, invariable in their values, what a facility would it produce in all concerns, what an assistance to trade! But as they are all limited or fixed to coins, and consequently vary from time to time, this example shews the utility of the invariable measure which we have described.

There is another circumstance which incapacitates the metals from performing the office of money; the substance of which the coin is made, is a commodity, which rises and sinks in its value with respect to other commodities, according to the wants, competition, and caprices of mankind. The advantage, therefore, found in putting an intrinsic value into that substance which performs the function of money of account, is compensated by the instability of that intrinsic value; and the advantage obtained by the fiability of paper, or symbolical money, is compensated by the defect it commonly has of not being at all times susceptible of realization into solid property or intrinsic value.

In order, therefore, to render material money more perfect, this quality of metal, that is, of a commodity, should be taken from it; and in order to render papery-money more perfect, it ought to be made to circulate upon metallic or land security:

1. There are several smaller inconveniences accompanying the use of the metals, which we shall here shortly enumerate:

1. No money made of gold or silver can circulate long, without losing of its weight, although it all along preserves the same denomination. This represents the contracting a pair of compasses which had been rightly adjusted to the scale.

2. Another inconvenience proceeds from the fabrication of money. Supposing the faith of princes who coin money to be inviolable, and the probity as well as capacity of those to whom they commit the inspection of the fineness of the metals to be sufficient, it is hardly possible for workmen to render every piece exactly of a proper weight; or to preserve the due proportion between pieces of different denominations; that is to say, to make every ten guineas exactly of the same weight with every crown-piece and every five shillings struck in a coinage. In proportion to such inaccuracies, the parts of the scale become unequal.

3. Another inconvenience, and far from being inconceivable, flows from the expense requisite for the coming of money. This expense adds to its value as a manufacture, without adding anything to its weight.

4. The last inconvenience is, that by fixing the money of account entirely to the coin, without having any independent common measure to mark and control these deviations from mathematical exactness, which are either inseparable.
inseparable from the metals themselves, or from the fabrication of them) the whole measure of value, and all the relative interests of debtors and creditors, become at the disposal not only of workers in the mint, of Jews who deal in money, of clippers and walters of coin, but they are also entirely at the mercy of princes, who have the right of coinage, and who have frequently also the right of raising or debasing the standard of the coin, according as they find it most for their present and temporary interest.

Methods which may be proposed for lessening the several inconveniences to which material money is liable.

The inconveniences from the variation in the relative value of the metals to one another, may in some measure be obviated by the following expedients.

1st. By considering one only as the standard, and leaving the other to seek its own value, like any other commodity.

2nd. By considering one only as the standard, and fixing the value of the other from time to time by authority, according as the market-price of the metals shall vary.

3rd. By fixing the standard of the unit according to the mean proportion of the metals, attaching it to neither; regulating the coin accordingly; and upon every considerable variation in the proportion between them, either to make a new coinage, or to raise the denomination of one of the species, and lower it in the other, in order to preserve the unit exactly in the mean proportion between the gold and silver.

4th. To have two units, and two standards, one of gold, and one of silver, and to allow every body to stipulate in either.

5th. Or last of all, to oblige all debtors to pay one half in gold, and one half in the silver standard.

Variations to which the value of the money-unit is exposed from every disorder in the coin.

Let us suppose, at present, the only disorder to consist in a want of the due proportion between the gold and silver in the coin.

This proportion can only be established by the market-price of the metals; because an augmentation and rife in the demand for gold or silver has the effect of augmenting the value of the metal demanded. Let us suppose, that to day one pound of gold may buy fifteen pounds of silver; if to-morrow there be a high demand for silver, a competition among merchants to have silver for gold will ensue; they will contend who shall get the silver at the rate of fifteen pounds for one of gold: this will raise the price of it; and in proportion to their views of profit, some will accept of less than the fifteen pounds. This is plainly a raise in the silver, more properly than a fall in the gold; because it is the competition for the silver which has occasioned the variation in the former proportion between the metals.

Let us now suppose, that a state, having with great exactness examined the proportion of the metals in the market, and having determined the precise quantity of each for realizing or representing the money-unit, shall execute a most exact coinage of gold and silver coin. As long as that proportion continues unvaried in the market, no inconvenience can result from that quarter, in making use of metals for money of account.

But let us suppose the proportion to change; that the silver, for example, shall rise in its value with regard to gold; will it not follow, from that moment, that the unit realized in the silver, will become of more value than the unit realized in the gold coin?

But as the law has ordered them to pass as equivalents for one another, and as debtors have always the option of paying in what legal coin they think fit, will they not all choose to pay in gold, and will not then the silver coin be melted down or exported, in order to be sold as bullion, above the value it bears when it circulates in coin? Will not this paying in gold also really diminish the value of the money unit, since upon this variation every thing must fall for more gold than before, as we have already observed?

Consequently, merchandise which have not varied in their relative value to any other thing but to gold and silver, must be measured by the mean proportion of the metals; and the application of any other measure to them is altering the standard. If they are measured by the gold, the standard is debased; if by silver, it is raised.

If, to prevent the inconvenience of melting down the silver, the state shall give up affixing the value of their unit to both species at once, and shall fix it to one, leaving the other to seek its value as any other commodity; in that case, no doubt, the melting down of the coin will be prevented; but will ever this restore the value of the money unit to its former standard? Would it, for example, in the foregoing supposition, raise the debased value of the money-unit in the gold coin, if that species were declared to be the standard? It would indeed render silver coin purely a merchandise, and, by allowing it to seek its value, would certainly prevent it from being melted down as before; because the pieces would rise conventionally in their denomination; or an agio, as it is called, would be taken in payments made in silver; but the gold would not, on that account, rise in its value, or begin to purchase any more merchandise than before. Were therefore the standard fixed to the gold, would not this be an arbitrary and a violent revolution in the value of the money-unit, and a debasement of the standard?

If, on the other hand, the state should fix the standard to the silver, which we suppose to have risen in its value, would that ever sink the advanced value which the silver coin had gained above the worth of the former standard? And would not this be a violent, and an arbitrary revolution in the value of the money unit, and a raising of the standard?

The only expedient, therefore, is, in such a case, to fix the numerary unit to neither of the metals, but to contrive a way to make it fluctuate in a mean proportion between them; which is in effect the introduction of a pure ideal money of account.

The regulation of fixing the unit by the mean proportion, ought to take place at the instant the standard unit is affixed with exactness both to the gold and silver. If it
it be introduced long after the market proportion between the metals has deviated from the proportion established in the coin; and if the new regulation is made to have a retrospective, with regard to the acquitting of permanent contracts entered into, while the value of the money-unit had attached itself to the lowest currency, in consequence of the principle above laid down; then the retorting the money-unit to that standard where it ought to have remained (to wit, to the mean proportion) is an injury to all debtors who have contracted since the time that the proportion of the metals began to vary.

This is clear from the former reasoning. The moment the market-price of the metals differs from that in the coin, every one who has payments to make, pays in that species which is the highest rated in the coin; consequently, he who lends, lends in that species. If after the contract, therefore, the unit is carried up to the mean proportion, this must be a loss to him who had borrowed.

From this we may perceive, why there is less inconvenience from the varying of the proportion of the metals, where the standard is fixed to one of them, than when it is fixed to both. In the first case, it is least uncertain whether the standard or the merchandize-species is to rise; consequently it is uncertain whether the debtors or the creditors are to gain by a variation. If the standard species should rise, the creditors will gain; if the merchandize species rises, the debtors will gain; but when the unit is attached to both species, then the creditors never can gain, let the metals vary as they will: if silver rises, then debtors will pay in gold; if gold rises, debtors will pay in silver. But whether the unit be attached to one or to both species, the infallible consequence of a variation is, that one half of the difference is either gained or lost by debtors and creditors. The invariable unit is constantly the mean proportional between the two measses.

How the variations in the intrinsic value of the unit of money must affect all the domestic interest of a Nation.

If the changing the content of the bushel by which grain is measured, would affect the interest of those who are obliged to pay, or who are intitled to receive, a certain number of bushels of grain for the rent of lands; in the same manner must every variation in the value of the unit of account affect all persons who, in permanent contracts, are obliged to make payments, or who are intitled to receive sums of money stipulated in multiples or in fractions of that money unit.

Every variation, therefore, upon the intrinsic value of the money unit, has the effect of benefiting the class of creditors, at the expense of debtors, or vice versa.

This consequence is deduced from an obvious principle. Money is more or less valuable in proportion as it can purchase more or less of every kind of merchandize. Now without entering anew into the causes of the rise and fall of prices, it is agreed upon all hands, that whether an augmentation of the general mafs of money in circulation has the effect of raising prices in general, or not, any augmentation of the quantity of the metals appointed to be put into the money-unit, must at least affect the value of that money-unit, and make it purchase more of any commodity than before; that is to say, if 113 grains of fine gold, the present weight of a pound sterling in gold, can buy 113 pounds of flour; were the pound sterling raised to 114 pounds of fine metal, it would buy 114 pounds of flour; consequently, were the pound sterling augmented by one grain of gold, every miller who paid a rent of ten pounds a year, would be obliged to sell 1140 pounds of his flour, in order to procure 10 pounds to pay his rent, in place of 1130 pounds of flour which he sold formerly to procure the same sum; consequently, by this innovation, the miller must lose yearly ten pounds of flour, which his master consequently must gain. From this example, it is plain, that every augmentation of metals put into the pound sterling, either of silver or gold, must imply an advantage to the whole class of creditors who are paid in pounds sterling, and consequently must be a proportional loss to all debtors who must pay by the same denomination.

Of the disorder in the British coin, so far as it arises from the melting down or the exporting of the specie.

The defects in the British coin are three.

1st. The proportion between the gold and silver in it is found to be as 1 to 15 2/3, whereas the market price may be supposed to be nearly as 1 to 14.

2do. Great part of the current money is worn and light.

3rd. From the second defect proceeds the third, to wit, that there are several currencies in circulation which pass for the same value, without being of the same weight.

From all these defects results the least greatest inconvenience, to wit, that some innovation must be made, in order to set matters on a right footing.

The English, besides the unit of their money which they call the pound sterling, have also the unit of their weight for weighing the precious metals.

This is called the pound troy, and consists of 12 ounces, every ounce of 20 penny-weight, and every penny-weight of 24 grains. The pound troy, therefore, consists of 240 penny-weight, and 5760 grains.

The fineness of the silver is reckoned by the number of ounces and penny-weights of the pure metals in the pound troy of the composed masts; or in other words, the pound troy, which contains 5760 grains of standard silver, contains 5328 grains of fine silver, and 432 grains of copper, called alloy.

Thus standard silver is 11 ounces 2 penny-weights of fine silver in the pound troy to 18 penny-weights copper, or 111 parts fine silver to 9 parts alloy.

Standard gold is 11 ounces fine to one ounce silver or copper employed for alloy, which together make the pound troy; consequently, the pound troy of standard gold, contains 5280 grains fine, and 480 grains alloy, which alloy is reckoned of no value.

This pound of standard silver is ordered, by statute of the 43d of Elizabeth, to be coined into 62 shillings, 20 of which make the pound sterling; consequently the 20 shillings contain 1718.7 grains of fine silver, and 1858.06 standard silver.

The pound troy of standard gold, 1/1 fine, is ordered by

Vol. III. No. 79. 2
by an act of King Charles II. to be cut into 44 ½ guineas; that is to say, every guinea contains 129.43 grains of standard gold, and 118.64 grains of fine gold; and the pound sterling, which is ⅓ of the guinea, contains 112.99 grains, which we may state at 113 grains of fine gold.

The coinage in England is entirely defrauded at the expense of the late. The mint price for the metals is the very same with the price of the coin. Whoever carries to the mint an ounce of standard silver, receives for it in silver coin 57. 2d. or 62d.; whoever carries an ounce of standard gold receives in gold coin 17s. 10d. the one and the other making exactly an ounce of the same fineness with the bullion. Coin, therefore, can have no value in the market above bullion; consequently, no loss can be incurred by those who melt it down.

When the guinea was first struck, the government (not inclining to fix the pound-sterling to the gold coin of the nation) fixed the guinea at 20 shillings, (which was then below its proportion to the silver) leaving it to seek its own price above that value, according to the course of the market.

By this regulation no harm was done to the English silver standard; because the guinea, or 118.64 grains fine gold being worth more at that time, than 20 shillings, or 1718.7 grains fine silver, no debtor would pay with gold at its standard value, and whatever it was received for above that price was purely conventional.

Accordingly guineas sought their own price until the year 1728, that they were fixed anew, not below their value as at first, but at what was then reckoned their exchange value, and whatever it was received for above that price was purely conventional.

The consequence of this has been, that the same guinea which was worth 1804.6 grains fine silver, at the time it was fixed at 21 shillings, is now worth no more than 1716.9 grains of fine silver according to the proportion of 14½ to 1.

Consequently, debtors, who have always the option of the legal species in paying their debts, will pay pounds sterling no more in silver but in gold; and as the gold pounds they pay in, are not intrinsically worth the silver pounds they paid in formerly, according to the statute of Elizabeth, it follows that the pound sterling in silver is really no more the standard, since no body will pay at that rate, and since no body can be compelled to do it.

Besides this want of proportion between the metals, the silver coined before the reign of George I. is now become light by circulation; and the guineas coined by all the Princes since Charles II. pass by tale, though many of them are considerably diminished in their weight.

Let us now examine what profit the want of proportion and the want of weight in the coin can afford to the money-jobbers, in melting it down or exporting it?

Did every body consider coin only as the measure for reckoning value, without attending to its value as a metal, the deviations of gold and silver coin from perfect exactness either as to proportion or weight would occasion little inconvenience.

Great numbers indeed, in every modern society, consider coin in no other light, than that of money of account; and have great difficulty to comprehend what inconvenience any one can find between a light shilling and a heavy one; or what inconvenience there can possibly result from a guinea's being some grains of fine gold too light to be worth 21 shillings standard weight. And did every one think in the same way, there would be no occasion for coin of the precious metals at all; leather, copper, iron, or paper, would keep the reckoning as well as gold and silver.

But although there be many who look no farther than at the stamp on the coin, there are others whose sole business it is to examine its intrinsic worth as a commodity, and to profit of every irregularity in the weight and proportion of metals.

By the very institution of coinage, it is implied, that every piece of the same metal, and same denomination with regard to the money-unit, shall pass current for the same value.

It is, therefore, the employment of money-jobbers, to examine, with a scrupulous exactness, the precise weight of every piece of coin which comes into their hands.

The first object of their attention is, the price of the metals in the market: a jobber finds, at present, that with 14.5 pounds of fine silver bullion, he can buy one pound of fine gold bullion.

He therefore buys up with gold coin, all the new silver as fast as it is coined, of which he can get at the rate of 15.2 pounds for one in gold; these 15.2 pounds silver coin he melts down into bullion, and converts that back into gold bullion, giving at the rate of only 14.5 pounds for one.

By this operation he remains with the value of \( \frac{1}{16} \) of one pound weight of silver bullion clear profit upon the 14½ pounds he bought; which \( \frac{1}{16} \) is really lost by the man who inadvertently coined silver at the mint, and gave it to the money-jobber for his gold. Thus the state loses the expence of the coinage, and the public the convenience of change for their guineas.

But here it may be asked, Why should the money-jobber melt down the silver coin? can he not buy gold with it as well without melting it down? He cannot; because when it is in coin, he cannot avail himself of its being new and weighty. Coin goes by tale, not by weight; therefore, were he to come to market with his new silver coin, gold bullion being sold at the mint price, we shall suppose, viz. at 3l. 17s. 10½d. sterling money per...
per ounce, he would be obliged to pay the price of what
he bought with heavy money, which he can equally do
with light.

He therefore melts down the new silver coin, and sells
it for bullion, at so many pence an ounce, the price of
which bullion is, in the English market, always above
the price of silver at the mint, for the reasons now to be
given.

When you sell standard silver bullion at the mint, you
are paid in weighty money; that is, you receive for your
bullion the very same weight in standard coin; the coin-
age costs nothing; but when you sell bullion in the mar-
et, you are paid in worn out silver, in gold, in bank
notes, in short, in every species of lawful current money.
Now all these payments have some defect: the silver you
are paid with is worn and light; the gold you are paid
with is over-rated, and perhaps also light; and the bank
notes must have the same value with the specie with which
the bank pays them; that is, with light silver or over-
rated gold.

It is for these reasons, that silver bullion, which is
bought by the mint at 5s. 2d. per ounce of heavy silver
money, may be bought at market at 6s. pence the ounce
in light silver, over-rated gold, or bank notes, which is
the same thing.

Farther, we have seen how the imposition of coinage
has the effect of raising coin above the value of bullion,
by adding a value to it which it had not as a metal.
Just so, when the unit is once affixed to certain deter-
mined quantities of both metals, if one of the metals
should afterwards rise in value in the market, the coin
made of that metal must lose a part of its value as coin,
although it retains it as a metal. Consequently, as in
the first case, it acquired an additional value by being
coined, it must now acquire an additional value by being
melted down. From this we may conclude, that when
the standard is affixed to both the metals in the coin, and
when the proportion of that value is not made to follow
the price of the market, that species which rises in the
market is melted down, and the bullion is sold for a price
as much exceeding the mint price as the metal has rifen
in its value.

If, therefore, in England, the price of silver bullion is
found to be at 65 pence the ounce, while at the mint it
is rated at 62 s; this proves that silver has rifen \(\frac{1}{12}\) above
the proportion observed in the coin, and that all coin of
standard weight may consequently be melted down with
a profit of \(\frac{1}{12}\). But as there are several other circum-
stances to be attended to, which regulate and influence
the price of bullion we shall here pass them in review,
the better to discover the nature of this disorder in the
English coin; and the advantages which money-jobbers
may draw from it.

The price of bullion, like that of every other merchan-
dize, is regulated by the value of the money it is paid
with.

If bullion, therefore, sells in England for 65 pence
an ounce, paid in silver coin, it must sell for 67 shillings
the pound troy; that is to say, the shillings it is com-
monly paid with do not exceed the weight of \(\frac{1}{12}\) of a
pound troy: for if the 65 shillings with which the pound
of bullion is paid weighed more than a pound troy, it
would be a shorter and better way for him who wants
bullion to melt down the shillings and make use of the
metal, than to go to market with them in order to get
lefs.

We may, therefore, be very certain, that no man will
buy silver bullion at 6s pence an ounce, with any shilling
which weighs above \(\frac{1}{12}\) of a pound troy.

We have gone upon the supposition that the ordinary
price of bullion in the English market is 65 pence per
ounce. This has been done upon the authority of some
late writers on this subject: it is now proper to point
out the causes which may make it deviate from that
value.

I. It may vary, and certainly will vary, in the price, ac-
cording as the currency is better or worse. When the
expences of a war, or a wrong balance of trade, have
carried off a great many heavy guineas, it is natural that
bullion should rife; because then it will be paid for more
commonly in light gold and silver; that is to say,
with pounds sterling, below the value of 113 grains
fine gold, the worth of the pound sterling in new guineas.

II. This wrong balance of trade, or a demand for
bullion abroad, becoming very great, may occasion a
scarcity of the metals in the market, as well as a scar-
city of the coin; consequently, an advanced price must be
given for it in proportion to the greatness and height of
the demand. In this case, both the specie and the bullion
must be bought with paper. But the rife in the price of
bullion proceeds from the demand for the metals, and
the competition between merchants to procure them, and
not because the paper given as the price is at all of inferior
value to the specie. The least discredit of this kind would
not tend to diminish the value of the paper; it would an-
nihilate it at once. Therefore, since the metals must be
had, and that the paper cannot supply the want of them
when they are to be exported, the price rifes in propor-
tion to the difficulties in finding metals elsewhere than in
the English market.

III. A sudden call for bullion, for the making of plate.
A goldsmith can well afford to give 67 pence for an ounce
of silver, that is to say, he can afford to give one pound
of gold for 14 pounds of silver, and perhaps for less,
notwithstanding that what he gives be more than the or-
dinary proportion between the metals, because he indemni-
fies himself amply by the price of his workmanship: juft as
a tavern keeper will pay any price for a fine fiffi, becaufe,
like the goldsmith, he buys for other people.

IV. The mint price has as great an effect in bringing
down the price of bullion, as exchange has in raising it.
In countries where the metals in the coin are jufily pro-
portioned, where all the currencies are of legal weight,
and where coinage is imposed, the operations of trade
make the price of bullion constantly to fluctuate be-
tween the value of the coin and the mint price of the
metals.

Now let us suppose that the current price of silver bul-
lion in the market is 65 pence the ounce, paid in lawful
money, no matter of what weight, or of what metal.
Upon this the money jobber falls to work. All shillings
which are above \(\frac{1}{12}\) of a pound troy, he throws into his
melting
melting pot, and sells them as bullion, for 63d. per ounce; all those which are below that weight he carries to market, and buys bullion with them, at 65d. per ounce.

What is the consequence of this?

That those who sell the bullion, finding the shillings which the money jobber pays with perhaps not above \( \frac{2}{3} \) of a pound troy, they on their side raise the price of their bullion to 66d. the ounce.

This makes new work for the money-jobber; for he must always gain. He now weighs all shillings as they come to hand; and as formerly he threw into his melting-pot those only which were worth more than \( \frac{2}{3} \) of a pound troy, he now throws in all that are in value above \( \frac{2}{3} \). He then sells the melted shillings at 66d. the ounce, and buys bullion with the light ones at the same price.

This is the consequence of ever permitting any species of coin to pass by the authority of the stamp, without controlling it at the same time by the weight: and this is the manner in which money-jobbers gain by the currency of light money.

It is no argument against this exposition of the matter to say, that silver bullion is seldom bought with silver coin; because the pence in new guineas are worth no more than the pence of shillings of 65 in the pound troy; that is to say, that 240 pence contained in \( \frac{2}{3} \) of a new guinea, and 240 pence contained in 28 shillings of 65 to the pound troy differ no more in the intrinsic value than 0.83 of a grain of fine silver upon the whole, which is a mere trifle.

-Whenever, therefore, shillings come below the weight of \( \frac{2}{3} \) of a pound troy, then there is an advantage in changing them for new guineas; and when that is the case, the new guineas will be melted down, and profit will be found in selling them for bullion, upon the principles we have just been explaining.

We have already given a specimen of the domestic operations of the money-jobbers; but there are not the most prejudicial to national concerns. The jobbers may be supposed to be Englishmen; and in that case the profit they make remains at home: but whenever there is a call for bullion to pay the balance of trade, it is evident that this will be paid in silver coin, never in gold, if heavy silver can be got; and this again carries away the silver coin, and renders it at home so rare, that great inconvenience are found for want of the better denominations of it. The loss, however, here is confined to an inconvenience; because the balance of trade being a debit which must be paid, we do not consider the exportation of the silver for that purpose as any consequence of the disorder of the coin. But besides this exportation which is necessary, there are others which are arbitrary, and which are made only with a view to profit of the wrong proportion.

When the money-jobbers find difficulty in carrying on the traffic we have described, in the English market, because of the competition among themselves, they carry the silver coin out of the country, and sell it abroad for gold, upon the same principles that the East India company send silver to China, in order to purchase gold.

It may be demanded, what hurt this trade can do to England, since those who export silver bring back the same value in gold? Were this trade carried on by natives, there would be no loss; because they would bring home gold for the whole intrinsic value of the silver. But if we suppose foreigners sending over gold to be coined at the English mint, and changing that gold into English silver coin, and then carrying off this coin, it is plain that they must gain the difference, as well as the money jobbers. But it may be answered, that having given gold for silver at the rate of the mint, they have given value for what they have received. Very right; but so did Sir Hans Sloane, when he paid five guineas for an overgrown toad: he got value for his money; but it was value only to himself. Just so, whenever the English government shall be obliged to restore the proportion of the metals, (as they must do,) this operation will annihilate that imaginary value which they have bitherto set upon gold; which imagination is the only thing which renders the exchange of their silver against the foreign gold equal.

But it is farther objected, that foreigners cannot carry off the heavy silver; because there is none to carry off. Very true; but then they have carried off a great quantity already: or if the English Jews have been too sharp to allow such a profit to fall to strangers, (which may or may not have been the case,) then this disorder is an effectual step to any more coinage of silver for circulation.

Of the disorder in the British coin, so far as it affects the value of the pound sterling currency.

From what has been said, it is evident, that there must be found in England two legal pounds sterling, of different values; the one worth 113 grains of fine gold, the other worth 1718.7 grains of fine silver. We call them different; because these two portions of the precious metals are of different values all the over Europe.

But besides these two different pounds sterling, which the change in the proportion of the metals have created, the other defects of the circulating coin produce similar effects. The guineas coined by all the Princes since K. Charles II. have been of the same standard weight and fineness, 44\(\frac{1}{4}\) in a pound troy of standard gold \(\frac{1}{2}\) fine: these have been constantly wearing ever since they have been coined; and in proportion to their wearing they are of less value.

If, therefore, the new guineas are below the value of a pound sterling in silver, standard weight, the old must be of less value still. Here then is another currency, that is, another pound sterling; or indeed, more properly speaking, there are as many different pounds sterling, as there are guineas of different weights. This is not all; the money jobbers having carried off all the weighty silver; that which is worn with use, and reduced even below the standard of gold, forms one currency more, and totally destroys all determinate proportion between the money unit and the currencies which are supposed to represent it.

It may be asked, how, at this rate, any silver has remained in England? It is answered, that the few weighty shillings which still remain in circulation, have marvelously escaped the hands of the money-jobbers; and as for the rest, the rubbing and wearing of these pieces has done
done what the state might have done; that is to say, it has reduced them to their due proportion with the lightest gold.

The disorder, therefore, of the English coin has rendered the standard of a pound sterling quite uncertain. To say that it is 1718.7 grains of fine silver, is quite ideal. Who are paid in rich pounds? To say that it is 113 grains of pure gold, may also not be true; because there are many currencies worse than the new guineas.

What then is the consequence of all this disorder? What effect has it upon the current value of a pound sterling? And which way can the value of that be determined?

The operations of trade bring value to an equation, notwithstanding the greatest irregularities possible, and so in fact a pound sterling has acquired a determinate value over all the world by the means of foreign exchange. This is a kind of ideal scale for measuring the British coin, although it has not all the properties of that described above.

Exchange considers the pound sterling as a value determined according to the combination of the values of all the different currencies, in proportion as payments are made in the one or the other; and as debtors generally take care to pay in the worst species they can, it consequently follows, that the value of the pound sterling should fall to that of the lowest currency.

Were there a sufficient quantity of worn gold and silver to acquit all bills of exchange, the pound sterling would come down to the value of them; but if the new gold be also necessary for that purpose, the value of it must be proportionally greater.

All these combinations are liquidated and compensated with one another, by the operations of trade and exchange: and the pound sterling, which is so different is itself, becomes thereby, in the eyes of commerce, a determinate unit, subject however to variations, from which it never can be exempted.

Exchange, therefore, is one of the best measures for valuing a pound sterling, present currency. Here occurs a question:

Does the great quantity of paper money in England tend to diminish the value of the pound sterling?

We answer in the negative. Paper money is just as good as gold or silver money, and no better. The variation of the standard; we have already said, must influence the interests of debtors and creditors proportionally everywhere. From this it follows, that all augmentation of the value of the money unit in the specie must hurt the debtors in the paper money; and all diminutions, on the other hand, must hurt the creditors in the paper money as well as every where else. The payments, therefore, made in paper money, never can contribute to the regulation of the standard of the pound sterling; it is the specie received in liquidation of that paper money which alone can contribute to mark the value of the British unit; because it is affixed to nothing else.

From this we may draw a principle, "That in countries where the money unit is entirely affixed to the coin, the actual value of it is not according to the legal standard of that coin, but according to the mean proportion of the actual worth of those currencies in which debts are paid.

From this we see the reason why the exchange between England and all other trading towns in Europe has long appeared so unfavourable. People calculate the real par, upon the supposition that a pound sterling is worth 1718.7 grains troy of fine silver, when in fact the currency is not perhaps worth 1638, the value of a new guinea in silver, at the market proportion of 1 to 14.3; that is to say, the currency is but 95.3 per cent of the silver standard of the 43d of Elizabeth. No wonder then if the exchange be thought unfavourable.

From the principle we have just laid down, we may gather a confirmation of what we advanced concerning the cause of the advanced price of bullion in the English market.

When people buy bullion with current money at a determinate price, that operation, in conjunction with the course of exchange, ought naturally to mark the actual value of the pound sterling with great exactness.

If therefore the price of standard bullion in the English market, when no demand is found for the exportation of the metals, that is to say, when paper is found for paper upon exchange, and when merchants versed in these matters judge exchange (that is, remittances) to be at par, if then, silver bullion cannot be bought at a lower price than 65 pence the ounce, it is evident that this bullion might be bought with 65 pence in shillings, of which 65 might be coined out of the pound troy English standard silver; since 65 per ounce implies 65 shillings for the 12 ounces or pound troy.

This plainly shews how standard silver bullion should sell for 65 pence the ounce, in a country where the ounce of standard silver in the coin is worth no more than 62; and were the market price of bullion to stand uniformly at 65 pence per ounce, that would shew the value of the pound sterling to be tolerably fixed. All the heavy silver coin is now carried off; because it was intrinsically worth more than the gold it passed for in currency. The silver therefore which remains is worn down to the market proportion of the metals, as has been said; that is to say, 20 shillings in silver currency are worth 113 grains of fine gold, at the proportion of 1 to 14.5 between gold and silver. Now, as 1 is to 14.5, so is 113 to 1638.

So the 20 shillings current weight but 1638 grains fine silver, instead of 1718.7, which they ought to do according to the standard.

Now let us speak of standard silver, since we are examining how far the English coin must be worn by use.

The pound troy contains 5760 grains. This, according to the standard, is coined into 62 shillings; consequently, every shilling ought to weigh 92.9 grains. Of such shillings it is impossible that ever standard bullion should sell at above 62 pence per ounce. If therefore bullion sells for 65 pence, the shillings with which it is bought must weigh no more than 88.64 grains standard silver; that is, they must lose 4.29 grains, and are reduced to 3/8 of a pound troy.

But it is not necessary that bullion be bought with shillings; no fluctuation of price is ever made farther, than at so many pence sterling per ounce. Does not this virtually determine the value of such currency with regard to it?
The price of bullion, therefore, when it is not influenced by extraordinary demand, (such as for the payment of a balance of trade, or for making an extraordinary provision of plate) but when it stands at what everybody knows to be meant by the common market price, is a very tolerable measure of the value of the actual money standard in any country.

If it be therefore true, that a pound sterling cannot purchase above $658$ grains of fine silver bullion, it will require not a little logic to prove that it is really, or has been for these many years, worth any more; notwithstanding the standard weight of it in England is regulated by the laws of the kingdom at $1718.7$ grains of fine silver.

If to this valuation of the pound sterling drawn from the price of bullion, we add the other drawn from the course of exchange; and if by this we find, that when paper is found for paper upon exchange, a pound sterling cannot purchase above $658$ grains of fine silver in any country in Europe; upon these two authorities we may very safely conclude (as to the matter of fact at least,) that the pound sterling is not worth more, either in London or in any other trading city; and if this be the case, it is just worth $20$ shillings of $65$ to the pound troy.

If therefore the mint were to coin shillings at that rate, and pay for silver bullion at the market price, that is, at the rate of $65$ pence per ounce in those new coined shillings, they would be in proportion to the gold; silver would be carried to the mint equally with gold, and would be as little subject to be exported or melted down.

It may be inquired in this place, how far the coining the pound troy into $65$ shillings is contrary to the laws of England?

The moment a state pronounces a certain quantity of gold to be worth a certain quantity of silver, and orders the respective quantities of each metal to be made as equivalents of each other, and as lawful money in payments, that moment gold is made a standard as much as silver. If therefore too small a quantity of gold be ordered or permitted to be considered as a standard for the unit, the silver standard is from that moment debased; or indeed, more properly speaking, all silver money is from that moment profligate; for who, from that time, will ever pay in silver, when he can pay cheaper in gold?

Gold, therefore, by such a law, is made the standard, and all declarations to the contrary are against the matter of fact.

Were the king, therefore, to coin silver at $65$ shillings in the pound, it is demonstration, that by such an act he would commit no adulteration upon the standard: the adulteration is already committed. The standard has descended to where it is, by slow degrees, and by the operation of political causes only; and nothing prevents it from falling lower, but the standard of the gold coin. Let guineas be now left to seek their value as they did formerly, and let light silver continue to go by tale, we shall see the guineas up at $30$ shillings in $20$ years time, as was the case in 1695.

It is as absurd to say that the standard of Queen Elizabeth has not been debased by enacting that the English unit shall be acquainted with $113$ grains of fine gold, as it would be to affirm that it would not be debased from what it is at present by enacting that a pound of butter should everywhere be received in payment for a pound sterling; although the pound sterling should continue to consist of $3$ ounces, $17$ pennyweights, and $10$ grains of standard silver, according to the statute of the $43d$ of Elizabeth. In that case most debtors would pay in butter, and silver would, as at present, acquire a conventional value as a metal, but would be looked upon no longer as a standard, or as money.

If therefore, by the law of England, a pound sterling must consist of $1718.7$ grains troy of fine silver; by the law of England also, $113$ grains of gold must be of the same value; but no law can establish that proportion; consequently, in which ever way a reformation be brought about, some law must be revered; consequently, expediency, and not compliance with law, must be the motive in reforming the abuse.

From what has been said, it is not at all surprising that the pound sterling should in fact be reduced nearly to the value of the gold. Whether it ought to be kept at that value is another question. All that we here decide is, that coining the pound troy into $65$ shillings would restore the proportion of the metals, and render both species common in circulation. But restoring the weight and proportion of the coin is not the difficulty which prevents a reformation of the English coinage.

Circumstances to be attended to in a new regulation of the British coin.

To people who do not understand the nature of such operations, it may have an air of justice to support the unit at what is commonly believed to be the standard of Queen Elizabeth, to wit, at $1718.5$ grains of fine silver.

The regulating the standard of both silver and gold to $113$ fine, and the pound sterling to four ounces standard silver, as it stood during the reign of Queen Mary I. has also its advantages, as Mr Harris has observed. It makes the crown piece to weigh just one ounce, the shilling four penny weight, and the penny eight grains; consequently, were the new statute to bear, that the weight of the coin should regulate its currency upon certain occasions, the having the pieces adjusted to certain aliquot parts of weight would make weighing easy, and would accustom the common people to judge of the value of money by its weight, and not by the stamp.

In that case, there might be a convenience in striking the gold coins of the same weight with the silver; because the proportion of their values would then constantly be the same with the proportion of the metals. The gold crowns would be worth at present, 3l. 12s. 6d. the
half crowns 17. 16 s. 3 d. the gold shillings 14 s. and 6 d.
and the half 7 s. and 3 d. This was anciently the prac-
tice in the Spanish mints.

The interests within the state can be no wise perfectly protected but by permitting conversions of value from the old to the new standard, whatever it be, and by regulating the footing of such conversions by act of parliament, according to circumstances.

For this purpose, we shall examine those interests which will chiefly merit the attention of government, when they form a regulation for the future of acquitting permanent contracts already entered into. Such as may be contrac-
ted afterwards will naturally follow the new standard.

The landed interest is, no doubt, the most considerable in the nation. Let us therefore examine, in the first place, what regulations it may be proper to make, in or-
der to do justice to this great class, with respect to the land-tax on one hand, and with respect to their leases on the other.

The valuation of the lands of England was made many years ago, and reasonably ought to be supported at the real value of the pound sterling at that time, according to the principles already laid down. The general valua-
tion, therefore, of the whole kingdom will rise according to this scheme. This will be considered as an injustice; and no doubt it would be so, if, for the future, the land tax be imposed as heretofore, without attending to this circumstance; but as that imposition is annual, as it is laid on by the landed interest itself, who compose the parliament, it is to be supposed that this great class will at least take care of their own interest.

Were the valuation of the lands to be fixed according to the valuation of the pound sterling of 1718 7 grains of silver, which is commonly supposed to be the standard of Elizabeth, there would be no great injury done: this would raise the valuation only 5 per cent. and the land tax in proportion.

There is no class of inhabitants in all England so much at their ease, and so free from taxes, as the class of far-
mers. By living in the country, and by consuming the fruits of the earth without their suffering any alienation, they avoid the effect of many excises, which, by those who live in corporations, are felt upon many articles of their consumption, as well as on those which are immedi-
ately loaded with these impositions. For this reason it will not, perhaps, appear unreasonable, if the addi-
tional 5 per cent. on the land tax were thrown upon this class, and not upon the landlords.

With respect to leases, it may be observed, that we have gone upon the supposition that the pound sterling in the year 1728, was worth 1718.7 grains of fine silver, and 113 grains of fine gold.

There would be no injustice done the lessors of all the lands in the kingdom, were their rents to be fixed at the mean proportion of these values. We have observed how the pound sterling has been gradually diminishing in its worth from that time by the gradual rise of the silver. This mean proportion, therefore, will nearly answer to what the value of the pound sterling was in 1743; sup-
poing the rise of the silver to have been uniform.

It may be farther alleged in favour of the landlords,
action of the month of December 1749. The great sums borrowed and paid back by the nation during that period will furnish data sufficient for that calculation. Let this value of the pound be specified in Troy grains of fine silver and fine gold bullion, without mentioning any denomination of money according to the exact proportion of the metals at that time. And let this pound be called the pound of national credit.

This first operation being determined, let it be estimated, that the pound sterling, by which the state is to borrow for the future, and that in which the creditors are to be paid, shall be the exact mean proportion between the quantities of gold and silver above specified, according to the actual proportion of the metals at the time such payments shall be made; or that the sums shall be borrowed or acquitted, one half in gold and one half in silver, at the respective requisitions of the creditors or of the state, when borrowing. All debts contracted posterior to 1749 may be made liable to conversions.

The consequence of this regulation will be the insensible establishment of a bank money. Nothing would be more difficult to establish, by a positive resolution, than such an invariable measure; and nothing will be found so easy as to let it establish itself by its own advantages. This bank money will be liable to much fewer inconveniences than that of Amsterdam. There the persons transacting must be upon the spot; here, the flerling currency may, every quarter of a year, be adjusted by the exchequer to this invariable standard, for the benefit of all debtors and creditors, who incline to profit of the stability of this measure of value.

This scheme is liable to no inconvenience from the variation of the metals, let them be ever so frequent, or hard to be determined; because upon every occasion where there is the smallest doubt as to the actual proportion, the option competent to creditors to be paid half in silver and half in gold will remove.

Such a regulation will also have this good effect, that it will give the nation more just ideas of the nature of money, and consequently of the influence it ought to have upon prices.

If the value of the pound sterling shall be found to have been by accident less in December 1749, than it is at present; or if at present the currency be found below what has commonly been since 1749, in justice to the creditors, and to prevent all complaints, the nation may grant them the mean proportion of the value of the pound sterling from 1749 to 1760; or any other which may to parliament appear reasonable.

This regulation must appear equitable in the eyes of all Europe; and the strongest proof of it will be, that it will not produce the smallest effect prejudicial to the interest of the foreign creditors. The course of exchange with regard to them will stand precisely as before.

A Dutch, French, or German creditor, will receive the same value for his interest in the English docks as heretofore. This must silence all clamours at home, being the most convincing proof, that the new regulation of the coin will have made no alteration upon the real value of any man's property, let him be debtor or creditor.

The interest of every other denomination of creditors, whose contracts are of a fresh date, may be regulated upon the same principles. But where debts are of an old standing, justice demands, that attention be had to the value of money at the time of contracting. Nothing but the stability of the English coin, when compared with that of other nations, can make such a proposal appear extraordinary. Nothing is better known in France than this stipulation added to obligations, Argent au cours de ce jours; that is to say, that the sum shall be paid in coin of the same intrinsic value with what has been lent. Why should such a clause be thought reasonable for guarding people against arbitrary operations upon the numerary value of the coin, and not be found just upon every occasion where the numerary value of it is found to be changed, let the cause be what it will?

The next interest we shall examine is that of trade. When men have attained the age of twenty one, they have no more occasion for guardians. This may be applied to traders: they can party with their pen every inconvenience which may result to other people from the changes upon money, provided only the laws permit them to do themselves justice with respect to their engagements. This class demands no more than a right to convert all reciprocal obligations into denominations of coin of the same intrinsic value with those they have contracted in.

The next interest is that of buyers and sellers; that is, of manufacturers with regard to consumers, and of servants with respect to those who hire their personal service.

The interest of this class requires a most particular attention. They must, literally speaking, be put to school, and taught the first principles of their trade, which is buying and selling. They must learn to judge of price by the grains of silver and gold they receive. They are children of a mercantile mother, however warlike the father's disposition may be. If it be the interest of the state that their bodies be rendered robust and active, it is no less the interest of the state that their minds be instructed in the first principle of the trade they exercise.

For this purpose, tables of conversion from the old standard to the new must be made, and ordered to be put up in every market, in every shop. All duties, all excises, must be converted in the same manner. Uniformity must be made to appear everywhere. The smallest deviation from this will be a stumbling block to the multitude.

Not only the interest of the individuals of the class we are at present considering, demands the nation's care and attention in this particular; but the prosperity of trade, and the well-being of the nation, are also deeply interested in the execution.

The whole delicacy of the intricate combinations of commerce depends upon a just and equitable vibration of prices, according as circumstances demand it. The more therefore the insidious classes are instructed in the principles which influence prices, the more easily will the machine move. A workman then learns to fix his price without regret, and can raise it without avidity. When principles are not understood, prices cannot gently fall, they
they must be pulled down; and merchants dare not suffer them to rise, for fear of abuse, even although the perfection of an infant manufacture should require it.

The last interest is that of the bank of England, which naturally must regulate that of every other.

Had this great company followed the example of other banks, and established a bank money of an invariable standard, as the measure of all their debts and credits, they would not have been liable to any inconvenience upon a variation of the standard.

The bank of England was projected about the year 1694, at a time when the current money of the nation was in the greatest disorder, and government in the greatest distress, both for money and credit. Commerce was then at a very low ebb; and the only, or at least the most profitable trade of any, was jobbing in coin, and carrying backwards and forwards the precious metals from Holland to England. Merchants profited also greatly from the effects which the utter disorder of the coin produced upon the price of merchandise.

At such a juncture the resolution was taken to make a new coinage; and upon the prospect of this, a company was found, who, for an exclusive charter to hold a bank for 13 years, willingly lent the government upwards of a million sterling at 8 per cent. (in light money we suppose) with a prospect of being repaid both interest and capital in heavy. This was not all: part of the money lent was to be applied for the establishment of the bank; and no less than 4000 pounds a year was allowed to the company, above the full interest, for defraying the charge of management.

Under such circumstances the introduction of bank-money was very superfluous, and would have been very impolitic. That invention is calculated against the raising of the standard; but here the bank profited of that rise in its quality of creditor for the money lent, and took care not to commence debtor by circulating their paper, until the effect of the new regulation took place in 1695; that is, after the general recoinage of all the clipped silver.

From that time till now, the bank of England has been the basis of the nation's credit, and with great reason has been constantly under the most intimate protection of every minister.

The value of the pound sterling, as we have seen, has been declining ever since the year 1601, the standard being fixed to silver during all that century, while the gold was constantly rising. No sooner had the proportion taken another turn, and silver begun to rise, than the government of England threw the standard virtually upon the gold, by regulating the value of the guineas at the exact proportion of the market. By these operations, however, the bank has constantly been a gainer (in its quality of debtor) upon all the paper in circulation; and therefore has lost nothing by not having established a bank-money.

The interest of this great company being established upon the principles we have endeavoured to explain, it is very evident, that the government of England never will take any step in the reformation of the coin which in its consequences can prove hurtful to the bank. Such a step would be contrary both to justice and to common sense. To make a regulation which, by raising the standard, will prove beneficial to the public creditors, to the prejudice of the bank (which we may call the public debtor) would be an operation upon public credit, like that of a person who is at great pains to support his house by props upon all sides, and who at the same time blows up the foundation of it with gun-powder.

We may therefore conclude, that with regard to the bank of England, as well as to every other private banker, the notes which are constantly payable upon demand must be made liable to a conversion at the actual value of the pound sterling at the time of the new regulation.

That the bank will gain by this, is very certain; but the circulation of their notes is so swift that it would be absurd to allow to the then possessors of them that indemnification which naturally should be shared by all those through whose hands they have passed, in proportion to the debasement of the standard during the time of their respective possession.

Besides these considerations, which are in common to all states, the government of Great Britain has one peculiar to itself. The interest of the bank, and that of the creditors, are diametrically opposite: every thing which raises the standard, hurts the bank; every thing which can sink it, hurts the creditors: and upon the right management of the one and the other, depends the solidity of public credit. For these reasons, without the most certain prospect of conducting a refutlation of the standard to the general advantage as well as approbation of the nation, no minister will probably ever undertake so dangerous an operation.

We shall now propose an expedient which may remove at least some of the inconveniences which would result from so extensive an undertaking as that of regulating the respective interests in Great Britain by a positive law, upon a change in the value of their money of account.

Suppose then, that, before any change is made in the coin, government should enter into a transaction with the public creditors, and ascertain a permanent value for the pound sterling for the future, specified in a determined proportion of the fine metals in common bullion, without any regard to money of account, or to any coin whatever.

This preliminary step being taken, let the intended alteration of the standard be proclaimed a certain time before it is to commence. Let the nature of the change be clearly explained, and let all such as are engaged in contracts which are dissoluble at will upon the prefcriptions stipulated, be acquitted between the parties, or innovated as they shall think proper, with certification, that, posterior to a certain day, the stipulations formerly entered into shall be binding according to the denominations of the money of account in the new standard.

As to permanent contracts, which cannot at once be fulfilled and dissolved, such as leases, the parliament may either prescribe the methods and terms of conversion; or a liberty may be given to the parties to annul the contract, upon the debtor's refusing to perform his agreement according to the new standard. Contracts, on the other hand, might remain liable, with respect to credi-
tors who would be satisfied with payments made on the footing of the old standard. If the rise intended should not be very considerable, no great injustice can follow such a regulation.

Annuities are now thoroughly understood, and the value of them is brought to so nice a calculation, that nothing will be easier than to regulate these upon the footing of the value paid for them, or of the subject affected by them. If by the regulation land rents are made to rise in denomination, the annuities charged upon them, ought to rise in proportion; if in intrinsic value, the annuity should remain as it was.

Regulations which the principles of this inquiry point out as expedient to be made by a new statute for regulating the British coin.

Let us now examine what regulations it may be proper to make by a new statute concerning the coin of Great Britain, in order to preserve always the same exact value per to make by a new statute concerning the coin of Great Britain, in order to preserve always the same exact value per pound troy fine.

The first point is to determine the exact number of grains of fine gold and fine silver which are to compose it, according to the proportion of the metals in the London market.

Let the new proportion between the market price of the metals be called \( P \) and \( S \).

1. To determine the proportion of these metals with the pound troy, and in regard that the standard of gold and silver is different, let the mint price of both metals be regulated according to the pound troy fine.

2. To fix the mint price within certain limits: that is to say, to leave to the King and Council, by proclamation, to carry the mint price of bullion up to the value of the coin, as is the present regulation, or to fix it to per cent. below that price, according as government shall incline to impose a duty upon coinage.

3. To determine the proportion of the metals above the pound troy fine, and in regard that the standard of gold and silver is different, let the mint price of bullion be regulated according to the pound troy fine.

4. To order, that silver and gold coin shall be struck of such denominations as the King shall think fit to appoint; in which the proportion of the metals above determined shall be constantly observed through every denomination of the coin, until necessity shall make a new general coinage unavoidable.

5. To have the number of grains of the fine metal in every piece marked upon the exergue, or upon the legend of the coin, in place of some initial letters of titles, which not one person in a thousand can decipher; and to make the coin of as compact a form as possible, diminishing the surface of it as much as is consistent with beauty.

6. That it shall be lawful for all contracting parties to stipulate their payments either in gold or silver coin, or to leave the option of the species to one of the parties.

7. That where no particular stipulation is made, creditors shall have power to demand payment, half in one species, half in the other; and when the sum cannot fall equally into gold and silver coins, the fractions to be paid in silver.

8. That in buying and selling, when no particular species has been stipulated, and when no act in writing has intervened, the option of the species shall be competent to the buyer.

9. That all sums paid or received by the King’s receivers, or by bankers, shall be delivered by weight, if demanded.

10. That all money which shall be found under the legal weight, from whatever cause it may proceed, may be rejected in every payment whatsoever; or if offered in payment of a debt above a certain sum, may be taken according to its weight, at the then mint price, in the option of the creditor.

11. That no penalty shall be incurred by those who melt down or export the nation’s coin; but that washing, clipping, or diminishing the weight of any part of it shall be deemed felony, as much as any other theft, if the person so degrading the coin shall afterwards make it circulate for lawful money.

To prevent the inconveniences proceeding from the variation in the proportion between the metals, it may be provided,

12. That upon every variation of proportion in the rise in denomination, the annuities charged upon them shall be regulated according to the following rule.

Let the price of the pound troy fine gold in the coin be called \( G \).

13. That no penalty shall be incurred by those who melt down or export the nation’s coin; but that washing, clipping, or diminishing the weight of any part of it shall be deemed felony, as much as any other theft, if the person so degrading the coin shall afterwards make it circulate for lawful money.

To prevent the inconveniences proceeding from the variation in the proportion between the metals, it may be provided,

12. That upon every variation of proportion in the rise in denomination, the annuities charged upon them shall be regulated according to the following rule.

Let the price of the pound troy fine gold in the coin be called \( G \).

13. That no penalty shall be incurred by those who melt down or export the nation’s coin; but that washing, clipping, or diminishing the weight of any part of it shall be deemed felony, as much as any other theft, if the person so degrading the coin shall afterwards make it circulate for lawful money.

To prevent the inconveniences proceeding from the variation in the proportion between the metals, it may be provided,
Let the guinea be called $G$. Let the difference between the old proportion and the new, which is $\frac{1}{20}$, be called $P$. Then lay,

$$S - \frac{P}{2} = \text{a pound sterling}, \quad \text{and } G + \frac{P}{2} = \text{a pound sterling}.$$

By this it appears that all the silver coin must be raised in its denomination $\frac{1}{20}$, and all the gold coin must be lowered in its denomination $\frac{1}{20}$; yet still $S + G$ will be equal to two pounds sterling, as before, whether they be considered according to the old, or according to the new denominations.

But it may be observed, that the imposition of coinage rendering the value of the coin greater than the value of the bullion, that circumstance gives a certain latitude in fixing the new denominations of the coin, so as to avoid minute fractions. For, providing the deviation from the exact proportion shall fall within the advanced price of the coin, no advantage can be taken by melting down one species preferably to another; since, in either case, the losses incurred by melting the coin must be greater than the profit made upon selling the bullion. The mint price of the metals, however, may be fixed exactly, that is, within the value of a farthing upon a pound of fine silver or gold. This is easily reckoned at the mint; although upon every piece in common circulation the fractions of farthings would be inconvenient.

15. That notwithstanding the temporary variations made upon the denomination of the gold and silver coins, all contracts formally entered into, and all stipulations in pounds shillings and pence, may continue to be acquit according to the old denominations of all foreign money of account, except as bullion at the actual price of the mint, or refused at the option of the creditor.

16. That notwithstanding the alterations on the mint price of the metals, and in the denomination of the coins, no change shall be made upon the weight of the particular pieces of the latter, except in the case of a general recoining of one denomination at least: that is to say, the mint must not coin new guineas, crowns, &c., of a different weight from those already in currency, although by so doing the fractions might be avoided. This would occasion confusion, and the remedy would cease to be of any use upon a new change in the proportion of the metals. But it may be found convenient, for removing the small fractions in shillings and sixpences, to recoin such denominations all together, and to put them to their integer numbers, of twelve and of six pence, without changing in any respect their proportion of value to all other denominations of the coin: this will be no great expense, when the bulk of the silver coin is put into 5 shilling pieces.

By this method of changing the denominations of the coin, there never can result any alteration in the value of the pound sterling: and although fractions of value may now and then be introduced, in order to prevent the abuses to which the coin would otherwise be exposed by the artifice of those who melt it down, yet still the inconvenience of such fractions may be avoided in paying, according to the old denominations, in both species, by equal parts. This will also prove demonstratively, that no change is thereby made in the true value of the national unit of money.

17. That it be ordered, that shillings and sixpences shall only be current for twenty years, and all other coins, both gold and silver, for forty years, or more. For ascertaining which term, there may be marked, upon the exergue of the coin, the last year of their currency, in place of the date of their fabrication. This term elapsed, or the date effaced, that they shall have no more currency whatsoever; and when offered in payment, may be received as bullion at the actual price of the mint, or refused at the option of the creditor.

18. That no foreign coin shall have any legal currency, except as bullion at the mint price.

By these or the like regulations may be prevented, 1. The melting or exporting of the coin in general, 2. The melting or exporting one species, in order to sell it as bullion, at an advanced price. 3. The profit in acquiring obligations preferably in one species to another. 4. The degradation of the standard, by the wearing of the coin, or by a change in the proportion between the metals. 5. The circulation of the coin below the legal weight. 6. The profit that other nations reap by paying their debts more cheaply to Great Britain than Great Britain can pay hers to them. And the great advantage of it is, that it is an uniform plan, and may serve as a perpetual regulation, compatible with all kinds of denominations of coins, variations in the proportion of the metals, and with the imposition of a duty upon coinage; or with the preferring it free; and further, that it may in time be adopted by other nations, who will find the advantage of having their money of account preferred perpetually at the same value, with respect to the denominations of all foreign money of account established on the same principles.

#### TABLE OF COINS,
MONK, a person who wholly dedicates himself to the service of religion, in some monastery, under the direction of some particular rules and rules.

The most probable account of the original of the monks is, that in the Decian persecution, in the middle of the third century, many persons in Egypt, to avoid the fury of the storm, fled to the neighboring deserts and mountains, where they not only found a safe retreat, but also more time and liberty to exercise themselves in acts of pious and divine contemplations; which sort of life became so agreeable, that when the persecution was over, they refused to return to their habitations again, choosing rather to continue in these cottages and cells, which they had made for themselves in the wilderness. From that time to the reign of Constantine, monachism was confined to the hermits or anchorites, who lived in private cells in the wilderenss; but when Pachominus had erected monasteries, other countries presently followed the example.

MONKEY, in zoology. See Simia.

MONMOUTH, the capital of Monmouth-shire, situated on the river Wye, twenty-five miles north of Bristol.

MONOCHORD, a musical instrument, composed of one string, used to try the variety and proportion of sounds.

MONOCULUS, in zoology, a genus of the order of aperta. The feet are fitted for swimming; the body is covered with a crustaceous skin; and the eyes are very near each other. There are nine species.

MONODON, in ichthyology, a genus of fishes belonging to the order of benth. It has a long wreathed tooth in the upper jaw, which perforates the upper-lip, and has the appearance of a horn; from this circumstance it has got the name of the unicorn-fish. This fish is of the whale kind, and often grows to 25 feet in length, though the general size is from 16 to 20.

MONODY, in ancient poetry, a mournful kind of song, sung by a person alone, to give vent to his grief.

MONOECLA, in botany. See Botany, p. 635.

MONOGAMY, the state or condition of those who have only been once married, and are restrained to a single wife.

MONOGRAM, a character or cypher, composed of one letter, more letters, interwoven; being a kind of abbreviation of a name, anciently used as a seal, badge, arms, &c.

MONOLOGUE, in poetry, a dramatic scene, in which a person appears alone on the stage, and speaks to himself.

MONOMOTOPA, a country of Africa, bounded by Monemugi on the north, and by Caffaria on the east, south, and west.

MONOPETALOUS, in botany, a term applied to flowers that have only one petal, or flower-leaf.

MONOPOL, a town in the kingdom of Naples, situated on the gulf of Venice: E. long. 18°, and N. lat. 4° 5'.

MONOPOLY, one or more persons making themselves the sole makers of the whole of a commodity, manufacture, and the like, in order to make private advantage of it, by selling it again at a very advanced price.

MONOPYRENEOUS, in botany, such fruit as contains only one seed, or kernel.

MONOSTICH, an epigram that consists of only one line verse.

MONOSYLLABLE, in grammar, a word that consists of only one syllable, and is composed of either one or more letters pronounced at the same time.

MONOTONY, an uniformity of sound, or a fault in pronunciation, when a long series of words are delivered in one unvaried tone.

MONOTROPA, in botany, a genus of the decandria monogynia class. It has no calyx; the petals are ten; and it has five capsules. There are two species, one of which, viz. the hypopithys, or bird's nest-smelling, like the roots of the primrose, is a native of Britain.

MONS, the capital of the province of Hainaut, in the Austrian Netherlands: situated twenty-six miles south-west of Brussels: easterly long. 3° 33', and southerly lat. 50° 34'.

MONSIEUR, a title of civility used by the French, in speaking to, or of their equals, or those that are but a little below them, synonymous with Sir in English.

MONSOON, in physiology, a species of trade wind, in the East-Indies, which for six months blows conjunctly the same way, and in the contrary way the other six months. See Pneumatics, Of Winds.

MONSTER, in general, denotes any production that deviates from the species to which it belongs, whether with respect to the number or disposition of its parts; in which sense, a man with six fingers on each hand, or six toes on each foot, is a monster. But the term monster seems to be chiefly applied to such productions as deviate very much from the ordinary course of nature.

MONTE SANTO, or MOUNT-ATHOS, a mountain of European Turkey, in the province of Macedonia: E. long. 23°, and N. lat. 40° 12'.

It is called Monte Sancto, or Holy Mountain, from twenty two monasteries situated upon it, in which are four thousand monks or friars, who never suffer a woman to come within sight of their convent.

MONTFERRAT, a duchy in Italy, bounded by the lordship of Vercell on the north, by the Alexandr in on the east, by the territory of Genoa on the south, and by the county of Afti on the west.

MONTFORT, the capital of the county of Montfort, in the circle of Swabia, in Germany: E. long. 9° 40', and N. lat. 47° 15'.

MONTGOMERY, the capital of Montgomeryshire, in Wales, situated on the river Severn, twenty miles south-west of Shrewsbury.

MONTH, the twelfth part of a year. See Astronomy.

MONTIA, in botany, a genus of the triandria trigynia class. The calyx consists of one leaf, and the corolla of one irregular petal; and the capsule has one cell and three valves. There is but one species, viz. the lentana, or water chickweed, a native of Britain.
MORAL PHILOSOPHY, or MORALS.

MORAL PHILOSOPHY is "The science of manners or duty; which it traces from man's nature and condition, and shews to terminate in his happiness." In other words, it is "The knowledge of our duty and felicity;" or, "The art of being virtuous and happy."

It is denominated an art, as it contains a system of rules for becoming virtuous and happy. Whoever practice or defigns rules, attains an habitual power or facility of performing virtuous and happy actions. It is likewise called a science, as it deduces those rules from the principles and connexions of our nature, and proves that the observance of them is productive of our happiness.

It is an art, and a science, of the highest dignity, importance, and use. Its object is man's duty, or his conduct in the several moral capacities and connections which he sustains. Its office is to direct or decide that conduct; to shew whence our obligations arise, and where they terminate. Its use, or end, is the attainment of happiness; and the means it employs are rules for the right conduct of our moral powers.

Moral Philosophy has this in common with Natural Philosophy, that it appeals to nature or fact; depends on observation; and builds its reasonings on plain uncontroverted experiments, or upon the fullest induction of particulars of which the subject will admit. We must observe, in both these sciences, how nature is affected, and what her conduct is in such and such circumstances. Or,

in other words, we must collect the appearances of nature in any given instance; trace these to some general principles, or laws of operation; and then apply these principles or laws to the explaining of other phenomena.

Therefore Moral Philosophy inquires, not how man might have been, but how he is, constituted: not into what principles or dispositions his actions may be artfully resolved; but from what principles and dispositions they actually flow: not what he may, by education, habit, or foreign influence, come to be, or do; but what, by his nature, or original constituent principles, he is formed to be and do. We discover the office, use, or definition of any work, whether natural or artificial, by observing its structure, the parts of which it consists, their connection or joint action. It is thus we understand the office and use of a watch, a plant, an eye, or hand. It is the same with a living creature, of the rational, or brute kind. Therefore, to determine the office, duty, or definition of a man; or, in other words, what his business is, or what conduct he is obliged to pursue; we must inspect his constitution, take every part to pieces, examine their mutual relations, serve to the other, and the common effort or tendency of the whole.

Of Man and his connections.

Man is born a weak, helpless, delicate creature; unsaved, unprovided with food, clothing, and whatever else is necessary for subsistence, or defence. And yet, exposed as he

by MONTIFRINGILLA, in zoology. See Fringilla.

MONTPELIER, a city of France, in the province of Languedoc and county of Nîmes, situated on the little river Lez, fifty miles north-east of Narbonne, and forty-five miles south-west of Avignon; a place famous for its delightful situation, and its healthy serene air.

MONTREAL, a city of Sicily, in the province of Messara, situated near the sea, five miles east of Palermo.

MONTROSE, a town of North Britain, in the shire of Angus, situated at the mouth of the river Elk, on the German ocean, forty-six miles north-east of Edinburgh.

Steel spaws are very numerous in the country about Montrose; besides these, there is a well near this town whose water is of a whitish colour, soft taste, and faintly discovering a mineral quality, and is of a different nature from the steel one. It is universally diuretic; and has been found useful in stranguries, fluxes of urine, scrofulous disorders, flatulencies, &c.

MONTSEFRA is also a town of Canada, in North America, situated on the river St Laurence, one hundred miles south of Quebec.

MONTROSE, a town of North Britain, in the shire of Angus, situated at the mouth of the river Elk, on the German ocean, forty-six miles north-east of Edinburgh.

Steel spaws are very numerous in the country about Montrose; besides these, there is a well near this town whose water is of a whitish colour, soft taste, and faintly discovering a mineral quality, and is of a different nature from the steel one. It is universally diuretic; and has been found useful in stranguries, fluxes of urine, scrofulous disorders, flatulencies, &c.

MORAL PHILOSOPHY is "The science of manners or duty; which it traces from man's nature and condition, and shews to terminate in his happiness." In other words, it is "The knowledge of our duty and felicity;" or, "The art of being virtuous and happy."

It is denominated an art, as it contains a system of rules for becoming virtuous and happy. Whoever practises these rules, attains an habitual power or facility of performing virtuous and happy actions. It is likewise called a science, as it deduces these rules from the principles and connexions of our nature, and proves that the observance of them is productive of our happiness.

It is an art, and a science, of the highest dignity, importance, and use. Its object is man's duty, or his conduct in the several moral capacities and connexions which he sustains. Its office is to direct that conduct; to shew whence our obligations arise, and where they terminate. Its use, or end, is the attainment of happiness; and the means it employs are rules for the right conduct of our moral powers.

Moral Philosophy has this in common with Natural Philosophy, that it appeals to nature or fact; depends on observation; and builds its reasonings on plain uncontroverted experiments, or upon the fullest induction of particulars of which the subject will admit. We must observe, in both these sciences, how nature is affected, and what her conduct is in such and such circumstances. Or,
the infant is to numberless wants and dangers, he is utterly incapable of supplying the former, or securing himself against the latter. But, though thus feeble and exposed, he finds immediate and sure resources in the affection and care of his parents, who refuse no labours, and forego no dangers, to nurse and rear up the tender babe. By these powerful instincts, as by some mighty chain, does nature link the parent to the child, and form the strongest moral connection on his part, before the child has the least apprehension of it. Hunger and thirst, with all the sensations that accompany or are connected with them, explain themselves by a language strongly expressive, and irresistibly moving. As the several senses bring in notices and informations of surrounding objects, we may perceive in the young spectator early signs of a growing wonder and admiration. Bright objects and striking sounds are beheld and heard with a fort of com-}
the wants of one period supplied by the capacities of another, and the weaknesses of one age tally to the passions of another.

Besides these, there are other passions and affections of a less amulatory nature; not peculiar to one period, but belonging to every age; and acting more or less in every breath throughout life; such as, for love, benevolence, love of life, honour, shame, hope, fear, desire, aversion, joy, sorrow, anger, and the like. The two first are affections of a cooler strain; one pointing to the good of the individual, the other to that of the species: joy, and sorrow, hope and fear, seem to be only modifications, or different exertions of the same original affections of love and hatred, desire and aversion, arising from the different circumstances or position of the object desired or abhorred, as it is present or absent. From these likewise rise other secondary, or occasional passions, which depend, as to their existence and several degrees, upon the original affections being gratified or disappointed; as, anger, complacency, confidence, jealousy, love, hatred, objection, exaltation, contentment, disgust, which do not form leading passions, but rather hold of them.

By these simple, but powerful springs, whether periodical or fixed, the life of man, weak and indigent as he is, is preferred and secured; and the creature is prompted to a constant round of action, even to supply his own numerous and ever-returning wants, and to guard against the various dangers and evils to which he is obnoxious. By these links, men are connected with each other, formed into families, drawn into particular communities, and all united, as by a common league, into one system or body, whose members feel and sympathize one with another. By this admirable adjustment of the constitution of man to his frame, and the gradual evolution of his powers, order is maintained, society upheld, and human life filled with that variety of passion and action, which at once enliven and diversify it.

This is a short sketch of the principal movements of the human mind. Yet these movements are not the whole of man; they impel to action, but do not direct it; they need a regulator to guide their motions, to measure and apply their forces. And accordingly they have one that naturally superintends and directs their action. We are conscious of a principle within us, which examines, compares, and weighs things; notes the differences, observes the forces, and foresees the consequences of affections and actions. By this power we look back on past times, and forward into futurity, gather experiences, estimate the real and comparative value of objects, lay out schemes, contrive means to execute them, and settle the whole order and economy of life. This power we commonly distinguish by the name of reason, or reflection; the business of which is, not to haggle any original notices or sensations, but to canvass, range, and make deductions from them.

We are intimately conscious of another principle within us, which approves of certain sentiments, passions, and actions, and disapproves of their contraries. In consequence of the decisions of this inward judge, we denominate some actions and principles of conduct right, beneficent, good; and others wrong, dishonest, ill. The former ex-
fignation of man, the having analyzed the principles of which he is composed. It is necessary, in the next place, to consider in what order, proportion, and measure of those inward principles, virtue, or a found moral temper and right conduct, consids; that we may discover whence moral obligations arise.

Of Duty, or Moral Obligation.

It is by the end or design of any power or movement, that we must direct it motions, and estimate the degree of force necessary to its just action. If it want the force requisite for the obtaining its end, we reckon it defective; if it has too much, so as to be carried beyond it, we say it is overcharged; and in either case it is imperfect, and ill contrived. If it has just enough to reach the scope, we esteem it right, and as it should be. Let us apply this reasoning to the passions.

The defence and security of the individual being the aim of the defensive passions, that security and defence must be the measure of their strength or indulgence. If they are so weak as to prove insufficient for that end, or if they carry us beyond it, i.e., raise unnecessary commotions, or continue longer than is needful, they are unfit to answer their original design, and therefore are in an unfound and unnatural state. The exercise of fear or of resentment has nothing desirable in it, nor can we give way to either without painful sensations. Without a certain degree of them, we are naked and exposed: with too high a proportion of them, we are miserable, and often injurious to others. Thus cowardice or timidity, which is the excess of fear, instead of saving us in danger, gives it too formidable an appearance, makes us incapable of attending to the best means of preservation, and disarms us of courage our natural armour. Fool-hardiness, which is the want of the due measure of fear, leads us heedlessly into danger, and lulls us into a pernicious security. Revenge, i.e., excessive resentment, by the violence of its commotion, robs us of that presence of mind which is often the best guard against injury, and inclines us to pursue the aggressor with more severity than self-defence requires. Puffillanimity, or the want of a just indignation against wrong, leaves us quite unguarded, and tends to sink the mind into a passive enervated tameness. Therefore, "to keep the defensive passions duly proportioned to our dangers, is their natural pitch and tenor."

The private passions lead us to pursue some positive species of private good. That good, therefore, which is the object and end of each, must be the measure of their respective force, and direct their operation. If they are too weak or flagitious to engage us in the pursuit of their several objects, they are evidently deficient; but if they defeat their end by their impetuosity, then are they strained beyond the just tone of nature. Thus vanity, or an excessive passion for applause, betrays into such mean and little arts of popularity, as makes us forfeit the honour we so anxiously court. On the other hand, a total indifference about the esteem of mankind, removes a strong guard and spur to virtue, and lays the mind open to the most abandoned professions. Therefore, "to keep our private passions and desires proportioned to our wants, is the just measure and pitch of this class of affections."

The defensive and private passions do all agree in general in their tendency or conduciveness to the interest or good of the individual. Therefore, when there is a collision of interests, as may sometimes happen, that aggregate of good or happiness, which is composed of the particular goods to which they respectively tend, must be the common standard by which their comparative degrees of strength are to be measured. That is to say, if any of them, in the degree in which they prevail, are incompatible with the greatest aggregate of good, or most extensive interest of the individual, then are they unequal and disproportionate. For, in judging of a particular system or conjunction of powers, we call that the supreme or principal end, in which the aims of the several parts or powers coincide, and to which they are subordinate; and reckon them in due proportion to each other, and right with regard to the whole, when they maintain that subordination or suberviency. Therefore, "to proportion our defensive and private passions in such measure to our dangers and wants, as belt to secure the individual, and obtain the greatest aggregate of private good or happiness, is their just balance or comparative standard in case of competition."

In like manner, as the public or social affections point at the good of others, that good must be the measure of their force. When a particular social affection, as gratitude or friendship, which belongs to a particular social connection, viz. that of a benefactor or of a friend, is too feeble to make us act the grateful or friendly part; that affection, being insufficient to answer its end, is defective and unfound. If, on the other hand, a particular passion of this class counteracts or defeats the interest it is designed to promote, by its violence or disproportion, then is that passion excessive and irregular. Thus natural affection, if it degenerates into a passionate fondness, not only renders the parents from judging coolly of the interest of their offspring, but often leads them into a most partial and pernicious indulgence.

As every kind affection points at the good of its particular object, it is possible there may be sometimes a collision of interests or goods. Thus the regard due to a friend may interfere with that which we owe to a community. In such a competition of interests, it is evident, that the greatest is to be chosen; and that is the greatest interest, which contains the greatest sum or aggregate of public good, greatest in quantity as well as duration. This then is the common standard, by which the respective forces and subordinations of the social affections must be adjusted. Therefore we conclude, that this "class of affections are found and regular, when they prompt us to pursue the interest of individuals in an entire consistency with the public good;" or, in other words, "when they are duly proportioned to the dangers and wants of others, and to the various relations in which we stand to individuals, or to society."

Thus we have found, by an induction of particulars, the natural pitch or tenor of the different orders of affection, considered apart by themselves. Now as the virtue or perfection of every creature lies in following its nature,
or acting suitably to the just proportion and harmony of its several powers; therefore, "the virtue of a creature endowed with such affections as man, must consist in observing or acting agreeably to their natural pitch and tenor."

But, as there are no independent affections in the fabric of the mind, no passion that stands by itself without some relation to the rest, we cannot pronounce of any one, considered apart, that it is either too strong or too weak. Its strength and just proportion must be measured, not only by its subserviency to its own immediate end, but by the respect it bears to the whole system of affection. Therefore, we say a passion is too strong, not only when it defeats its own end, but when it impairs the force of other passions, which are equally necessary to form a temper of mind suited to a certain economy or state; and too weak, nor merely on account of its insufficiency to answer its end, but because it cannot sustain its part or office in the balance of the whole system. Thus the love of life may be too strong, when it takes from the regard due to one’s country, and will not allow one bravely to encounter dangers, or even death, on its account. Again, the love of fame may be too weak, when it throws down the fences which render virtue more secure, or weakens the incentives which make it more active and public-spirited.

If it be asked, "How far may the affections towards private good or happiness be indulged?" one limit was before fixed for the particular indulgencies of each, viz. their subordination to the common aggregate of good to the private system. In these, therefore, a due regard is always supposed to be had to health, reputation, fortune, the freedom of action, the unimpaired exercise of reason, the calm enjoyment of one’s self, which are all private goods. Another limit now results from the balance of affection just named, viz. "The security and happiness of others;" or, to express it more generally, "a private affection may be safely indulged, when, by that indulgence, we do not violate the obligations which result from our higher relations, or public connections."

A just respect therefore being had to these boundaries, which nature has fixed in the breast of every man, What should limit our pursuits of private happiness? Is nature sullen and penurious? Or does the God of nature envy the happiness of his offspring?

Whether there is ever a real collision of interests between the public and private system of affections, or the ends which each class has in view, will be afterwards considered; but where there is no collision, there is little or no danger of carrying either, but especially the public affection, to excess, provided both kinds are kept subordinate to a different and cool self-love, and to a calm and universal benevolence; which principles stand as guards at the head of each system.

This then is the conduct of the passions, considered as particular and separate forces, carrying us out to their respective ends; and this is their balance or economy, considered as compound powers, or powers mutually related, acting in conjunction towards a common end, and consequently as forming a system or whole.

Now, whatever adjusts or maintains this balance, whatever in the human constitution is formed for directing the passions, so as to keep them from defeating their own end or interfering with each other, must be a principle of a superior nature to them, and ought to direct their measures, and govern their proportions. But it was found, that reason or reflection is such a principle, which points out the tendency of our passions, weighs their influence upon private and public happiness, and shews the best means of attaining either. It having been likewise found, that there is another directing or controlling principle, which we call conscience, or the moral sense, which, by a native kind of authority, judges of affections and actions, pronouncing some just and good, and others unjust and ill; it follows, that the passions, which are mere impulses, or blind forces, are principles inferior and subordinate to this judging faculty. Therefore, if we would observe the mutual respects and the subordination which the different parts of the human constitution bear one to another, the passions ought to be subjected to the direction and authority of the leading or controlling principles.

We conclude therefore from this induction, that "the constitution or just economy of human nature consists in a regular subordination of the passions and affections to the authority of conscience, and the direction of reason."

That subordination is regular, when the proportion formerly mentioned is maintained; that is to say, "When the defensive passions are kept proportioned to our dangers; when the private passions are proportioned to our wants; and when the public affections are adapted to our public connections, and proportioned to the wants and dangers of others."

But the natural state, or the found and vigorous constitution, of any creature, or the just economy of its powers, we call its health and perfection; and the acting agreeably to these, its virtue or goodness. Therefore, " the health and perfection of man must lie in the aforesaid supremacy of conscience and reason, and in the subordination of the passions to their authority and direction; and his virtue or goodness must consist in acting agreeably to that order or economy."

That such an economy of the mind, and such a conduct of its power and passions, will stand the test of reason, cannot admit of any dispute. For, upon a fair examination into the consequences of things, or the relations and aptitudes of means to ends, reason evidently demonstrates, and experience confirms it, that "to have our defensive passions duly proportioned to our dangers, is the surest way to avoid or get clear of them, and obtain the security we seek after." — "To proportion our private passions to our wants, is the best means to supply them;—and, to adapt our public affections to our social relations and the good of others, is the most effectual method of fulfilling one, and procuring the other." In this sense, therefore, virtue may be said to be a "conduct conformable to reason, as reason discovers an apparent aptitude in such an order and economy of powers and passions to answer the end for which they are naturally formed."

If the idea of moral obligation is to be deduced merely from this aptitude or connection between certain passions, or a certain order and balance of passions, and certain ends
ends obtained or to be obtained by them; then is reason
or reflection, which perceives that aptitude or connection,
the proper judge of moral obligation; and on this
supposition it may be defined, "the connection between the
affection and the end, or between the action and the mo-
tive;" for the end is the motive, or the final cause; and
the affection is the action, or its immediate natural cause.
A man, from mere self love, may be induced to fulfil that
obligation which is founded on the connection between the
defensive passions and their ends, or the private passions
and their ends; because, in that case, his own interest
will prompt him to indulge them in the due proportion
required. But if he has no affections which point
beyond himself, no principle but self-love or some subtle
modification of it, what shall interest him in the happiness
of others, where there is no connection between it and
his own? or what sense can he have of moral obligation
to promote it? Upon this scheme therefore, without pub-
lick or social affections there could be no motive, and
consequently no moral obligation, to a beneficent disme-
relished conduct.

But the mere connection between certain passions, or
a certain order of passions, and certain ends, is what
constitutes or gives us the idea of moral obligation; then
why may not the appositeness of any temper or conduct,
nay, of any piece of machinery, to obtain its end, form
an equally strict moral obligation? For the connection
and aptitude are as strong and invariable in the latter
instances as in the former. But as this is confounding
the most obvious differences of things, we must trace
the idea of moral obligation to another and a more natu-
ral source.

Let us appeal therefore to sense and experience, "how
we stand affected to these different sets of passions in the
just measure and balance of which we found a right tem-
per to confult." For this is entirely a matter of expe-
rience, in which we must examine, as in any other natural
inquiry, "what are the genuine feelings and operations
of nature, and what affections or symptoms of them ap-
ppear in the given instance."

The defensive passions, as anger and fear, give us ra-
ther pain than pleasure; yet we cannot help feeling them
when provoked by injury or exposed to harm. We
account the creature imperfect that wants them, because
they are necessary to his defense. Nay, we should in
some measure condemn ourselves, did we want the nec-
essary degree of repentance and caution. But if our reten-
ment exceeds the wrong received, or our caution the e-
sy kind of sensation, to pursue the good of their re-
pective objects, as pity, natural affection, and the like;
and those calm dispassionate affections and desires which
prompt us more steadily and uniformly to promote the
happiness of others. The former we generally call pa-
fions; to distinguish them from the other fort, which go
more commonly by the name of affections, or calm de-
fires. The first kind we approve indeed, and delight in;
but we feel still higher degrees of approbation and moral
compliance towards the last, and towards all limitations
of the particular instincts, by the principle of universal
benevolence. The more objects the calm affections take
in, and the worthier these are, their dignity rises in pro-
portion, and with this our approbation keeps an exact
pace. A character, on the other hand, which is quite
diveiled of these public affections, which feels no love
for the species, but, instead of it, entertains malice, ra-
cour, and ill-will, we reckon totally immoral and unnatural.

Such then are the sentiments and dispositions we feel,
when these several orders of affection pass before the
mental eye.

Therefore, "that slate in which we feel ourselves mo-
ved, in the manner above described, towards those affec-
tions and passions, as they come under the mind's review,
in which we are infamnlaneous, and independently of
our choice or volition, prompted to a correspondent con-
duct, we call a slate of moral obligation." Let us sup-
pose, for instance, a parent, a friend, a benefactor, re-
duced
duced to a condition of the utmost indigence and distress, and that it is in our power to give them immediate relief. To what conduct are we obliged? what duty does nature dictate and require in such a case? Attend, and nature will tell with a voice irresistibly audible and commanding to the human heart, "that immediate relief ought to be given." Again, let a friend, a neighbour, or even a stranger, have lodged a deposit in our hands, and after some time reclaim it; no sooner do these ideas of the confidence reposed in us, and of property not transferred but deposited, occur, than we immediately and unavoidably feel and recognize the obligation to restore it. In both these cases, we should condemn ourselves, if we acted otherwise, as having done, or omitted doing, what we ought not;—as having acted beneath the dignity of our nature,—contrary to our most intimate sense of right and wrong,—we should accuse ourselves as guilty of ingratitude, injustice, and inhumanity;—and be conscious of deferving the censure, and therefore dread the resentment, of all rational beings. But in complying with the obligation, we feel joy and self-approbation,—are conscious of an inviolable harmony between our nature and duty,—and think ourselves entitled to the applause of every impartial spectator of our conduct.

To describe therefore what we cannot perhaps define, a state of moral obligation, is "that state in which a creature, endowed with such senses, powers, and affections as man, would condemn himself, and think he deserved the condemnation of all others, should he refuse to fulfill it; but would approve himself, and expect the approbation of all others, upon complying with it."

And we call him a moral agent, who is in such a state, or is subject to moral obligation. Therefore as man's structure and connections often subject him to such a state of moral obligation, we conclude that he is a moral agent. But as man may sometimes act without knowing what he does, as in cases of frenzy or disease, or in many natural functions; or, knowing what he does, he may act without choice or affection, as in cases of necessity or compulsion; therefore, to denominate an action moral, i.e. approveable, or blameable, it must be done knowingly and willingly, or from affection and choice. A morally good action, then, is "to fulfill a moral obligation knowingly and willingly;" and a morally bad action, or an immoral action, is "to violate a moral obligation knowingly and willingly."

As not an action, but a series of actions constitute a character; as not an affection, but a series of affections constitute a temper; and as we denominate things by the gros, à fortiori, or by the qualities which chiefly prevail in them: "therefore we call that a morally good character, in which a series of morally good actions prevail; and that a morally good temper, in which a series of morally good affections have the ascendant." A bad character and bad temper are the reverse. But where the above mentioned order or proportion of passions is maintained, there a series of morally good affections and actions will prevail. Therefore, "to maintain that order and proportion, is to have a morally good temper and character." But a "morally good temper and character" is moral rectitude, integrity, virtue, or the completion of duty.

If it be asked, after all, "How we come by the idea of moral obligation or duty?" we may answer, that we come by it in the same way as by our other original and primary perceptions. We receive them all from nature, or the great Author of nature. For this idea of moral obligation is not a creature of the mind, or dependent on any previous act of volition; but arises on certain occasions, or when certain other ideas are presented to the mind, as necessarily, instantaneously, and unavoidably, as pain does upon too near an approach to the fire, or pleasure from the fruition of any good. It does not, for instance, depend on our choice, whether we shall feel the obligation to succour a distressed parent, or to restore a deposit intrusted to us when it is recalled. We cannot call this a compound idea made up of one or more simple ideas. We may indeed, nay, we must, have some ideas antecedent to it, e.g. that of a parent—in distress—of a child—able to relieve—of the relation of one to the other,—of a trust,—of right, &c. But none of these ideas constitute the perception of obligation. These indeed, by a law of our nature, are the occasion of suggesting it; but they are as totally different from it, as colours are from sounds. By sense or reflection we perceive the correlative properties, our memory recalls the favours or deposits we received, the various circumstances of the case are matters of fact or experience; but some delicate inward organ or power, or call it what we please, does, by a certain instantaneous sympathy, antecedent to the cool deductions of reason, and independent of previous instruction, art, or volition, perceive the moral harmony, the living irresistible charm of moral obligation, which immediately interests the correspondent passions, and prompts us to fulfill its awful dictates.

We need not apprehend any danger from the quickness of its decisions; nor be frightened, because it looks like instinct, and has been called so. Would we approve one for deliberating long, or reasoning the matter much at leisure, whether he should relieve a distressed parent, feed a starving neighbour, or restore the trust committed to him? Should we not suspect the reasoner of knavery, or of very weak affections to virtue? We employ reason in examining the condition, relations, and other circumstances of the agent or patient, or of those with whom either of them are connected, or, in other words, the state of the case; and in complicated cases, where the circumstances are many, it may require no small attention to find the true state of the case: but when the relations of the agent or patient, and the circumstances of the actions, are obvious, or come out such after a fair trial, we should scarce approve him who demurs on the obligation to that conduct which the case suggets.

From what has been said it is evident, that it is not the pleasure or agreeable sensations which accompany the exercise of the several affections, nor those consequent to the actions, that constitute moral obligation, or excite in us the idea of it. That pleasure is posterior to the idea of obligation; and frequently we are obliged, and acknowledge ourselves under an obligation, to such affections...
We have now taken a general prospect of man, and of his moral powers and connections; and on these erected a scheme of duty, or moral obligation, which seems to be confirmed by experience, consonant to reason, and approved by his most inward and most sacred senses. It may be proper, in the next place, to take a more particular view of the final causes of those delicate springs by which he is impelled to action, and of those clogs by which he is restrained from it. By this detail we shall be able to judge of their aptitude to answer their end, in a creature endowed with his capacities, subject to his wants, exposed to his dangers, and susceptible of his enjoyments; and from thence, we shall be in condition to pronounce concerning the end of his whole structure, its harmony with his state, and consequently its subserviency to answer the great and benevolent intentions of its author.

The supreme being has been fit to blend in the whole of things a prodigious variety of discordant and contrary principles, light and darkness, pleasure and pain, good and evil. There are multifarious natures, higher and lower, and many intermediate ones between the wide-distant extremes. These are differently situated, variously adjusted, and subjected to each other; and all of them subordinate to the order and perfection of the whole. We may suppose man placed as in a centre amidst those innumerable orders of beings; by his outward frame drawn to the material system, and by his inward connected with the intellectual or moral, and of course affected by the laws which govern both, or affected by that good and all that ill which result from those laws. In this infinite variety of relations with which he is surrounded, and contingencies to which he is liable, he feels strong attractions to the good, and violent repulsions or aversions to the ill. But as good and ill are often blended, and wonderfully complicated one with the other; as they sometimes immediately produce and run up into each other, and at other times lie at great distances, yet, by means of intervening links, introduce one another; and as these effects are often brought about in consequence of hidden relations, and general laws, of the energy of which he is an incompetent judge; it is easy for him to mistake good for evil, and evil for good; and consequently he may be frequently attracted by such things as are destructive, or repel such as are salutary. Thus, by the tender and complicated frame of his body, he is subjected to a great variety of ills, to sickness, cold, heat, fatigue, and innumerable wants. Yet his knowledge is so narrow withal, and his reason so weak, that in many cases he cannot judge, in the way of investigation, or reasoning, of the connections of those effects with their respective causes, or of the various latent energies of natural things.

He is therefore informed of this connection by the experience of certain senses, or organs of perception, which, by a mechanical instantaneous motion, feel the good and the ill, receiving pleasure from one, and pain from the other. By these, without any reasoning, he is taught to attract or chuse what tends to his welfare, and to repel and avoid what tends to his ruin. Thus, by his senses of taste and smell, or by the pleasure he receives from certain kinds of food, he is admonished which agree with his constitution, and, by an opposite sense of pain, he is informed which forts disagree, or are destructive of it; but is not by means of these instructed in the inward natures and constitutions of things.

Some of those senses are armed with strong degrees of uneasiness or pain, in order to urge him to seek after such objects as are suited to them. And these respect his more immediate and pressing wants; as the sense of hunger, thirst, cold, and the like; which by their painful importunities, compel him to provide food, drink, raiment, and shelter. Those instincts by which we are thus prompted, with some kind of commotion or violence, to attract and pursue good, or to repel and avoid ill, we call appetites and passions. By our senses then we are informed of what is good or ill to the private system, or the individual; and by our private appetites and passions we are impelled to one, and restrained from the other.

In consequence of this machinery, and the great train of wants to which our nature subjects us, we are engaged in a continued series of occupations, which often require much application of thought, or great bodily labour, or both. The necessaries of life, food, cloaths, shelter, and the like, must be provided; conveniences must be acquired to render life still more easy and comfortable. In order to obtain these, arts, industry, manufactures, and trade are necessary: and to secure to us the peaceable enjoyment of their fruits, civil government, policy, and laws must be contrived, and the various business of public life carried on. Thus while man is concerned and busied in making provision, or obtaining security for himself, he is by degrees engaged in connections with a family, friends, neighbours, a community, or a commonwealth. Hence arise new wants, new interests, new cares, and new employments. The passions of one man interfere with those of another. Interests are opposed. Competitions arise; contrary courses are taken. Disappointments happen, distractions are made; and parties formed. This opens a vast scene of distraction and embarrassment, and introduces a mighty train of good and ill, both public and private. Yet amidst all this confusion and hurry, plans of action must be laid, consequences foreseen or guarded against, inconveniences provided for; and frequently particular resolutions must be taken, and schemes executed, without reasoning or delay.

Now, what provision has the Author of our nature made for this necessitous condition? How has he fitted the actor, man, for playing his part in this perplexed and busy scene?

Our supreme Parent, watchful for the whole, has not left himself without a witness here neither, and hath made nothing imperfect, but all things are double one against another. He has not left man to be informed, only by the cool notices of reason, of the good or ill, the happiness or misery of his fellow creatures. He has made
made him sensible of their good and happiness, but especially of their ill and misery, by an immediate sympathy, or quick feeling of pleasure and of pain.

The latter we call pity or compassion. For the former, though every one who is not quite divested of humanity feels it in some degree, we have not got a name, unless we call it congratulation, or joyful sympathy, or that good humour which arises on seeing others pleased or happy. Both these feelings have been called, in general, the public or common sense, by which we feel for others, and are interested in their concerns as really, though perhaps less sensibly, than in our own.

When we see our fellow-creatures unhappy through the fault or injury of others, we feel resentment or indignation against the unjust causes of that misery. If we are conscious that it has happened through our fault or injurious conduct, we feel shame; and both these classes of senses and passions, regarding misery and wrong, are armed with such sharp sensations of pain, as not only prove a powerful guard and security to the species, or public system, against these ills it may, but serve also to lessen or remove those ills it does, suffer.

Compassion draws us out of ourselves to bear a part of the misfortunes of others, powerfully solicits us in their favour, melts us at sight of their distress, and makes us in some degree unhappy till they are relieved from it. It is peculiarly well adapted to the condition of human life, because it is more and oftener in our power to do mischief than good, and to prevent or lessen misery than to communicate positive happiness; and therefore it is an admirable restraint upon the more selfish passions, or those violent impulses that carry us to the hurt of others.

There are other particular instincts or passions, which interest us in the concerns of others, even while we are most busy about our own, and which are strongly attractive of good, and repulsive of ill to them. Such are natural affection, friendship, love, gratitude, desire of fame, love of society, of one's country. Now as the private appetites and passions were found to be armed with strong sensations of desire and uneasiness, to prompt man the more effectively to sustain labours, and encounter dangers, in pursuit of those goods that are necessary for the preservation and welfare of the individual, and to avoid those ills which tend to his destruction; in like manner it was necessary that this other class of desires and affections should be prompted with as quick sensations of pain, not only to counteract the strength of their antagonists, but to engage us in a virtuous activity for our relations, families, friends, neighbours, country. Indeed our sense of right and wrong will admonish us that it is our duty, and reason and experience further assure us that it is both our interest and security, to promote the happiness of others; but that sense, that reason, and that experience, would frequently prove but weak and ineffectual prompters to such a conduct, especially in cafes of danger and hardship, and amidst all the importunities of nature, and that constant hurry in which the private passions involve us, without the aid of those particular kind affections, which mark out to us particular spheres of duty, and with an agreeable violence engage and fix us down to them.

It is evident therefore, that these two classes of affection, the private and public, are set one against the other, and designed to control and limit each other's influence, and thereby to produce a just balance in the whole. In general, the violent sensations of pain or uneasiness which accompany hunger, thirst, and the other private appetites, or too great fatigue of mind as well as of body, prevent the individual from running to great excesses in the exercise of the higher functions of the mind; as too intense thought in the search of truth, violent application to business of any kind, and different degrees of romantic heroism. On the other hand, the finer senses of perception, and those generous desires and affections which are connected with them, the love of action, of imitation, of truth, honour, public virtue, and the like, are wisely placed in the opposite scale, in order to prevent us from sinking into the dregs of the animal life, and debasing the dignity of man below the condition of brutes. So that by the mutual reaction of those opposite powers, the bad effects are prevented that would naturally result from their acting singly and apart; and the good effects are produced which each are severally formed to produce.

The same wholesome opposition appears likewise in the particular counterworkings of the private and public affections one against the other. Thus compassion is adapted to counterpoise the love of ease, of pleasure, and of life; and to disarm, or to set bounds to resentment and resentment of injury done to ourselves or to our friends, prevents an effeminate compassion or confirmation; and gives us a noble contempt of labour, pain, and death. Natural affection, friendship, love of one's country, may, zeal for any particular virtue, are frequently more than a match for the whole train of selfish passions. On the other hand, without that intimate over-riding passion of self-love, and those private desires which are connected with it, the social and tender instincts of the human heart would degenerate into the wilderst dotage, the most torturing anxiety, and downright frenzy.

But not only are the different orders or classes of affection checks one upon another, but passions of the same classes are mutual clogs. Thus, how many are withheld from the violent outrages of resentment by fear? and how easily is fear controlled in its turn, while mighty wrongs awaken a mighty resentment? The private passions often interfere, and therefore moderate the violence of each other; and a calm self-love is placed at their head to direct, influence, and control their particular motions. Thus most part, if not all the passions have a twofold aspect, and serve a twofold end. In one view they may be considered as powers, impelling mankind to a certain course, with a force proportioned to the apprehended moment of the good they aim at. In another view they appear as weights balancing the action of the powers, and controlling the violence of their impulses. By means of these powers and weights a natural poise is settled in the human breast by its all-wise Author, by
by which the creature is kept tolerably steady and regular in his course, amidst that variety of changes through which he must pass.

But this is not all the provision which God has made for the hurry and perplexity of the scene in which man is destined to act. Amidst those infinite attractions and repulsions towards private and public good and ill, mankind either cannot often foresee the consequences or tendencies of all their actions towards one or other of these, especially where those tendencies are intricate and point different ways, or those consequences remote and complicated: or though, by careful and cool inquiry, and due improvement of their rational powers, they might find them out; yet distracted as they are with business, amused with trifles, dispirited by pleasure, and disturbed by passion, they either have, or can find, no leisure to attend to those consequences, or to examine how far this or that conduct is productive of private or public good on the whole. Therefore, were it left entirely to the flow of passions and other deductions of reason to trace those tendencies and make out those consequences, it is evident, that, in many particular instances, the business of life must stand still, and many important occasions of action be lost, or perhaps the greatest blunders be committed. On this account the Deity, besides that general approbation which we bestow on every degree of kind affection, has moreover implanted in man many particular perceptions, or determinations, to approve of certain qualities or actions, which, in effect, tend to the advantage of society, and are connected with private good, though he does not always see that tendency, nor mind that connection. And these perceptions or determinations do, without reasoning, point out, and, antecedent to views of interest, prompt to a conduct beneficial to the public, and useful to the private system. Such is that sense of candor and veracity, that abhorrence of fraud and falsehood, that sense of fidelity, justice, gratitude, greatness of mind, fortitude, clemency, decorum; and that disapprobation of knavery, injustice, ingratitude, meanness of spirit, cowardice, cruelty and indecorum, which are natural to the human mind. The former of those dispositions, and the actions flowing from them, are approved, and those of the latter kind disapproved by us, even abstracted from the view of their tendency or conduciveness to the happiness or misery of others or of ourselves. In one we discern a beauty, a superior excellency, a congruity to the dignity of man; in the other a deformity, a littleness, a debasement of human nature.

There are other principles also, connected with the good of society, or the happiness and perfection of the individual, though that connection is not immediately apparent, which we behold with real complacency and approbation, though perhaps inferior in degree, if not in kind; such as gravity, modesty, simplicity of deportment, temperance, prudent economy; and we feel some degree of contempt and dislike where they are wanting, or where the opposite qualities prevail. These and the like perceptions or feelings are either different modifications of the moral sense, or subordinate to it, and plainly serve the same important purpose, being expedient monitors in the several emergencies of a various and distracted life, of what is right, what is wrong, what is to be pursued, and what avoided; and, by the pleasant or painful conscientiousness which attends them, exerting their influence as powerful prompters to a suitable conduct.

From a slight inspection of the above-named principles, it is evident they all carry a friendly aspect to society and the individual, and have a more immediate or a more remote tendency to promote the perfection or good of both. This tendency cannot be always foreseen, and would be often mistaken, or else devoted to by a weak, busy, short-sighted creature, like man, both rash and variable in his opinions, a dupe to his own passions or to the designs of others, liable to sickness, to want, and to error. Principles, therefore, which are so nearly linked with private security and public good, by directing him, without operose reasoning, where to find one, and how to promote the other, and by prompting him to a conduct conducive to both, are admirably adapted to the exigencies of his present state, and wisely calculated to obtain the ends of universal benevolence.

It were easy, by considering the subject in another light, to shew, in a curious detail of particulars, how wonderfully the inside of man, or that allomining train of moral powers and affections with which he is endowed, is fitted to the several stages of that progressive and probationary state, through which he is destined to pass. As our faculties are narrow and limited, and rise from very small and imperfect beginnings, they must be improved by exercise, by attention, and repeated trials. And this holds true, not only of our intellectual, but of our moral and active powers. The former are liable to errors in speculation, the latter to blunders in practice, and both often terminate in misfortunes and pains: and those errors and blunders are generally owing to our passions, or to our too forward and warm admiration of those partial goods they naturally pursue, or to our fear of those partial ills they naturally repel. Those misfortunes therefore lead us back to consider where our misconduct lay, and whence our errors flowed; and consequently are salutary pieces of trial, which tend to enlarge our views, to correct and refine our passions, and consequently improve both our intellectual and moral powers.—Our passions then are the rude materials of our virtue, which heaven has given us to work up, to refine and polish into an harmonious and divine piece of workmanship. They furnish out the whole machinery, the calms and storms, the lights and shades of human life. They blew mankind in every attitude and variety of character, and give virtue both its struggles and its triumphs. To conduct them well in every state, is merit; to abuse or misapply them, is demerit.

The different sorts of senses, powers, and passions, which unfold themselves in those successive stages, are both necessary, and adapted to that rising and progressive state. Enlarging views and growing connections require new passions and new habits; and thus the mind, by these continually expanding and finding a progressive exercise, rises to higher improvements, and pushes forward to maturity and perfection.

In this beautiful economy and harmony of our structure, both outward and inward, with that state, we may at
at once discern the great lines of our duty, traced out in the fairest and brightest characters, and contemplate with admiration a more august and marvellous scene of divine wisdom and goodness hid in the human breast, than we shall perhaps find in the whole compass of nature.

From this detail it appears, that man, by his original frame, is made for a temperate, compassionate, benevolent, active, and progressive state. He is strongly attractive of the good, and repulsive of the ill, which befall others as well as himself. He feels the highest approbation and moral complacency in those affections and in those actions which immediately and directly respect the good of others, and the highest disapprobation and abhorrence of the contrary. Besides these, he has many particular perceptions or infinities of approbation, which though perhaps not of the same kind with the others, yet are accompanied with correspondent degrees of affection, proportioned to their respective tendencies to the public good. Therefore, by acting agreeably to these principles, man is agreeably to his structure, and fulfils the benevolent intentions of its Author.

The principal Distinctions of Duty or Virtue.

We have now considered the constitution and connections of man; and on these erected a general system of duty or moral obligation, consonant to reason, approved by his most sacred and intimate sense, suitable to his mixed condition, and confirmed by the experience of mankind. We have also traced the final causes of his moral faculties and affections to those noble purposes they answer with regard both to the private and the public system.

From this induction it is evident, that there is one order or class of duties which man owes to himself; another to society; and a third to God.

The duties he owes to himself are founded chiefly on the defensive and private passions, which prompt him to pursue whatever tends to private good or happiness, and to avoid or ward off whatever tends to private ill or misery. Among the various goods which allure and solicit him, and the various ills which attack or threaten him, "To be intelligent and accurate in selecting one, and rejecting the other, or in preferring the most excellent goods, and avoiding the most terrible ills, when there is a competition among either, and to be discreet in using the belt means to attain the goods and avoid the ills, is what we call prudence." This, in our inward frame, corresponds to sagacity, or a quickness of sense in our outward.—"To proportion our defensive passions to our dangers, we call fortitude," which always implies "a just mixture of calm resentment or animosity, and well governed caution." And this firmness of mind answers to the strength and muscling of the body.—And "duly to adjust our private passions to our wants, or to the respective moment of the good we affect or pursue, we call temperance;" which does therefore always imply "a just balance or command of the passions."

The second class of duties arises from the public or social affections; "the just harmony or proportion of which to the dangers and wants of others, and to the general relations we bear, commonly goes by the name of justice." This includes the whole of our duty to society, to its parent, and the general polity of nature; particularly gratitude, friendship, sincerity, natural affection, benevolence, and the other social virtues. The virtues comprehended under the former class, especially prudence and fortitude, may likewise be transferred to this; and according to the various circumstances in which they are placed, and the more confined or more extensive sphere in which they operate, may be denominated private, economical, or civil prudence, fortitude, &c. These direct our conduct with regard to the wants and dangers of those lesser or greater circles with which we are connected.

The third class of duties respects the Deity, and arises also from the public affections, and the several glorious relations which he sustains to us, as our creator, benefactor, law-giver, judge, &c.

We chose to consider this set of duties in the last place, because, though prior in dignity and excellency, they seem to be last in order of time, as thinking it the most simple and easy method to follow the gradual progress of nature, as it takes its rise from individuals, and spreads through the social system, and still ascends upwards, till at length it stretches to its almighty Parent and Head, and so terminates in those duties which are highest and best.

The duties resulting from these relations, are reverence, gratitude, love, resignation, dependence, obedience, worship, praise; which, according to the model of our finite capacities, must maintain some sort of proportion to the grandeur and perfection of the object whom we venerate, love, and obey. "This proportion or harmony, is expressed by the general name of piety or devotion," which is always stronger or weaker, according to the greater or less apprehended excellency of its object. This sublime principle of virtue, is the enlivening soul which animates the moral system, and that cement which binds and sustains the other duties which man owes to himself or to society.

This then is the general temper and constitution of virtue, and these are the principal lines or divisions of duty. To those good dispositions, which respect the several objects of our duty, and to all actions which flow from such dispositions, the mind gives its sanction or testimony. And this sanction or judgment concerning the moral quality, or the goodness of actions or dispositions, moralists call conscience. When it judges of an action that is to be performed, it is called an antecedent conscience; and when it passes sentence on an action which is performed, it is called a subsequent conscience. The tendency of an action to produce happiness, or its external conformity to a law, is termed its material goodness; but the good dispositions from which an action proceeds, or its conformity to law in every respect, constitutes its formal goodness.

When the mind is ignorant or uncertain about the moment of an action, or its tendency to private or public good; or when there are several circumstances in the case, some of which being doubtful, render the mind dubious concerning the morality of the action; this is called a doubtful or scrupulous conscience: if it mistakes concern-

 reckoned innocent, or net imputable. If the error or cure one, or ward off the other, we feed neither defire out to, and ultimately refte in, the firft kind of obje&ts, rather than a diredt and immediate affedtion. All the o-a fubordinate manner, or with an incited!; and refledtive, pleafure nor pain, and are apprehended of no ufe to pro-
cal! averfion or hatred. To obje&ts which fuggeft neither judge wrong, as it often does, viz. Hy giving it proper science which errs ; for its fentence is always conformable to the view of the cafe which lies before it; and is juft, if thofe circumftances are fairly and fully ftated, the

If it be asked, "How an erroneous confcience fhall be rectified, fince it is fuppo ed to be the only guide of life, and judge of morals?" we answer, In the very fame way that we would rectify reafon, if at any time it fhould judge wrong, as it often does, viz. By giving it proper and fufficient materials for judging right, i.e. by inquiring into the whole flate of the cafe; the relations, connections, and feveral obligations of the actor; the confequences, and other circumftances of the action; or the fufpence of private or public good which results, or is likely to reft, from the action or from the omission of it. If thofe circumftances are fairly and fully flated, the confcience will be just and impartial in its decision. For, by a neceflary law of our nature, it approves, and is well affected to the moral form; and if it feme to approve of vice or immorality, it is always under the notion or mark of fome virtue. So that, strictly speaking, it is not confcience which errs; for its fentence is always conformable to the view of the cafe which lies before it; and is juft, upon the fuppofition that the cafe is truly fuch as it is re-

Of Man's Duty to Himself. Of the Nature & Good, and the chief Good.

Ev ery creature, by the conftitution of his nature, is determined to love himfelf, to purfu e whatever tends to his prefervation and happiness, and to avoid whatever tends to his hurt and misery. Being endued with fens and perception, he muft necessarily receive pleafure from fome obje&ts, and pain from others. Thofe obje&ts which give pleafure are called good, and thofe which give pain evil. To the former he feels that attraction or motion we call defire, or love: To the latter that impulse we call aversion or hatred. To obje&ts which fugges t neither pleafure nor pain, and are apprehended of no ufe to procure one, or ward off the other, we feel neither defire nor aversion; and fuch obje&ts are called indifferent. Thofe obje&ts which do not of themfev e felves produce pleafure or pain, but are the means of procuring either, we call ufeful or noxious. Towards them we are affected in a fubordinate manner, or with an indirect and refleктивive, rather than a diredt and immediate affedtion. All the o-

ving thefe, it is called an erroneous confcience. If the error or ignorance is involuntary or invincible, the action proceeding from that error, or from that ignorance, is reckoned innocent, or net imputable. If the error or ignorance is fupine or aected, i.e. the effect of negligence, or of affection and wilful inadvertence, the conduct flowing from fuch error, or fuch ignorance, is criminal and imputable. Not to follow one's confcience, though erroneous and ill-formed, is criminal, as it is the guide of life; and to counterfeit it, fhews a depraved and incorrigible spirit: Yet, to follow an erroneous confcience is likewise criminal, if that error which misled the confcience was the effect of inattention, or of any criminal affection.

But besides thofe forts of obje&ts which we call good, merely and solely as they give pleafure, or are means of procuring it, there is an higher and nobler fpecies of good, towards which we feel that peculiar movement we call approbation or moral complacency, and which we therefore denominate moral good. Such are our affections, and the confequent actions to them. The perception of this is quite diftinct in kind from the perception of the other fpecies; and though it may be connected with pleafure or advantage by the benevolent conftitution of nature, yet it constitutes a good independent of that pleafure and that advantage, and far superior, not in degree only, but in dignity, to both. The other, viz. the natural good, confists in obtaining thofe pleafures which are adapted to the peculiar fenes and paffions fuscceptible of them, and is as various as are thofe fenes and paffions. This, viz. the moral good, lies in the right con-
duct of the feveral fenes and paffions, or their juft proportion and accommodation to their respective obje&ts and relations; and this is of a more fimple and invariant kind.

By our feveral fenes we are capable of a great variety of pleafing fentations. Thofe constitute di@iue ends or obje&ts ultimately purfuable for their own fake. To thofe ends, or ultimate obje&ts, correpond peculiar appetites or affections, which prompt the mind to purfu e them. When thofe ends are attained, there it rests and looks no farther. Whatever therefore is purfuable, not on its own account, but as subfervient or neceffary to the at-
tainment of fomething elfe that is intrinifically valuable or for its own fake, we call a mean, and not an end. So that ends, and not means, confitute the materials or the very effence of our happiness. Confequently, happiness cannot be one fimple uniform thing in creatures conftituted, as we are, with fuch various fenes of pleafure, or fuch different capacities or enjoyment. Now, the fame principle or law of our nature which determines us to purfu e any one end or fpecies of good, prompts us to purfu e every other end or fpecies of good of which we are fuscceptible, or to which our Maker has adapted an origin-
al propenfion. But amidst the great multiplicity of ends or goods, which form the various ingredients of our happiness, we perceive an evident gradation or subdivision, futed to that gradation of fenes, powers, and paffions, which prevails in our mixed and various con-

Thus the goods of the body, or of the external fenes, feem to hold the lowest rank in this gradation of goods. Thofe we have in common with the brutes: and though many men are brutifh enough to purfu e the goods of the body with a more than brutal fury; yet when at any time they come in competition with goods of an higher order, the unanimous verdict of mankind, by giving the left the preference, condemns the firft to the

Vol. III. No. 80.
MORAL PHILOSOPHY.

meant greatest place. Goods consisting in exterior social connections, as fame, fortune, power, civil authority, seem to succeed next, and are chiefly valuable as the means of procuring natural or moral good, but principally the latter. Goods of the intellect are still superior; as taste, knowledge, memory, judgment, &c. The highest are moral goods of the mind, directly and ultimately regarding ourselves; as command of the appetites and passions, prudence, fortitude, benevolence, &c. These are the great objects of our pursuit, and the principal ingredients of our happiness. Let us consider each of them, as they rise one above the other in this natural series or scale, and touch briefly on our obligations to pursue them.

The first of the body are health, strength, agility, hardiness, and patience of change, neatness, and decency.

Good health, and a regular easy flow of spirits, are in themselves sweet natural enjoyments, a great fund of pleasure, and indeed the proper seasoning which gives a flavour and poignancy to every other pleasurable. The want of health unites us for most duties of life, and it especially renders the unhappy sufferer peevish and full of discontent at the allotments of providence, and consequently apt to entertain sordid and gloomy sentiments of its Author. It obliterates the free exercise and full improvement of our reason, makes us a burden to our friends, and useless to society. Whereas the uninterrupted enjoyment of good health, is a constant source of good humour; and good humour is a great friend to openness and benignity of heart; enables us to encounter the various ills and disappointments of life with more courage, or to sustain them with more patience; and, in short, conduces much, if we are otherwise duly qualified, to our acting our part in every exigency of life with more firmness, constancy, and dignity. Therefore it imports us much to preserve and improve an habit or enjoyment, without which every other external entertainment is tasteless, and most other advantages of little avail. And this is best done by a strict temperance in diet and regimen, by regular exercise, and by keeping the mind serene and unruffled by violent passions, and unfettered by intense and constant labours, which greatly impair, and gradually destroy, the strongest constitutions.

Strength, agility, hardiness, and patience of change, suppose health, and are unattainable without it; but they imply something more, and are necessary to guard it, to give us the perfect use of life and limbs, and to secure us against many otherwise unavoidable ills. The exercise of the necessary manual, and of most the elegant arts of life, depends on strength and agility of body; personal dangers, private and public dangers, the demands of our friends, our families and country require them; they are necessary in war, and ornamental in peace; fit for the employments of a country and a town life, and they exalt the entertainments and diversions of both. They are chiefly obtained by moderate and regular exercise.

Few are so much raised above want and dependence, or so exempted from business and care, as not to be often exposed to inequalities and changes of diet, exercise, air, climate, and other irregularities. Now, what can be so effectual to secure one against the mischiefs arising from such unavoidable alterations, as hardiness, and a certain versatilitv of constitution, which can bear extraordinary labours, and submit to great changes, without any fenible uneasiness or bad consequences. This is best attained, not by an over great delicacy and minute attentions to forms, or by an invariable regularity in diet, hours, and way of living, but rather by a bold different latitude of regimen. Besides, deviations from established rules in forms of living, if kept within the bounds of sobriety and reason, are friendly to thought and original sentiments, animate the dull scene of ordinary life and busines, and agreeably stir the passions, which stimulate or breed ill humour in the calms of life.

Neatness, cleanliness, and decency, to which we may add dignity of countenance and demeanour, seem to have something refined and moral in them. At least we generally esteem them indications of an orderly, genteel, and well governed mind, conscious of inward worth, or the respect due to one's nature. Whereas naiveté, looseness, awkwardness, and indecency, are presage symptoms of something mean, careless, and deficient, and betray a mind untaught, illiberal, unconscious of what is due to one's self or to others. How much cleanliness conduces to health needs hardly to be mentioned; and how necessary it is to maintain one's character and rank in life, and to render us agreeable to others as well as to ourselves, is as evident.—There are certain motions, airs and gestures, which become the human countenance and form, in which we perceive a comeliness, openness, simplicity, gracefulness; and there are others, which, to our sense of decorum, appear uncomely, affected, disingenuous, and awkward, quite unfitting to the native dignity of our face and form. The first are in themselves the most easy, natural, and commodious; give one boldness and preference of mind, a modest assurance, an address both awful and alluring, they bespeak candour and greatness of mind, raise the most agreeable prejudices in one's favour, render society engaging, command respect, and often love, and give weight and authority both in conversation and business: in fine, they are the colouring of virtue, which flew it to the greatest advantage in whomsoever it is; and not only imitate, but in some measure supply it where it is wanting. Whereas the last, viz. rudeness, affectedness, indecorum, and the like, have all the contrary effects; they are burdensome to one's self, a dishonour to our nature and a nuisance in society. The former qualities or goods are best attained by a liberal education, by preferring a judicious and improve an habit or enjoyment, without which every other external entertainment is tasteless, and most other advantages of little avail. And this is best done by a strict temperance in diet and regimen, by regular exercise, and by keeping the mind serene and unruffled by violent passions, and unfettered by intense and constant labours, which greatly impair, and gradually destroy, the strongest constitutions.

We are next to consider those goods which consist in exterior social connections; as fame, fortune, civil authority, power.

The first has a twofold aspect; as a good pleasance in itself, or gratifying to an original passion; and then, as expedient or useful towards a farther end. Honour from the wife and good, on the account of a virtuous conduct, is regaling to a good man. There are few quite indifferent even...
even to the commendation of the vulgar. Though we cannot approve that conduct which proceeds entirely from this principle, and not from good affection or love of the conduct itself; yet as it is often a guard and additional motive to virtue in creatures imperfect as we are, and often disfrigted by interfering passions, it might be dangerous to suppress it altogether, however wise it may be to restrain it within due bounds, and however laudable to use it only as a scaffolding to our virtue, which may be taken down when that glorious structure is finished, but hardly till then.

To pursue fame for itself, is innocent; to regard it only as an auxiliary to virtue, is noble; to seek it chiefly as an engine of public usefulness, is still more noble. For though the opinion and breath of men are transient and fading things; often obtained without merit, and lost without cause; yet as our business is with men, and as our capacity of serving them is generally increased in proportion to their esteem of us; therefore found and well established moral applause may, and will, modestly, not ostentatiously, flourish after by the good; not indeed as a solitary refined sort of luxury, but as a public and proper instrument to advance and embellish mankind. At the same time they will learn to despise that reputation which is founded on rank, fortune, and any other circumstances or accomplishments that are foreign to real merit, or to useful services done to others; and think that praise of little avail which is purchased without desert, and bestowed without judgment.

Fortune, power, and civil authority, or whatever is called influence and weight among mankind, are goods of the second division; that is, valuable and purchasable only as they are useful, or as means to a farther end, viz. the procuring or preferring the immediate objects of enjoyment or happiness to ourselves or others. Therefore, to love such goods on their own account, and to pursue them as ends, not the means of enjoyment, must be highly preposterous and absurd. There can be no measure, no limit to such pursuit; all must be whim, caprice, extravagance. Accordingly, such appetites, unlike all the natural ones, are increased by possession, and whetted by enjoyment. They are always precarious, and never without fears because the objects lie without one's self; they are seldom without sorrow and vexation, because no accession of wealth or power can satisfy them. But if those goods are considered only as the materials or means of private or public happiness; then the same obligations which bind us to pursue the latter, bind us likewise to pursue the former. We may, and no doubt we ought, to seek such a measure of wealth as is necessary to supply all our wants, to raise us above servile dependence, and provide us with such conveniences as are suited to our rank and condition in life. To be regardles of this measure of wealth is to expose ourselves to all the temptations of poverty and corruption; to forfeit our natural independence and freedom; to degrade, and consequently to render the rank we hold, and the character we sustain in society, useless, if not contemptible. When these important ends are secured, we ought not to murmur or repine that we possess no more; yet we are not secluded by any obligation, moral or divine, from seeking more, in order to give us that happiness and most God-like of all powers, the power of doing good. A supine indolence in this respect is both absurd and criminal; absurd, as it robs us of an inexhausted fund of the most refined and durable enjoyments; and criminal, as it renders us so far useless to the society to which we belong. "That pursuit of wealth which goes beyond the former end, viz. the obtaining the necessaries, or such conveniences of life, as in the estimation of reason, not of vanity or passion, are suited to our rank and condition, and yet is not directed to the latter, viz. the doing good, is what we call avarice." And "that pursuit of power, which, after securing one's self, i.e. attaining the proper independence and liberty of a rational social creature, is not directed to the good of others, is what we call ambition, or the lust of power." To what extent the first measures of virtue will allow us to pursue either wealth, or power, and civil authority, is not perhaps possible precisely to determine. That must be left to prudence, and the peculiar character, condition, and other circumstances of each man. Only thus far a limit may be set, that the pursuit of either must encroach upon no other duty or obligation which we owe to ourselves, to society, or to its Parent and Head. The same reasoning is to be applied to power as to wealth. It is only valuable as an instrument of our own security, and of the free enjoyment of those original goods it may, and often does, administer to us; and as an engine of more extensive happiness to our friends, our country, and mankind.

Now the best, and indeed the only way to obtain a solid and lasting fame, is an uniform inflexible course of virtue, the employing one's ability and wealth in supplying the wants, and using one's power in promoting or securing the happiness, the rights and liberties of mankind, joined to an universal affability and politeness of manners. And surely one will not mistake the matter much, who thinks the same course conducive to the acquiring greater accessions both of wealth and power: especially if he adds to those qualifications a vigorous industry, a constant attention to the characters and wants of men, to the conjunctions of times, and continually varying geniuses of affairs; and a sedate intrepid honesty, that will not yield to the allurements, nor be overawed with the terrors of that corrupt and corrupting scene in which we live. We have sometimes heard, indeed, of other ways and means, as fraud, dissimulation, sordidity, and prostitution, and the like ignoble arts, by which the men of the world (as they are called, through politicians, and men of address!) amass wealth, and procure power; but as we want rather to form a man of virtue, an honest, contented, happy man, we leave to the men of the world their own ways, and permit them unencumbered, and unmimimetically, to reap the fruit of their doings.

The next species of objects in the scale of good, are the goods of the intellect; as knowledge, memory, judgement, taste, sagacity, docility, and whatever else we call intellectual virtues. Let us consider them a little, and the means as well as obligations to improve them.

As man is a rational creature, capable of knowing the differences of things and actions;—as he not only sees and feels what is present, but remembers what is past, and often foresees what is future;—as he advances, from small beginnings
beginnings, by slow degrees, and with much labour and difficulty, to knowledge and experience;—as his opinions sway his passions;—as his passions influence his conduct,—and as his conduct draws consequences after it, which extend not only to the present, but to the future time, and therefore is the principal source of his happiness or misery;—it is evident, that he is formed for intellectual improvements, and that it must be of the utmost consequence for him to improve and cultivate his intellectual powers, on which those opinions, those passions, and that conduct depend.

But besides the future consequences and moment of improving our intellectual powers, their immediate exercise on their proper objects yields the most rational and refined pleasures. Knowledge and a right taste in the arts of imitation and design, as poetry, painting, sculpture, music, architecture, afford not only an innocent, but a most sensible and sublime entertainment. By these the understanding is instructed in ancient and modern life, the history of men and things, the energies and effects of the passions, the consequences of virtue and vice; by these the imagination is at once entertained and nourished with the beauties of nature and art, lighted up and spread out with the novelty, grandeur, and harmony of the universe; and in fine, the passions are agreeably roused, and suitably engaged by the greatest and most interesting objects that can fill the human mind. He who has a taste formed to these ingenious delights, and plenty of materials to gratify it, can never want the most agreeable exercise and entertainment, nor once have reason to make that fashionable complaint of the tediousness of time. Nor can he want a proper subject for the discipline and improvement of his heart. For being daily conversant with beauty, order and design, in inferior subjects, he bids fair for growing in due time an admirer of what is fair and well-proportioned in the conduct of life, and the order of society, which is only order and design exerted in their highest subject. He will learn to transfer the numbers of poetry to the harmony of the mind, and of well-governed passions; and from admiring the virtues of others in moral paintings, come to approve and imitate them himself. Therefore to cultivate a true and correct taste, must be both our interest and our duty, when the circumstances of our situation give leisure and opportunity for it, and when the doing it is not inconsistent with our higher obligations or engagements to society and mankind.

It is best attained by reading the best books, where good sense has more the ascendant than learning, and which retain more to practice than to speculation; by studying the best models, i.e. those which profess to imitate nature most, and approach the nearest to it; and by converting with men of the most refined taste, and the greatest experience in life.

As to the other intellectual goods, what a fund of entertainment must it be to investigate the truth and various relations of things; to trace the operations of nature to general laws; to explain by these its manifold phenomena; to understand that order by which the universe is upheld, and that economy by which it is governed; to be acquainted with the human mind, the connection, subordinations, and uses of its powers, and to mark their energy in life! How agreeable to the ingenious inquirer, to observe the manifold relations and combinations of individual minds in society; to discern the causes why they flourish or decay; and from thence to ascend, through the vast fable of beings, to that General Mind which presides over all, and operates unseen in every fylem, and in every age, through the whole compass and progression of nature! Devoted to such entertainments as these, the contemplative have abandoned every other pleasure, and sequestrated themselves from social intercourse; for these the busy have often preferred, to the hurry and din of life, the calm retreats of contemplation; for these, when once they came to taste them, even the gay and voluptuous have thrown up the lawless pursuits of flene and appetite, and acknowledged these mental enjoyments to be the most refined, and indeed the only luxury. Besides, by a just and large knowledge of nature, we recognize the perfections of its Author; and thus piety, and all those pious affections which depend on just sentiments of his character, are awakened and confirmed; and a thousand superstitious fears, that arise from partial views of his nature and works, will of course be excluded. An extensive prospect of human life, and of the periods and revolutions of human things, will conduct much to the giving a certain greatness of mind, and a noble contempt of those little competitions about power, honour, and wealth, which disturb and divide the bulk of mankind; and promote a calm indulgence of those inconveniences and ills that are the common appendages of humanity. Add to all, that a just knowledge of human nature, and of those hinges upon which the business and fortunes of men turn, will prevent our thinking either too highly, or too meanly of our fellow-creatures; give no small scope to the exercise of friendship, confidence, and goodwill; and, at the same time, brace the mind with a proper caution and distrust, and give a greater mastery in the conduct of private as well as public life. Therefore, by cultivating our intellectual abilities, we shall be assisted to secure our interest, and be qualified for acting our part in society with more honour to ourselves, as well as advantage to mankind. Consequentially, to improve them to the utmost of our power is our duty; they are talents committed to us by the Almighty Head of society, and we are accountable to him for the use of them.

The intellectual virtues are best improved by accurate and impartial observation, extensive reading, and unconfined converse with men of all characters, especially with those who, to private study, have joined the widest acquaintance with the world and greatest practice in its affairs; but above all, by being much in the world, and having large dealings with mankind. Such opportunities contribute much to divest one of prejudices and a servile attachment to crude systems, to open one's views, and to give that experience on which the most useful knowledge is built, and from which the surest maxims for the conduct of life are deduced.

The highest goods which enter into the composition of human happiness are moral goods of the mind, directly and ultimately regarding ourselves; as command of the appetites and passions, prudence and caution, magnanimity, fortitude,
Morality is another virtue of high rank and dignity, though often mistaken by proud mortals for meanness and puillanimit. It is opposed to pride, which commonly includes in it a false or over-rated estimation of our own merit, an aperception of it to ourselves as its only and original cause, an undue comparison of ourselves with others, and, in consequence of that suppos'd superiority, an arrogant preference of ourselves, and a supercilious contempt of them. Humility, on the other hand, seems to denote that modest and ingenuous temper of mind, which arises from a just and equal estimate of our own advantages compared with those of others, and from a sense of our deriving all originally from the Author of our being. Its ordinary attendants are meekness, a gentle forbearance, and an easy unassuming humanity with regard to the imperfections and faults of others; virtues rare indeed, but of the fairest completion, the proper offspring of so lovely a parent, the best ornaments of such imperfect creatures as we are, precious in the sight of God, and which sweetly allure the hearts of men.

Resignation is that mild and heroic temper of mind, which arises from a sense of an infinitely wise and good providence, and enables one to acquiesce with a Cordial affection in its just appointments. This virtue has something very peculiar in its nature, and sublime in its efficacy. For it teaches us to bear ills, not only with patience, and as being unavoidable; but it transforms, as it were, ill into good, by leading us to consider it, and every thing that has the least appearance of ills, as a divine dispensation, a wise and benevolent temper of things, subservient to universal good, and of course including that of every individual, especially of such as calmly flock to it. In this light, the administration itself, nay, every act of it, becomes an object of affection; the evil disappears, or is converted into a balm which both heals and nourishes the mind. For, though the first unexpected access of ills may surprize the soul into grief; yet that grief, when the mind calmly reviews its object, changes into contentment, and is by degrees exalted into generation and a divine composure. Our private will is lost in that of the Almighty, and our security against every real ill rests on the same bottom as the throne of Him who lives and reigns for ever.
Before we finish this section, it may be fit to observe, that as the Deity is the supreme and inexhausted source of good, on whom the happiness of the whole creation depends; as he is the highest object in nature, and the only object who is fully proportioned to the intellectual and moral powers of the mind, in whom they ultimately rest and find their most perfect exercise and completion; he is therefore termed the chief good of man objectively considered: And virtue, or the proportioned and vigorous exercise of the several powers and affections on their respective objects, as above described, is, in the schools, termed the chief good formally considered, or its formal idea, being the inward temper and native constitution of human happiness.

From the detail we have gone through, the following corollaries may be deduced.

1. It is evident that the happiness of such a progressive creature as man can never be at a stand, or continue a fixed invariable thing. His finite nature, let it rise ever so high, admits still higher degrees of perfection and perfection: and his progress in improvement, or virtue, always makes way for a progression in happiness. So that no possible point can be assigned in any period of his existence in which he is perfectly happy; that is, so happy as to exclude higher degrees of happiness. All his perfection is only comparative. 2. It appears that many things must concur to complete the happiness of so various a creature as man, subject to so many wants, and susceptible of such different pleasures. 3. As his capacities of pleasure cannot be all gratified at the same time, and must often interfere with each other in such a precarious and fleeting state as human life, or be frequently disappointed, perfect happiness, i.e. the undisturbed enjoyment of the several pleasures of which we are capable, is unattainable in our present state. 4. That state is most to be sought after, in which the fewest competitions and disappointments can happen, which least of all impairs any sense of pleasure, and opens an inexhausted source of the most refined and lasting enjoyments. 5. That state which is attended with all those advantages is a state or course of virtue. 6. Therefore, a state of virtue, in which the moral goods of the mind are attained, is the happiest state.

DUTIES TO SOCIETY.

Filial and Fraternal duty.

As we have followed the order of nature in tracing the history of man, and those duties which he owes to himself; it seems reasonable to take the same method with those he owes to society, which constitute the second class of his obligations.

His parents are among the earliest objects of his attention; he becomes sooner acquainted with them, reposes a peculiar confidence in them, and seems to regard them with a fond affection, the early prognostics of his future piety and gratitude. Thus does nature dictate the first lines of filial duty, even before a just sense of the connection is formed. But when the child is grown up, and has attained to such a degree of understanding as to comprehend the moral tie, and be sensible of the obligations he is under to his parents; when he looks back on their tender and disinterested affection, their incessant cares and labours in nursing, educating and providing for him during that state in which he had neither prudence nor strength to care and provide for himself; he must be conscious that he owes to them these peculiar duties.

1. To reverence and honour them as the instruments of nature in introducing him to life, and to that state of comfort and happiness which he enjoys; and therefore to esteem and imitate their good qualities, to alleviate and bear with, and spread as much as possible a decent veil over their faults and weaknesses.

2. To be highly grateful to them for those favours which it can hardly ever be in his power fully to repay; to shew this gratitude by a strict attention to their wants, and a solicitous care to supply them; by a submissive deference to their authority and advice; by yielding to, rather than peremptorily contending with their humours, as remembering how oft they have been persecuted by his; and in fine, by soothing their cares, lightening their sorrows, supporting the infirmities of age, and making the remainder of their life as comfortable and joyful as possible.

As his brethren and sisters are the next with whom the creature forms a social and moral connection, to them he owes a fraternal regard; and with them ought he to enter into a strict league of friendship, mutual sympathy, advice, assistance, and a generous intercourse of kind offices, remembering their relation to common parents, and that brotherhood of nature which unites them into a closer community of interest and affection.

Concerning Marriage.

When man arrives to a certain age, he becomes sensible of a peculiar sympathy and tenderness towards the other sex; the charms of beauty engage his attention, and call forth new and softer dispositions than he has yet felt. The many amiable qualities exhibited by a fair outside, or by the mild allurement of female manners, or which the prejudiced spectator without much reasoning supposes those to include, with several other circumstances, point his view and affection to a particular object, and of course conduct that general rambling regard, which was lost and useless among the undistinguished crowd, into a peculiar and permanent attachment to one woman, which ordinarily terminates in the most important, venerable, and delightful connection in life.

The state of the brute-creation is very different from that of human creatures. The former are clothed and generally armed by their structure, easily find what is necessary to their subsistence, and soon attain their vigour and maturity; so that they need the care and aid of their parents but for a short while; and therefore we see that nature has assigned to them vagrant and transient amours. The connection being purely natural, and formed merely for propagating and rearing their offspring; no sooner is that end answered, than the connection dissolves of course. But the human race are of a more tender and defenceless constitution; their infancy and non-age continue longer; they advance slowly to strength of body, and maturity of reason; they need constant attention, and a long series of cares.
MORAL PHILOSOPHY.

289

cares and labours to train them up to decency, virtue, and the various arts of life. Nature has, therefore, provided them with the most affectionate and anxious tutors, to aid their weakens, to supply their wants, and to accomplish them in those necessary arts; even their own parents, on whom she has devolved this mighty charge, rendered agreeable by the most alluring and powerful of all ties, parental affection. But unless both concur in this grateful task, and continue their joint labours, till they have reared up and planted out their young colony, it must become a prey to every rude invader, and the purpose of nature in the original union of the human pair be defeated. Therefore our structure as well as condition is an evident indication, that the human sexes are defined for a more intimate, for a moral and lasting union. It appears likewise, that the principal end of marriage is not to propagate and nurse up an offspring, but to educate and form minds for the great duties and extensive definitions of life. Society must be supplied from this original nursery with useful members, and its fairest ornaments and supports.

The mind is apt to be diffipated in its views, and acts of friendship and humanity; unless the former be directed to a particular object, and the latter employed in a particular province. When men once indulge to this diffipation, there is no stopping their career; they grow insensible to moral attractions, and, by obstructing or impairing the decent and regular exercise of the tender and generous feelings of the human heart, they in time become unqualified for, or adverse to, the forming a moral union of souls, which is the cement of society, and the source of the purest domestic joys. Whereas a rational undepraved love, and its fair companion marriage, collect a man's views, guide his heart to its proper object, and by confining his affection to that object do really enlarge its influence and use. Besides, it is but too evident from the conduct of mankind, that the common ties of humanity are too feeble to engage and interest the passions of the generality in the affairs of society. The connections of neighbourhood, acquaintance, and general intercourse, are too wide a field of action for many; and those of a public or community are so for more, and in which they either care not or know not how to exert themselves. Therefore nature, ever wise and benevolent, by implanting that strong sympathy which reigns between the individuals of each sex, and by urging them to form a particular moral connexion, the spring of many domestic endearments, has measured out to each pair a particular sphere of action, proportioned to their views, and adapted to their respective capacities. Besides, by intereting them deeply in the concerns of their own little circle, she has connected them more closely with society, which is composed of particular families, and bound them down to their good behaviour in that particular community to which they belong. This moral connexion is marriage, and this sphere of action is a family.

Of the conjugal alliance the following are the natural conqueuence of the matrimonial connexion, and the duties which they owe them result as naturally from that connexion. The feeble state of children, subject to so many wants and dangers, requires their incessant care and attention; their ignorant and uncultivated minds demand their continual instruction and culture. Had human creatures come into the world with the full strength of men, and the weaknesses of reason and vehemence of passions which prevail in children, they would have been too strong or too flabby to have submitted to the government and instruction of their parents. But, as they were designed for a progeileion in knowledge and virtue, it was proper that the growth of their bodies should keep pace with that of their minds, left the purposes of that progression should have been defeated. Among other admirable purposes which this gradual expansion of their outward as well as inward structure serves, this is one, that it affords ample scope to the exercise of many tender and generous affections, which fill up the domestic life with a beautiful variety of duties and enjoyments; and are of course a noble discipline for the heart, and an hardy kind of education for the more honourable and important duties of public life.

The above-mentioned weak and ignorant state of children, seems plainly to invest their parents with such authority.
authority and power as is necessary to their support, protection, and education; but that authority and power can be continued to extend no farther than is necessary to answer those ends, and to last no longer than that weakness and ignorance continue; wherefore, the foundation or reason of the authority and power ceasing, they cease of course. Whatever power or authority, then, it may be necessary or lawful for parents to exercise during the non-age of their children, to allure or usurp the fame when they have attained the maturity or full exercise of their strength and reason, would be tyrannical and unjust. From hence it is evident, that parents have no right to punish the persons of their children more severely than the nature of their wardship requires; much less to invade their lives, to encroach upon their liberty, or transfer them as their property to any matter whatsoever.

The first clas of duties which parents owe their children respect their natural life; and these comprehend protection, nurture, provision, introducing them into the world in a manner suitable to their rank and fortune, and the like.

The second order of duties regards the intellectual and moral life of their children, or their education in such arts and accomplishments as are necessary to qualify them for performing the duties they owe to themselves and to others. As this was found to be the principal design of the matrimonial alliance, so the fulfilling that design is the most important and dignified of all the parental duties. In order therefore to fit the child for acting his part wisely and worthly, as a man, as a citizen, and a creature of God, both parents ought to combine their joint wisdom, authority, and power, and each apart to employ those talents which are the peculiar excellency and ornament of their respective sex. The father ought to lay out and superintend their education; the mother to execute and manage the detail of which she is capable. The former should direct the manly exertion of the intellectual and moral powers of his child. His imagination, and the manner of those exertions, are the peculiar province of the latter. The former should advise, protect, command, and, by his experience, masculine vigour, and that superior authority which is commonly ascribed to his sex, brace and strengthen his pupil for active life, for gravity, integrity, and firmness in suffering. The feminine of the latter is to bend and soften her male pupil, by the charms of her conversation, and the softness and decency of her manners, for social life, for politeness of taste, and the elegant decorums of and enjoyments of humanity; and to improve and refine the tenderness and modesty of her female pupil, and form her to all those mild domestic virtues, which are the peculiar characteristics and ornaments of her sex.

To conduct the opening minds of their sweet charge through the several periods of their progress; to assist them in each period in throwing out the latent seeds of reason and ingenuity, and in gaining fresh accretions of light and virtue; and at length, with all these advantages, to produce the young adventurers upon the great theatre of human life, to play their several parts in the fight of their friends, of society, and mankind.

Herite and Servile Duty.

In the natural course of human affairs it must necessarily happen, that some of mankind will live in plenty and opulence, and others be reduced to a state of indigence and poverty. The former need the labours of the latter, and the latter the provision and support of the former. This mutual necessity is the foundation of that connection, whether we call it moral or civil, which subordinates masters and servants. He who feeds another has a right to some equivalent, the labour of him whom he maintains, and the fruits of it. And he who labours for another has a right to expect that he should support him. But as the labours of a man of ordinary strength are certainly of greater value than mere food and clothing; because they would actually produce more, even the maintenance of a family, were the labourer to employ them in his own behalf; therefore he has an undoubted right to rate and dispose of his service for certain wages above mere maintenance; and if he has incantually disposed of it for the latter only, yet the contract being of the onerous kind, he may equitably claim a supply of that deficiency. If the service be specified, the servant is bound to that only; if not, then he is to be construed as bound only to such services as are consistent with the laws of justice and humanity. By the voluntary servitude to which he subjects himself, he forfeits no rights but such as are necessarily included in that servitude, and is obnoxious to no punishment but such as a voluntary failure in the service may be supposed reasonably to require. The offspring of such servants have a right to that liberty which neither they nor their parents have forfeited.

As to those who, because of some heinous offence, or for some notorious damage, for which they cannot otherwise compensate, are condemned to perpetual service; they do not, on that account, forfeit all the rights of men; but those, the loss of which is necessary to secure society against the like offences for the future, or to repair the damage they have done.

With regard to captives taken in war, it is barbarous and inhuman to make perpetual slaves of them, unless some peculiar and aggravated circumstances of guilt have attended their hostility. The bulk of the subjects of any government engaged in war, may be fairly esteemed innocent enemies; and therefore they have a right to that clemency which is consistent with the common safety of mankind, and the particular security of that society against which they are engaged. Though ordinary captives have a right to their lives; yet to pay their liberty as an equivalent, is much too high a price. There are other ways of acknowledging or returning the favour, than by surrendering what is far dearer than life itself. To those who, under pretext of the necessities of commerce, drive the unnatural trade of bargaining for human flesh, and configning their innocent but unfortunate fellow-creatures to eternal servitude and misery, we may address the words of a fine writer: "Let avance defend it as it will, there is an honest reluctance in humanity against buying and selling and regarding those of our own species as our wealth and possessions."
Social Duties of the private Kind.

Hitherto we have considered only the domestic economical duties, because these are first in the progress of nature. But as man passes beyond the little circle of a family, he forms connections with relations, friends, neighbours, and others; from whence results a new train of duties of the more private social kind, as friendship, chastity, courtesy, good-neighbourhood, charity, forgiveness, hospitality.

Man is admirably formed for particular social attachments and duties. There is a peculiar and strong propensity in his nature to be affected with the sentiments and dispositions of others. Men, like certain musical instruments, are set to each other, so that the vibrations or notes excited in one raise correspondent notes and vibrations in the others. The impulses of pleasure or pain, joy or sorrow, made on one mind, are, by an instantaneous sympathy of nature, communicated in some degree to all; especially when hearts are in unison of kindness; the joy that vibrates in one, communicates to the other also. We may add, that though joy thus imparted swells the harmony; yet grief vibrated to the heart of a friend, and rebounding from thence in sympathetic notes, melts, as it were, and almost dies away. All the passions, but especially those of the social kind, are contagious; and when the passions of one man mingle with those of another, they increase and multiply prodigiously. There is a most moving eloquence in the human countenance, air, voice, and gesture, wonderfully expressive of the most latent feelings and passions of the soul, which darts them, like a subtle flame, into the hearts of others, and raises correspondent feelings there: friendship, love, good-humour, joy, spread through every feature, and particularly shoot from the eyes their softer and fiercer fires with an irresistible energy. And in like manner, the opposite passions of hatred, enmity, ill humour, melancholy, diffuse a sultry and fadening air over the face, and, glancing from eye to eye, kindle a train of similar passions. By these and other admirable pieces of machinery, men are formed for society and the delightful interchange of friendly sentiment and duties; to increase the happiness of others by participation, and their own by rebound; and to diminish, by dividing, the common flock of their misery.

The first emanations of the social principle beyond the bounds of a family, lead us to form a nearer conjunction of friendship or goodwill with those who are anywise connected with us by blood or domestic alliance. To them our affection does, commonly, exert itself in a greater or less degree, according to the nearness or distance of the relation. And this proportion is admirably fitted to the extent of our powers and the indifference of our state; for it is only within those closer circles of consanguinity or alliance, that the generality of mankind are adapted to display their abilities or benevolence, and consequently to uphold their connection with society and subserviency to a public interest. Therefore it is our duty to regard these closer connections as the next department to that of a family, in which nature has marked out for us a sphere of activity and usefulness; and to cultivate the kind affections which are the cement of those endearing alliances.

Frequently, the view of distinguishing moral qualities in some of our acquaintance may give birth to that more noble connection we call friendship, which is far superior to the alliances of consanguinity. For these are, of a superficial, and often of a transitory nature; of which, as they hold more of infinint than of reason, we cannot give such a rational account. But friendship derives all its strength and beauty, and the only existence which is durable, from the qualities of the heart, or from virtuous and lovely dispositions. Therefore friendship may be described to be, "The union of two souls, by means of virtue, the common object and cement of their mutual affection." Without virtue, or the supposition of it, friendship is only a mercenary league, an alliance of interest, which must dissolve of course when that interest decays or subsides no longer. It is not so much any particular passion, as a composition of some of the noblest feelings and passions of the mind. Good sense, a just taste and love of virtue, a thorough candor and benignity of heart, or what we usually call a good temper, and a generous sympathy of sentiments and affections, are the necessary ingredients of this virtuous connection. When it is grafted on esteem, strengthened by habit, and mulled over by time, it yields infinite pleasure ever new and ever growing, is a noble support amidst the various trials and vicissitudes of life, and an high seasoning to most of our other enjoyments. To form and cultivate virtuous friendship must be very improving to the temper; as its principal object is virtue, set off with all the allurement of countenance, air, and manners, shining forth in the native graces of many honest sentiments and affections, and rendered visible as it were to the friendly spectator in a conduct unaffectedly great and good; and as its principal exercices are the very energies of virtue, or its effects and emanations. So that, wherever this amiable attachment prevails, it will exalt our admiration and attachment to virtue, and, unless impeded in its course by unnatural prejudices, run out into a friendship to the human race. For as no one can merit, and none ought to usurp, the sacred name of friend, who hates mankind; so, whoever truly loves them, possesses the most effential quality of a true friend.

The duties of friendship are, a mutual esteem of each other, unbribed by interest, and independent of it; a generous confidence, as far distanted from suspicion as from reserve; an inviolable harmony of sentiments and dispositions, of designs and interests; a fidelity unshaken by the changes of fortune; a constancy unalterable by distance of time or place; a renunciation of one's personal interests to those of one's friend; and a reciprocal, unenvious, unreserved exchange of kind offices. But amidst all the exertions of this moral connection, humane and generous as it is, we must remember that it operates within a narrow sphere, and its immediate operations respect only the individual; and therefore particular impulses must still be subordinated to a more public interest, or be always directed and controlled by the more extensive connections of our nature.

When our friendship terminates on any of the other

Vol. III. N°. 81.
sex, in whom beauty or agreeableness of person and external gracefulness of manners conspire to express and heighten the moral charm of a tender honest heart, and sweet, ingenious, modest temper, lighted up by good sense, it generally grows into a more soft and endearing attachment. When this attachment is improved by a growing acquaintance with the worth of its object, is conducted by discretion, and issues at length, as it ought to do, in the moral connection of marriage, it becomes the source of many amiable duties, of a communication of passions and interests, of the most refined decencies, and of a thousand nameless deep-seated joys of reciprocal tenderness and love, flowing from every look, word, and action. Here friendship acts with double energy, and the natural conspires with the moral charm to strengthen and secure the love of virtue. As the delicate nature of female honour and decorum, and the inexpressible grace of a chaste and modest behaviour, are the fairest and indeed the only means of kindling at first, and ever after of keeping alive this tender and elegant flame, and of accomplishing the excellent ends designed by it; to attempt by fraud to violate one, or, under pretence of passion, fully and corrupt the other, and, by so doing, to expose the too often credulous and unguarded object, with a wanton cruelty, to the hatred of her own sex, and the scorn of ours, and to the lowest infamy of both, is a conduct not only base and criminal, but inconsistent with that truly rational and refined enjoyment, the spirit and quintessence of which is derived from the bafilful and sacred charms of virtue kept untainted, and therefore ever alluring to the lover's heart.

Courtesy, good-neighbourhood, affability, and the like duties which are founded on our private social connections, are no less necessary and obligatory to creatures united in society, and supporting and supported by each other in a chain of mutual want and dependence. They do not conflict in a smooth address, an artificial or obsequious air, fawning adulation, or a polite servility of manners; but in a just and modest sense of our own dignity and that of others, and of the reverence due to mankind, especially to those who hold the higher links of the social chain; in a different and manly accommodation of ourselves to the fables and humours of others; in a strict observance of the rules of decorum and civility; but above all in a frank obliging carriage, and generous interchange of good deeds rather than words. Such a conduct is of great use and advantage, as it is an excellent security against injury, and the best claim and recommendation to the esteem, civility, and universal respect of mankind. This inferior order of virtues unites the particular members of society more closely, and form the less pillars of the civil fabric; which, in many instances, supply the unavoidable defects of laws, and maintain the harmony and decorum of social intercourse, where the more important and essential lines of virtue are wanting.

Charity and forgiveness are truly amiable and useful duties of the social kind. There is a twofold distinction of rights commonly taken notice of by moral writers, viz. perfect and imperfect. To fulfill the former, is necessary to the being and support of society; to fulfill the latter, is a duty equally sacred and obligatory, and tends to the improvement and prosperity of society: but as the violation of them is not equally prejudicial to the public good, the fulfilling them is not subjected to the cognizance of laws, but left to the candor, humanity, and gratitude of individuals. And by this means ample scope is given to exercise all the generosity, and display the genuine merit and luftre of virtue. Thus the wants and misfortunes of others call for our charitable assistance and feaonable supplies: and the good man, unconstrained by law, and uncontrolled by human authority, will cheerfully acknowledge and generously satisfy this mournful and moving claim; a claim supported by the sanction of heaven, of whose bounties he is honoured to be the grateful trustee. If his own perfect rights are invaded by the injustice of others, he will not therefore reject their imperfect right to pity and forgiveness, unless his grant of these should be inconsistent with the more extensive rights of society or the public good. In that case he will have recourse to public justice and the laws; and even then he will prosecute the injury with no unnecessary severity, but rather with mildness and humanity. When the injury is merely personal, and of such a nature as to admit of alleviations, and the forgiveness of which would be attended with no worse confequences, especially of a public kind, the good man will generously forgive his offending brother. And it is his duty to do so, and not to take private revenge, or retaliate evil for evil. For though resentment of injury is a natural passion, and implanted, as was observed above, for wise and good ends; yet, considering the manifold partialities which most men have for themselves, was every one to act as judge in his own cause, and to execute the sentence dictated by his own resentment, it is but too evident that mankind would pass all bounds in their fury, and the last sufferer be provoked in his turn to make full reprisals. So that evil, thus encountering with evil, would produce one continued series of violence and misery, and render society intolerable, if not impracticable. Therefore, where the security of the individual, or good of the public, does not require a proportionable retaliation, it is agreeable to the general law of benevolence, and to the particular end of the passion (which is to prevent injury, and the misery occasioned by it) to forgive personal injuries, or not to return evil for evil. This duty is one of the noble refinements which Christianity has made upon the general maxims and practice of mankind, and enforced with a peculiar strength and beauty by sentiments no less alluring than awful. And indeed the practice of it is generally its own reward; by expelling from the mind the most dreadful intruders upon its repose, those rancorous passions which are begot and nursed by resentment; and by disarming and even subduing every enemy one has, except such as have nothing left of men but the outward form.

The most enlarged and humane connection of the private kind, seems to be the hospitable alliance from which flow the amiable and disinterested duties we owe to strangers. If the exercise of passions of the most private and instinctive kind is held with moral approbation and delight, how lovely and venerable must those appear, which result from a calm philanthropy, are founded in the common rights and connections of society, and embrace men, not...
not of a particular sect, party, or nation, but all in general without distinction, and without any of the little partialities of self-love!

Social Duties of the Commercial Kind.

The next order of connections are those which arise from the wants and weaknesses of mankind, and from the various circumstances in which their different situations place them. These we may call commercial connections; and the duties which result from them commercial duties, as justice, fair-dealing, sincerity, fidelity to compacts, and the like.

Though nature is perfect in all her works, yet she has observed a manifest and eminent distinction among them. To all such as lie beyond the reach of human skill and power, and are properly of her own department, she has given the finishing hand. These may design after and imitate; but he can neither rival them, nor add to their beauty or perfection; such are the forms and structures of vegetables, animals, and many of their productions. There are others of her works which she has of design left unfinished, as it were, in order to exercise the ingenuity and power of man. She has presented to him a rich profusion of materials of every kind for his convenience and use; but they are rude and unpolished, or not to be come at without art and labour. These therefore he must apply, in order to adapt them to his use, and to enjoy them in perfection. Thus nature has given him an infinite variety of herbs, grain, fossils, minerals, wood, water, earth, and a thousand other crude materials to supply his numerous wants. But he must saw, plant, dig, refine, polish, build, and, in short, manufacture the various produce of nature, in order to obtain even the necessaries, and much more the conveniences and elegancies of life. These, then, are the price of his labour and industry; and, without that, nature will fell him nothing. But as the wants of mankind are many, and the single strength of individuals small, they could hardly find the necessaries, and much less the conveniences of life, without uniting their ingenuity and strength in acquiring these, and without a mutual intercourse of good offices. Some men are better formed for some kinds of ingenuity and labour, and others for other kinds; and different soils and climates are enriched with different productions; so that men, by exchanging the produce of their respective labours, and supplying the wants of one country with the superfluities of another, do, in effect, diminish the labours of each, and increase the abundance of all. This is the foundation of all commerce, or exchange of commodities and goods one with another; in order to facilitate which, men have contrived different species of coin or money, as a common standard by which to estimate the comparative values of their respective goods. But, to render commerce secure and effectual, justice, fair-dealing, sincerity, and fidelity to compacts are absolutely necessary.

Justice, or fair dealing, or, in other words, a disposition to treat others as we would be treated by them, is a virtue of the first importance, and inseparable from the virtuous character. It is the cement of society, or that pervading spirit which connects its members, inspires its various relations, and maintains the order and subordination of each part to the whole. Without it, society would become a den of thieves and banditti, hating and hated, devouring and devoured, by one another.

Sincerity or veracity in our words and actions is another virtue or duty of great importance to society, being one of the great bands of mutual intercourse, and the foundation of mutual trust. Without it, society would be the dominion of mistrust, jealousy and fraud, and conversation a traffic of lies and dissimulation. It includes in it a conformity of our words with our sentiments, a correspondence between our actions and dispositions, a strict regard to truth, and an irreconcilable abhorrence of falsehood. It does not indeed require that we expose our sentiments indifferently, or tell all the truth in every case; but certainly it does not and cannot admit the least violation of truth, or contradiction to our sentiments. For if these bounds are once passed, no possible limit can be assigned where the violation shall stop; and no pretence of private or public good can possibly counterbalance the ill consequences of such a violation.

Fidelity to promises, compacts and engagements, is likewise a duty of such importance to the security of commerce and interchange of benevolence among mankind, that society would soon grow intolerable without the strict observance of it. Hobbes, and others who follow the same track, have taken a wonderful deal of pains to puzzle this subject, and to make all the virtues of this fort merely artificial, and not at all obligatory, antecedent to human conventions. No doubt, compacts suppose people who make them, and promises suppose persons to whom they are made; and therefore both suppose some society more or less between those who enter into these mutual engagements. But is not a compact or promise binding, till men have agreed that they shall be binding? Or are they only binding because it is our interest to be bound by them, or to fulfill them? Do not we highly approve the man who fulfills them, even though they should prove to be against his interest? And do not we condemn him as a knave, who violates them on that account? A promise is a voluntary declaration, by words, or by an action equally significant, of our resolution to do something in behalf of another, or for his service. When a promise is made, the person who makes it is by all supposed under an obligation to perform it; and he to whom it is made may demand the performance as his right. That perception of obligation is a simple idea, and is on the same footing as our other moral perceptions; which may be described by instances, but cannot be defined. Whether we have a perception of such obligation quite distinct from the interest, either public or private, that may accompany the fulfillment of it, must be referred to the conscience of every individual. And, whether the mere sense of that obligation, apart from its concomitants, is not a sufficient inducement or motive to keep one's promise, without having recourse to any selfish principle of our nature, must be likewise appealed to the conscience of every honest man. Fair dealing and fidelity to compacts require that we take no advantage of the ignorance, passion, or incapacity of others, from whatever cause that incapacity arises;—that we be explicit and candid in making bargains, just and faithful
faithful in fulfilling our part of them. And if the other party violates his engagements, redress is to be sought from the laws, or from those who are intrusted with the execution of them. In fine, the commercial virtues and duties require that we not only do not invade, but maintain the rights of others; —that we be fair and impartial in transferring, bartering, or exchanging property, whether in goods or service; —and be inviolably faithful to our word and our engagements, where the matter of them is not criminal, and where they are not extorted by force.

Social Duties of the Political Kind.

We are now arrived at the last and highest order of duties respecting society, which result from the exercise of the most generous and heroic affections, and are founded on our most elegant connections.

The social principle in man is of such an expansive nature, that it cannot be confined within the circuit of a family, of friends, or a neighbourhood; it spreads into wider systems, and draws men into larger confederacies, communities, and commonwealths. —It is in these only that the higher powers of our nature attain the highest improvement and perfection of which they are capable. These principles hardly find objects in the solitary state of nature. There the principle of action rises no higher at first than natural affections towards one's offspring. There personal or family-wants entirely engross the creature's attention and labour, and allow no leisure, or, if they did, no exercise for views and affections of a more enlarged kind. In solitude all are employed in the same way, in providing for the animal life. And even after their utmost labour and care, single and unaided by the industry of others, they find but a sorry supply of their wants, and a feeble precarious security against dangers from wild beasts, from inclement skies and seasons, from the mistakes or petulant passions of their fellow-creatures, from their preference of themselves to their neighbours, and from all the little exorbitances of self-love. But in society, the mutual aids which men give and receive shorten the labours of each, and the combined strength and reason of individuals give security and protection to the whole body. There is both a variety and subordination of genius among mankind. Some are formed to lead and direct others; to contrive plans of happiness for individuals, and of government for communities; to take in a public interest; to invent laws and arts, and superintend their execution; and, in short, to refine and civilize human life. Others, who have not such good heads, may have as honest hearts, a truly public spirit, love of liberty, hatred of corruption and tyranny, a generous submission to laws, order, and public institutions, and an extensive philanthropy. And others, who have none of those capacities either of heart, or head, may be well formed for manual exercises and bodily labour. The former of these principles have no scope in solitude, where a man's thoughts and concerns do all either center in himself, or extend no farther than a family; into which little circle all the duty and virtue of the solitary mortal is crowded. But society finds proper objects and exercises for every genius, and the noblest objects and exercises for the noblest geniuses, and for the highest principles in the human constitution: particularly for that warmest and most divine passion, which God hath kindled in our bosoms, the inclination of doing good, and reverencing our nature; which may find here both employment, and the most exquisite satisfaction. In society a man has not only more leisure, but better opportunities of applying his talents with much greater perfection and success, especially as he is furnished with the joint advice and assistance of his fellow-creatures, who are now more closely united one with the other, and sustain a common relation to the same moral system, or community.

This then is an object proportioned to his most enlarged social affections, and in serving it he finds scope for the exercise and refinement of his highest intellectual and moral powers. Therefore society, or a state of civil government, rests on these two principal pillars; “that in it we find security against those evils which are unavoidable in solitude; and obtain those goods, some of which cannot be obtained at all, and others not so well, in that state, where men depend solely on their individual sagacity and industry.”

From this short detail it appears that man is a social creature, and formed for a social state; and that society, being adapted to the higher principles and dispositions of his nature, must, of necessity, be his natural state.

The duties suited to that state, and resulting from those principles and dispositions, or, in other words, from our social affections and social connections, or relation to a public system, are love of our country, resignation and obedience to the laws, public spirit, love of liberty, sacrifice of life and all to the public, and like.

Love of our country is one of the noblest passions that can warm and animate the human breast. It includes all the limited and particular affections to our parents, children, friends, neighbours, fellow-citizens, countrymen. It ought to direct and limit their more confined and partial actions within their proper and natural bounds, and never let them incroach on those sacred and first regards we owe to the great public to which we belong. Were we solitary creatures, detached from the rest of mankind, and without any capacity of comprehending a public interest, or without affections leading us to desire and pursue it, it would not be our duty to mind it, nor criminal to neglect it. But, as we are parts of the public system, and are not only capable of taking in large views of its interests, but by the strongest affections connected with it, and prompted to take a share of its concerns, we are under the most sacred ties to prosecute its security and welfare with the utmost ardor, especially in times of public trial. This love of our country does not import an attachment to any particular soil, climate, or spot of earth, where perhaps we first drew our breath, though those natural ideas are often associated with the moral ones, and, like external signs or symbols, help to ascertain and bind them; but it imports an affection to that moral system, or community, which is governed by the same laws and magistrates, and whose several parts are variously connected one with the other, and all united upon the bottom of a common interest. Perhaps indeed every member of the community cannot comprehend so large an object, especially if it extends through large provinces.
provinces, and over vast tracts of land; and still less can be formed such an idea, if there is no public, i.e., if all are subjected to the caprice and unlimited will of one man: but the preference the generality shew to their native country, the concern and longing after it which they express when they have been long absent from it, the labours they undertake and sufferings they endure to save or serve it, and the peculiar attachment they have to their countrymen, evidently demonstrate that the passion is natural, and never fails to exert itself, when it is fairly disengaged from foreign clogs, and is directed to its proper object. Where-ever it prevails in its genuine vigour and extent, it swallows up all forbid and selfish regards; it conquers the love of ease, power, pleasure and wealth; nay, when the amiable partialities of friendship, gratitude, private affection, or regard to a family come in competition with it, it will teach us bravely to sacrifice all, in order to maintain the rights and promote or defend the honour and happiness of our country.

Resignation and obedience to the laws and orders of the society to which we belong, are political duties necessary to its very being and security, without which it must soon degenerate into a state of licence and anarchy. The welfare, nay, the nature of civil society, requires that there should be a subordination of orders or diversity of ranks and conditions in it;—that certain men, or orders of men, be appointed to superintend and manage such affairs as concern the public safety and happiness;—that all have their particular provinces assigned them;—that such a subordination be settled among them, as none of them may interfere with another;—and finally, that certain rules or common measures of action be agreed on, by which each is to discharge his respective duty to govern or be governed, and all may concur in securing the order and promoting the felicity of the whole political body. Those rules of action are the laws of the community; and those different orders are the several officers, or magistrates, appointed by the public to explain them, and superintend or assist in their execution. In consequence of this settlement of things, it is the duty of each individual to obey the laws enacted, to submit to the execution of them with all due deference and homage according to their respective ranks and dignity, as to the keepers of the public peace, and the guardians of public liberty; to maintain his own rank, and perform the functions of his own station with diligence, fidelity, and incorruption.

The superiority of the higher orders, or the authority with which the state has invested them, entitle them, especially if they employ their authority well, to the obedience and submission of the lower, and to a proportionable honour and respect from all. The subordination of the lower ranks claims protection, defence, and security from the higher. And the laws, being superior to all, require the obedience and submission of all; being the last resort, beyond which there is no decision or appeal.

Public spirit, heroic zeal, love of liberty, and the other political duties, do, above all others, recommend those who practise them to the admiration and homage of mankind; because, as they are the offspring of the noblest minds, so are they the parents of the greatest blessings to society. Yet, exalted as they are, it is only in equal and free governments where they can be exercised and have their due effect: for there only does a true public prevail, and there only is the public good made the standard of the civil constitution. As the end of society is the common interest and welfare of the people associated, this end must of necessity be the supreme law or common standard by which the particular rules of action of the several members of the society towards each other are to be regulated. But a common interest can be no other than that which is the result of the common reason, or common feelings of all. Private men, or a particular order of men, have interests and feelings peculiar to themselves, and of which they may be good judges: but these may be separate from, and often contrary to the interests and feelings of the rest of the society; and therefore they can have no right to make, much less to impose, laws on their fellow-citizens, inconscient with, or opposite to, those interests and those feelings. Therefore a society, a government, a real public, truly worthy the name; and not a confederacy of banditti, a clan of lawless savages, or a band of slaves under the whip of a master; must be such a one as consists of freemen, chusing or confenting to laws themselves, or, since it often happens that they cannot assemble and act in a collective body, delegating a sufficient number of representatives, i.e. such a number as shall most fully comprehend, and most equally represent, their common feelings and common interests, to digest and vote laws for the conduct and control of the whole body the most agreeable to those common feelings and common interests.

A society thus constituted by common reason, and formed on the plan of a common interest, becomes immediately an object of public attention, public veneration, public obedience, a public and inviolable attachment, which ought neither to be seduced by bribes, nor awed by terrors; an object, in fine, of all those extensive and important duties which arise from so glorious a confederacy. To watch over such a system; to contribute all he can to promote its good by his reason, his ingenuity, his strength, and every other ability, whether natural or acquired; to resist, and to the utmost of his power defeat, every incroachment upon it, whether carried on by secret corruption, or open violence; and to sacrifice his ease, his wealth, his power, his life itself, and, what is dearer still, his family and friends, to defend or save it; is the duty, the honour, the interest, and the happiness of every citizen; it will make him venerable and beloved while he lives, be lamented and honoured if he falls in so glorious a cause, and transmit his name with immortal renown to the latest posterity.

As the people are the fountain of power and authority, the original seat of majesty, the authors of laws, and the creators of officers to execute them; if they shall find the power they have conferred abused by their traitors, their majesty violated by tyranny or by usurpation, their authority prostituted to support violence or screen corruption, the laws grown pernicious through accidents unforeseen or unavoidable, or rendered ineffectual thro' the infidelity and corruption of the executors of them; then it is their right, and what is their duty, to...
ty, to resume that delegated power, and call their trustees to an account; to redress the usurpation, and extirpate the tyranny; to restore their fullied majesty and prostituted authority; to suspend, alter, or abrogate those laws, and punish their unfaithful and corrupt officers. Nor is it the duty only of the united body, but every member of it ought, according to his respective rank, power, and weight in the community, to concur in advancing and supporting those glorious designs.

**Duty to God.**

Or all the relations which the human mind sustains, that which subsists between the Creator and his creatures, the Supreme Lawgiver and his subjects, is the highest and the best. This relation arises from the nature of a creature in general, and the constitution of the human mind in particular; the noblest powers and affections of which point to an Universal Mind, and would be imperfect and abortive without such a direction. How lame then must that system of morals be, which leaves a Deity out of the question! How disconsolate, and how destitute of its firmest support!

It does not appear, from any true history or experience of the mind's progress, that any man, by any formal deduction of his dispassionate powers, ever reasoned himself into the belief of a God. Whether such a belief is only some natural anticipation of soul; or is derived from father to son, and from one man to another, in the way of tradition; or is suggested to us in consequence of an immutable law of our nature, on beholding the august aspect and beautiful order of the universe; we will not pretend to determine. What seems most agreeable to experience is, that a sense of its beauty and grandeur, and the admirable fitness of one thing to another in its vast apparatus, leads the mind necessarily and unavoidably to a perception of design, or of a designing cause, the origin of all, by a progress as simple and natural as that by which a beautiful picture or a fine building suggests to us the idea of an excellent artist. For it seems to hold universally true, that whenever we discern a tendency or cooperation of things towards a certain end, or producing a common effect; there, by a necessary law of association, we apprehend design, a designing energy or cause: See **Metaphysics.** As we conceive this Being or First Cause before all, above all, and greater than all, we naturally, and without reasoning, ascribe to him every kind of perfection, wisdom, power, and goodness without bounds, existing through all time, and pervading all space. We apply to him those glorious epithets of our Creator, Preparator, Benefactor, the Supreme Lord and Law-giver of the whole society of rational intelligent creatures.

Not only the imperfections and wants of our being and condition, but some of the noblest instincts and affections of our minds, connect us with this great and universal nature. The mind, in its progress from object to object, from one character and prospect of beauty to another, finds some blemish or deficiency in each; and soon exhausts or grows weary and dissatisfied with its subject: it feels no character of excellency among men, equal to that pitch of esteem which it is capable of excelling; no object within the compass of human things adapted to the strength of its affection. Nor can it stop anywhere in this self-expansive progress, or find repose after its highest flights, till it arrives at a Being of unbounded greatness and worth, on whom it may employ its sublimest powers without exhausting the subject, and give scope to the utmost force and fulness of its love without fatiety or disgust. So that the nature of this Being corresponds to the nature of man; nor can his intelligent and moral powers obtain their entire end, but on the supposition of such a Being, and without a real sympathy and communication with him. The native propensity of the mind to reverence whatever is great and wonderful in nature, finds a proper object of homage in him who spread out the heavens and the earth, and who sustains and governs the whole of things. The admiration of beauty, the love of order, and the complacency we feel in goodnes, must rise to the highest pitch, and attain the full vigour and joy of their operations, when they unite in Him who is the sum and source of all perfection.

It is evident, from the slightest survey of morals, that how punctual ever one may be in performing the duties which result from our relations to mankind; yet to be quite deficient in performing those which arise from our relation to the Almighty, must argue a strange perversion of reason or depravity of heart. If imperfect degrees of worth attract our veneration, and if the want of it would imply an insensibility, or which is worse, an aversion to merit; what lameness of affection, and immorality of character, must it be, to be unaffected with, and much more to be ill-affected to, a Being of superlative worth! To love society, or particular members of it, and yet to have no sense of our connection with its Head, no affection to our common Parent and Benefactor; to be concerned about the approbation or cenure of our fellow-creatures, and yet to feel nothing of this kind towards Him who feeds and weighs our actions with unerring wisdom and justice, and can fully reward or punish them; betrays equal madness and partiality of mind. It is plain, therefore, beyond all doubt, that some regards are due to the great Father of all, in whom every lovely and adorable quality combines to inspire veneration and homage.

As it has been observed already, that our affections depend on our opinions of their objects, and generally keep pace with them, it must be of the highest importance, and seems to be among the first duties we owe to the Author of our being, "to form the least imperfect, since we cannot form perfect conceptions of his character and administration." For such conceptions, thoroughly imbibed, will render our religion rational, and our dispositions refined. If our opinions are diminutive and distorted, our religion will be superstitious, and our temper abject. The foundation, then, of all true religion is a rational faith. And of a rational faith these seem to be the chief articles: To believe, "that an infinite all-perfect Mind exists, who has no opposite nor any separate interest from that of his creatures;—that he superintends and governs all creatures and things;—that his goodnes extends to all his creatures, in different degrees indeed, according to their respective natures, but without any partiality or envy:—that he does every thing for the best, or
or in a subserviency to the perfection and happiness of the whole;—particularly, that he directs and governs the affairs of men,—insects their actions,—distinguishes the good from the bad,—loves and befriends the former,—is displeased with and pities the latter in this world,—and will, according to their respective defects, reward the one, and punish the other in the next—that, in fine, he is always carrying on a scheme of virtue and happiness through an unlimited duration,—and is ever guiding the universe through its successive stages and periods, to higher degrees of perfection and felicity.” This is true therein, the glorious scheme of divine faith; a scheme exhibited in all the works of God, and executed through his whole administration.

This faith, well-founded and deeply felt, is nearly connected with a true moral taste, and hath a powerful efficacy on the temper and manners of the theft. He who adores goodness in others, and delights in the practice of it, must be conscious of a reigning order within, a rectitude and candor of heart which dispels him to entertain favourable apprehensions of men, and, from an impartial survey of things, to presume that good order and good meaning prevail in the universe; and if good meaning and good order, then an ordering, and intending Mind, who is no enemy, no tyrant to his creatures, but a friend, a benefactor, an indulgent sovereign. On the other hand, a bad man, having nothing goodly or generous to contemplate within, no right intentions, nor honesty of heart, suspects every person and every thing; and beholding nature through the gloom of a selfish and guilty mind, is either averse to the belief of a reigning order; or, if he cannot suppress the unconquerable anticipations of a governing mind, he is prone to tarnish the beauty of nature, and to impute malvolence, or blindness and impotence at least, to the Sovereign Ruler. He turns the universe into a forlorn and horrid waste; and transfers his own character to the Deity, by ascribing to him that uncommunicative grandeur, that arbitrary or revengeful spirit which he affects or admires in himself. As such a temper of mind naturally leads to atheism, or to a superstitious ful as bad; therefore, as far as that temper depends on the unhappy creature in whom it prevails, the propensity to atheism or superstition consequent thereto must be immoral. Farther, it is true that the belief or feene of a Deity is natural to the mind, and the evidence of his existence reflected from his works to full as to strike even the most superficial observer with conviction; then the supplanting or corrupting that sense, or the want of due attention to that evidence, and, in consequence of both, a supine ignorance or affected unbelief of a Deity, must argue a bad temper, or an immoral turn of mind. In the case of invincible ignorance, or a very bad education, though nothing can be concluded directly against the character, yet whenever ill passions and habits pervert the judgment, and by perverting the judgment terminate in atheism, then the case becomes plainly criminal.

But let casuists determine this as they will, a true faith in the divine character and administration is generally the consequence of a virtuous state of mind. The man who is truly and habitually good, feels the love of order, of beauty, and goodness, in the strongest degree; and therefore cannot be insensible to those emanations of them which appear in all the works of God, nor help loving their Supreme Source and Model. He cannot but think, that He who has poured such beauty and goodness over all his works, must Himself delight in beauty and goodness, and what He delights in must be both amiable and happy. Some indeed there are, and it is pity there should be any such, who, through the unhappy influence of a wrong education, have entertained dark and unfriendly thoughts of a Deity and his administration, though otherwise of a virtuous temper themselves. However, it must be acknowledged, that such sentiments have, for the most part, a bad effect on the temper; and when they have not, it is because the undepraved affections of an honest heart are more powerful in their operation, than the speculative opinions of an ill-formed head.

But where ever right conceptions of the Deity and his providence prevail, when he is considered as the inexhausted source of light and love and joy, as acting in the joint character of a father and governor, imparting an endless variety of capacities to his creatures, and supplying them with every thing necessary to their full comple tion and happiness; what veneration and gratitude must such conceptions thoroughly believed excite in the mind! How natural and delightful must it be to one whose heart is open to the perception of truth, and of every thing fair, great, and wonderful in nature, to contemplate and adore Him, who is the First Fair, the First Great, and First Wonderful; in whom wisdom, power and goodness dwell vitally, essentially, originally, and in perfect concord! What grandeur is here to fill the most enlarged capacity, what beauty to engage the most ardent love, and what a mass of wonders in such exuberance of perfection, to astonish and delight the human mind through an unfailling duration!

If the Deity is considered as our supreme guardian and benefactor, as the father of mercies, who loves his creatures with infinite tenderness, and in a particular manner all good men, nay, who delights in goodness even in its most imperfect degrees; what resignation, what dependence, what generous confidence, what hope in God and his all-wise providence, must arise in the foul that is possessed of such amiable views of him! All those exercises of piety, and above all a superstitious efficacy and love, are directed to God as to their natural, their ultimate, and indeed their only adequate object; and though the immense obligations we have received from him may excite in us more lively feelings of divine goodness than a general and abstracted contemplation of it; yet the affections of gratitude and love are themselves of the generous disinterested kind, not the result of selfish interest, or views of reward. A perfect character, in which we always suppose infinite goodness, guided by unerring wisdom, and supported by almighty power, is the proper object of perfect love; and though that character suffrains to us the relation of a benefactor, yet the mind, deeply struck with that perfection, is quite lost amid such a blaze of beauty.
ty, and grows as it were insensible to those minutest ir-
radiations of it upon itself. To talk, therefore, of a mer-
cenary love of God, or which has fear for its principal
ingredient, is equally impious and absurd. If we do not
love the loveliest object in the universe for its own sake,
no prospect of good or fear of ill can ever inspire our ef-
ferve, or captivate our love. These affections are too
noble to be bought or sold, or barred in the way of
gain; worth, or merit, as their object, and their reward
is something similar in kind. Whoever indulges fuch
sentiments and affections towards the Deity, must be con-
firmed in the love of virtue, in a desire to imitate its all-
perfect Pattern, and in a cheerful security that all his great
concerns, those of his friends and of the universe, shall
be absolutely safe under the conduct of unerring wis-
dom and unbounded goodness. It is in his care and
providence alone that the good man, who is anxious for
the happiness of all, finds perfect serenity, a serenity
neither ruffled by partial ill, nor soured by private disap-
pointment.

When we consider the unslained purity and absolute
perfection of the divine nature, and reflect withal on the
imperfection and various blemishes of our own, we must
sink, or be convinced we ought to sink, into the deepest
humility and prostration of soul before Him who is so
wonderfully great and holy. When, farther, we call to
mind what low and languid feelings we have of the Divine
Presence and Majesty; what insensibility of his fatherly
and universal goodness, nay, what ungrateful returns we
have made to it; how far we come short of the perfection
of his law, and the dignity of our own nature; how much
we have indulged to the selfish passions, and how little to
the benevolent ones; we must be conscious that it is our
duty to repent of a temper and conduct so unworthy our
nature, and unbecoming our obligations to its Author,
and to resolve and endeavour to act a wiser and better
part for the future.

Nevertheless, from the character which his works ex-
hibit of him, from those delays or alleviations of punish-
ment which offenders often experience, and from the
merciful tenour of his administration in many other in-
fiances, the sincere penitent may entertain good hopes that
his Parent and Judge will not be strict to mark iniquity, but
will be propitious and favourable to him, if he honestly
endeavours to avoid his former practices, and subdue his
former habits, and to live in a greater conformity to the
divine will for the future. If any doubts or fears should
still remain, how far it may be consistent with the recti-
tude and equity of the divine government to let his in-
quities pass unpunished; yet he cannot think it unsuitable
to his paternal clemency and wisdom to contrive a method
of retrieving the penitent offender, that shall unite and
reconcile the majesty and mercy of his government. If
reason cannot of itself suggest such a scheme, it gives at
least some ground to expect it. But though natural reli-
gion cannot let in more light and assurance on so interes-
ting a subject, yet it will teach the humble thief to wait with
great submissiveness for any farther intimations it may please
the Supreme Governor to give of his will; examine with
candour and impartiality whatever evidence shall be pro-
posed to him of a divine revelation, whether that evidence
is natural or supernatural; to embrace it with veneration
and cheerfulnes, if the evidence is clear and convincing;
and finally, if it bring to light any new relations or con-
nections, natural religion will persuade its sincere votary
faithfully to comply with the obligations, and perform the
duties which result from those relations and connections.

—This is theism, piety, the completion of morality!

We must further observe, that all those affections which
we suppos'd to regard the Deity as their immediate and
primary object, are vital energies of the soul, and conse-
quentially exert themselves into act; and like all its other
energies, gain strength or greater activity by that exertion,
It is therefore our duty, as well as highest interest, often,
at flated times, and by decent and solemn acts, to con-
template and adore the great Original of our existence, the
Parent of all beauty, and of all good; to express our ve-
neration and love, by an awful and devout recognition of
his perfections; and to evidence our gratitude, by celebra-
ting his goodness, and thankfully acknowledging all his
benefts. It is likewise our duty, by proper exercises of
forrow and humiliation, to confess our ingratitude and
folly; to signify our dependence on God, and our con-
science in his goodness, by imploring his blessing and gra-
cious concurrence in assisting the weakens, and curing the
corruptions of our own nature; and finally, to testify our fe-
ne of his authority, and our faith in his government, by de-
voiting ourselves to do his will, and resigned ourselves to
deipofal. These duties are not therefore obligatory,
because the Deity needs or can be profited by them; but
as they are apparently decent and moral; suitable to the
relations he fulfains of our Creator, Benefactor, Law-giver
and Judge; expressive of our state and obligations; and
improving to our tempers, by making us more rational,
social, godlike, and consequently more happy.

We have now confidered internal piety, or the worship
of the mind, that which is in spirit and in truth; we shall
conclude the fection with a short account of that which is
external. External worship is founded on the fame prin-
ciples as internal, and of a ftrict moral obligation. It is
either private or public. Devotion, that is inward, or
purely intellectual, is too spiritual and abstruded an ope-
ration for the bulk of mankind. The operations of their
minds, such especially as are employed on the most sublime
immaterial objects, must be abstrued by their outward
organs, or by some help from the imagination, otherwise
they will be soon dissipated by fensible impressions, or grow
tiresome if too long continued. Ideas are such fleeting
things that they muft be fixed, and fo fubtle that they
must be expressed and delineated, as it were, by fensible
marks and images; otherwise we cannot attend at them,
nor be much affected to them. Therefore verbal adora-
tion, prayer, praise, thanking, and confeffion, are ad-
mirable aids to inward devotion, fix our attention, com-
pone and enliven our thoughts, impress us more deeply
with a fenfe of the awful prefeuce in which we are, and,
by a natural and mechanical fort of influence, tend to
heighten those devout feelings and affections which we
ought to entertain, and after this manner reduce into for-
mal and explicit act.

This holds true in an higher degree in the cafe of pub-
lic worship, where the presence of our fellow-creatures,
and the powerful contagion of the social affections, con-
spire to kindle and spread the devout flame with greater
energy.
energy. To conclude: As God is the parent and head of the social system; as he has formed us for a social state; as by one we find the best security against the ills of life, and in the other enjoy its greatest comforts; and as, by means of both, our nature attains its highest improvement and perfection: and moreover, as there are public blessings and crimes in which we all share in some degree, and public wants and dangers to which all are exposed; it is therefore evident, that the various and solemn offices of public religion, are duties of indissoluble moral obligation, among the best cements of society, the firmest prop of government, and the fairest ornament of both.

Of Practical Ethics, or the Culture of the Mind.

We have now gone through a particular detail of the several duties we owe to ourselves, to society, and to God. In considering the first order of duties, we just touched on the methods of acquiring the different kinds of goods which we are led by nature to pursue; only we left the consideration of the method of acquiring the moral goods of the mind to a feeling by itself, because of its singular importance. This section, then, will contain a brief enumeration of the arts of acquiring virtuous habits, and of eradicating vicious ones, as far as is consistent with the brevity of such a work; a subject of the utmost difficulty as well as importance in morals: to which, nevertheless, the least attention has been generally given by moral writers, especially those of a modern date. This will properly follow a detail of duty, as it will direct us to such means or helps as are most necessary and conducive to the practice of it.

In the first part of this inquiry we traced the order in which the passions shoot up in the different periods of human life. That order is not accidental, nor dependent on the caprice of men, or the influence of custom and education; but arises from the original constitution and laws of our nature; of which this is one, viz. “That sensible objects make the first strongest impressions on the mind.” These, by means of our outward organs, being conveyed to the mind, become objects of its attention on which it reflects when the outward objects are no longer present, or, in other words, when the impressions upon the outward organs cease. These objects of the mind’s reflection are called ideas or images. Towards these, by another law of our nature, we are not altogether indifferent; but correspondent movements of desire or aversion, love or hatred, affections, according as the objects of which they are images or copies made an agreeable or disagreeable impression on our organs. These ideas and affections which we experience in the first period of life, we refer to the body, or to sense; and the taste which is formed towards them, we call a sensible, or a merely natural taste; and the objects corresponding to them we in general call good or pleasant.

But, as the mind moves forward in its course, it extends its views, and receives a new and more complex set of ideas, in which it observes uniformity, variety, finitude, symmetry of parts, reference to an end, novelty, grandeur. These compose a vast train and diversity of images, which the mind compounds, divides, and moulds into a thousand forms, in the absence of those objects which first introduced it. And this more complicated imagery fuses a new train of desires and affections, full as sprightly and engaging as any which have yet appeared.

This whole class of perceptions or impressions is referred to the imagination, and forms an higher taste than the sensible, and which has an immediate and mighty influence on the finer passions of our nature, and is commonly termed a fine taste.

The objects which correspond to this taste we use to call beautiful, harmonious, great, or wonderful, or, in general, by the name of beauty.

The mind still pushing onwards, and increasing its flock of ideas, ascends to those to an higher species of objects, viz. the order and mutual relations of minds to each other, their reciprocal affections, characters, actions, and various aspects. In these it discovers a beauty, a grandeur, a decorum more interesting and alluring than in any of the former kinds. These objects, or the images of them, passing in review before the mind, do, by a necessary law of our nature, call forth another and nobler set of affections, as admiration, esteem, love, honour, gratitude, benevolence, and others of the like tribe. This class of perceptions, and their correspondent affections, we refer, because of their objects (manners,) to a moral sense; and call the taste or temper they excite, moral: and the objects which are agreeable to this taste or temper we denominate by the general name of moral beauty; in order to distinguish it from the other, which is termed natural.

These different sets of ideas or images are the materials about which the mind employs itself; which it blends, ranges, and diversifies ten thousand different ways. It feels a strong propensity to connect and associate those ideas among which it observes any similarity, or any aptitude, whether original and natural, or customary and artificial, to suggest each other. See Metaphysics.

But whatever the reasons are, whether similitude, co-existence, causality, or any other aptitude or relation, why any two or more ideas are connected by the mind at first, it is an established law of our nature, “That when two or more ideas have often started in company, they form a strong union, that it is very difficult ever after to separate them.” Thus the lover cannot separate the idea of merit from his mistress; the courtier that of dignity from his title or ribbon; the miser that of happiness from his bags. — It is these associations of worth or happiness with any set of objects or images that form our taste or complex idea of good. By another law of our nature, “our affections follow and are governed by this taste; and to these affections our character and conduct are similar and proportioned, on the general tenor of which our happiness principally depends.”

As all our leading passions, then, depend on the direction which our taste takes, and as it is always of the same train with our leading affections, it is worth while to inquire a little more particularly how these are formed, in order to detect the secret sources from whence our passions derive their principal strength, their various rises
and falls. For this will give us the true key to their management, and let us into the right method of correcting the bad, and improving the good.

No kind of objects makes so powerful an impression on us as those which are immediately impressed on our senses, or strongly painted on our imaginations. Whatever is purely intellectual, as abstracted or scientific truths, the subtle relations and difference of things, has a fainter sort of existence in the mind; and, though it may exercise and whet the memory, the judgment, or the reasoning powers, gives hardly any impulse at all to the active powers, the passions, which are the main springs of motion. On the other hand, were the mind entirely under the direction of sense, and impervious only by such objects as are present and strike some of the outward organs, we should then be precisely in the state of the brute creation, and be governed solely by instinct or appetite, and have no power to control whatever impressions are made upon us. Nature has therefore endowed us with a middle faculty, wonderfully adapted to our mixed state; which holds partly of sense, and partly of reason; being strongly allied to the former, and the common receptacle in which all the notices that come from that quarter are treasured up; and yet greatly subservient and ministerial to the latter, by giving a body, a coherence, and beauty to its conceptions. This middle faculty is called the imagination, one of the most busy and fruitful powers of the mind. Into this common storehouse are mixed all those moral images or forms which are derived from our moral faculties of perception; and there they often undergo new changes and appearances, by being mixed and wrought up with the images and forms of sensible or natural things. By this coalition of imagery, natural beauty is dignified and heightened by moral qualities and perfections, and moral qualities are at once exhibited and set off by natural beauty. The sensible beauty, or good, is refined from its dross by parings or appearing, and sensible enjoyments, we contract early a sensual relish or love of pleasure in the lower sense of the word. In order, however, to justify this relish, the mind, as it becomes open to higher perceptions of beauty and good, borrows from thence a nobler heter of images, as fine taste, generosity, social affection, friendship, good-fellowship, and the like; and, by dressing out the old pursuits with these new ornaments, gives them an additional dignity and lustre. By these ways the desire of a table, love of finery, intrigue, and pleasure, are vastly increased beyond their natural pitch, having an impulse combined of the force of the natural appetites and of the superadded strength of those passions which tend to the moral species.

—When the mind becomes more sensible to those objects or appearances, in which it perceives beauty, uniformity, grandeur, and harmony, as fine cloaths, elegant furniture, plate, pictures, gardens, houses, equipage, the beauty of animals, and particularly the attractions of the sex; to these objects the mind is led by nature, or taught by custom, the opinion and example of others, to annex certain ideas of moral character, dignity, decorum, honour, liberality, tenderness, and active or social enjoyment. The consequence of this association is, that the objects to which these are annexed, mult rise in their value, and be pursued with proportionable ardor. The enjoyment of them is often attended with pleasure; and the mere possession of them, where that is wanting, frequently draws respect from one's fellow-creatures: this respect is, by many, thought equivalent to the pleasure of enjoyment. Hence it happens, that the idea of happiness is connected with the mere possession; which is therefore eagerly sought after, without any regard to the generous use, or honourable enjoyment. Thus the passion relying on the means, not the end, i.e., losing sight of its natural object, becomes wild and extravagant.

In fine, any object, or external denomination, a staff, a garter, a cup, a crown, a title, may become a moral badge or emblem of merit, magnificence, or honour, according as these have been found or thought by the possessors or admirers of them to accompany them; yet, by the deception formerly mentioned, the merit or the conduct which entitled, or should entitle, to those marks of distinction, shall be forgot or neglected, and the badges themselves be passionately affected, or pursued, as including every excellence. If these are attained by any means, all the concomitants which nature, custom, or accidents have joined to them, will be supposed to follow of course. Thus moral ends, with which the unhappy admirer is apt to colour over his passion and views, will, in his opinion, justify the most immoral means, as profition, seduction, fraud, treachery, and every species of knavery, whether more open or more disguised.

When men are once engaged in active life, and find that wealth and power, generally called interests, are the great avenues to every kind of enjoyment, they are apt to throw in many engaging moral forms to the object of their pursuit, in order to justify their passion, and varnish over the measures they take to gratify it; as, independency on the vices or passions of others, provision and security to themselves and their enemies who are all villains, honourable service, and many other ingredients of merit. To attain such capacities of usefulness or enjoyment, what arts, nay, what meaneries can be thought blameable by those cool pursuers of interest?—Nor have they, whom the gay world is pleased to indulge with the title of men of pleasure, their imaginations less pregnant with moral images, with which they never fail to ennoble, or, if they cannot do that, to palliate their gross pursuits. Thus, admiration of wit, of sentiments and merit, friendship, love, generous sympathy, mutual confidence, giving and receiving pleasure, are the ordinary ingredients with which they feed their gallantry and pleasurable entertainments; and by which they impose on themselves, and endeavour to impose on others, that their amours are the joint issue of good sense and virtue.

These associations, variously combined and proportioned by the imagination, form the chief private passions which govern the lives of the generality; as the love of action, of pleasure, power, wealth, and fame: they influence the defensive, and affect the public passions, and raise joy
joy or sorrow, as they are gratified or disappointed. So that, in effect, these associations of good and evil, beauty and deformity, and the passions they raise, are the main hinges of life and manners, and the great sources of our happiness or misery. It is evident, therefore, that the whole of moral culture must depend on giving a right direction to the leading passions, and duly proportioning them to the value of the objects or goods pursued, under what name forever they may appear.

Now, in order to give them this right direction and due proportion, it appears, from the foregoing detail, that these associations of ideas, upon which the passions depend, must be duly regulated: that is to say, as an exorbitant passion for wealth, pleasure, or power, flows from an association or opinion that more beauty and good, whether natural or moral, enters into the enjoyment or possession of them, than really belongs to either; therefore, in restoring those passions to their just proportion, we must begin with correcting the opinion, or breaking the false association; or, in other words, we must decompose the complex phantom of happiness or good, which we fondly admire; disunite those ideas, that have no natural alliance; and separate the original idea of wealth, power, or pleasure, from the foreign mixtures incorporated with it, which enhance its value, or give it its chief power to enchant and seduce the mind. For instance, let it be considered how poor and inconsiderable a thing wealth is, if it be disjoined from real use, or from ideas of capacity in the possessor to do good, from independence, generosity, provision for a family or friends, and social communication with others. By this standard let its true value be fixed; let its misapplication, or unbenevolent enjoyment, be accounted for; and infamous; and nothing worthy or estimable be ascribed to the mere possession of it, which is not borrowed from its generous use.

If that complex form of good which is called pleasure, engages us, let it be analyzed into its constituent principles, or those allurements it draws from the heart and imagination, in order to heighten the low part of indulgence; let the separate and comparative moment of each be distinctly ascertained, and deduced from that gross part; and this remainder of the accumulative enjoyment will dwindle down into a poor, insipid, transitory thing. In proportion as the opinion of the good purposed abates, the admiration must decay, and the passion lose strength of course. One effectual way to lower the opinion, and consequently to weaken the habit founded on it, is to practice lesser pieces of self-denial, or to abstain, to a certain pitch, from the pursuit or enjoyment of the favourite object; and, that this may be the more easily accomplished, one must avoid those occasions, that company, those places, and the other circumstances that inflamed one; and endeared the other: And, as a counter-proofs, let higher or even different enjoyments be brought in view, other passions played upon the former, different places frequented, other exercises tried, company kept with persons of a different or more correct way of thinking both in natural and moral subjects.

As much depends on our setting out well in life, let the youthful fancy, which is apt to be very florid and luxuriant, be early accustomed, by instruction, example, and significant moral exercises, nay, by looks, gestures, and every other testimony of just approbation or blame, to annex ideas of merit, honour, and happiness—not to birth, dreads, rank, beauty, fortune, power, popularity, and the like outward things—but to moral and truly virtuous qualities, and to those enjoyments which spring from a well-informed judgment, and a regular conduct of the affections, especially those of the social and disinterested kind. Such dignified forms of beauty and good, often fuggelled, and, by moving pictures and examples, warmly recommended to the imagination, enforced by the authority of conscience, and demonstrated by reason to be the surest means of enjoyment, and the only independent, undepriable and durable goods, will be the best counter-balance to meaner passions, and the firmest foundation and security to virtue.

It is of great importance to the forming a just taste, or pure and large conceptions of happiness, to study and understand human nature well, to remember what a complicated system it is, particularly to have deeply imprinted on our mind that gradation of fennis, faculties, and powers of enjoyment formerly mentioned, and the subordination of goods resulting from thence, which nature points out, and the experience of mankind confirms; who, when they think seriously, and are not under the immediate influence of some violent prejudice or passion, prefer not the pleasures of action, contemplation, society, and most exercises and joys of the moral kind, as friendship, natural affection, and the like, to all sensual gratifications whatsoever? Where the different species of pleasure are blended into one complex form, let them be accurately distinguished, and be referred each to its proper faculty and sense, and examined apart what they have peculiar, what common with others, and what foreign and adventitious. Let wealth, grandeur, luxury, love, fame, and the like, be tried by this test, and their true alloy will be found out. Let it be farther considered, whether the mind may not be easy, and enjoy itself greatly, though it want many of those elegancies and superfluities of life which some possess, or that load of wealth and power which others eagerly pursue, and under which they groan. Let the difficulty of attaining, the precariousness of possession, and the many abatements in enjoying overgrown wealth and envied greatness, of which the weary possessors so frequently complain, as the hurry of busies, the burden of company, of paying attendance to the few, and giving it to the many, the cares of keeping, the fears of losing, and the desires of increasing what they have, and the other troubles which accompany this pitiful drudgery and pompous servitude; let these and the like circumstances be often considered that are conducive to the removing or lessening the opinion of such goods, and the attendant passion or set of passions will decay of course.

Let the peculiar bent of our nature and character be observed, whether we are most inclined to form associations and relish objects of the sensible, intellectual, or moral kind. Let that which has the ascendant be particularly watched; let it be directed to right objects, be improved by proportioned exercises, and guarded by proper checks from an opposite quarter. Thus, the sensible turn
turn may be exalted by the intellectual and a taste for the beauty of the fine arts, and both may be made subservient to convey and rivet sentiments highly moral and public-spirited. This inward fury must extend to the strength and weakness of one's nature, one's condition, connections, habits, fortune, studies, acquaintance, and the other circumstances of one's life; from which every man will form the justest estimate of his own dispositions and character, and the best rules for correcting and improving them. And, in order to do this with more advantage, let those times or critical seasons be watched when the mind is best disposed towards a change, and let them be improved by vigorous resolution, promises, or whatever else will engage the mind to persevere in virtue. Let the conduct, in fine, be often reviewed, and the causes of its corruption or improvement be carefully observed.

It will greatly conduce to refine the moral taste and strengthen the virtuous temper, to accustom the mind to the frequent exercise of moral sentiments and determinations, by reading history, poetry, particularly of the picturesque and dramatic kind, the study of the fine arts; by converting with the most eminent for good-fence and virtue; but, above all, by frequent and repeated acts of humanity, compassion, friendship, politeness, and hospitality. It is exercise gives health and strength. He that reasons most frequently, becomes the wisest, and most enjoys the pleasures of wisdom. He who is most often affected by objects of compassion in poetry, history, or real life, will have his soul most open to pity and its delightful pains and duties. So he also who practices most diligently the offices of kindness and charity, will by it cultivate that disposition, from whence all his pretensions to personal merit must arise, his present and his future happiness.

An useful and honourable employment in life will administer a thousand opportunities of this kind and greatly strengthen a sense of virtue and good affections, which must be nourished by right training, as well as our understandings. For such an employment, by enlarging one's experience, giving an habit of attention and caution, or obliging one, from necessity or interest, to keep a guard over the passions, and study the outward decencies and appearances of virtue, will by degrees produce good habit, and at length infinuate the love of virtue and honestly for its own sake.

It is a great inducement to the exercise of benevolence, to view human nature in a favourable light, to observe the characters and circumstances of mankind on the fairest sides; to put the best constructions on their actions they will bear, and to consider them as the result of partial and mistaken, rather than ill affections, or, at worst, as the excesses of a pardonable self-love, seldom or never the effects of pure malice.

Above all, the nature and consequences of virtue and vice, their consequences being the law of our nature and will of heaven; the light in which they appear to our supreme Parent and Law-giver, and the reception they will meet with from him; must be often attended to. The exercises of piety, as adoration and praise of the Divine Excellence, invocation of and dependence on his aid, confession, thanksgiving, and resignation, are habitually to be indulged, and frequently performed, not only as medicinal, but highly improving to the temper.

To conclude: It will be of admirable efficacy towards eradicating bad habits, and implanting good ones, frequently to contemplate human life as the great nursery of our future and immortal existence, as that state of probation in which we are to be educated for a divine life; to remember that our virtues or vices will be immortal as ourselves, and influence our future as well as our present happiness, and therefore that every disposition and action is to be regarded as pointing beyond the present to an immortal duration. An habitual attention to this wide and important connection will give a vast compass and dignity to our sentiments and actions, a noble superiority to the pleasures and pains of life, and a generous ambition to make our virtue as immortal as our being.

Motives to Virtue from personal Happiness.

We have already considered our obligations to the practice of virtue, arising from the constitution of our nature, by which we are led to approve a certain order andconomy of affections, and a certain course of action correspondent to it. But besides this, there are several motives which strengthen and secure virtue, though not themselves of a moral kind. These are, its tendency to personal happiness, and the contrary tendency of vice. "Personal happiness arises, either from the state of a man's own mind, or from the state and disposition of external causes towards him."

We shall first examine the "tendency of virtue to happiness with respect to the state of a man's own mind."—This is a point of the utmost consequence in morals; because, unless we can convince ourselves, or shew to others, that, by doing our duty, or fulfilling our moral obligations, we consult the greatest satisfaction of our own mind, or our highest interest on the whole, it will raise strong and often insurmountable prejudices against the practice of virtue, especially whenever there arises any appearance of opposition between our duty and our satisfaction or interest. To creatures so dearful of happiness and averse to misery as we are, and often so oddily situated amidst contending passions and interests, it is necessary that virtue appear not only an honourable, but a pleasing and beneficent form. And in order to justify our choice to ourselves, as well as before others, we must ourselves feel, and be able to avow in the face of the whole world, that her ways are ways of pleasantness, and her paths the paths of peace. This will shew, beyond all contradiction, that we not only approve, but can give a sufficient reason for what we do.

Let a man in a cool hour, when he is disengaged from business, and undisturbed by passion, as such cool hours will sometimes happen, sit down, and seriously reflect with himself what state or temper of mind he would choose to feel and indulge, in order to be easy and to enjoy himself. Would he choose, for that purpose, to be in a constant dissipation and hurry of thought; to be disturbed in the exercise of his reason; to have various, and often interfering phantoms of good playing before his imagination, soliciting and distracting him by turns, now soothing him with
with amusing hopes, then torturing him with anxious fears; and to approve this minute what he shall condemn the next? Would he chuse to have a strong and painful sense of every petty injury; quick apprehensions of every impending evil; incessant and insatiable desires of power, wealth, honour, pleasure; an irreconcilable antipathy against all competitors and rivals; insatiable and tyrannical dispositions to all below him; fawning, and at the same time envious, dispositions to all above him; with dark suspicions and jealousies of every mortal? Would he chuse neither to love, nor to be beloved of any; to have no friend in whom to confide, or with whom to interchange his sentiments or designs; no favourite, on whom to shower his kindnecfs, or vent his passions; in fine, to be conscious of no merit with mankind, no affection from any creature, no good affection to his Maker, no concerns for or hopes of his approbation; but, instead of all these, to hate, and know that he is hated, to contempt, and know that he is contemned by all; by the good because he is so unlike, and by the bad because he is so like themselves; to hate or to dread the very Being that made him; and, in short, to have his breast the prey of pride and passion, petulance and revenge, deep melancholy, cool malignity, and all the other furies that ever overpoffed and tortured mankind?—Would our calm inquirer after happiness pitch on fhuch a state, and such a temper of mind, as the most likely means to put him in possession of his deified eafe and self-enjoyment?

Or would he rather chuse a ferene and eafy flow of thought; a reason clear and composed; a judgment unbiassed by prejudice, and undistracted by passion; a sober and well-governed fancy, which presents the images of things true and unmixed with delusive and unnatural charms, and therefore administers no improper or dangerous fuel to the passions, but leaves the mind free to chufe or reject, as becomes a reasonable creature; a sweet and sedate temper, not easily ruffled by hopes or fears, prone neither to fulpicion nor revenge, apt to view men and things in the fairest lights, and to bend gently to the humours of others rather than obstinately to contend with them? Would he chuse such moderation and continence of mind, as neither to be ambitious of power, fond of honours, covetous of wealth, nor a flave to pleasure; a mind of course neither elated with successes, nor dejected with disappojgment; such a modest and noble spirit as supports power without in perlion, wears honours without out pride, ufs wealth without profusion or parsimony; and rejoices more in giving than in receiving pleasure; such fortitude and equanimity as rises above misfortunes, or turns them into blessings; such integrity and greatness of mind, as neither flatters the vices, nor triumphs over the follies of men; as equally spares fervitude and tyranny, and will neither engage in low defigns, nor abet them in others? Would he chufe, in fine, such mildnedfs and benignity of heart as takes part in all the joys, and refuses none of the sorrows of others; stands well affected to all mankind; is conscious of meritmg the efteeinc of all, and of being beloved by the best; a mind which delights in doing good without any shew, and yet arrogates nothing on that account; rejoices in loving and being beloved by its Maker, acts ever under his eye, reigns

VoL. III. N°. 81. 2
being sensibly alive over the whole system, his heart receives and becomes responsive to every touch given to any part. So that he gathers contentment and delight from the pleased and happy state of those around him, from accounts and relations of such happiness, from the very countenances, gestures, voices, and sounds even of creatures foreign to our kind, whose signs of joy and contentment he can in any way discern.

Nor do those generous affections stop any other natural source of joy whatever, or deaden his fens of any innocent gratification. They rather keep the several fenses and powers of enjoyment open and indigested, intense, and uncorrupted by riot or abuse; as is evident to any one who considers the diffipated unfeeling state of men of pleasure, ambition, or interest, and compares it with the serene and gentle state of a mind at peace with itself, and friendly to all mankind, unrufted by any violent emotion, and fitile to every good-natured and alluring joy.

It were easy, by going through the different sorts of affections, to shew, that it is only by maintaining the proportion settled there that the mind arrives at true repose and satisfaction. If fear exceeds that proportion, it sinks into melancholy and dejection. If anger passes just bounds, it ferment into rage and revenge, or subsides into a sullen corroding gloom, which embitters every day; and renders one excessively fitile to every ill. The private passions, the love of honour especially, whose impulses are more generous as its effects are more diffuse, are instruments of private pleasure; but if they are disproportioned to our wants, or to the value of the several objects, or to the balance of other passions equally necessary and more amicable, they become instruments of intense pain and misery. For, being now delirious of that counterpoise which held them at a due pitch, they grow turbulent, peevish, and revengeful, the cause of constant restlessness and torment, sometimes flying out into a wild delirious joy, at other times settling into a deep splanetic grief. The concert between reason and passion is then broke; all is dissonance and distraction within. The mind is out of frame, and feels an agony proportional to the violence of the reigning passion.

The cause is much the same, or rather worse, when any of the particular kind affections are out of their natural order and proportion; as happens in the case of effeminate pity, exorbitant love, parental dotage, or any party passion, where the just regards to society are supplanted. The more social and disinterested the passion is, it breaks out into the wilder excesses, and makes the more dreadful havoc, both within and abroad, as is but too apparent in those cafes where a false species of religion, honour, zeal, or party-rage, has feized on the natural enthusiasm of the mind, and worked it up to madness. It breaks through all ties natural and civil, counteracts the most sacred and solemn obligations, silences every other affection whether public or private, and transforms the most gentle natures into the most savage and inhuman.

Whereas the man who keeps the balance of affection even, is easy and serene in his motions; mild, and yet affectionate; uniform and consistent with himself; is not liable to disagreeable collisions of interests and passions; gives always place to the most friendly and humane affections; and never to dispositions or acts of restraint, but on high occasions, when the security of the private, or welfare of the public system, or the great interests of mankind necessitiously require a noble indignation; and even then he observes a just measure in wrath; and last of all, he proportions every passion to the value of the object he affects, or to the importance of the end he pursues.

To sum up this part of the argument, the honest and good man has eminently the advantage of the knavish and selfish wretch in every respect. The pleasures which the last enjoys flow chiefly from external advantages and gratifications; are superficial and transitory; dashed with long intervals of satiety, and frequent returns of remorse and fear; dependent on favourable accidents and conjunctures; and subjected to the humours of men. But the good man is satisfied from himself; his principal passions lie within, and therefore beyond the reach of the caprice of men or fortune; his enjoyments are exquisite and permanent; accompanied with no inward checks to damp them, and always with ideas of dignity and self-approbation; may be tasted at any time, and in any place. The gratifications of vice are turbulent and unnatural, generally arising from the relief of passions in themselves intolerable, and inflating in tormenting reflections; often irritated by disappointment, always inflamed by enjoyment, and yet ever cloyed with repetition. The pleasures of virtue are calm and natural; flowing from the exercise of kind affections, or delightful reflections in consequence of them; not only agreeable in the prospect, but in the present feeling? they never satiate, or lose their relish; nay, rather the admiration of virtue grows stronger every day; and not only is the desire but the possession of it purchased without a bribe, and possessed in the humblest as well as the most triumphant fortune; they can bear the strictest review, do not change with circumstances, nor grow old with time. Force cannot rob, nor fraud cheat us of them; and, to crown all, instead of abating, they enhance every other pleasure.

But the happy consequences of virtue are seen, not only in the internal enjoyments it affords a man, but "in the favourable disposition of external causes towards him, to which it contributes."

As virtue gives the sober possession of one's self and the command of one's passions, the consequence must be, heart's ease, and a fine natural flow of spirits, which conduct more than anything else to health and long life. Violent passions, and the excesses they occasion, gradually impair and wear down the machine. But the calm, placid state of a temperate mind, and the healthful exercises in which virtue engages her faithful votaries, preserve the natural functions in full vigour and harmony, and exhilarate the spirits, which are the chief instruments of action.

It may by some be thought odd to affect, that virtue is no enemy to a man's fortune in the present state of things.
things.—But if, by fortune, be meant a moderate or competent share of wealth, power, or credit, not overgrown degrees of them, what should hinder the virtuous man from obtaining that? He cannot cringe or fawn, it is true; but he can be civil and obliging as well as the knave: and purely, his civility is more alluring, because it has more manifest grace in it than the mean adulation of the other: he cannot cheat or undermine; but he may be cautious, provident, watchful of occasions, and equally prompt with the rogue in improving them: he scorces to prostitute himself as a pander to the passions, or as a tool to the vices of mankind; but he may have as found an understanding, and as good capacities for promoting their real interests, as the veriest court-flave; and then, he is more faithful and true to those who employ him. In the common course of business, he has the same chances with the knave of acquiring a fortune, and rising in the world. He may have equal abilities, equal industry, equal attention to business; and in other respects he has greatly the advantage of him. People love better to deal with him; they can trust him more; they know he will not impose on them, nor take advantage of them, and can depend more on his word than on the oath or strongest securities of others. Whereas what is commonly called cunning, which is the offspring of ignorance, and constant companion of knavery, is not only a mean-spirited, but a very short-sighted, and a fundamental obstacle in the road of business. It may procure indeed immediate and petty gains; but it is attended with dreadful abatements, which do more than over-balance them, both as it links a man's credit when discovered, and cramps that largeness of mind, which extends to the remotest as well as the nearest interest, and takes in the most durable equally with the most transient gains. It is therefore easy to see how much a man's credit and reputation, and consequently his success, depend on his honesty and virtue.

With regard to security and peace with his neighbours, it may be thought, perhaps, that the man of a quiet forgiving temper, and a flowing benevolence and courtesy, is much exposed to injury and fronts from every proud or peevish mortal who has the power or will to do mischief. If we suppose, indeed, this quietness and gentleness of nature accompanied with cowardice or pusillanimity, this may often be the case; but in reality, the good man is bold as a lion, and so much the bolder for being the calmer. Such a person will hardly be a butt to mankind. The ill-natured will be afraid to provoke him, and the good-natured will not incline to do it. Besides, true virtue, which is conducted by reason, and exerted gracefully and without parade, is a most infinuating and commanding thing; if it cannot disarm malice and reformation at once, it will wear them out by degrees, and subdue them at length. How many have, by favours, and prudently yielding, triumphed over an enemy who would have been inflamed into tenfold rage by the fiercest opposition? In fine, goodness is the most universally popular thing that can be.

To conclude, the good man may have some enemies, but he will have more friends; and having given so many marks of private friendship or public virtue, he can hardly be deftite of a patron to protect, or a fanctuary to entertain him, or to entertain or protect his children when he is gone. Though he should have little else to leave them, he bequeaths them the fairest, and generally the most unenvied, inheritance of a good name; which, like good feed sown in the field of futurity, will often raise up unfulfilled friends, and yield a benevolent harvest of unexpected charities. But should the fragrance of the parent's virtue prove offensive to a perverse or envious age, or even draw perfecution on the friendless orphans, there is One in heaven, who will be more than a father to them, and recompence their parent's virtues by showering down blessings on them.

Motives to Virtue from the Being and Providence of God.

Besides the interesting motive mentioned in the last section, there are two great motives to virtue, firstly connected with human life, and resulting from the very constitution of the human mind. The first is the being and providence of God; the second is the immortality of the soul, with future rewards and punishments.

It appears from what has been said, that man, by the constitution of his nature, is designed to be a religious creature. He is intimately connected with the Deity, and necessarily dependent on him. From that connection and necessary dependence result various obligations and duties; without fulfilling which, some of his sublimest powers and affections would be incomplete and abortive. If he be likewise an immortal creature, and if his present conduct shall affect his future happiness in another state as well as in the present; it is evident, that we take only a partial view of the creature if we leave out this important property of his nature, and make a partial estimate of human life if we strike out of the account, or overlook that part of his duration which runs out into eternity.

It is evident, that "to have a respect to the Deity in our temper and conduct, to venerate and love his character, to adore his goodness, to depend upon and resign ourselves to his providence, to seek his approbation, and act under a sense of his authority, is a fundamental part of moral virtue, and the completion of the highest designation of our nature."

But as piety is an essential part of virtue, so likewise it is a great support and enforcement to the practice of it. To contemplate and admire a being of such transcendent dignity and perfections as God, must naturally and necessarily open and enlarge the mind, give a freedom and ampleness to its powers, and a grandeur and elevation to its aims. For, "the greatness of an object, and the excellency of the act of any agent about a transcendent object, doth mightily tend to the enlargement and improvement of his faculties." Little objects, mean company, mean cares, and mean business, cramp the mind, contract its views, and give it a creeping air and deportment. But when it soars above mortal cares and mortal pursuits into the regions of divinity, and converses with the Greatest and Beh of Beings, it spreads itself into a wider compass, takes higher flights in reason and goodness, and becomes Godlike in its air and manners. Virtue is, if one may say so, both the effect and cause of largeness of mind. It requires
Moral Philosophy.

requires that one think freely, and act nobly. Now, what can conduce more to freedom of thought and dignity of action, than to conceive worthily of God, to reverence and adore his unrivalled excellency, to imitate and transfer his excellency into our own nature, to remember our relation to him, and that we are the image and representatives of his glory to the rest of the creation? Such feelings and exercises must and will make us scorn all actions that are base, unhandsome, or unworthy our state; and the relation we stand in to God will irradiate the mind with the light of wisdom, and enable it with the liberty and dominion of virtue.

The influence and efficacy of religion may be considered in another light. We all know that the presence of a friend, a neighbour, or any number of spectators, but especially an august assembly of them, uses to be a considerable check upon the conduct of one who is not lost to all sense of honour and shame, and contributes to restrain many irregular fancies of passion. In the same manner we may imagine, that the awe of some Superior Mind, who is supposed privy to our secret conduct, and armed with full power to reward or punish it, will impose a restraint on us in such actions as fall not under the control or animadversion of others. If we go still higher, and suppose our inmost thoughts and darkest designs, as well as our most secret actions, to lie open to the notice of the Supreme and Universal Mind, who is both the spectator and judge of human actions; it is evident, that the belief of so august a presence, and such awful inspection, must carry a restraint and weight with it proportioned to the strength of that belief, and be an additional motive to the practice of many duties which would not have been performed without it.

It may be observed farther, that "to live under an habitual sense of the Deity and his great administration, is to be conversant with wisdom, order, and beauty, in the highest subjects, and to receive the delightful reflections and benign feelings which these excite, while they irradiate upon him from every scene of nature and providence." How improving must such views be to the mind, in dilating and exalting it above those puny interests and competitions which agitate and enflame the bulk of mankind against each other!—

Motive to Virtue from the Immortality of the Soul, &c.

The other motive mentioned was the immortality of the soul, with future rewards and punishments. The metaphysical proofs of the soul's immortality, are commonly drawn—from its simple, uncompound, and indivisible nature; from whence it is concluded, that it cannot be corrupted or extinguished by a dissolution or destruction of parts:—from its having a beginning of motion within itself; whence it is inferred, that it cannot discontinue and lose its motion—from the different properties of matter and mind; the fluggishness and inactivity of one, and the immense activity of the other; its prodigious flight of thought and imagination; its penetration, memory, foresight, and anticipations of futurity; from whence it is concluded, that a being of so divine a nature cannot be extinguished. But as these metaphysical proofs depend on intricate reasonings concerning the nature, properties, and distinction of body and mind, with which we are not very well acquainted, they are not obvious to ordinary understandings, and are seldom convincing, even to those of higher reach, as not to leave some doubts behind them. Therefore, perhaps, it is not so safe to rest the proof of such an important article on what many may call the subtleties of school-learning. Those proofs which are brought from analogy, from the moral constitution and phenomena of the human mind, the moral attributes of God, and the present course of things, and which are therefore called the moral arguments, are the plainest, and generally the most satisfying. We shall select only one or two from the rest.

In tracing the nature and definition of any being, we form the surest judgment from his powers of action, and the scope and limits of these, compared with his state, or with that field in which they are exercised. If this being passes through different states or fields of action, and we find a succession of powers adapted to the different periods of his progress, we conclude that he was designed for those successive states, and reckon his nature progressive. If, besides the immediate set of powers which fit him for action in his present state, we observe another set which appears superfluous if he was to be confined to it, and which point to another or higher one, we naturally conclude, that he is not designed to remain in his present state, but to advance to that for which those supernumerary powers are adapted. Thus we argue, that the insect, which has wings forming or formed, and all the apparatus proper for flight, is not designed always to creep on the ground, or to continue in the torpid state of adhering to a wall, but is designed in its season to take its flight in air. Without this farther definition, the admirable mechanism of wings, and the other apparatus, would be useless and absurd. The same kind of reasoning may be applied to man, while he lives only a sort of vegetative life in the womb. He is furnished even there with a beautiful apparatus of organs, eyes, ears, and other delicate senses, which receive nourishment indeed, but are in a manner folded up, and have no proper exercise or use in their present confinement. Let us suppose some intelligent spectator, who never had any connection with man, nor the least acquaintance with human affairs, to see this odd phenomenon; a creature formed after such a manner, and placed in a situation apparently unsuitable to such various machinery; must he not be strangely puzzled about the use of his complicated structure, and reckon such a profusion of art and admirable workmanship lost on the subject; or reason, by way of anticipation, that a creature, endowed with such various, yet unexerted capacities, was designed for a more enlarged sphere of action, in which those latent capacities shall have full play? The vast variety, and yet beautiful symmetry and proportions, of the several parts and organs by which the creature is endowed, and their apt cohesion with, and dependence on, the curious receptacle of their life and nourishment, would forbid his concluding the whole to be the birth of chance, or the bungling effort of an unskilful artist, at least would make him demur a while at so harrowing a sentence. But if, while he is in this state of uncertainty, we suppose him to see the babe, after a few successful struggles,
MORAL PHILOSOPHY.

Vol. III. No. 81.

are in the womb. Nay, those who on an aspiring genius have added all the affinities of art, leisure, and the most liberal education, what narrow prospects can even they take of this unbounded scene of things from that little eminence on which they stand? And how eagerly do they still grasp at new discoveries, without any satisfaction or limit to their ambition?

But should it be said, that man is made for action, and not for speculation, or fruitless searches after knowledge; we ask, For what kind of action? Is it only for bodily exercises; or for moral, political, and religious ones? Of all these he is capable; yet, by the unavoidable consequences of his lot, he is tied down to the former; and has hardly any leisure to think of the latter; or, if he has, wants the proper instruments of exerting them. The love of virtue, of one’s friends and country, the generous sympathy with mankind, and heroic zeal of doing good, which are all so natural to great and good minds, and some traces of which are found in the lowest, are seldom united with proportioned means or opportunities of exercising them; so that the moral spring, the noble energies and impulses of the mind, can hardly find proper scope, even in the most fortunate condition; but are much depressed in some, and almost entirely restrained in the generality, by the numerous clogs of an indigent, sickly, or embarrassed life. Were such mighty powers, such Godlike affections planted in the human breast, to be folded up in the narrow womb of our present existence, never to be produced into a more perfect life, nor to expatiate in the ample career of immortality?

Let it be considered, at the same time, that no perfection, no enjoyment within the round of mortal things, is commenurate to the desires, or adequate to the capacities of the mind. The most envied condition has its abatements; the happiest conjunction of fortune leaves many wishes behind; and after the highest gratifications, the mind is carried forward in pursuit of new ones without end. Add to all, the fond desire of immortality, the secret dread of non-existence, and the high unremitting pulse of the soul beating for perfection. Joined to the improbability or the impossibility of attaining it here; and then judge whether this elaborate structure, this magnificent apparatus of inward powers and organs, does not plainly point out an hereafter, and intimate eternity to man? Does nature give the finishing touches to the leisuer and ignoble infinaces of her scull, and raise every other creature to the maturity and perfection of his being; and shall she leave her principal workmanship unfinished?

Does the carry the vegetative and animal life in man to their full vigour, and highest deification; and shall she suffer his intellectual, his moral, his divine life to fade away, and be for ever extinguished? Would such abortions in the moral world be congruous to that perfection of wisdom and goodnes which upholds and adorns the natural?

We must therefore conclude, from this detail, that the present state, even at its best, is only the womb of man’s being, in which the noblest principles of his nature are in a manner fettered or secluded from a correspondent sphere of action; and therefore designed for a future and unbounded state, where they shall emancipate themselves, and
and exert the fulness of their strength. The most accomplished mortal, in this low and dark appartment of nature, is only the rudiments of what he shall be, when he takes his eternal flight, and puts on immortality. Without a reference to that state, man were a mere abortion, a rude unfinishéd embryo, a monster in nature. But this being once supposéd, he still maintains his rank, of the matter-piece of the creation; his latent powers are all suitable to the harmony and progress of nature; his noble aspirations, and the pains of his dissolution, are his efforts towards a second birth, the pangs of his delivery into light, liberty, and perfection; and death his discharge from gaol, his separation from his fellow-prisoners, and introduction into the assembly of those heroic spirits who are gone before him, and of their great eternal Parent. The fetters of his mortal coil being loosed, and his prison-walls broke down, he will be bare and open on every side to the admission of truth and virtue, and their fair attendant happiness; every vital and intellectual spring will evolve itself, with a divine elasticity, in the free air of heaven. He will not then peep at the universe and its glorious Author through a dark grate, or a grofs medium, nor receive the reflections of his glory through the strait openings of fenitive organs; but will be all eye, all ear, all ethereal and divine feeling. Let one part, however, of the analogy be attended to; That, as in the womb we receive our original constitution, form, and the essential flamina of our being, which we carry along with us into the light, and which greatly affect the succeeding periods of our life; so our temper and condition in the future life will depend on the con duct we have observed, and the character we have formed in the present life. We are here in miniature what we shall be at full length hereafter. The first rude sketch, or out-lines of reason and virtue, must be drawn at present, to be afterwards enlarged to the stature and beauty of angels.

This, if duly attended to, must prove not only a guard, but an admirable incentive to virtue. For he who faithfully and ardentely follows the light of knowledge, and pangs after higher improvements in virtue, will be wonder fully animated and inflamed in that pursuit, by a full conviction that the scene does not close with life;—that his struggles arising from the weaknesses of nature, and the strength of habit, will be turned into triumphs;—that his career in the tracts of wisdom and goodness will be both swifter and smoother;—and those generous arors with which he glows towards heaven, i. e. the perfection and immortality of virtue, will find their adequate object and exercise in a sphere proportionally enlarged, incorruptible, immortal. On the other hand, what an inexplicable dump must it be to the good man, to dread the total extinction of that light and virtue, without which life, may immortality itself, were not worth a single wish?

Many writers draw their proofs of the immortality of the soul, and of a future state of rewards and punishments, from the unequal distribution of these here. It cannot be dissembled that wicked men often escape the outward punishment due to their crimes, and do not feel the inward in that measure their demerit seems to require, partly from the callousness induced upon their nature by the habits of vice, and partly from the dissipation of their minds abroad by pleasure or business; and sometimes good men do not reap all the natural and genuine fruits of their virtue, through the many unforeseen or unavoidable calamities in which they are involved. This, no doubt, upon the supposition of an all-wise and good Providence, were an argument, and a strong one too, for a future state, in which those inequalities shall be corrected. But unless we suppose a propitious good order in the present scene of things, we weaken the proof of the divine administration, and the presumption of better order in any future period of it.

Virtue has present rewards, and vice present punishments, annexed to it; such rewards and punishments as make virtue, in most cases that happen, far more eligible than vice; but, in the infinite variety of human contingencies, it may sometimes fall out, that the inflexible practice of virtue shall deprive a man of considerable advantages to himself, his family, or friends, which he might gain by a well-timed piece of roguery, supposo by betraying his trust, voting against his conscience, selling his country, or any other crime where the security against discovery shall heighten the temptation. Or, it may happen, that a strict adherence to his honour, to his religion, to the cause of liberty and virtue, shall expose him, or his family, to the loss of every thing, nay to poverty, slavery, death itself, or to torments far more intolerable. Now, what shall secure a man's virtue in circumstances of such trial? What shall enforce the obligations of conscience against the allurements of so many interests, the dread of so many and so terrible evils, and the almost insurmountable aversion of human nature to excessive pain? The conflict is the greater, when the circumstances of the crime are such as easily admit a variety of alleviations from necessity, natural affection, love to one's family, or friends, perhaps in indigence: These will give it even the air of virtue. Add to all, that the crime may be thought to have few bad consequences,—may be easily concealed,—or imagined possible to be retrieved in a good measure by future good conduct.

It is obvious to which side most men will lean in such a case, and how much need there is of a balance in the opposite scale, from the consideration of a God, of a providence, and of an immortal state of retribution, to keep the mind firm and incorrupt in those or like instances of singular trial or distress.

But without supposing such peculiar instances, a sense of a Governing Mind, and a persuasion that virtue is not only befriended by him here, but will be crowned by him hereafter with rewards suitable to its nature, vaft in themselves, and immortal in their duration, must be not only a mighty support and incentive to the practice of virtue, but a strong barrier against vice. The thoughts of an almighty Judge, and of an impartial future reckoning, are often alarming, inexplicably so, even to the stoutest offenders. On the other hand, how supporting must it be to the good man, to think that he acts under the eye of his Friend, as well as Judge! How improving, to consider the present state as connected with a future one, and every relation in which hestands as a school of discipline for his affections, every trial as the exercise of some virtue, and the virtuous deeds which result from both as introductory to higher scenes of action and enjoyment! Finally, how transporting
MORAL sense, that whereby we perceive what is good, virtuous, and beautiful in actions, manners, and characters. See Morals.

MORALITY. See Moral Philosophy.

MORASS, a low, moist land, which receives the waters from the higher grounds without having any defcent to carry them off.

MORAVIA, a marquise, or province in Bohemia, bounded by Silesia on the north-east, by Hungary and Austria on the south, and by Bohemia on the north-west.

MORAVIANS, a sect of Protestants, who have been settled for a considerable time past at Hernhuth in Germany, and have of late years spread themselves over most of our American colonies, as well as in several parts of England, where they are permitted to settle by a late act of parliament. They have a kind of church-government peculiar to themselves, and are commonly known by the name of Unitas Fratrum, or The Brethren. They profess the utmost veneration for our bleffed Saviour, whom they consider as their immediate Head and Director; enjoin the most implicit obedience to the rulers of their church; and are said to practise much brotherly love amongst one another.

MORBID, among physicians, signifies diseased or corrupt; a term applied either to an unfound constitution, or to those parts or humours that are infected by a disease.

MORDELLA, in zoology, a genus of the coleoptera class of insects. The antennæ are thread-shap'd, and serrated; the head is defcended under the neck; the pappi are elevated, compressed, and obliquely blunt'd; and the elytra are bent backwards near the apex. There are six species, all natives of different parts of Europe.

MOREA, the ancient Peloponnesus, is a province of European Turkey, and is a peninsula about one hundred and eighty miles long, and one hundred and thirty broad, bounded by the gulphs of Lepanto and Eginia on the north; by the Egean sea, or Archipelago, on the east; and by the Mediterranean on the south and west.

MORESK, or morisco, is a kind of painting, carving, &c. done after the manner of the Moors; consisting of several grotesque pieces and compartments, promiscuously mingled, not containing any perfect figure of a man, or other animal; but a wild resemblance of birds, beasts, trees, &c.

MORAY, in ichthyology. See Squalus.

MORINA, in botany, a genus of the diandria monogynia class. The corolla is unequal; the calyx of the fruit consists of one dentated leaf; the calyx of the flower is bifid; and there is but one seed under the flower-calix. There is but one species, a native of Peru.

MORINDA, in botany, a genus of the polyandria monogynia class. The flowers are aggregate and monopetalous; the stigma is bifid; and the drupae are aggregate. There are three species, none of them natives of Britain.

MORINELLUS, in ornithology. See Charadrius.

MORINELLUS, in ornithology. See Charadrius.

MOROCHO, or Moresco, a port-town of France, in the province of Britany: W. long. 40°, N. lat. 47° 37'.

MOROCHTHUS, in natural history, an indurated clay, called by us French chalk; serving tailors and others.
MOS (310) MOS

The method of performing Mosaic-work of glafs is this:

They provide little pieces of glafs, of as many different colours and sizes as possible.

Now, in order to apply these several pieces, and out of them to form a picture, they in the first place procure a cartoon or design to be drawn; this is transferred to the ground or plaster by calking, as in painting in fresco. See Fresco.

As this plaster is to be laid thick on the wall, and therefore will continue fresh and soft a considerable time, so that there may be enough prepared at once, to serve for as much work as will take up three or four days.

This plaster is composed of lime, made of hard stone, with brick dust very fine, gum tragacanth, and whites of eggs: when this plaster has been thus prepared and laid on the wall, and made the design of what is to be represented, they take out the little pieces of glafs with a pair of pliers, and range them one after another, still keeping strictly to the light, shadow, different tints and colours represented in the design before; pressing or flattening them down with a ruler, which serves both to sink them within the ground, and to render the surface even.

Thus in a long time, and with a great deal of labour, they finish the work, which is still the more beautiful, as the pieces of glafs are more uniform, and ranged at an even height.

Some of these pieces of mosaic-work are performed with that exactness, that they appear as smooth as a table of marble, and as finished and mafterly as a painting in fresco; with this advantage, that they have a fine lustre, and will last ages.

The finest works of this kind that have remained till our time, and those by whom the moderns have retrieved the art, which was in a manner lost, are those in the church of St Agnes, formerly the temple of Bacchus at Rome; and some at Pisa, Florence, and other cities of Italy. The most esteemed among the works of the moderns are those of Joseph Pine, and the chevalier Lanfranc in the church of St Peter at Rome: these also are very good ones at Venice.

Method of performing Mosaic-work of marble and precious stones is this: The ground of mosaic-works, wholly marble, is usually a malleable marble, either white or black. On this ground the design is cut with a chisel, after it has been sifted calked. After it has been cut out of a considerable depth, i.e. an inch or more, the cavities are filled up with marble of a proper colour, sift furnished according to the design, and reduced to the thickness of the indentures with various instruments. To make the pieces thus fitted into the indentures cleave fast, whose several colours are to imitate those of the design, they use a stucco, composed of lime and marble-duft; or a kind of maltie, which is prepared by each workman, after a different manner peculiar to himself.

The figures being marked out, the painter or sculp- tor himself draws with a pencil the colours of the figures, not determined by the ground, and in the same manner makes strokes or hatchings in the place, with
Manner of performing MOSAIC WORK of gypsum. Of the

MOSAMBIQUE, the capital of a province of the same
corner in Zanguebar, in Africa, situated on an island
deep stone. If it be of plaster of Paris, they spread it
in a wooden frame, of the length and breadth of the
work intended, and in thicknesses about an inch and a
half. This frame is so contrived, that the tenons be-
ing only joined to the mortises by single pins, they
may be taken afunder, and the frame be dismounted,
when the plaster is dry. The frame is covered on one
side with a strong linen cloth, nailed all round, which
being placed horizontally with the linen at the bottom,
is filled with plaster sifted through a wide sieve.
When the plaster is half dry, the frame is set up per-
pendicularly, and left till it is quite dry; then it is
taken out, by taking the frame to pieces.

In this mosaic, the ground is the most important part.
Now in order to the preparation of this sifted gypsum,
which is to be applied on this ground, it is dissolved
and boiled in the best English glue, and mixed with
the colour that it is to be of; then the whole is work-
ed up together into the usual consistence of plaster,
and then is taken and spread on the ground five or six
inches thick. If the work be such, as that mouldings
are required, they are formed with gougues and other
instruments.

It is on this plaster, thus coloured like marble or
precious stone, and which is to serve as a ground to a
work, either of lapis, agate, alabaster, or the like,
that the design to be represented is drawn; having been
first pounded or calculated. To hollow or imprest the
design, they use the fame instruments that sculptors
do; the ground whereon they are to work not being
much less hard than the marble itself. The cavities
being thus made in the ground, are filled with the fame
gypsum boiled in glue, only differently coloured, and
thus are the different colours of the original repre-

tented. In order that the necessary colours and teints
may be ready at hand, the quantities of the gypsum
are tempered with the several colours in pots.

After the design has been thus filled and rendered
visible, by half-polishing it with brick and soft stone,
they go over it again, cutting such plates as are either
to be weaker or more faded, and filling them with
gypsum; which work they repeat, till all the colours
being added one after the other, represent the origi-
nal to the life.

When the work is finished, they scour it with soft
stone, sand, and water; after that, with a pumice-
stone; and in the last place polish it with a wooden
mallet and emery. Then, lastly, they give it a lu-
flre, by smearing it over with oil, and rubbing it a
long time with the palm of the hand, which gives it
a luflre no ways inferior to that of natural marble.

MOSAMBIQUE, the capital of a province of the same
name in Zanguebar, in Africa, situated on an island
at the mouth of the river Mosambique: E. lon. 42°.
S. lat. 15°.

MOSCHUS, a genus of quadrupeds of the order of pe-
cora, having no horns; the canine teeth of the upper
jaw are exerted. There are three species, viz. 1. The
moschiferus, or muck animal, has a bag or pellicle near
the navel, in which the perfume called muck is contained.

This
This creature, when full grown, is three feet in length, from the tip of the nose to the rump; the head is oblong, and the anterior part much like the greyhound; the ears are large and erect, they resemble those of the rabbit, and are equal in length to the diameter of the forehead; the tail is not more than two inches in length, and the creature always carries it erect; the body is tolerably flabby, and rounded; the legs about a foot in length, and very robust; the feet deeply divided, each into two claws in the anterior part, and as many heels behind. The fur on the head and that on the legs is about half an inch long, that on the belly is an inch and a half, and that which grows on the back three inches; these hairs are thicker than in any other known animal, and are variegated, from the base to the extremity, with distinct patches of brown and white. The vessel or bag in which the perfume is contained, is three inches long and two broad, and hangs under the belly, protuberating near three quarters of an inch beyond the surface. It is a native of Tartary.—2. The grimmia has a protuberant belt upon its head, and is found in Africa. 3. The pygmaeus has feet narrower than a man's finger. It is found in Asia and Guinea.

MOSCOW, the capital of the province of the same name in Muscovy, situated on the river Moscowa, 360 miles south-east of Peterburg: E. long. 38°, N. lat. 55° 45'.

MOSCUWA, a river which rises in the west part of the province of Moscow, and falls into the river Ocka at Kolomna.

MOSELLE, a river of Germany, which rises in the mountains of Vauge, in Lorrain, and, running through the Rhine at Coblentz.

MOSKITO, a country of North America, situated between 85° and 88° of west longitude, and between 13° and 15° of north latitude; having the north sea on the north and east, Nicaragua on the south, and Honduras on the west.

MOSBURG, or MOSTBURG, a town of Germany, in the circle of Bavaria, situated at the confluence of the rivers Iler and Amburg, thirty miles north-east of Munich.

MOUSE, a temple, or place of religious worship, among the Mahometans.

All mosques are square buildings, generally built with stone. Before the chief gate there is a square court, paved with white marble; and low galleries round it, whose roof is supported by marble pillars. In these galleries the Turks wash themselves before they go into the mosque. In each mosque there is a great number of lamps; and between these hang many crystal rings, oilriches eggs, and other curiosities, which when the lamps are lighted make a fine show. As it is not lawful to enter the mosques with shoes or stockings on, the pavements are covered with pieces of fluffed together, each being wide enough to hold a row of men kneeling, sitting, or prostrate. The women are not allowed to enter the mosque, but stay in the porches without. About every mosque there are six high towers, called minarets, each of which has three little open galleries, one above another; these towers, as well as the mosques, are covered with lead, and adorned with gilding and other ornaments; and from thence, instead of a bell, the people are called to prayers by certain officers appointed for that purpose. Most of the mosques have a kind of hospital belonging to them, in which travellers, of what religion soever, are entertained during three days. Each mosque has also a place called Tarbe, which is the burying-place of its founders; within which is a tomb six or seven feet long, covered with green velvet or satin; at the ends of which are two tapers, and round it several seats for those who read the koran and pray for the souls of the deceased.

MOSS, in botany. See Muscus.

Moss is also a name given to boggy grounds in many parts of the kingdom. These consist of a turfy surface, below which is a black, moist, spongy earth, which being dug up with spades somewhat in the form of bricks, and dried, is what they call peats, used as fuel in several parts; and the upper part, being cut and dried, makes turfs, another coarser sort of fuel.

MOSTRA, in the Italian music, a mark at the end of a line or space, to show that the first note of the next line is in that place; and if this note be accompanied with a sharp or flat, it is proper to place these characters along with the montra.

MOTACILLA, in ornithology, a genus of birds, of the order of the pafferes, distinguished by a straight beak, of a tubulated figure, and a lacerated tongue. There are 49 species belonging to this genus, most of which feed upon insects, and migrate from the north to the southern countries in order to procure subsistence in winter.

MOTHE, in law-books, signifies court or convention; as a ward-mote, burg-mote, swain-mote, &c.

MOTH, in zoology. See PHALENA.

MOTHER, a term of relation, denoting a woman who hath born a child.

MOTION is defined to be the continued and successive change of place. See Mechanics.

MOTTO, in armoury, a short sentence or phrase, and sometimes containing whatever pleases the fancy of the deviser.

MOVEABLE, in general, denotes any thing capable of being moved.

MOVEABLE Subject, in Scots law, any thing that moves itself, or can be moved; in contradistinction to immoveable or heritable subjects, as lands, houses, &c.

MOVEMENT, in mechanics, a machine that is moved by clock-work. See Watch.

Perpetual Movement. Some have attempted to find a perpetual movement, but without success; and there is reason to think, from the principles of mechanics, that such a movement is impossible: for though in many cases of bodies acting upon one another, there is a
Mount St Michael, a borough-town of Cornwall,

Mount, an elevation of earth, called also mountain.

Mount Sorrel, a market-town of Leicestershire, seven miles north of Leiceter.

Mount of Piety, certain funds or establishments in Italy, where money is lent out, on some small security. We had also mounts of piety in England, raised by contribution for the benefit of people ruined by the extortions of the Jews.

Mount, in heraldry, a ball or globe with a cross upon it, otherwise the movement will not be perpetual; so that any action by which the absolute quantity of force is increased, of which there are several forts, must have its corresponding counter-action, by which the gain of force is destroyed, and the quantity of force restored to its first state.

Thus, by these actions, there will never be any gain of direct force, to overcome the friction and the resistances of the medium; so that every motion being diminished by these resistances, they must at length languish and cease.

Mount, in agriculture, a loose kind of earth, everywhere where obvious on the surface of the ground, called also natural or mother earth; by some also loam.

Mountains, a part of the earth, rising to a considerable height above the level of the surface thereof.

Mouse-tail. See Myosurus.

Mouse, in zoology. See Mus.

Moulinet is also a kind of turnstile, or wooden cross, used in mechanics, to signify a roller, by which the gain of motion is destroyed, and the quantity of force restored to its first state.

Thus, by these actions, there will never be any gain of direct force, to overcome the friction and the resistances of the medium; so that every motion being diminished by these resistances, they must at length languish and cease.

Mould, in agriculture, a loose kind of earth, everywhere where obvious on the surface of the ground, called also natural or mother earth; by some also loam.

Mouldiness, a term applied to bodies which contain moisture, where it is evident that the quantity of force is increased, of which there are several forts, must have its corresponding counter-action, by which the gain of force is destroyed, and the quantity of force restored to its first state.

Mould, or Mould, in the mechanic arts, &c. a cavity cut with a design to give its form or impression to some softer matter applied therein, of great use in sculpture, foundry, &c.

Mould, in agriculture, a loose kind of earth, everywhere where obvious on the surface of the ground, called also natural or mother earth; by some also loam.

Mouldings, in architecture, projectures beyond the naked wall, column, wainscot, &c. the assemblage of which forms cornices, door-cases, and other decorations of architecture. See Architecture.

Moulinet is used in mechanics, to signify a roller, which being crossed with two levers, is usually applied to cranes, capstans, and other sorts of engines of the like nature, to draw ropes, and heave up stones, &c.

Moulinet is also a kind of turnstile, or wooden cross, which turns horizontally upon a flake fixed in the ground; usually placed in passages to keep out horses, and to oblige passengers to go and come one by one. These moulinets are often set near the outworks of fortified places at the sides of the barriers; through which people pass on foot.

Mould, a term used for a bank or rampart, or other fence, particularly that of earth.

Mound, in heraldry, a ball or globe with a cross upon it, such as our kings are usually drawn with, holding it in their left hand, as they do the sceptre in the right.

Mount, an elevation of earth, called also mountain.

Mount St Michael, a borough-town of Cornwall,

Mount Sorrel, a market-town of Leicestershire, seven miles north of Leiceter.

Mount of Piety, certain funds or establishments in Italy, where money is lent out, on some small security. We had also mounts of piety in England, raised by contribution for the benefit of people ruined by the extortions of the Jews.

Mount, in heraldry, a ball or globe with a cross upon it, otherwise the movement will not be perpetual; so that any action by which the absolute quantity of force is increased, of which there are several forts, must have its corresponding counter-action, by which the gain of force is destroyed, and the quantity of force restored to its first state.

Thus, by these actions, there will never be any gain of direct force, to overcome the friction and the resistances of the medium; so that every motion being diminished by these resistances, they must at length languish and cease.

Mould, a term used for a bank or rampart, or other fence, particularly that of earth.

Mound, in heraldry, a ball or globe with a cross upon it, such as our kings are usually drawn with, holding it in their left hand, as they do the sceptre in the right.
MULE, in zoology, a mongrel kind of quadruped, usu-
ally generated between an as and a mare, and some-
times between a horse and a she-as.

MULLERAS, a town of Germany, in the circle of
Upper Saxony, and marquisate of Brandenburg, sit-
tated thirty-eight miles south-east of Berlin.

MULLET, in ichthyology. See Mugil.

MULLETT, or MULLET, in heraldry, a bearing in form
of a flat, or rather of the rowel of a spur, which it o-
riginally represented.

MULSOM, a liquor made of wine and honey, or even
of wine and water.

MULTAN, or MOUTAN, a city of hither India in Asia,
capital of the province of Multan, situated on the river
Indus. E. long. 72° 15'; N. lat. 30°.

MULTIPLE, in arithmetic, a number which compre-
hends some other several times, thus 6 is a multiple of
2, and 12 is a multiple of 6, 4, and 3, comprehending
the first twice, the second thrice, &c.

ACTION of MULTIPLYING, in Scots law. See
Law, Tit. xxx. 24.

MULTIPLICAND, in arithmetic. See Arithmetic,
p. 371.

MULTIPLICATION, in general, the act of increas-
ing the number of any thing.

Multiplication in arithmetic, is a rule by which any
given number may be speedily increased, according to
any proposed number of times. See Arithmetic,
p. 371.

MULTIPLICATION, in algebra. See Algebra, p.
81.

MULTIPLICATOR, or Multiplier, in arithmetic.
See Arithmetic, p. 371.

MULTIPLYING GLASS, in optics, one wherein objects
appear increased in number. See Optics.

MULTURE, in Scots law, the quantity of grain paid
to the proprietor or tacksman of a mill for grinding.
See Law, Tit. xvi. 12.

MULVIA, a river of Barbary, in Africa, which rises in
the mountains of Atlas, and divides the empire of Mo-
rocco from the kingdom of Algiers, and then falls in-
to the Mediterranean, west of Marfalquivier.

MUM, a kind of malt-liquor, much drank in Germany;
and chiefly brought from Brunswick, which is the place
of most note for making it. The process of brew-
ing mum, as recorded in the town-house of that city,
is as follows: Take sixty-three gallons of water that
has been boiled till one third part is consumed, and
brew it with seven bushels of wheaten malt, one bushel
of oat-meal, and one bushel of ground beans; when it
is tinned, the hoghead must not be filled too full at
first: as soon as it begins to work, put into it three pounds
of the inner rind of fir, one pound of the tops of fir
and beech, three handfuls of card, us benedictus, a
handful or two of the flower of rofa folis; add burnet,
betony,
bony, marjoram, avens, pennyroyal, and wild thyme,
of each a handful and a half; of elder flowers, two
handfuls or more; seeds of cardamum bruised, thirty
ounces; barberries bruised, one ounce; when the li-
quor has worked a while, put the herbs and seeds into
the vessel; and, after they are added, let it work over
as little as possible; then fill it up: lastly, when it is
stopped, put into the hoghead ten newly laid eggs un-
broken; stop it up close, and drink it at two years end.
Our English brewers, instead of the inner rind of fir,
ufc cardamum, ginger, and cassiafras; and also add ele-
campane, muskder, and red sanders. Mum, on being
imported, pays for every barrel 1 l. 5s.

MUMMY, a body embalmed or dried, in the manner
used by the ancient Egyptians; or the composition with
which it is embalmed. There are two kinds of bodies
denominated mummies: the first are only carcasses
dried by the heat of the sun, and by that means kept
from putrefaction: These are frequently found in the
fands of Lybia. Some imagine, that these are the
bodies of deceased people buried there on purpose
to keep them entire without embalming; others think
they are the carcasses of travellers, who have been over-whelmed
by the clouds of sand raised by the hurricanes fre-
fquent in thofe deserts. The second kind of mummies
are bodies taken out of the catacombs near Cairo, in
which the Egyptians deposited their dead after embalm-
ing.

We have two different substances preferred for me-
dicine under the name of mummy, though both in
some degree of the same origin. The one is the
dried and preferred flefh of human bodies, embalmed
with myrrh and spices; the other is the liquor running
from such mummies, when newly prepared, or when
affected by great heat or damp. The latter is some-
times in a liquid, sometimes of a solid form, as it is
preferred in vials well stopped, or suffered to dry and
harden in the air. The first kind of mummy is brought
to us in large pieces, of a lax and friable texture, light
and spungy, of a blackish brown colour, and often
damp and clammy on the surface: it is of a strong but
difagreeable smell. The second kind of mummy, in its
liquid state, is a thick, opaque, and viscous fluid, of a
blackish colour, but not disagreeable smell. In its indu-
rated state, it is a dry solid substance, of a fine fheining
black colour, and close texture, easily broken, and of
a good smell; very inflammable, and yielding a fcent
of myrrh and aromatic ingredients while burning.
This, if we cannot be content without medicines from
our own bodies, ought to be the mummy used in the
shops; but it is very scarce and dear; while the other
is fo cheap, that it will always be moft in ufe.

All these kinds of mummy are brought from Egypt.
But we are not to imagine, that any body breaks up
the real Egyptian mummies, to sell them in pieces to
the druggists, as they may make a much better market
of them in Europe whole, when they can contrive to
get them. What our druggists are supplied with, is
the flesh of executed criminals, or of any other bodies
the Jews can get, who fill them with the common bitu-
men so plentiful in that part of the world; and adding

Vol. III. No. 82. 2

a little aloes, and two
send them to be baked in
exhaled, and the embalming thus
thoroughly that the flefh will keep and bear transport-
ing into Europe. Mummy has been esteemed resinous
and balsamic: but whatever virtues have been attribu-
ted to it, seem to be fuch as depend more upon the in-
gredients used in preparing the flefh, than in the flefh
itself; and it would furely be better to give thofe in-
gredients without fo shocking an addition.

MUMMY, among gardeners, a kind of wax used in graft-
ing and planting the roots of trees, made in the follow-
ing manner: Take one pound of black pitch, and a
quarter of a pound of turpentine; put them together
into an earthen pot, and let them on fire in the open
air, holding something in your hand to cover and
quench the mixture in time, which is to be alternately
lighted and quenched till all the nitrous and volatile
parts be evaporated. To this a little common wax is
to be added; and the composition is then to be set by
for ufe.

MUNGATS, or MUNKATS, a town of upper Hungary:
E. long. 22°, N. lat. 49° 36'.

MUNICH, a large and elegant city, the capital of the
electorate and duchy of Bavaria situated on the river
Ifer: E. long. 11° 23', N. lat. 48° 5'.

MUNICIPAL, in the Roman civil law, an epithet which
signifies invested with the rights and privileges of Roman
citizens. Thus the municipal cities were thofe whole
inhabitants were capable of enjoying civil offices in the
city of Rome: These cities, however, according to
Mariana, had fewer privileges than the colonies: They
had no suffrages or votes at Rome; but were left to
be governed by their own laws and magiftrates. Some
few municipal cities, however, obtained the liberty of
votes.

Municipal, among us, is applied to the laws that
obtain in any particular city or province. And thofe
are called municipal officers who are elected to defend
the interest of cities, to maintain their rights and pri-
ileges, and to preferve order and harmony among the
citizens; fuch as mayors, sheriffs, confuls, &c.

MUNITION, the provisions with which a place is fur-
fified in order for defence; or that which follows a
camp for its subsiftence.

MUNSTER, the capital of the bilhoprick of the fame
name, and of the circle of Westphalia, situated on the
river Aa: E. long. 7° 10', N. lat. 52° 53'.

MUNSTER, is also a town of Germany, in the Landgra-
viate of Alftia, subject to France: E. long. 7° 5',
N. lat. 48° 8'.

MUNSTER MEINFELT, a town of Germany, in the circle
of the lower Rhine, and electorate of Triers: E. long.
7°, N. lat. 50° 15'.

MUNSTERBERG, the capital of the duchy of the fame
name in Silefia: E. long. 16°, N. lat. 56° 35'.

MUNTINGIA, in botany, a genus of the polyandria
claf*. The calix confifts of five fegmenis,
and the corolla of five petals; and the berry has one
several segments; barberries bruised, one ounce; and also add ele-
campane, muskder, and red sanders. Mum, on being
imported, pays for every barrel 1 l. 5s.

MUNSTER, is also a town of Germany, in the Landgra-
viate of Alftia, subject to France: E. long. 7° 5',
N. lat. 48° 8'.

MUNSTER MEINFELT, a town of Germany, in the circle
of the lower Rhine, and electorate of Triers: E. long.
7°, N. lat. 50° 15'.

MUNSTERBERG, the capital of the duchy of the same
name in Silesia: E. long. 16°, N. lat. 56° 35'.

MUNTINGIA, in botany, a genus of the polyandria
claf*. The calix consists of five segments, and the corolla of five petals; and the berry has one
seed containing many seeds. There is but one species,
a native of America.

MURÆNA,
MURCIA, the capital of the province of the same name in Spain: W. long. 1° 12', N. lat. 38° 6'.

MURDER, or MURDERER, in law, is the wilful and felonious killing a person from premeditated malice; provided the party wounded, or otherwise hurt, die within a year and a day after the fact was committed. See Law, Tit. xxxiii.

MURDERERS, or MURDERING-Pieces, in a ship, are small pieces of ordnance, either of brass or iron, which have chambers, put in at their breeches. They are used at the bulk-heads of the fore-castle, half-deck, or steerage, in order to clear the deck, on the ship's being boarded by an enemy.

MURENGERS, two officers of great antiquity in the city of Chester, annually chosen out of the aldermen, to see that the walls are kept in repair, and to receive a certain toll and custom for the maintenance thereof.

MUREX, in zoology, a genus of shells belonging to the order of vermes testacea. This animal is of the snail kind; the shell consists of one spiral valve, rough with membranaceous furrows; and the aperture terminates in an entire canal either straight or somewhat ascending.

MURY, in heraldry, a kind of purple colour. See Salt.

MUS, in zoology, a genus of quadrupeds, belonging to the order of grises; the generic character of which is, that the fore-teeth of the lower jaws are faturated. There are 21 species. 1. The porcellus, or guiney-pig, has no tail; there are four toes on the fore-feet, and three on the hind ones. This animal makes a grunting noise, is very refrail, and flamps with its hind-feet when teased. It loves heat, and feeds upon vegetables. The female has two dugs. The colour is very various. It is a native of Brazil. 2. The aguti has a short tail, four toes on the fore-feet, three on the hind ones, and a yellowish belly. It is a native of Brazil, Surinam, and Guinea. 3. The leporinus has the same characters with the former, only the belly is white. It is found in Java and Sumatra. 4. The citellus has a short tail, an ash-coloured body, and no ears. It is found in Bohemia, &c. below ground. 5. The lemmus, has a short tail, five toes on both fore and hind-feet, and the body is variegated with green and yellow. They are found in the Lapland mountains under little hillocks, and feed solely on vegetables. 6. The paca, has a short tail, five toes on each foot, and there are three yellowish lines on each side. It is a native of Brazil. 7. The marmota has a short hairy tail, round ears, and gibbous cheeks. It digs deep holes in the earth with amazing quickness; sleeps profoundly during the winter; lifts its food to its mouth with the fore-feet; often sits erect; it is easily tamed, and is found in Switzerland. 8. The monax has a hairy tail, an ash-coloured body, roundish ears, and four toes on the fore feet and five on the hind ones. It is a native of America. 9. The cricetus has a tail of a moderate length, round ears, a black belly, and reddish sides, with three white spots. This animal digs deep caverns in the earth, divided into many different cells in which it deposits and prefers large quantities of fruits and grains. The female brings forth six young ones twice in the year, each of which lives in a separate cell. They are hunted for food, for their skins, and even for the quantity of grain found in their cells. It is a native of Germany. 10. The terrestris has a hairy tail, with four toes on the fore-feet, and five on the hind ones, and ears shorter than the hair. This animal, which is about half the size of a rat, digs in the gardens like a mole, and eats the bark off the roots of trees, &c. It swims in ditches, and devours young ducks in the ponds. It is a native of Europe. 11. The amphibious has a long hairy tail, with palmed feet. It digs in the banks of ditches and under the roots of trees, and feeds upon vegetables. It is found both in Europe and Africa. 12. The rattus, or rat, has a long naked tail, four toes on the fore-feet, and five on the hind ones, and a claw on the large toe. This animal infests the houres every where through Europe, and is devoured by cats and other animals of the same class. It is reported by several authors, that rats were originally transported from America in a ship belonging to Antwerp. 13. The muculus, or common mouse, has a long naked tail, four toes on the fore-feet and five on the hind ones, but has no claw on the large toe. This animal is a native of Europe, feeds upon grain and flesh of all kinds. 14. The avellanarius has a long hairy tail, a reddish body, a white throat, and the hind toes have no claws. It frequents the woods of Europe, feeds upon nuts, which it lays up in the earth, and sleeps during winter. 15. The querimus has a long hairy tail, with a black ring under the eyes. It is a native of the south of Europe. 16. The gregarius has a tail about one third of the length of its body, and somewhat hairy; the body is of a greyish colour, and the legs are white. It
It is a native of Germany. 17. The Sylvaticus has a tail of a middling length, four toes on the fore feet, and five on the hind ones; the body is grey, intermixed with black hairs, and the belly is white. It is found in the gardens and woods of Europe. 18. The friatus has four toes on the fore-feet, and five on the hind ones; it has longitudinal streaks on the body, with white spots. It is a native of India. 19. The longipes has a long covered tail, four toes on the fore feet, five on the hind ones, and very long thighs. It is found in the torrid zone. 20. The Jaculus has a long feecy tail, with very long thighs, and short fore-legs. It walks on its hind-feet only, and has a jumping motion. It is found in Arabia, Egypt, &c. 21. The Volans has a long hairy tail, four toes on the fore feet and five on the hind ones, and the skin from the ears to the tail is extended like wings, by which it is enabled to fly. It is native of Virginia and Mexico.

Musca, the plantain-tree, in botany, a genus of the polygama monzae claps. The calyx is a spathe; the corolla consists of two petals; one of them straight and teethed; and the other is concave, short, and furnished with a nectarium. It has fix filaments, and one stigmas. There are four species, all natives of the Indies.

Muscadinct, a rich kind of wine, of the growth of Provence and Languedoc, in France.

Muscle, in anatomy. See Anatomy, p. 192.

Muscle, in natural history. See Mytulus.

Museum, a name which originally signified a part of the palace of Alexandria, which took up at least one fourth of that city. This quarter was called the Museum, from its being set apart for the musees and the study of the sciences. Here were lodged and entered the men of learning who were divided into many companies or colleges, according to the sciences of which they were the profesfors; and to each of these houses or colleges was allotted a handsome revenue. The foundation of this establishment is attributed to Ptolemy Philadelpbus, who here placed his library. Hence the word Museum is now applied to any place set apart as a repository for things that have an immediate relation to the arts.

The Museum at Oxford, called the Ashmolean Museum, is a noble pile of building, erected at the expense of the university, at the west end of the theatre, at which side it has a magnificent portal, sultained by pillars of the Corinthian order. The front, which is to the street, extends about sixty feet, where there is this inscription over the entrance, in gilt characters, Museum Ashmoleanum, schola naturales historie, officina eunica.

It was begun in 1679, and finished in 1683, when a valuable collection of curiosities was presented to the university by Elias Ashmole, Esq. which were the same day reposited there. And several accessions have been since made to the Museum; among which are hieoglyphics and other Egyptian antiquities, an entire mummy, Roman antiquities, alars, medals, lamps, &c. and a variety of natural curiosities.

The British Museum in London is a large, beautiful, and magnificent building, and the noblest cabinet of curiosities in the world. This edifice was erected in 1677, and was called Montague-house, from having been the town residence of the dukes of Montague. In the year 1753, the British parliament having passed an act for purchasing the Museum of the late Sir Hans Sloan, and the collection of manuscripts of the late lord Oxford, called the Harleian Library, for the use of the public; 26 trustees were appointed and incorporated, to provide a repository for those and some other collections, which repository was to be called the British Museum. These trustees elected fifteen other trustees; and having bought Montague-house, fitted it up for the reception of these collections: they also appointed officers to superintend the museum; and having ordained certain statutes with respect to viewing the collection contained in it, the public were admitted to view it in 1757.

Muses, certain fabulous divinities among the pagans, supposed to preside over the arts and sciences; for this reason it is usual for the poets, at the beginning of a poem, to invoke these goddesses to their aid. Some reckon the muses to be no more than three, viz. Mneme, Aede, and Melete; that is, memory, singing, and meditation; but the most ancient authors, and particularly Homer and Hesiod, reckon nine; viz. Clio, which means glory; Euterpe, pleasuring; Thalia, flourishing; Melpomene, attracting; Terpsichore, rejoicing the heart; Erato, the amiable; Polyhymnia, a multitude of songs; Urania, the heavenly; and Calliope, sweetness of voice. To Clio, they attributed the invention of history; to Melpomene, tragedy; to Thalia, comedy; to Euterpe, the use of the flute; to Terpsichore, the harp; and to Erato, the lyre and lute; to Calliope, heroic verse; to Urania, astrology; and to Polyhymnia, rhetoric.

Mushroom, in botany. See Fungus.
disposing and conducting sounds considered as acute and grave; and proportioning them among themselves, and separating them by just intervals pleasing to the sense.

Mr Malcom defines it a science that teaches how found, under certain measures of time and tune, may be produced; and so ordered and disposed, as either in consonance (i.e. joint-sounding) or succession, or both, they may raise agreeable sensations.

From this definition, the science naturally divides into two general parts, viz. theoretical and practical.

PART I. THE THEORY OF MUSICK.

AXIOM I. The ear is the sole judge of sound. Every sound is not a musical sound. For to this two things are required: first, That the sound please the ear; secondly, That it be within a certain compass. A musical sound is clear, uninterrupted, and uniform; and ought not to exceed the power of the ear to judge of it.

For sounds, very deep or very high, are not easily distinguished, but by an ear very conversant in music.

Sound being a simple idea, cannot be defined but by an imperfect description of its cause; which is a voluntary motion of the air, communicated by the vibration of the parts of bodies to the organ of hearing.

The diversities of sounds, and their proportions, are perfectly discerned by the ear, are the object of the theory of music, the grounds and principles of the practice, as well as the causes of pleasure in the sense and imagination.

These diversities of sounds are expressed by the terms high and low, acute and grave, or sharp and flat. Hence, from any given sound, we can conceive a succession of them; wherein the last in order is more acute than the former; and this series is called notes ascending.

Or, on the contrary, when, in a succession of sounds, the last in order is more grave than the former; this series is called notes descending.

AXIOM II. From this order of notes ascending and descending are deduced all the proportions which constitute harmony; and upon which the whole superstructure of music is raised.

First, of the intervals of sounds lying in their natural order. Of these there are seven intervals, named from the first seven letters of the alphabet, viz. A, B, C, D, E, F, G.

The distance between any two of these, whether immediate or remote, is called an interval. And every interval is named from the natural numbers; beginning at unity.

In naming an interval, it is always understood of the ascending notes; and both terms are inclusive. Thus AB is called a 2d, AE a 5th, BE a 4th, EG a 3d, AA an 8th or octave; and so of the rest.

We proceed now to lay down an exact description of all the intervals in music. For from the knowledge of these are discovered all the proportions which constitute harmony; and upon which the whole superstructure of music is raised.

First, of the intervals of sounds lying in their natural order. Of these there are seven intervals, named either the greater tone, the lesser tone, and the half-tone or semitone. See the Music Plates, No. 1, 2.

In this series of 8 notes are contained 5 whole tones; three greater, and two lesser; and 2 semitones. Reducing them therefore to the lowest denomination, they will be found to contain 12 half-tones; and inclusively 13. Every octave then contains 13 half tones; out of the various combinations of which arise the several concords and discords, as will be shewn in its proper place. The lesser tones are alike divided into half tones, as are the greater. We shall therefore, for brevity sake, hereafter use the distinction only of whole tones and half tones: the reason for which shall be assigned below.

From the inequality in the order of these intervals we draw the following corollary.
Cor. II. Harmonical proportion is of a species different from all other proportions, and can be demonstrated only from principles peculiar to itself. This will be seen when we come to shew the method of dividing a line harmonically; as well as from the proportion stated in numbers.

The first of the notes in the examples above is called the key-note, or key. Notwithstanding the intervals may be reckoned from any given note; yet it will answer our purpose better to begin with the key.

In the first example,

The first interval, or distance between the key and second, contains 2
Between the 2d and 3d 2
3d and 4th 1
4th and 5th 2
5th and 6th 2
6th and 7th 2
7th and 8th 2

In the second example,

The first interval, or distance between the key and second, contains 2 semitones.
Between the 2d and 3d 1
3d and 4th 2
4th and 5th 2
5th and 6th 1
6th and 7th 2
7th and 8th 2

From this comparison of the two series, it is evident there is but one difference, and this arising from the order of the notes, or place of the semitone. For if you begin to read the second series at the interval between the 3d and 4th, the semitones will be found exactly in the same order as in the first example.

In the first example, the first semitone falls on the 4th note, or that which is next above the 3d to the key; which 3d is 5 half-tones above the key inclusively. In the 2d example, the half-tone falls on the 3d note; and is therefore itself the third to the key, and is four half-tones above the key inclusively.

This distinction of the place of the semitone is most worthy of observation; it being the only essential difference of tune, the ground work of all that beautiful variety which may be introduced in the air or melody, as well as it is the principle or hinge on which turns the resolution of every discord. The key-note of every tune is that wherein the tune ends; though it may be altered for variety in the upper part, yet the last note of the bass is ever the key.

When the 3d to the key is 5 semitones to the key, as in the first example, that tune is said to be composed in a sharp key. When the 3d to the key is 4 semitones to the key, as in the second example, the tune is in a flat key. And this, as was said before, is the only difference in tune.

This distinction of flat and sharp third holds good, not only in relation to the key, but likewise to every note in the scale of music. And in this light it is the foundation of composing in different keys; of changing the key in the same tune which introduces the so much desired variety in music; and of writing the same tune in divers keys, which is called transposition. Hence we establish the following axioms.

Axiom III. As the difference of the flat and sharp third to the key constitutes the key, and is essential to the tune: so no tune composed in a sharp key can be composed into a flat one, nor a flat into a sharp; for that would be altering the permanent nature of things.

The truth of this axiom will most evidently appear, when we shall, in the second part, or practice, have learned the art of transposition.

Axiom IV. The great and constant object which must be sought after in music, whether in composition, or performance of thorough bass, is variety with uniformity. For the proportions already laid down, and the prodigious variety emerging from them, as they lie in the order of nature, before they are modified, divided or combined by art, do not only point out this variety to us; but the concords and discords likewise made out of these, and arranged by art, will not only not suffer us to recede from the established precept, but by a kind of sweet violence constrain us to pursue this darling object.

On the truth of this axiom is grounded the reason for the mixture of discord with harmony, and the occasion of this precept in playing thorough bass, namely, that the hands should as much as possible move in a contrary direction.

As to the place of the other semitone, which in the flat key is on the 6th, the reason shall be told in its proper place. And moreover, it must be observed, that the greater 7th in the sharp key, which causes the second semitone to fall on the 8th in that key, is also common to the flat key in many passages, but unexceptionably at the end of the tune, or close.

Sect. 3. Of the Concord and Discord.

Of the intervals standing in their natural order are compounded the greater intervals, namely, the concords and discords.

These are the next things to be considered. Now, to investigate the order of these, and their proportions to each other, we must have recourse to the original cause of sound; that is, to the tremulous motion of the air, excited by the percussion of some solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the moregrave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is produced from all solid bodies, by exciting the same degree of quickness of the air, excited by the percussion of the same solid body, as a bell, string, or pipe.
proportional to the lengths. Thus in two firings of the same matter, and equal diameters; if one be double the length of the other, it will give half the quickness of pulses; that is, half the number of pulses in the same time: or, the lengths being as 2 to 1, the vibrations are as 1 to 2. On this axiom are demonstrated the order and proportions of the concords, as follows.

**Proportion of the Octave.**

Let AB, a musical firing, be divided equally in C, and stop there: CB will found an octave to the whole or open firing AB. Now, CB, AB, are as 1 to 2; therefore, the vibrations are as 2 to 1; that is, the proportion of the octave or diapason is double, or 2 to 1.

**Proportion of the 5th.**

Let AB be divided into three equal parts, and stop in C: CB will found a 5th to the whole or open firing. Now, CB is to AB as 2 to 3; therefore the vibrations are as 3 to 2; that is, the proportion of the 5th, or diapente, is sesquialteral, or 3 to 2.

**Proportion of the sharp 3d.**

Stop the firing in C, the 5th part: CB will found a greater 3d to AB. But CB is to AB as 4 to 5. Therefore the vibrations are as 5 to 4; or, the proportion of the sharp 3d is as 5 to 4.

**Proportion of the flat 3d.**

Stop in C the 6th part: CB will found the lesser or flat third. But, &c. Therefore the proportion of the flat third is as 6 to 5.

**Proportion of the greater or sharp 6th.**

CB 4ths of AB will found the greater 6th. Therefore the proportion of the sharp 6th, is as 5 to 3.
The 3ds and 6ths imperfect concords. The 4th, of a practice.

Example of two concording with the open string or bass. No 4.

Next follows an example of three concording with the bass. No 5.

Having thus discovered the concords, their order and proportions; it is worth remarking, that the first concord, or 3d, which arises from the most simple division of a line, is the most perfect concord; the 5th is the next perfect concord; and so of the rest, in the order they have been found by the division of the string. For the nature and perfection of the 4th, accounted by some a very imperfect concord, shall be explained in the corollaries of the demonstration of the harmony, in Part II. on practice.

The 8ths and 9ths then are called the perfect concords.

The 3d and 6ths imperfect concords. The 4th, of a middle nature between the others, may be called an improper concord; for this reason, that with the 6th, with which it is always accompanied in harmony, though it make perfect harmony with the given note, yet they change the chord into that of the 4th to that note.

Likewise the 6th, whether joined with the 3d or 4th to the given note, tho' it make perfect harmony with either, yet they change the chord into that of the 6th or 4th to the same note.

Hence the reason why the 6ths are more imperfect concords than the 3ds.

From the order and perfection of the concords thus discovered; we deduce the following corollary.

Cor. III. The most perfect harmony is that which will be produced by the perfect concords, namely, the 3d, 5th, and 8th. Thus No. 6.

From the foregoing corollary, we are able to give a just definition of harmony. Harmony consists in one certain invariable proportion of distance of four founds performed at the same instant of time, and most pleasing to the ear.

These proportions of the first series are called simple concords. If the notes of a second series be added to the first octave, the proportion of any two concording notes compounded with the octave retains the same and nature of the simple concord; as a tenth, compounded of an octave and third, is called a third; a twelfth, compounded of an octave and fifth is called a fifth; a fiftenth, compounded of two octaves, is called an octave, or double octave. And so on to a third series.

These are the compound concords.

All other proportions founded together are harsh and disagreeable to the ear; and are for this reason called discords.

From the compounding and dividing the proportions delivered, not only the harmonical intervals are computed, but the discords likewise.

And this the following calculations demonstrate.

The proportion of the octave is the proportion of the 4th and 5th: for, by compounding $\frac{3}{4} \cdot \frac{5}{4} = \frac{15}{16}$, or $\frac{5}{4}$ the proportion of the octave.

Again, it is the proportion of the sharp 3d and flat 6th: for, $\frac{9}{8} \cdot \frac{16}{15} = \frac{144}{120}$ in its lowest terms.

Again, the flat 2d and sharp 6th: for, $\frac{3}{2} \cdot \frac{16}{15} = \frac{24}{15}$ or $\frac{8}{5}$ the proportion of the octave.

Now, since the 4th and 5th, the 3d and 6th, as also the 2d and 7th, compounded, make the octave; that is, any two numbers making 9, the middle term or note being repeated, or common to both; it follows, that to fall a 4th or rise a 5th, as also to fall a 3d or rise a 6th, and to fall a 2d or rise a 7th, and the contrary, answers the same purpose of harmony; for they meet in the octave.

This observation will be of great use in setting the bass, and figuring the same, by producing that variety and contrary motion demonstrated necessary in the 4th axiom.

Proportion of the 5th.

The proportion of the 5th is the proportion of the sharp 3d and flat 3d; for by compounding $\frac{3}{4} \cdot \frac{5}{4}$ or $\frac{15}{16}$ the sesquialteral and known proportion of the 5th.

Proportion of the Sharp 6th.

The proportion of the sharp 6th is the compound proportions of the fourth and sharp 3d; for $\frac{3}{4} \cdot \frac{5}{4}$ or $\frac{15}{16}$.

Of the flat 6th, the proportion is of the 4th and flat 3d; for $\frac{3}{4} \cdot \frac{5}{4}$ or $\frac{15}{16}$.

By the same manner of compounding are found the proportions of the concords of the 3ds; which shall be shewn when we shall have got the tones and semitones; which, as being discords, arise by dividing the harmonic proportions as follows.

Proportions of the Discords proved.

Proportion of the Greater Tone.

The proportion of the greater tone is the difference of the 4th and 5th; for $\frac{3}{4} \cdot \frac{5}{4}$ the proportion of the greater tone.

Proportion of the Less Tone.

The proportion of the lesser tone is the difference of the 5th and sharp 6th; for $\frac{3}{4} \cdot \frac{5}{4}$ the proportion of the lesser tone.

Proportion of the Semitone.

The proportion of the semitone is the difference of the sharp 3d and 4th; for $\frac{3}{4} \cdot \frac{5}{4}$ the proportion of the semitone.

Having now the proportions of the tones and semitones, we are enabled to prove the proportion of the semitone, or flat 2d and sharp 7th to the 8th; as likewise all the remaining proportions, whether discord or concord: For, the 4th and sharp 3d, $\frac{3}{4} \cdot \frac{5}{4}$ give $\frac{15}{16}$ the greater 7th; and the sharp 9th and semitone $\frac{9}{8} \cdot \frac{15}{16}$ in its lowest terms $\frac{3}{2}$ the proportion of the octave.

To go on; The proportion of the sharp 3d is that of the greater.
greater and lesser tones; for, \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) in its lowest terms, the greater 3d.

And the proportion of the flat 3d is compounded of the greater tone and semitone; for, \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) in its lowest terms, the proportion of the flat 3d.

The proportion of the 4th is that of the sharp 3d and semitone; for, \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) in its lowest terms, the proportion of the sharp 3d.

The proportion of the discord of the sharp 4th is found by compounding its constituent intervals, the 4th and semitone; for, \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the proportion of the sharp 4th.

And lastly, the proportion of the flat 7th is compounded of two 4ths, or \( \frac{1}{2} \); for, \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the proportion of the flat 7th.

These proportions, in the natural order of the first series, or sharp key, stand thus:

\[
\begin{align*}
K & \quad 2d \quad Sharp \ 3d \quad 4th \quad 5th \quad Sharp \ 6th \quad Sharp \ 7th \quad 8th \\
1 & \quad \frac{2}{3} \quad \frac{5}{12} \quad \frac{1}{6} \quad \frac{1}{4} \quad \frac{1}{3} \quad \frac{1}{2} \\
K & \quad 2d \quad Flat \ 3d \quad 4th \quad 5th \quad Flat \ 6th \quad Flat \ 7th \quad 8th \\
1 & \quad \frac{2}{3} \quad \frac{5}{12} \quad \frac{1}{6} \quad \frac{1}{4} \quad \frac{1}{3} \quad \frac{1}{2} \\
\end{align*}
\]

Hence we can demonstrate (what before was taken for granted) the places of the greater and lesser tones, and semitone.

Now, the relative proportion or difference is found by division of the two next proportions in the natural order as above.

The places of the greater and lesser tones and semitones in the sharp key.

1) \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the greater tone, or 2d.

2) \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) in its lowest terms, \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the lesser tone, or flat 2d.

3) \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the greater tone, or 4th.

4) \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) in its lowest terms, \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the lesser tone, or flat 4th.

The places of the greater and lesser tones and semitones in the flat key.

1) \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the greater tone, or 2d.

2) \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) in its lowest terms, \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the lesser tone, or flat 2d.

3) \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the greater tone, or 4th.

4) \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) in its lowest terms, \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) the lesser tone, or flat 4th.

The use of this theory is chiefly on account of ascertaining the places of the semitones; the difference of the major and minor tones, which is as \( \frac{2}{3} \), \( \frac{5}{12} \), \( \frac{1}{6} \), \( \frac{1}{4} \), \( \frac{1}{3} \), \( \frac{1}{2} \) having not been hitherto reduced to practice.

We shall therefore hereafter admit no other distinction than that of whole and half tones.

The intervals then contained in the octave, in both keys, excluding the first term, will be more easily described thus:

The --- 2d is one tone.

Flat 3d a tone and a half.

Sharp 3d two tones.

I C K.

4th two tones and a half.

Sharp 4th three tones.

5th three tones and a half.

Flat 6th four tones.

Sharp 6th four tones and a half.

Flat 7th five tones.

Sharp 7th five tones and a half.

8th six tones.

Having found all the intervals, their order and proportions; it will be necessary to take in one view the semitones of the octave, marked by their different names and intervals. For every semitone hath two names in respect to the preceding and following note in the natural order. As in the following example. The knowledge of this is most necessary to learning the art of composition. No 7.

The discords being, as hath been shewn, the lefser 2d, or semitone, and greater 2d, the sharp 4th or false 5th, the lefser and greater 7ths, it is to be understood, that not any two or three of these are to be found together, to frame the discord; as the members of any concord are, to make the harmony: but each discordant note hath its discordant and concordant notes proper to itself, which will fill up the discord; and which are called the accompaniments.

The five discords, then, being distinct and unlike each other; the definition of discord must be this:

Discord consists in certain variable proportions of the distance of sounds, performed at the same instant of time, and disagreeable to the ear.

Chap. II. Of the Scale of Musick.

Having found that the larger combinations of the 13 semitones in the octave constitute the concords and discords; for the better application of them to our purpose, we shall next consider them singly and distinctly.

Diapason — — — Octave — 8th.

Semidipason

Defective 8th, or — — — greater sharp 7th.

Sept. major

Sept. minor — — — lefser flat 7th.

Hexachordon major — — — greater sharp 6th.

Hexachordon minor — — — lefser flat 6th.

Diapente

Defepentese, or — — — — — — sharp 4th.

Tri one

Diatessaron

Ditone — — — — — — — — — — — — flat 4th.

Semiditone — — — — — — — — — — — — lefser, or flat 3d.

Tone — — — — — — — — — — — — greater — — 2d.

Unison — — — — — — — — — — — — one found.

As they succeed each other in the natural order of both keys, as above demonstrated; this is called the scale of musick.

In this scale we shall likewise take a view of the concords of the same denomination, as they arise in succession from the same natural order of the simple tones, and also of the discords as oft as they occur.

There are two scales in use: the diatonic scale, and the chromatic.

In the diatonic scale, the notes arise by two tones, a semitone,
The Chromatic Scale.

The chromatic scale, which is no other than the natural semitones in their order, except the first tone, is only used when mixed with the diatonic. That is to say, when a semitone, not belonging to the harmony of the key, is introduced in the middle of a tone. And this may be done by the note ascending by a semitone, or defcending: in either of which cases, the key is changed in that part of the strain. This is the cause of great variety in the air; as well as it new-modulates the harmony. This is another effect of the semitone, on which turns so much variety and elegance. It must be executed by the composer with all the address and art imaginable. For this we must refer to the second part of practice, which will be given for the rules of the mixture of the chromatic. Pieces of music where it is frequently used, are now commonly called chromatic music.

The diatonic scale being that which we are chiefly concerned to understand, as well as the first in order, and before any use of the chromatic can take place, we shall proceed to view it in another light, whereby we shall discover such properties of it as will be useful to the composer. Sharp key. No. 12.

From the key the thirds ascend, as in the above example, by one sharp 3d, two flat 3ds, two sharp 3ds, a flat 3d, and lastly another flat 3d on the 2d to the key.

All the 4ths being perfect, are like; except that one which falls on the sharp 7th; this is called a sharp 4th, or false 5th. No. 13.

All the 5ths are perfect, and therefore like; except that formed by the sharp 7th and 4th, which likewise is a flat 5th or sharp 4th. No. 14.

The 6ths stand thus: two sharp 6ths, one flat 6th, two sharp 6ths, two flat 6ths. No. 15.

There are but two greater 7ths which are the sharp 3d and sharp 7th to the key: they stand under the two semitones.

All the 8ths are perfect and alike.

Vol. III. No. 82.
found the 5th, which two are the constituent intervals of the octave. And the same division of the sounds is constantly preserved, if the length of an octave be equally divided between any two stops.

Again, the length of a 5th between two stops, or note and stop, equally divided; the half next the bridge gives the greater 3d, the other half the lesser 3d. And again, the length of the greater 3d, thus divided, gives the greater and lesser tone. And the greater tone's length, equally divided, gives the greater and lesser semitone. And the length of the greater semitone, equally divided, gives the sounds in proportion as 5 and 4. The greater interval being next the bridge, and so continually.

Hence the necessity of the greater and lesser tones and semitones in music is evident; and the truth confirmed, which is asserted in the 24th corollary.

Now, in the diatonic scale, wherever the semitones lie, that is, whether the air be in a flat or sharp key, the graver part of the tone will be the lesser semitone, and the acuter the great semitone; and in the chromatic, which ascends by semitones, the greater and lesser semitones will, for the same reason, succeed each other alternately. Wherefore, if any series of chromatic notes be removed a semitone higher or lower; it must happen, that the lesser semitone will succeed into the place of the greater, and the greater into the place of the lesser. Hence dissonances will happen in the diatonic scale, as being composed of the same materials with the chromatic, if the key be injudiciously changed by transposition. For, as the dissonance will be evident, if the transposition be by one semitone; so the disproportion will full appear, if the removal be by any odd number of semitones within the compass of the 4th.

As the proportions of the concords have been demonstrated from the division of a line; so are they likewise to be found in the geometrical proportions of solid bodies, and therefore may be illustrated by the same.

We shall begin with the proportion of the 8th.

The proportion of the 8th being the compound proportions of the 5th and 4th, is, by corollary of the 34th proposition of Archimedes, as the whole superficies of a right cylinder described about a sphere, to the whole superficies of an equilateral cylinder inscribed as 2 to 1. For, the circumscribed is to the spherical superficies as 12 is to 8 (by 22 of this), but the spherical is to the inscribed as 8 is to 6 by the present proposition; therefore the circumscribed is to the inscribed as 12 is to 6, or 2 to 1.

In harmonic terms thus expressed: the 5th is to a given note or key as 12 is to 8; but the proportion of the 4th is as 8 to 6. Therefore, the proportion of the 8th is as 8 to 5 as 2 to 1.

Again, the proportion of the 5th, and the next harmonic proportion arising out of the 5th, is beautifully illustrated in the admirable proportion of the sphere, right cylinder, and equilateral cone circumscribed about each other. The last proportion being invented by Andrew Fiacquet; and that of the two first by Archimedes, as demonstrated in his 45th proposition in Tacquet's Euclid.
PART II. THE PRACTICE OF MUSICK.

The practice of music is founded on the principles delivered in the theory. Its several parts are composition, figuring the bass, melody, transposition, and singing by note.

Of these we shall treat separately in the above order.

Composition is the setting together two or more notes in harmony, to be founded at the same time.

When in the succession of concords, in the parts, the notes of each part are of the same length, or time of sounding, the composition is called counterpoint.

When the succession of concords is by notes of different lengths in the several parts, it is called plain counterpoint.

The mixture of discord and concord, by notes of the same or different lengths or time in the parts, is called figurate counterpoint. Of these in their order: and first of all, we shall treat of composition, figuring the bass, melody, transposition, and the different clavus wherein the parts of music are usually written.

The following account of the proportions of the lengths of notes, the time and clavus, being well understood by every one acquainted even a little with music, might well have been omitted in an essay of this kind; (where, instead of using repetitions, it is hoped we have offered to the public something new; at least in the manner of demonstrating the rules of composition, both in discord and harmony;) but that we would leave nothing in our power untold, which may contribute to form a complete musician.

The longest note, now generally in use in instrumental music, is called a semibreve. Its time is as long as you can distinctly count for.

Out of the division and subdivision of the semibreve are formed the lengths of all other notes; according to the following proportions. No. 22.

A semibreve, whole time, is as one, two, three, four; as long as the end of this line with the other end A, by drawing AG; and then taking any point, as B, at pleasure, in the given line, there draw EF parallel to DG, and in it take BE equal to BF; and then draw EG, and that shall find the point C required: and when calling, as above, the whole line Z, A B = t, B C = m, and D C = c, I say Z = a : e : m,

\[ Z : e : : a : m \]

Wherefore Z \( \frac{a}{m} \) be to c.

And, to divide any given right line thus harmonically, as suppose AD: From either end of it draw a right line, as DG; make an angle with it, and of any length; connect the end of this line with the other end A, by drawing AG; and then taking any point, as B, at pleasure, in the given line, there draw EF parallel to DG, and in it take BE equal to BF; then draw EG, and that shall find the point C required: and when calling, as above, the whole line Z, A B = t, B C = m, and D C = c, I say Z = a : e : m.

For the triangles ADG, ABF, and BEC, are all similar: and consequently AD : AB :: DG : BF ; or as DG to BF, so BE to BC. But as DG : BF : CD : BC; (by working about the equal angles D and E, and the different clavus wherein the parts of music are usually written.) Therefore, by equality, AD : AB :: CD : BC; that is, Z : a : c : m. Q.E.D.

And from hence it is plain, that the ratio of the whole line AD, to the segment A B, may be taken as pleasure; but that the intermediate part B C must be less than either A B or C D.

A dot after any note, signifies the time of such note must be lengthened to one half of the plain note. No. 23.

The proportions are thus;

A dotted semibreve is equal to 3 minims.
A dotted minim to 3 crotchets.
A dotted crotchet to 3 quavers.
And so of the rest.

Thus we are furnished with notes according to the odd and even numbers. And this naturally divides the time of any song or music into odd and even time.

COMMON TIME.

When the air moves according to the even numbers; and every bar is measured by beating the time into two equal and even parts, the music is composed in common time: known by one of the following marks prefixed to the time, as the letter C, having 4 crotchets in a bar.

TRIPLE TIME.

But when the music moves according to the odd numbers; and every bar is measured by beating the time into two unequal parts, as two and one, the song is composed in triple time; which is known by one of these signs prefixed to the time.

3, or \( \frac{3}{4} \), for 3 minims in a bar.
4, 3 Crotchets in a bar.
5, 3 Quavers in a bar.
6, 3 Crotchets in a bar.
7, 3 Quavers in a bar.
8, 3 Semiquavers in a bar.
9, 3 Demisemiquavers in a bar.
10, 3 Crotchets in a bar.
11, 3 Quavers in a bar.
12, 3 Semiquavers in a bar.
13, 3 Demisemiquavers in a bar.
14, 3 Crotchets in a bar.
15, 3 Quavers in a bar.
16, 3 Semiquavers in a bar.
17, 3 Demisemiquavers in a bar.
18, 3 Crotchets in a bar.
19, 3 Quavers in a bar.
20, 3 Semiquavers in a bar.
21, 3 Demisemiquavers in a bar.
22, 3 Crotchets in a bar.
23, 3 Quavers in a bar.
24, 3 Semiquavers in a bar.
25, 3 Demisemiquavers in a bar.
26, 3 Crotchets in a bar.
27, 3 Quavers in a bar.
28, 3 Semiquavers in a bar.
29, 3 Demisemiquavers in a bar.
tion of their lengths, contracted into the time of 2 quavers, or one crotchet, contantly noted by the figure (3) over them.

And lastly, the most common movement of jiggs, which is by fix or twelve quavers in a bar, have their bass, for the smoothnes of the movement, often written in plain crotchets; 2 in a bar for the treble \( \frac{3}{4} \); and four, marked thus C, for the treble \( \frac{4}{4} \). It is plain, therefore, that all tunes in these movements truly belong to common time, since every bar is measured by the beating, or dividing it into even parts, as expressed in the bass.

A pause or rest in musick, is a cessation of the sound, in one or more of the parts; or of all the parts together. Nothing hath a finer effect in musick than a pause of all the parts judiciously made; or of one, or more of the parts, for the sake of imitation. The rests therefore are written down in the place of notes, and each note hath its own rest, which is of the same length with the note whose name it bears. Thus,

A semibreve rest is as long as a semibreve. A minum rest as long as a minum.

And so of the rest.
The next thing to be considered is the cliff in which any part of the musick is laid to be written; according as the cliff is prefixed to each flave of the writing.
The use of the cliff is to ascertain the names of the notes; and to denominate that part of the musick to which it is prefixed.

There are three cliffs, to answer and distinguish the three parts in musick: The bass, or F cliff; the tenor, or C cliff; and the treble, or G cliff.

The bass is so called, from its being the lowest part, the tenor, or middle part, hath its name from holding the bass and upper parts together. This will be clearly understood, when we shall have learned to compose in four parts.
The uppermost part is called the counter-tenor in vocal musick; and, in instrumental, the first treble.
The bass and treble cliffs are now constantly written in the same places as in the examples. The tenor cliff is often removed, according to the fancy of the composer or writer of musick; to answer the convenience of the notes standing, as much as may be, within the compass of the five lines, or flave. Which convenience is the reason for the invention of the diversity of clifs, as well as the uses already named. For it is easy to apprehend, that the natural tones, and their proportions, are invariably the same, whether expressed by the voice, or an instrument, however they may be distinguished by artificial signs. Observe, that the clifs, according to their names, rise above each other by the interval of a 5th; thus the tenor is equally distant from each other part. For C is a 5th to F, as it is also a 5th below G.

**Chapter I. Of Composition in Counterpoint.**

**Composition in counterpoint is when, in the succession of concords in the parts, the notes of each part are of the same length, or time of founding.**

According to the 2d axiom, we shall begin with the harmony of the key note; and proceed to demonstrate the harmony of the remaining notes of the octave in their natural order.

**Demonstration of the Harmony of the Key.**

The harmony of the key is the concord of itself. The harmony of the key must be perfect harmony. Now, the notes concording in perfect harmony, are, by corollary 3d, the 3d, 5th, and 8th. But these, with the key, are the concord of itself. Therefore, the harmony of the key is the concord of itself.

This demonstration is grounded on this evident truth; namely, that any other concord would, by the term, or name of it, in effect change the key; whereby the unity of the tune would be destroyed, and by this contradiction the author's meaning rendered unintelligible. The necessity of perfect harmony in the key being evident, no other sort of demonstration is required, nor indeed can be admitted.

Let it be required to set a bass to the notes of an octave ascending in G sharp. No 25.

Any one of the three notes in the bass is concording, by corollary 3; but the 8th is preferable when it is the first or last note of the tune; for thus it best ascertains the key. The preference of either of the other two depends on the following rules.

First, The 5th cannot take place when the concord immediately preceding shall happen to be a 5th, the forbidding the consecution of 5ths being ascertained in corollary the 4th.

Again, the movement of the bass ought generally to be by descending a 5th, or rising a 4th, 6th, or 8th, or any other great interval; whereby meeting the treble, and effecting variety and contrary motion of the parts; the established rules of harmony by the 4th axiom.

Lastly, The air of the bass must be consulted; and, if possible, an imitation of some foregoing passage in the upper part.

The application of these rules will decide which of the two or three notes is preferable in this or any other concord.

**Demonstration of the Harmony of the 2d.**

The harmony of the 2d is the concord of the 5th. The harmony of the key having been shown, we must consider it as an immovable point, in relation to which we are to order the rest of our computations, consistent with the established principle of uniformity.

The 2d to the key immediately descending into the key, will have, for its next concordant note, the greater 7th; which at the same time ascends by a semitone into the key; to which 7th the 2d is a 3d.

For, by axiom 2, the combination of sounds are deduced from the natural order of notes ascending and descending. But the 2d and 7th can admit no other concordant note but the 5th to the key. For the 3d is discord with the 2d; and the 4th, 6th, and 8th discord with the sharp 7th.

Now, the 2d, 7th, and 5th are the concord of the 5th; therefore, the harmony of the 2d is the concord of the 5th. No. 26.
The 5th must always be taken at the close; or when the treble is descending into the key; for then the bass will fall a 5th into the key; which movement is called the great cadence. Otherwise the 7th or 5th may be taken indiscriminately; yet, under the restriction of the rules, (p. 326. col. 2.) for setting the harmony of the key.

**Demonstration of the harmony of the 3d.**

The harmony of the 3d is the concord of the key.

From the demonstration of the harmony of the key, the key will have its 3d; and, by inverting, the 3d will have the key. Now, the key and its 3d will admit no other concordant note but its 5th. For the 2d is discord to both, the 4th is discord to the 3d, and the 7th discord to the key; but the key, its 3d and 5th, are the concord of the key. Therefore, the harmony of the 3d is the concord of the key.

The 6th indeed, which is a 4th to the 3d, which is an improper concord, will, with the key, form the concord of the 6th; but the demonstration of the concord of the 6th in a sharp key, depending on another principle, as will be shown in its place, can, for the same reason, bear no relation to the harmony of the 3d, which is a member of the key. No. 27.

The two notes in the bass may be taken indiscriminately; yet complying with the rules. (p. 326. col. 2.) But, if the 3d in the treble be prepared to descend into the key, by its passage into the 2d, then the 5th is more eligible; which falling an 8th for the next note, thence descends by a 5th into the key. This is the most fitting movement of the bass; and, at the same time, the most common, at a final close in either flat or sharp key.

**Demonstration of the harmony of the 4th.**

The harmony of the 4th is the concord of itself.

In a sharp key, the places of the two greater 7ths are the sharp 3d and sharp 7th to the key; and, of the semitones, the 4th and 8th, or key; Therefore, the 3d is to the 4th as the sharp 7th to the key. Now, since by axiom 2d, the combinations are deduced from the natural order of the notes ascending and descending; the harmony of the 4th will be as the harmony of the key. But the harmony of the key is (by demonstration 1.) the concord of itself; therefore, the harmony of the 4th is the concord of itself. No. 28.

The notes in the bass may be taken indiscriminately: only observing the foregoing rules. If a close on the 4th be prepared from the 4th itself, either note will do; yet the key is preferable, in order to prepare for the great cadence.

**Demonstration of the harmony of the 5th.**

The harmony of the 5th is the concord of the key.

From the demonstration of the harmony of the key, the key will have its 5th; and, by inverting, the 5th will have the key. Now, the key and its 5th will admit no other concordant note than the 3d. For, the 2d and 4th are discord to the key and 5th; the 6th discord with the 5th; and the 7th discord with the key. But the key, its 5th and 2d, are the concord of the key:

**Demonstration of the harmony of the 6th.**

The harmony of the 6th is the concord of the 4th.

From the demonstration of the 4th, its harmony is its own concord. The 4th, then, will have its 3d; and, by inverting its 3d (that is, the 6th) will have the 4th. Now, the 4th and 6th will admit no other concordant note than the 5th: For the 2d is, (with the 4th and 6th,) a discord, as will be shown in the demonstration of the discords. The 3d and 5th are discord to the 4th, and, the 7th to the 6th. But the 4th, 6th, and 8th, are the concord of the 4th: therefore, the harmony of the 6th is the concord of the 4th. No. 30.

Either note in the bass may be taken at will. But if there be a preparation for a close on the 4th, the second note, or key, is preferable, for the reasons assigned in the demonstration of the 4th, which is, to make the great cadence, prepared by the bass, first descending an 8th, and then a 5th, into the 4th, or close.

**Demonstration of the harmony of the 7th.**

The harmony of the 7th is the concord of the 5th.

The harmony of the 7th is part of the harmony of the 2d, (by demonstration 2.) but the harmony of the 2d is the concord of the 5th: therefore the harmony of the 7th is the concord of the 5th. No. 31.

If the 7th, or treble note, precede a close on the key, the first note in the example must be the bass note, in order to make the great cadence.

The 8th being the key, hath for harmony its own concord; as by demonstration 1.

From the foregoing demonstrations, the bass notes, set to the 8 ascending notes in the treble, will stand thus.

**General Rule.** The consecution of 8ths, 7ths, and 4ths, is not allowed. (as by corollary 4.) except by contrary motion of the parts, or in the passage of very quick notes in composition of many parts. No. 32.

From taking in one view the harmony of the seven notes, we shall deduce some useful corollaries. No. 33.

Key 2d, 3d, 4th, 5th, 6th, 7th, 8th, hath the harmony of the Key 5th, Key 4th, Key and 5th, 4th, 5th, Semitone. Semitone. Semitone.

Cor. I. Every note in the octave (except the 2d to the key) admits in its harmony a 3d.

Cor. II. The key, the 2d and 5th, admit in their harmony a 4th.

**Scholia.**

When the key admits a 4th, the concord is of the 4th. When the 2d admits a 4th, the concord is of the 5th. When the 5th admits a 4th, the concord is of the key.

Hence the interval of that note which admits a 4th, is in fact a 5th; therefore two 4ths are no more allowed in
This then demonstrates what was asserted, by way of pre-theory) to be the most sparingly used, as not producing it makes a part of harmony.

In consecution than two 5ths. And hence likewise the interval of the 4th, which we have called an improper concord, appears to be of a middle nature between concord and discord; being a fourth in name and appearance in the natural order of sounds; yet a 5th in name and effect in composition, as member of that chord wherein it makes a part of harmony.

Con. III. The key, the 4th and 5th, admit in their harmony a 5th.

When the key admits a 5th, the concord is of the key.

When the 4th admits a 5th, the chord is of the 4th.

When the 5th admits a 5th, the concord is of the 5th.

Hence, when a note admits a 5th, the harmony is the concord of the same note.

Cor. IV. Every note but the 4th admits a 6th; for, the 4th having its concord for harmony, will have only its 5th.

Every note admits its 8th; for any note may be substituted for its octave. But 8ths are (by corollary 4. of the theory) to be the most sparingly used, as not producing that variety or mixture of sounds requisite to bind the harmony, especially, where it can be best avoided, in the composition of two parts.

From the foregoing demonstrations and corollaries, arise the following observations.

The 3ds and 6ths most frequently occur in composition. This then demonstrates what was asserted, by way of precept, in the 4th corollary of the theory as well as part of the 4th axiom; namely, that the proportions of musical sounds, and the variety emerging from them, point out to us this variety, and will not suffer us to depart from the established precept.

It will be necessary to see the same truths confirmed in the following notes. We shall therefore set down instances of composition in the following notes of the octave upon the same principles, and wherein the same demonstrations and corollaries do take place.

Example of composition in the following notes of the octave. No. 3d.

In the ascending notes, when the upper part rises by a semitone, the bass generally falls a 5th; when the upper part falls by a whole tone to a close, the bass also falls a 5th. This fall of the bass, or great cadence, must be effected when chromatic notes are introduced ascending; it being the property of the new semitone, thus formed by the note rising a half tone, to imitate the key or close. By axiom 2, the proportions of sounds, and properties of the same, are deduced from the natural order of the notes. Now, by the new semitone introduced, the note below imitates the greater 7th to the key: therefore in this case, as in a close on the key, the bass must fall a 5th.

Notwithstanding, this must be understood not of the passage of quick notes; and chiefly at a close.

Sect. 2. Of Composition in a Flat Key.

From the difference between the flat and the sharp key which lies in the different places of the semitone, there will arise a variety in the composition in a flat key, yet resting on the principles and demonstrations delivered in the last section.

The places of the semitone in the sharp key are the 4th and 5th. In a flat key, the semitone stands in the 3d and 6th places. The variety in the composition will happen where the semitones are concerned. For, as the middle close is made in the sharp key on the 4th, which is the semitone; or, as the 4th in the sharp key hath (by demonstration of the harmony of the 4th) its own concord for harmony: so the middle close in the flat key is made on the 3d, which is the semitone; or the flat 3d will have for harmony its own concord. Now, as the 4th hath its 3d and 5th for harmony, (which are the 6th and 8th of the key,) so the flat 3d will have its 3d and 5th, which are the 7th and 9th of the key.

Again, the flat 7th of the key being the 5th to the 3d, will, like the 5th of the sharp key, have for harmony its own concord. This will cause the 2d of the key to appear as the sharp 7th to the 3d, and the 4th of the key as a 2d (which it really is) to the 3d. Thus the whole harmony will be new modulated by the power of the semitone. Again, the flat 6th being the semitone, a middle close may be made on that note; and then the same proportional variety succeeds, and new harmony, as in the former case.

Lastly, at the end of the music, where there must of necessity be a close, the flat key will have the greater 7th, like the sharp one. Of so great consequence is the semitone. Nor indeed can a close be made at all, without the passage of a semitone in one or other of the parts. No. 35.

Differences in the flat key noted.

In the first example the harmony of the 2d is the concord of the flat 7th, as being 5th to the third. The close is made on the 3d, the bass falling a 5th. The 4th has its own concord, as in the sharp key. The 5th standing in an octave, may be understood as part of the harmony of the 3d, as the 3d to the key, in a sharp key.

The 6th is part of the 4th's concord, as in the sharp key; as above in the remark on the 4th.

At the close, there is the sharp 7th, from which the bass makes the greater cadence.

In this example there happen four 8ths: the first and last are absolutely necessary to ascertain the key; by the second there is a close made on the 3d; and that on the 5th, is for the sake of the air in the bass.

In the second example, the harmony of the 4th is the concord of the flat 7th, as 5th to the 3d.

The harmony of the flat 6th is its own concord, being the place of the semitone; where the bass rises a 4th (the same as falling a 5th) as a close on the treble ascending by the semitone.

In the 3d example, these differences of the flat key are left out; and the notes set as if they were part of a sharp key: that is to say, there is no close made on the 3d; the 4th hath its chord for harmony; and the 6th is likewise part of the harmony of the 4th.

For, notwithstanding the propriety of making a close on the 3d and 6th, which are semitones; yet the composer...
is not under the necessity of making a close in those places in every passage; and then he is at liberty of setting the notes as in the example. This observation clearly points out the difference of composition in a flat key, and where it is to be practised.

And indeed an author, whose sole end is to please the ear, will defignedly introduce a close on the flat 3rd, and in as many other passages as he can, to create the variety so much desired. In these cases, the rules delivered for composition in the flat key must undoubtedly take place.

The fourth example is set to shew the movement of the bass to the descending notes. The composition is the same as in the other examples.

Let us now take, in one view, the full harmony of every note in the flat key, and where the difference between it and the sharp key lies: from which we may derive some useful corollaries. No. 36.

The harmony of the
2d, 3d, 3d, 4th,
is the concord of the
Flat 7th, 3d, Flat 6th, Flat 7th.

Cor. I. The 2d admits a 3d; then the concord is of the flat 7th.
Cor. II. The 3d admits a 5th; the concord is of the flat 6th.
Cor. III. Again, the 3d admits a 4th; then the concord is of the flat 7th.
Cor. IV. The 4th admits a 4th and 6th; the concord is of the flat 7th.

By comparing these with the corollaries on the sharp key, it will be evident, that each note in the flat key admits for its harmony that note which was excluded in the sharp key. And therefore, that all harmony is divided between the flat and sharp keys; and wonderfully diversified by changing the places of the semitone.

From the demonstration of the harmony of the 7th, with corollary 3, on the sharp key, and the solmisation 3, on the same, we gather how great a share of the harmony belongs to the 7th. For it is part of the harmony of the key, and of the 2d (which chord is its own, or that of the 7th) in both flat and sharp key: and, in the flat key, it is likewise in the harmony of the 2d.

The nature and properties of the semitone being the same in both keys, we can now more clearly demonstrate the harmony of it in the following manner.

The harmony of every semitone is the concord of the same.

The key always stands between the greater 7th below, and the whole tone, or 2d, above. Now, by axiom 2, of the theory, the proportions, properties and relations of sounds are deduced from the natural order of the notes ascending and descending: The 4th (in a sharp key,) the flat 3d, and flat 6th, being semitones, are distant by a half tone below, and a whole tone above, is the key; therefore they have the same properties with the key. But the harmony of the key is the chord of the key: therefore the harmony of the semitone, or 4th, flat 3d, and flat 6th, is the chord of the same. Hence we raise the following axiom.

Axiom I. The harmony of every member of the concord of the key, is the concord of the key. And the harmony of every note in the compass of music, proved by the rules of harmony, is part either of the concord of the key, or of its 5th, or of a semitone. Hence variety in music is introduced by the contrary motion of the parts, and by changing the key, by bringing in new semitones. The better to illustrate this axiom, we shall hereafter in the examples set harmonical figures over every note, expressive of the chord.

First Example.

Let it be required to set a bass to this treble in G sharp.

Harmony of the

Second Example. No. 38.

Harmony of the

Third Example.

In A flat, No. 39.

Fourth Example.

In G flat, No. 40.

Fifth Example.

In A flat, No. 41.

Sixth Example.

In D sharp, No. 42.

In these examples every passage occurs which hath been delivered in the precepts of composition.

Take notice, that in the last example, the four passages, where the harmonic figures are not set over the notes, are part of a discord; which would take place, if the composition were in three parts; and which we cannot explain till we come to figurate descant.

Sect. 3. Of Composition in Three Parts.

The harmony, or full concord, of every note being well understood, both by reading the foregoing examples, as well as making application of the rules of composition on which the examples are framed, by trial of setting basses to other airs; the next step will be to proceed to composition of three parts.

This requireth no other precept than those already delivered, touching the harmony of each note. For the third part consists of the remaining notes of each concord which have not been made use of in the composition of two parts. Yet this caution must be used, that the two upper parts stand in the nearest concord to each other: that is to say, in 3ds as much as may be, and is consistent with variety and contrary motion of them. For hereby two points will be gained: first, it will bind the harmony; and secondly, the bass, being more at liberty to rise and fall by greater intervals, will meet the upper parts at every point, and produce variety by his contrary motion. The following examples are the same let in two parts above.

Prob. Let it be required to set a bass and second part to this treble. No. 43.

Prob. Let it be required to set the ascending notes of the octave in three parts, in a flat key.

In G flat, No. 44.

In A flat, No. 45.

In G flat, No. 46.
The harmony of the seventh bar in the last example, is altered in the repetition; though the notes of the first treble be the same.

In the first instance, the concords are of the key and 4th. In the repetition, the concords are of the 3d and flat 7th.

In the first instance, the passage from the 5th into the key, (in the 8th bar,) being the great cadence, is just.

But if otherwise a close had been made on the 3d, (in the 8th bar,) the harmony in the second instance, is of the key, and that of the 2d the concord of the 5th; or, when the harmony of the 3d is to be its own concord, and that of the 2d or 4th part of the concord of the flat 7th.

Hence it will be easy to decide in all flat keys, (to which only this case belongs) when the harmony of the 3d is to be part of the concord of the key, and that of the 2d the concord of the 5th; or, when the harmony of the 3d is to be its own concord, and that of the 2d or 4th part of the concord of the flat 7th.

Hence, and from corollary 1. of the theory, and from the demonstration of the harmony of the semitone, we deduce this general theorem.

The truest harmony is produced by the whole concords taken together falling in succession, as frequent as is consistent with the approved rules of harmony, by a 5th.

We shall put an end to composition in three parts, with the following example in a flat key, being one of the above in two parts. No. 47.

The use we shall make of this example is to remark, that although the basses be altered from that which is set in the same example in two parts: yet the harmony is the same, as is evident from the harmonic figures set over each.

Secondly, The 4th having its own concord, passes into the key, or 3d, in the passage of quick notes, and where there is not a close. But where, on the 6th bar, a close is made on the 3d, the basses making the great cadence, the 4th in the preceding bar is part of the concord of the flat 7th. And thus the whole harmony falls a 5th.

We have altered the basses also to answer the purpose of the movement of the upper parts in the closest harmony. And likewise to prove, that composition of many parts differs from that of two only. A truth which every composer should always have in view. For it will be found, upon trial, that, when the musick is set in two parts, if it be required to add a third, it will not be in the power of the composer to give that third part an air. A matter which ought to be studied by all means; and which, is evident from the example, can be executed, without injuring the harmony in the least, by composing the three parts together.

We therefore recommend it to the practitioner to make himself perfect in the composition of two parts, before he engages in three; as he will thereby not only sooner become master of the harmony; but also, by discovering more clearly the difference we are pointing out, will execute the composition of three parts with more ease and propriety.

Sect. 4. Composition of Four Parts.

In composition of 4 parts, every note in the concord is taken; or to every note there is full harmony.

The fourth part, or tenor, now to be added, consists of the remaining note of the concord, which was not used in composition of three. The octave therefore will take place in the concord of every note. The consecution of which, as well as of 5ths and 4ths, is to be avoided between the same parts. The rules already delivered in the composition of three parts must be attended to in this.

Example of the ascending notes of the octave in composition of 4 parts. No. 48.

Second Example.

In the descending notes of the octave in composition of 4 parts. No. 49.

Third Example in 4 Parts.

In A flat, No. 50.

Fourth Example in 4 Parts.

In G flat, No. 51.

In composition of 4 parts, it was said, that to every note there is full harmony. Notwithstanding, in the first example, the sixth notes of the first treble and tenor are in unison; each being a 6th to the bass; so that the octave hath no part in that concord. This is done to avoid the consecution of 8ths, by the succeeding note of the tenor, whose place must be, for the air's sake, the 8th to the bass, as well as to bind the harmony.

In the second example, the seventh notes in the first and second trebles are in unison; both being a 5th to the basses. Let not this be understood to be a consecution of 7ths, as they are members of the same chord; but is done for the sake of the air of the second treble. Let this remark serve for every like instance which may happen hereafter.

In the fifth bar of the third example, the second note, the second treble and tenor are in unison. This is done to avoid the consecution of 4ths, which, had the tenor kept his place, would have happened from the foregoing note between the first treble and tenor.

In the same example, there is a consecution of 5ths in the two next bars, by the tenor falling a 4th, and the basses rising a 5th. This seeming error is tolerated since it is effected by contrary motion of these parts. For as well as it is by the contrary motion of the parts, that the consecution of perfect concords is avoided; so for the same reason, the sameness of the harmony disappears, or escapes the ear; especially in composition of many parts.

By this reason, the consecution of 4ths is prevented by the basses rising a 3d, according to the first obligation on this example, at the 5th bar. For that would have happened by all the parts descending; that is, not having contrary motion. The second note then of the basses in that bar is changed from that which is set in the same example in three parts.

A few general remarks occur in this place, from comparing the composition of four parts with that of three.

First, Whereas the perfect concords have place in some part of the harmony of every note in musick of 4 parts; so the chances of the consecution of 8ths and 5ths being more frequent, the more skill and attention will be required to avoid them.
Section 5. Composition of Five Parts.

The four concordant notes answering exactly to four parts in composition; when a fifth part is to be added, it is evident one note of the harmony must be repeated in every concord. The fifth part therefore consists of the notes which are by turns repeated in each of the former, in which the avoiding the consecution of the perfect concords is to be observed as before; and the air of this part attended to as far as may be consistent with the rules delivered.

Example of composition of 5 parts in the ascending notes of the octave. No. 52.

Second Example in 5 parts. No. 53.

The two octaves between the tenor and bass on the sixth and seventh notes of this example, are allowed; as the parts do not move into other notes, or make a new concord.

Third Example in 5 parts. No. 54.

The consecution of 5ths between the tenor and bass is admitted, as they meet by contrary motion of the parts.

Fourth Example in 5 parts. No. 55.

It is observable from these examples, that the most difficult composition is that of 4 parts. The other 4 parts, consisting of a repetition of one or more of the concordant notes of the first 4 parts, are more easily contrived, nothing more being required than to avoid the consecution of the perfect concords between any two parts.

Section 6. Composition of Six Parts.

In music of six parts there is a repetition of two concordant notes. The sixth part therefore consists of the notes which take place in each of the five former, by turns.

An example or two will sufficiently illustrate this.

Example of composition of 6 parts. No. 56.

There is a consecution of 8ths between the fourth line and bass, on the 3d and 4th notes; but it being the effect of contrary motion is admitted.

Second Example in 6 parts. No. 57.

The two 8ths between the tenor and bass are allowed; for, as they do not move, they are in effect but one.

Third Example in 6 parts. No. 58.

The consecution of 8ths is by repetition of the same note, and therefore reckoned as one.

Fourth Example in 6 parts. No. 59.

In the 8th bar there is a consecution of 8ths between the third part and tenor effected by contrary motion of these parts.

Section 7. Composition of Seven Parts.

In composition of seven parts, three notes of the harmony are repeated in each concord. The seventh part therefore consists of the notes which are taken by turns from each of the six former; or, which is the same thing, from the first four; under the restriction of the rules concerning the consecution of 8ths, 5ths and 4ths between any two of the parts, unless produced by contrary motion of the same, or repetition of the notes, or in the octave, as said above. The seventh part is written in the tenor cliff, and is a second tenor to the first; so that, like the upper parts, it must stand in the nearest concord to the first tenor, or next part.

First example of composition of 7 parts. No. 60.

Notwithstanding it hath been said, that three notes of the harmony are repeated in each concord in seven parts; yet it doth not appear in every instance in the example. The reasons are, that in every close, whether middle or final, it is preferable that most of the parts should end in the concord note of the close, and especially of the last close, that the harmony of the key may make the deeper impression on the sense.

Secondly, The air of each part should be consulted; for this will not only justify, but demand the changing of one note of the harmony for another.

Again, as the parts next each other should stand in the closest concord; so, in order to effect this sentiment by contrary motion, they will meet in unison; and therefore the repetition of the three notes will not take place in every chord.

These rules will be sufficient to answer any doubt, or determine any choice to be made of any note of the concord, as well as justify the meeting of the parts in unison, in music of any number of parts whatever.

Second example in 7 parts. No. 61.

Third example in 7 parts. No. 62.

Section 8. Composition of Eight Parts.

The eighth and last part is the second bass; consisting...
ing which the following rules and observations must be premised.

If the music be composed for voices and instruments in full choir, it will be elegant and proper that the second bass and in the nearest concord with the first, after the example of the trebles and tenors.

The reason is, that the two choirs singing either together, or in responses, will thus exhibit greater variety.

After this manner we shall set the two following examples.

If the music be for instruments only, the difference of the basses consists in two things: First, the organ hath the figures of the thorough bass written. Secondly, the bass viol performs the solo parts, while the organ reffers. And in full concert the two basses move in unison. This is the manner in which the basses of instrumenental music are set by the most approved masters.

We shall in this place offer our opinion on the subject of two basses in instrumental music, relating to some alteration from the usual method of practice described above; which, as being perhaps new, will be received according to the notice it deserves.

We would have the part for the organ move in long notes, and by the least intervals; the figures filling up the harmony and discord; while the part for the violoncello moving in quicker notes, and greater intervals, becomes deficient to the other basses. Of this an example shall be given when we come, in the next place, to treat of plain descant.

To return: In music of 8 parts, the four notes of every chord are repeated, (allowing the exceptions remarked above.) Therefore, the full harmony of every note is double. The due mixture of which, according to the rules delivered, and the contrary motion of the parts, produce all the variety which harmony without discord is capable of affording.

First example of composition of 8 parts. No. 63.
Second example in 8 parts. No. 64.

Having given examples sufficient for instruction in composition of harmony in the several parts of music, and having illustrated in the same examples what hath been said concerning the harmony proper both to flat and sharp keys; we shall proceed to make such observations on composition in general, as may assist the practitioner in the application of the rules at the beginning, or first attempts.

And first, concerning the confection of perfects; which must be avoided, except in contrary motion of the parts, or repetition of the concord in the same notes in each part, or in the octave.

Let the intervals which constitute the octave be remembered, as hath been said above (in p. 321.) namely, a 5th and 4th, a 6th and 3d, a 7th and 2d; taking care, that when the note of one part rises or falls by one of these intervals, the note of the other part should not fall or rise by the interval which is the complement of the octave.

Thus the confection of 8ths will be easily avoided, and much trouble thereby saved in setting the parts.

Again, by the same caution, we avoid the confection of 5ths. For the notes set in the concord of a 5th, rising and falling together in the different parts, in the same constituent intervals of the octave, will likewise meet in a 5th; and, by avoiding such movement of the notes of a 4th, the confection of the same is in the same manner prevented.

One instance of each will shew this evidently. No. 65.

The confection of perfects, it is true, is tolerated, when effected by contrary motion of the parts. But these observations are made for the sake of a beginner, that he may not too often incur the abuse of this liberty.

The next observation is concerning the harmony of the 4th in a flat key.

The 4th in a flat key is either part of the concord of the flat 7th, or hath for harmony its own chord.

The harmonical figures over the examples point out this to flight. Notwithstanding, it may be asked in what case either harmony is to be preferred.

We shall endeavour to ascertain this matter upon the principles on which what hath been already taught is demonstrated.

In page 430. col. 1. we deduced this general theorem; That the truest harmony is produced by the whole concords taken together, falling in succession, as frequent as is consistent with the approved rules of harmony, by a 5th.

Therefore, when a close is made on the semitone, or flat 3d, the harmony of the 4th or immediately preceding note, must be the concord of the flat 7th. For thus the whole chord, or harmony, according to the foregoing theorem, falls a 5th.

And this theorem extends to the harmony of every note whose interval is a semitone, or which stands a half tone above and a whole tone below its contiguous notes, whose movement into the next chord must be falling a 5th.

The places of the semitone in the harmony of the key, are the key, the flat 3d, the 4th in a flat key, and the flat 6th, and not in the harmony of the key, whereas a semitone is introduced by the addition of a sharp or flat, whereby a close may be made on the semitone above.

Thus the truth of the first axiom of the practice is established; where it is said, That the harmony of every note in the compass of music, proved by the rules of harmony, is part of the concord of the key, or its 5th, or a semitone. For the flat 7th is to the flat 3d a 5th.

In the other case, when a close is not made on the flat 3d, or when the harmony need not fall a 5th, then the 4th may have for harmony its own chord. And here the 4th stands generally in the basses. Thus No. 66.

The proof of this depends on the relative proportion of the flat and sharp keys; and will be given, by that analogy, under the article of transposition.

The last observation is in respect of the practice of authors of instrumenetal music, in composition of many parts.

Whereas in the composition of 7 and 8 parts, the harmony of the notes are doubled; this is effected by the common practice, after the most easy manner, by doubling whole parts; that is to say, by two alternate parts moving through every note in unison, when in full concert; and likewise other two alternate parts. Thus the first and third violins play in unison; and the second and
and fourth. And, when these parts are not thus doubled, the third and fourth parts relt. Or otherwise, in some passages they take part of the harmony from the other parts, as in the examples above of 7 and 8 parts; excepting only in longer notes than the upper parts. The concertos of Corelli, Geminiani, and the overtures of Handel, are instances of this.

In a word, whatever form the parts of music may be disposed in, the principles of harmony are the same.

And when the rules of composition in counterpoint, which is the ground-work, are well understood, and confirmed by practice, the remaining part will become easy in proportion as the composer will find himself more at liberty to dispose of the parts to such advantage as he will judge most suitable to the genius of the music he is about to compose.

CHAP. II. OF PLAIN DESCANT.

The second manner of composing is when the succession of concords is by notes of different lengths in the several parts. It differs from counterpoint, not in the principles of harmony, but only in the form.

The effect of descant is variety; which is produced, either when two or more notes of one part are set against one note in another, or when a long passage in one part is set against a single note in the other. This last manner is properly called descanting on that note. Or lastly, When a subject is set in the basses, and constantly repeated; while at every repetition of the same, there is a variation in the treble, which diversifies the harmony, but doth not deviate from the rules of art.

This bass, which is the first written part, is called a ground bass; and the piece of music is called a ground.

Again, in descanting, it is usual for the parts to relieve each other; the basses sometimes holding the note, while the descant is in the treble; and again, the note is held in the treble, while the descant is in the basses.

The finest descant is where the discords are introduced in the passage of the notes. For here the air is least constrained; and the variety, in respect of the harmony, greater. This is figured descant, which shall be treated of in the next chapter.

To return to plain descant: The movement of every part is more free than in counterpoint; and not so easy and unconstrained as in figured descant. From this then arise its chief uses.

In the first place, it is the best introduction to the practitioner, to give an air to every part of his music: It is also the ground-work of inventing variations upon a plain subject in the same part. The rules for plain descant are these.

Every note in the descant must be one of the harmony of each note in the bass; as demonstrated in composition in counterpoint.

Secondly, If the descant be variation on a given subject, in the treble, the original air must be preferred as much as possible in imitation of the same.

The harmony then being the same as in counterpoint, the difference being only in the form or length of the notes, one example, after so many given in counterpoint before, will be sufficient to illustrate this part.

Whatever the subject of descant may be, whether a ground bass, or air in the treble, (the descant on which is called variations,) the practice is the same; as in the example, where the bass is the ground to the four trebles, and the other three descant on the bass; as well as variations on the subject, or first line.

For the more easy execution of both kinds, take these following rules of practice.

If you are to raise descant on a ground bass, then on this supposition the bass is first framed. Next let plain notes in the treble be set, as in the example, though no other use were to be made of them than to guide the composer's eye, and thereby furnish matter more readily for a better air and for the descant.

If the subject be an air in the treble, on which you are to make variations; as in this case, the air is the first part written, so it is the object on the book to which you are to attend contentantly as a pattern for the variations or descant.

It would be advisable also to set a plain bass to the treble or plain song, before you begin the variations. For, as the basses, or second note, in many cases determines the concord of the note; it thereby assists and rules the descant to be raised.

In general, when the two parts are set in plain harmony, the descant ought to imitate, and not depart from that design. If otherwise a discord be introduced in the composition of the two plain parts, or a discordant note be brought in in the treble or air, the descant must take part of the discord.

This properly belongs to figured descant. Notwithstanding, it is an elegance common in practice, to throw in a discordant note in the variation, which is not in the plain song.

But these rules are addressed only to beginners.

Having done with plain descant, we shall here give an example of what hath been offered (p. 532. col. 1.) relating to the manner in which we would have the two basses set in composition of many parts; which is, That the part for the organ should move in long notes, and by the least intervals; the figures filling up the harmony and discord; while the part for the violoncello, moving by quicker notes, and greater intervals, becomes descant to the other basses.

The manner of setting the two basses depending on the principles of plain descant, and implying nothing more than what is contained in the last example, one instance of this will sufficiently answer our intention here.

Example of two basses in composition of many parts.

No. 68.

The variety will be still greater if this manner be pursu ed in figured descant. For as undoubtedly that is the best and most perfect composition where discord is intermixed; so there is no variety, which music is capable of, produced from the form or disposition of the parts, that will not receive improvement from the more perfect composition.
The last example therefore, and what hath been said of the two basses in plain descant, is meant as an introduction to a trial of the same in the more perfect, or figurate descant, both in the composition and performance.

Chap. III. Of FIGURATE DESCANT.

**Figurate descant** is the mixture of discord and concord, by notes of the same or different lengths or time, in the several parts.

Every interval in music which is not harmony, must be discord.

The discords therefore are six: namely, the lesser and greater 2d; the sharp 4th, or flat 6th; the lesser and greater 7th; and the 9th. The reason for repeating the 9th, which is the 8th to the 2d, shall be shown in its place.

The use of discord is twofold: To give a better air to every part of the music; and to create variety. For the discords standing in the natural order of the notes, between the concords, afford an easy passage of the same; and, at the same time, mix with, and bind the harmony.

Discords are introduced in composition several ways.

First, When the notes passing in the natural order, two, three, or more of one part are set against one of another part. This passage of the notes is said to be by diminution; as in the following example.

Example of discords in passage by diminution. No. 69.

When the treble descends, the discords descend likewise into the concords; that is, the 9ths pass into 8ths, the 7ths into 6ths, and so forth. The same thing happens when the bass ascends.

When the treble ascends, or the bass descends, the contrary happens; that is, the 2ds pass into 3ds, and the 7ths into 9ths, or the discords into concords, according to the natural numbers.

When a single discordant note is set, the change of that note into a concord is properly called the passage of the discord.

When the accompaniments are set along with the discords; that is, when the whole discord, either in composition of many parts, or in figures in the bass, is expressed, the change of the same into a concord is justly called the resolution of the discord. The passage of the discord in single notes moving according to the natural order, as in the last example, is evident.

The accompaniments and resolution of the whole discord depend on certain principles; on which we shall, in its place, demonstrate the same.

To proceed, then, on single discords.

The second way in which discords are used in composition is, when the notes of each part move alternately, a long note between two short ones, so that the note of one part breaks off and ends in the middle of the note of the other part. This is called syncopation or binding; for the frequent mixture of the discord here supports and binds the harmony:

As in this example. No. 70.

In this manner the air of either part is less constrained, by the constant return of the discord, and passage into the concord. In some places this happens by the natural suc-cession of the notes by diminution, as in the first example, though not so frequently as in the last manner by syncopation. But there is a passage of the discord into the concord, formed by the notes moving by greater intervals.

This music is preferable on account of the great variety produced by this unexpected, and, we may say, surprising mixture of the discord and harmony. For variety itself causes new pleasure, when it is least expected, or when attended by novelty.

This moving of the notes by greater intervals, is the third way of introducing discord; and is the effect of the discords and concords constantly meeting by contrary motion of the parts.

In this manner the variety arises from the passage into concords, different from those which must succeed, either in the natural order of the notes, or by syncopation.

The variety also is greater by the constant succession of discord and harmony almost through every note.

For here the composer is at liberty to pass into any concord he pleases; and to resume any discord. For as the passage into the perfect concords, between two parts, cannot be effected, but from the nearest discord, when the notes move in the natural order; so, when the notes move by greater intervals, there is opportunity for many passages, which could not take place in any other way.

All this will be evident, when we come to understand the resolution of the discords.

Example of the more perfect mixture of discord and harmony. No. 71.

In this example are set forth the two first ways of using discords; namely, by diminution and syncopation, as well as passing by greater intervals; being set according to the rules relative to each manner. Where the discord and harmony move by greater intervals, there the passage is from discords new and unpracticed in the other two.

The composition, where this liberty is taken, does most justly challenge the name of ornamental or figurate descant.

And the music, wherein the discord is used these three several ways in their turn, must be esteemed the best, as exhibiting greater variety than could be expressed the other ways only. Let it be remarked in this place, that this new passage of the discord is effected by both parts generally moving by a semitone; the power of which will be seen when we shall have demonstrated the accompaniments and resolutions of the whole discord.

There is a fourth way wherein discords are admitted in composition. This is when discords succeed each other; or, where there is no passage into a concord. This is setting discords note against note. It is to be done two ways. First, when the discord passes into one of another denomination, in the natural order of the notes, by contrary passage of the notes of each part, of the same or nearly equal quantity.

This passage of the discord is necessary, as we cannot ascend or descend by the degrees of a great interval; but the intermediate discords will take place, and thence oft-times two will succeed each other.
This liberty is to be used chiefly in short notes, and by diminution.

Example of discords succeeding each other, or set note against note. No. 72.

Secondly, Discords are admitted, note against note, when the same discord is often repeated. This liberty is taken with the discord of the flat 7th above all others; and is most justly practised in music of three parts. When this discord is brought in successively in two parts, the complement of the chord ought to be written in the treble.

Example of the discord of the flat 7th successively. No. 73.

This example is taken out of the eleventh sonata of Corelli's fourth opera.

In this example, it is, remarkable, that the first and second trebles furnish by turns the discord to the bass; which constantly descends by a 7th, while the intervals of the upper parts are 5ths and 4ths to the bass alternately. Observe, when the note in the bass is flat, the discord will be the sharp 7th.

The imitation of this passage may be learned by inspection of the example. The demonstration depends on the demonstration of the third resolution of the discords following; which we must therefore reserve for that place.

An example of this passage shall be given when we come to teach the use of discords in music of three parts.

Having done with the single discords and their passages, we proceed, in the next place, to the complex ones; by which are meant the same discords with their accompaniments and resolutions.

Now, as, by axiom the second of the theory, from the natural order of notes, the properties, proportions and relations of sounds, which arise out of their various combinations and succeffions, are deduced; we shall demonstrate the properties of the discords upon the same principle.

The first property of the discord is the notes which are to be played in the thorough bass, in concert with the discord. These notes are called the accompaniments.

On the exact knowledge of these depends the second property of the discord; namely, its passage into a succeeding concord.

This passage is called the resolution of the discord, as mentioned above.

Each discord hath its own distinct properties. Therefore the definition of discord already given is just; where it is said, that discord consists in certain variable proportions of the distance of sounds.

As two single notes standing at a certain interval, form the discord, so they may easily be resolved into the proper succeeding concord, as we have already shewn.

And on instruments which have not keys, no more than the two notes can well be performed. Yet, as the resolutions of the discords cannot be demonstrated without the knowledge of the accompaniments, we shall consider the whole discord together; and demonstrate the accompaniments of each particular discord, after the same method we have proved the harmony of each note of the octave in counterpoint.

Vol. III. No. 83. 2

Theorem. Since every interval in music is discord or harmony, the accompaniments of most discords will be harmony in themselves; for thus they will be discord to the given note. But it will also happen, that some note of the accompaniment in other cases will also be harmony to the given note, yet the whole accompaniment discord in itself. For the soul so accords with harmony, as not to bear an entire perfect discord.

Now, as more or less of discord with the given note prevails; so the discords are naturally divided into proper and inharmonious.

A proper discord is the concord of some member of itself, and only discord in part with the bass or given note.

An inharmonic discord is an absolute discord in itself, and partly concord to the bass or given note.

There are five proper discords; namely, the lesser and greater 2d, the sharp 4th (or flat 5th), the sharp 7th, and the 9th.

There is one inharmonic discord; which is, the flat 7th.

It hath three places in the compass of the octave; where it appears in three different forms.

It is called inharmonic; not only because it is an absolute discord in itself, but also because it is not the accompaniment to the bass note, from whence the order of the discords is traced in the natural series; except in one place or form, which is the second; wherein the flat 7th is the uppermost note of the chord. This will be seen most clearly, when we shall have gone through the discords of each kind in their natural order, in the table of discord and harmony. No. 82.

We proceed therefore to the demonstration of the discords. And, according to the 2d axiom of the theory, shall begin with the demonstration of the accompaniments of the 2d.

As in the demonstration of the concords we begin with the key-note, which we considered as an immovable point, from whence our calculations were to proceed; so shall here consider the bass, or lower note of the discord, that immovable point; and the upper discordant note the interval in question, whose properties are to be found.

Demonstration of the accompaniments of the 2d.

The accompaniments of the 2d are the 4th and 6th to the bass or given note, or the discord of the 2d is the concord of the same.

The 2d is a proper discord: Therefore the accompaniments of the 2d are its 3d and 5th. But the 3d and 5th to the 2d, or discordant note, are to the given note the 4th and 6th; therefore, the accompaniments of the 2d are the 4th and 6th.

Example of the first discord, or discord of the 2d. No. 74.

Proper discord.

The discord of the 2d must be a proper discord: for the 3d and 5th to the bass with the 2d would be intolerable discord, seeing they are three notes in the natural order, and the 5th and 7th is the harmony of the 2d; therefore they must be the 6th and 8th, which is the given note in counterpoint.
given note: But the 6th will have the 4th; therefore the discord of the 2d is a proper discord.

By the 2d axiom of the theory, the properties, proportions and relation of sounds are deduced from the natural order of the same. Which axiom is extended to the discords, as they are combined of the natural notes, and differ from the concords only in form.

On this axiom, then, we are to investigate the next succeeding discord. The 2d discord is the 2d, 4th, and sharp 7th to the given note. For these are the next succeeding discordant notes.

**Demonstration of the second discord.**

The 2d and 4th cannot have the flat 7th; for they are harmony, or concord of the flat 7th; and the 5th is the given note: therefore it remains, that the second discord is the 2d, 4th, and sharp 7th to the given note. For these are the next succeeding discordant notes.

The 2d, 4th, and sharp 7th to the given note: therefore it remains, that the second discord is the 2d, 4th, and sharp 7th to the given note. For these are the next succeeding discordant notes.

**Inharmonic discord.**

This is an inharmonic discord; being an absolute discord in itself. It hath but one concordant note with the bafs; which is the 4th. This 4th is the flat 7th to the given note’s 5th: which 5th is the bafs to this discord; the given note in this place being considered only as a point, or unity, from which we are to investigate the next discordant notes, according to the 2d axiom.

The property of this inharmonic discord, or flat 7th, is, that it’s own discordant interval, or that which is formed by the accompaniment, is always a sharp 4th, or flat 5th, which distinguishes it at sight from every other discord. And every inharmonic, wherever found, hath the same property. The resolution also of every inharmonic is the same; as we shall see, when we come, in the next place, to shew the resolutions of the discords.

The next discord, according to the 2d axiom, is the sharp 3d, 5th, and flat 7th to the given note. This is also an inharmonic, or flat 7th; and having the same property with the former, namely, the flat 5th, must not be accounted a new discord. No. 76.

**Inharmonic discord.**

This is the inharmonic discord in that form, whose accompaniments are relative to the bafs, or given note. The third discord is the 3d, 5th, and sharp 7th to the bafs, or given note.

**Demonstration of the third discord.**

The sharp 3d, 5th, and sharp 7th must constitute the next discord. For the flat 3d, 5th, and flat 7th, are harmony, or concord of the flat 3d; and the 8th with the 3d and 5th, are the chord of the bafs note; and the flat 7th, with the sharp 3d and 5th, are the inharmonic flat mentioned; therefore, the sharp 3d, 5th, and sharp 7th, are the 3d discord.

Example of the third discord. No. 77.

**Proper discord.**

This is a proper discord, being the concord of the 3d to the bafs; and the sharp 7th the discordant note.

To proceed then according to our 2d axiom, the next discordant notes in order, are the 4th, 6th, and 9th: But these being the notes which constitute the first discord, varying only in place and name of the 9th, for the 2d, are in effect the same discord.

The next successive discordant notes are, according to our well known axiom, the 4th, sharp 7th, and 9th. But these likewise constitute the 2d discord in like manner, as was said in the former case; and therefore cannot be reckoned a new discord.

To proceed then by our axiom: The next ascending notes, by the smallest intervals, are the sharp 4th, 6th, and 8th. This is an inharmonic, or flat 7th; its flat 7th being formed by the sharp 4th and 8th; therefore no new discord. No. 78.

To go on, the next discordant notes will be found the sharp 4th, 6th, and 9th.

**Demonstration of the fourth discord.**

From the proof of the last inharmonic discord, the sharp 4th and 6th can form a proper discord with no other interval but the 9th; for the 7th would produce three notes in the natural order, and intolerable discord. Therefore the fourth discord is the sharp 4th, 6th, and 9th.

Example of the fourth discord. No. 79.

This is a proper discord, being a concord in itself, and only discordant to the bafs note. The discordant notes of it are the sharp 4th and 9th.

The next which presents itself, is the 5th, sharp 7th, and 9th, by the same axiom.

**Demonstration of the fifth discord.**

The 5th will admit no other discordant notes but the sharp 7th and 9th. For the 8th and 10th make the concord of the bafs note; and the sharp 7th and 10th is, with the 5th, the third discord already proved; and any other note would be double discord, and intolerable: therefore, the fifth discord is the 5th, sharp 7th, and 9th.

Example of the fifth discord. No. 80.

**Proper discord.**

This is a proper discord, being a concord in itself; and discordant only with the given note. Its discordant notes are the 7th and 9th.

We have purposely reserved the discord of the lesser 2d to the sixth and last place, 1st. Because, as the interval next above the key is always a whole tone, we cannot, according to our 2d axiom, erect this discord as relative to the given note, or key; as we have done the others. Now, the resolution of this discord will be found different from that of the greater second; for reasons which will abundantly appear, when we speak of the resolutions. This discord may properly be called the discord of the semitone.

**Demonstration of the discord of the semitone.**

The discord of the semitone, or lesser 2d, is, like that of the greater 2d, or whole tone, the 2d, 4th, and 6th. The demonstration is the same as that of the greater 2d, and therefore need not be repeated here.

Example of the sixth discord. No. 81.

This is a proper discord, like that of the greater 2d, being
MUS

being a concord in itself. Its note discordant with the bafs is the 2d.

It hath been faid, that all harmony is divided between the flat and sharp keys.

The mixture of discord and harmony enables us to extend the like observation in this place much further.

Hence the following corollary.

The composition of all musick, of any number of parts whatever, is divided between the harmony of the flat and sharp keys, and the joint mixture of discord with it.

To illustrate these truths, we shall set in one view every concord and discord, in the whole compass of musick, in their natural order. No. 82.

Hence we shall derive some useful corollaries, which will lead us to discover what is next to be considered, the second property of the discords, or their resolutions into the concords.

The manner of reading this is as follows:

This concord is the concord of the key.

This concord is the concord of the 2d to the key, or given-note.

This concord is the concord of the flat 7th.

This discord is inharmonic, and so forth: descending still from the uppermost lines of harmony, or discord, to the lowest line, or bafs.

In this view is seen the mixture of discord with harmony, each in the natural order. Wherein, indeed, nothing regular or proportioned appears to sight. The reason of this is evident from the demonstration of the harmonic proportions. For, if they be of a species different from all other proportions, as by corollary 2d of the theory, and must be demonstrated on principles peculiar to them; then the succession of the discords, constantly taking place between the intervals of harmony, must be disportioned too. This appears to sight in the next example, or view of harmony and discord in the natural order. No. 82.

However irregular this may seem, an uniformity prevails through the whole, which supports that variety in musick so deplorable: Without which variety, there could have been but one concord among sounds; a sameness prevailing through the whole; without semitone, and consequently without discord. In this case, musick never could have existed as an object of pleasure to the sense; much les of science.

This admirable structure is raised on the power and property of the semitone, which shall be the subject of the following corollaries.

Cor. I. Every semitone in the octave hath either a concord or discord proper and peculiar to itself. Yet, the natural succession of the concords and discords is not according to the ascending and descending semitones. For, it is evident, in the annexed table, that the corresponding bafs notes constantly descend by 3ds, the variety, at the same time, flowing throughout the harmony and discord in the upper parts, ascending by semitones. Yet the bafs expreffes every semitone in its passage by 3ds, uniformly to its period.

This most strongly illustrates the truth of the 4th axiom of the theory; namely, that the concords and discords, either in their natural order, or arranged by art, will not suffer us to depart from the established precept of variety amid uniformity.

The same uniformity, or rather unity, is exhibited still more plainly in the 5th discord, in the coincidence of discord and harmony in the same individual sounds.

For this discord, which is the discord of the 9th, is also the harmony of the 5th.

This is truly admirable, and furnishes us with the most interesting remark in the compass of musick, as in the following corollary.

Cor. II. The scope of musick, and motion of the parts, must at length terminate, and meet in one invariable thing Harmony.

Thus are we arrived at the full extent, or bounds of musick. It is fit we now return to make such further observations as will lead us to the knowledge of the resolutions of the discords, which is the next thing to be spoken to.

The division of discords into proper and inharmonic, we have made for the sake of clearness and method. The difference already pointed out between the discords must be remembered; which is, that the property of the inharmonic, or flat 7th, (which note does ever, with another note of the chord, frame the sharp 4th, or flat 5th) is the same, in whatever place or form it is met with; whereas the proper discords essentially differ from each other, and in every particular.

The three inharmonic therefore, in the natural order of the discords, are not so properly three, as the same discord in different light; where it is a preparation for a close on the key, and on the 4th and 5th to the key.

The bafs to the discords moves by 3ds descending in a sharp key.

The notes of the bafs, corresponding to the proportions of the flat key, have no relation to the discords in the line next above; but are the bafs to the concords in the flat key, as demonstrated in the rules of harmony.

The two discords, which are a repetition of the 1st and second, are set down in compliance with the 2d axiom, to pursue the natural order. And hence they serve to demonstrate there can be no other discord than those exemplified in the scheme. For there is no semitone in the octave which doth not appear there to have its discord or harmony connected with it.

In this scheme then is comprised every interval of musick, with the members of each chord respectively, both discord and harmony, in the natural order.

From the same order, we shall demonstrate the passage of the discords, into the concords or resolutions of the same.

In the theory, it hath been said, that the semitone is the principle or hinge, on which turns the resolution of every discord.

On this principle, then, we shall now demonstrate the same.

The discords stand in the natural order between the concords; but every note of the chord is not equally nearrespectively.

From the idea of harmony, which is fitness or proportion,
tion, the passage of the discord must be to the nearest 
cord; therefore, the resolution will be by the smallest 
interval, that is, by the semitone.

This is the general theorem for the resolution of every 
cord. We will now apply it,

The resolution of the discord of the 2d is into the 
cord of the given note.

The 4th, or semitone, will move into the 3d, but the 3d 
will have for harmony its 3d; therefore, the 6th must descend 
into the 5th, and the 2d's passage by the nearest interval 
will be into the given note. By these passages is formed 
the chord of the same; therefore, the resolution of the 
cord of the 2d is into the concord of the given note.

In a flat key, there are two passages by semitones; that 
of the flat 6th into the 5th, and of the 2d ascending, by 
contrary motion, into the 3d.

Example of the resolution of the discord of the 2d, or 
first discord. No. 83.

Proper discord.

The resolution of this discord being into the given note, 
the bass does not move.

The resolution of the second discord is into the concord 
of the given note.

The second discord is the 2d, 4th, and sharp 7th. The 
sharp 7th and 4th move by the semitones and contrary 
motion into the 8th and 3d, while the 2d falls a 5th into 
the 5th. These are the concord of the given note; there-
fore, the resolution of this discord is into the concord of 
the given note.

Example of the resolution of the second discord being 
inharmonic. No. 84.

Inharmonic discord.

The resolution of this discord being into the concord 
of the given note, the bass ascends by a semitone.

The passage of this inharmonic by contrary motion of 
two semitones, and the other note falling a 5th, is the 
resolution of every inharmonic, where ever introduced. 
This therefore needs no repetition. But if the succeeding 
cord has a flat 3d, the passage is by two ascending fe-
mitone's; the 2d rising into the 3d, the 7th into the 8th, 
and the 4th by a whole tone into the 5th. This move-
ment can only happen in the resolution into the key.

The other, of much more extensive use, is the true re-
solution of the inharmonic discord; and more intereting, 
as, by its contrary motion of the semitones, it better binds 
the harmony.

It is necessary here to explain further the nature of the 
inharmonic discord.

The inharmonic discord, then, is always the chord in a 
sharp 3d, with a flat 7th; which two notes frame the in-
terval which characterizes this chord, namely, the sharp 
4th, or flat 5th: when the flat 7th is the upper note of 
the two, the interval is the flat 5th; when the sharp 3d 
is the upper note, the same interval is called the sharp 
4th. These notes being relative to the fundamental note 
either of them determine the 'chord.'

As the inharmonic is found in different places of the 
 octave, so consequently the note of the chord must vary 
accordingly; the second inharmonic therefore only, in the 
natural order, hath reference to the given note in the 
table, as that happens to be the note of the chord. For 
the given note there is to be accounted 'only a point or 
unity, from whence we proceeded to trace the discords in 
their natural order, as they lie between the concords.

The chord note, therefore, of the first inharmonic is the 
5th to the given note; and of the last inharmonic, it is 
the 2d to the same. Now, as the whole chord falls a 
5th in the resolution, so the first is a preparation for 
a close on the key, the second for a close on the 4th, and 
the last for a close on the 5th; now, as any note of the 
chord may stand in the bass, so the third is often prefer-
bred before the chord note, for the sake of the movement 
of the bass by a semitone, as well as because falling a 5th in 
the bass is more properly the part of harmony.

The flat 7th is likewise chosen for the bass note; for 
the same reason, the movement of the bass by a semitone 
defending, which is no incon siderable use of discords. 
For in figurate descent, as we have said, all the parts 
move more freely.

The next discord is likewise inharmonic. It is the sharp 
3d, 5th, and flat 7th to the given note; which note is like-
wise that of the chord. No. 85.

Note, the resolution of every inharmonic being into 
its 5th below the chord, the resolution of this will be 
into the 4th of the given note; as rising a 4th, and fall-
ing a 5th, answers the same thing in estimating the inter-
vals of harmony.

Inharmonic discord.

Example of the second inharmonic discord and its re-
solution: here the bass note is the note of the chord; 
therefore, in the resolution it falls a 5th, which is the 4th 
to the given note.

The flat 7th descends by a semitone into the 3d, the 
3d rises by a semitone into the 8th, and the 5th falls a 
5th into the 5th of the concord. The resolution therefore 
is into the 4th of the key.

This is that form of the inharmonic discord on which 
the composition of the passage taken out of Corelli, (No. 
73.) is grounded. Observe, that in the cited passage, 
and also in every like passage, the two notes of the bass 
move to only one note of the second part, which becomes 
the flat 7th by this movement of the bass.

Thus the flat 7th is given, in the upper parts by 
turns, to every note in the bass, as hath been before re-
marked.

Resolution of the third discord.

The third discord is the 3d, 5th, and sharp 7th, to 
the given note; it is resolved into the 6th to the same. 
For the 7th ascends into the 8th or 6th's 3d, the 5th rises 
a whole tone into the 6th, and the 3d not moving becomes 
the 5th. The resolution of this discord therefore is into 
the chord of the 6th.

Example of the resolution of the third discord. 
No. 86.

Proper discord.

This is a proper discord; in the resolution of which 
the bass falls a 3d, while the whole discord falls a 5th.

The
The next discord is the sharp 4th, 6th, and 8th. It is inharmonic. Its resolution is into the chord of the given note's 5th. No. 87.

**Resolution of the third inharmonic discord.**

Of this discord the bass note is the flat 7th; it descends by a semitone, while the whole-chord falls a 5th.

**Inharmonic discord.**

Its resolution is the same as that of every inharmonic, in what form ever, by the contrary motion of the two semitones, while the third note falls a 5th.

**Resolution of the fourth discord.**

The fourth discord is the sharp 4th, 6th, and 9th. Its resolution is likewise into the chord of the note's 5th.

For the sharp 4th ascends into the succeeding concord's 8th, the 6th passes into the 3d, and the 9th not moving becomes the 5th. There are the chord of the note's 5th.

Example of the resolution of the fourth discord. No. 88.

**Proper discord.**

This discord is a mixture of the proper and inharmonic. It is a proper discord, for that the notes of the treble are concord; and inharmonic, in respect of the bass, with which it makes the discord of the sharp 4th.

It differs from the foregoing, where the flat 7th is expressed in both treble and bass; whereas, in this, it is only in the bass.

The bass here also descends by a semitone, while the chord falls a 5th.

**Resolution of the fifth discord.**

The fifth discord is the 5th, sharp 7th, and 9th. It is resolved into the concord of the bass note.

For the 5th is that note's 5th; the sharp 7th ascends by a semitone into the 8th; and the 9th (or 2d) passes into the 3d. Thus it is resolved into the chord of the given, or bass note.

Example of the resolution of the fifth discord. No. 89.

**Proper discord.**

In this resolution the whole chord falls a 5th, while the bass stands still, or descends into the octave.

This is plainly the last discord in the order of sounds. Its resolution is into the given note or key, by the passage of the great cadence, or descent by a 5th. It is a concord in itself; and is in harmony the concord of the 5th.

In this discord concord and harmony are united. When it stands in discord with the bass, the bass doth not move in the resolution; when it stands perfect harmony with the bass, then the bass descends a 5th.

Therefore, we conclude, Harmony and discord are like two finite lines, whose beginnings are at a certain distance; and in the natural progression converge constantly, until they meet in a point.

The discord, which we here referred to the sixth place, is that of the lesser 2d, or semitone.

Its places in a flat key are the 3d and 6th; and in a sharp key the 4th and 8th, or where ever a new semitone is introduced.

It is a proper discord, being a concord in itself, whole-chord hath always a sharp 3d.

Its properties are everywhere alike; but its resolution differs from that of the greater 2d, for the reason assigned in the resolution of every discord; that is, the passage by the semitone.

**Resolution of the lesser 2d, or semitone.**

The discord of the lesser 2d is the 2d, 4th, and 6th to the bass; or, the concord of itself.

Its resolution is into the concord of its own 3d or 5th. It rises into the concord of its 3d by the single passage of the semitone descending. And into the concord of its 5th by the 4th descending along with the semitone.

Example of the resolution of the discord of the semitone. No. 90.

In the first resolution, the chord rises a 3d, and the bass falls a 5th. In the second, the chord rises a 5th, and the bass falls a 3d, the reverse of the former.

From the resolutions of the discords, we derive the following corollaries.

**Cor. I.** There is no interval of harmony that is performed by the bass in the resolution of one discord or another.

Hence we may conceive that harmony regulates even the discords, and prefigures in every part of music.

**Cor. II.** The inharmonic discord, or flat 7th, is a preparation to a close on a key, the 4th and 5th, flat 3d and flat 6th; for into the harmony of these it is resolved; they being the intervals on which closes may be made according to the established rules of melody. And universally, wherefore a close may be made by introducing a new semitone, the preparation may be made by the flat 7th, or inharmonic discord.

This discord, being of such extensive use, will deserve some further remarks, which may render the setting of the same more easy, and assist the performer in the taking and resolution of it.

In the inharmonic discord, then, are three notes chiefly concerned, which are the note of the concord; its 3d, (which is always sharp;) and the flat 7th: either of these may be set in the bass. Hence there will arise three varieties.

If the note of the chord be the bass note, the figure is the flat 7th; the chord is that of the same note; and the bass falls a 5th.

Secondly, When the 3d is the bass note, the figures are flat 5th and 6th; the chord is that of the 6th to the same 3d; and the bass ascends by a semitone.

Thirdly, If the flat 7th stand in the bass, the figures are the sharp 4th, 6th, and 9th; the chord is that of the 3d to the bass note; and the bass descends by a semitone.

**Example.** No. 91.

The 5th of the chord may likewise stand in the bass; but as the movement of the same is by a whole tone descending, it is very seldom used.

The figures are sharp 6th.

The figures are flat 3d.
Cor. III. Hence the bass ascending or descending by a semitone, furnishes an opportunity of introducing notes in the upper parts, which will constitute the inharmonic discord.

And again, the sharp 3d of any chord in the treble, or any note having the addition of a sharp, and thereby becoming the greater 7th, may be the 3d of an inharmonic; the bass taking the flat 7th. For the sharp 3d of the chord, (which is the sharp 4th to the flat 7th in the bass, or elsewhere,) and the flat 7th, in whatever part they are fat, in bass or treble, or both in the treble, constantly move each his own way; the first ascending, and the latter descending by a semitone.

These are the simple disords as they are found to lie in the natural order of sounds between the concords; whose accompaniments are, for the most part, harmony among themselves. It is evident, from the method in which we traced them, that there is no other discord among sounds. Notwithstanding, from the combination of two simple disords, a new form of discord may be framed, which taketh part of the inharmonic and discord of the semitone; which, therefore, we call the compound discord.

This discord is the sharp 3d, flat 7th, and flat 6th, or semitone to any note whose chord hath a sharp 3d.

It is resolved, by the passage of three semitones, two descending, and one ascending, into any concord with a sharp 3d; and therefore may be introduced as a preparation to any concord, in either flat or sharp key, where the greater 3d is.

Example of the compound discord, and its resolution. No. 92.

The resolution of this discord, as it is compounded of the disords of the flat 7th, and semitone, will partake of the resolution of the same. Thus the upper note, or semitone, descends into the 5th of the concord; and the flat 7th and 3d meet by contrary passage of a semitone each into the 3d and 8th part of the resolution of every inharmonic, while the bass descends a 5th. Thus the passage into every note of the concord is by a semitone; so great a favourite of nature is the semitone.

By changing the form of this discord, it will be resolved into a chord with a flat 3d, by one semitone descending, and two ascending; the two extreme notes of which are the same as in the example above; but the middle note is the 5th ascending into the 3d, instead of the flat 7th descending. The upper notes therefore form the flat 5th, or inharmonic interval. No. 93.

The properties of those discordant notes of the semitones are, in musick of two parts, a preparation to, or pafs by contrary motion of the semitones into the concords of the sharp 3d, flat 6th, and 5th. When the flat 7th is the uppermost note, and the lower the sharp 3d, they pass into a sharp 3d.

When the upper note is the sharp 3d, and the flat 7th is below, they pass into the flat 6th; so do likewise the flat 7th above, and the chord note below.

Lastly, the two extreme notes of the compound discord pass into the concord of the 5th.

I C K.

Example of the passage of disords in musick of two parts. No. 94.

In like manner there is a passage into the octave from a discordant interval; the upper note of which is part of a concord, and the lower the semitone of the compound discord. No. 95. Or the contrary.

There is no passage by two semitones into the flat 3d and sharp 6th from any discordant interval, except the semitone. For, in the passage of quick notes encountering each other by contrary motion, this, or any other discordant interval, may fall into the concords. But such, being tolerated only for their quickness, need not be reduced, as indeed they cannot, to any rules of art.

Lastly, the bass will admit two notes together, each concording with it, namely, the 5th and 6th, and making a discord between themselves.

This discord, which differs from the proper and inharmonic, is rightly called the mixed discord; each of the two notes being in harmony with the bass, and discordant to each other.

The framing of this discord depends upon the rules of harmony, and may be let to any note of the bass which hath for harmony its own concord, and is likewise the member of another.

Therefore, in the sharp key, the key and 5th, and in the flat key, the key 3d, 5th, and flat 7th, admit a 5th and 6th.

When we shall have proved, under the article of transposition, the 5th in a flat key, and 6th in a sharp key, to have their own concord; they will be found, no doubt, to have the privilege of admitting a 5th and 6th.

For thus it is understood. The key hath a 5th in its own right, and a 6th as member of the 4th.

The 5th hath a 5th in its own right, and a 6th as member of the key.

The flat 3d hath a 5th in his own right, and a 6th as member of the key.

The flat 7th hath a 5th in his own right, and a 6th as member of the 3d.

Thus the 5th and 6th will stand together to the bass.

The properties of sounds in the natural order may be transferred by art, and improved into all the variety possible; as this is no other than an imitation of nature.

Hence we infer, that every note, which assumes the nature of the key, by the addition of the greater 7th, will admit a 5th and 6th.

This 5th is easily distinguished from the 5th of the inharmonic, which is always an imperfect one, and ought constantly to have a flat prefixed.

Now the chord of the inharmonic with a flat 5th is that of the 6th to the bass note, as hath been said. But the chord of the mixt discord may be better understood to be the chord of the bass note, with a 6th added.

Sect. 2. Of Figuring the Bass.

Having delivered all that hath fallen under our observation concerning the nature, proportion, and use of discord; we shall now make an application of the same, in order to explain the figuring of the bass; the next article proposed to be spoken to.

First, Of figuring the concords.
That the notes whose harmony is their own chords, need no figures, is evident from the definition of harmony; which consists of one certain, invariable proportion of sounds.

These are the key, flat 3d, 4th of a sharp key, 5th, flat 6th, flat 7th.

They which, as members of other chords, require the figures of harmony set over them, are these following; and are reduced to this general rule:

The 3d of every concord hath a \( \frac{5}{4} \); and the 5th of every concord hath a \( \frac{6}{5} \).

Therefore, \( \begin{align*} \text{Key} & \quad \text{5th of a flat key} & \quad \text{5th of a sharp key} \\ \\
\text{Flat 3d and sharp} & \quad \text{have a} & \quad \text{have a} \\ & \frac{5}{4} & \frac{5}{2} \\ \text{Flat 6th and sharp} & \frac{6}{5} & \frac{6}{5} \\
\end{align*} \)

Sharp 7th

Lastly, The 4th in a flat key, when it has its own chord, must have a 5th set over it, to distinguish the chord from that of the flat 7th. And the 6th in the sharp key, when it hath its own chord, must have a 5th likewise set over it, to distinguish the chord from that of the 7th.

The proof of the 6th in a sharp key, having for harmony its own concord, depends on the relative proportion of the flat and sharp keys; as will be shown in the chapter on transposition. So much for figuring the bas in concords.

Let us now inquire into the shortest and clearest method of figuring the discords. This will be no difficult matter, when we consider well the whole discords, as they are all figured in every example.

There the figures set over the bas express the intervals which the notes in the upper parts form with them. These taken together make the whole discord. And as these, with the harmonic chords in succession, express the whole composition, they are therefore called the thorough-bas.

To render the performance of the thorough-bas easy and expeditious being the chief intention of figuring the bas; this will be best answered by distinguishing the discords, which have some figures in common with each other, by such figures only as will strongly mark each discord. For though all the figures set down in the examples be necessary to demonstrate the properties of the discords, and truth of the composition; the bas is quite otherwise in respect to the sight; many marks causing perplexity and confusion, when one single mark in this, as in all other cases, best discovers the difference. The proper discords then being concords in themselves, the figure, or figures, discordant with the bas note, will distinguish each of these.

The inharmonic discords being the same in different form, will be distinguished by the discordant figures peculiar to each form.

Of the properties of this discord, and manner of taking the bas, we have spoken sufficiently. We shall therefore only set down the discordant figures of each form, in the following example.

Example of the proper discords figured for taking the bas at sight. No. 96.
Music is the air of the uppermost or first part in music, commonly called the tune.

In a plain song, the air is formed without considering the relation which the other parts, which may be set in composition with it, may bear. For, being first framed, and for the sole end of pleasing the ear and fancy; it must, it is evident, be independent of them.

For as to framing the bass first, and setting the treble to it, there appears no necessity either in reason or the rules of composition, they equally serving the purpose of beginning with any part, no part being privileged with any particular member of discord or harmony; as is abundantly manifest from the various positions which the discordant notes have been shown to stand in; as well as from the 4th axiom of the theory, which establishes variety for conducting and rendering even harmony acceptable; a sameness in the successive concords being the only thing exceptionable in that part of composition.

All the parts of music then being equally concerned in the composition; to prefer any one part, as a bass, or unerring guide, on which to erect the music, or bring in the parts, is doing injury to that liberty which nature and the rules of art put us in possession of.

But the air of the first part is essential to the tune, or rather the tune itself, compels us to decide in favour of framing the treble first. In which it will be found impossible to succeed, when it is confined to what the bass, if it be first framed, must of necessity prescribe.

This preference in framing the treble first, chiefly respects a plain song, or air. For, in more elaborate pieces, where the design of the author is imitation of passages in the several parts by turns, according to his choice or fancy making use of the fame liberty, he will take any for the leading part, and accordingly write the passage in that part, and finish the composition in the rest.

The air or first part in instrumental music is called the first treble; the air for a single voice is called the voice part, or song; and in music for many voices, the upper part is called the counter-tenor.

In this music, the air of the tenor, and of every part performed by the voice, is studied with more exactness than the inward parts of instrumental music.

The reason for this difference is, that in instrumental music, the first violin generally predominates, or leads the music by its air; as this is the composer's design, the other parts must of necessity be accommodated to it.

Whereas in music for voices, every voice repeating the same words, that is, expressing the same sense, at the same time, or immediately succeeding; nothing can defeat the end of the music so much, which is the setting of words, or rather sentiments, to notes as expressive of the sense as inarticulate sounds can possibly do, as for one part to excel the others so much in this necessary point, as by comparison to depreciate, weaken, or alter the sense in the others.

The air, therefore, of every part in vocal music must be consulted; not only for the sake of harmony, (for a good air in each part improves even the harmony;) but also for the sentiment sake, without which the music must be absurd and disjointed.

Notwithstanding the liberty which everyone may justly challenge of framing an air agreeable to his own fancy; yet it cannot be said, that this liberty is uncontrollable, or beyond the power of art to prescribe bounds to: For then indeed every strain composed by even a bad and injudicious ear might stand in competition with the most finished pieces. But as this will not be allowed on any hand, even an undistinguishing ear conceiving a degree of pleasure in hearing good music; so there is no doubt but that there must be some precept or manner found out by experience, to ascertain and conduct the air or strain, and which will render it to a good and judicious ear plainly preferable.

The rules therefore which we shall lay down for melody, are such only as are founded in truth and reason; the result of experience, joined to skill; and which are admitted in every liberal art: These are unity, imitation, and order. If it shall be said, that persons unskilled in music, but otherwise very capable from a natural good ear, will sing an air which an artist cannot find fault with, we confefs it may be in some fort true.

But the strains of such composers are always very short; and as they seldom or never depart from the key, so they afford not that variety so definable in music: Nay, what is this but saying that the rules of art are conclusions taken from nature, as in truth they are; so then they must be asserted or right? This must be so, when the appeal is made from art to nature.

As to those essays called voluntaries, there was never a good one performed but by a good master. The music was always good in proportion to the master's skill in the art; in proportion to the variety he introduced according to the rules of art. Therefore even voluntaries are the effects of knowledge and deliberation.

But to return. The first rule of melody is unity.

The unity of tone is said to be in respect of the key, and of the subject.

The air or first part in vocal music is called the first treble; the air for a single voice is called the voice part, or song; and in music for many voices, the upper part is called the counter-tenor.

In this music, the air of the tenor, and of every part performed by the voice, is studied with more exactness than the inward parts of instrumental music.

The reason for this difference is, that in instrumental music, the first violin generally predominates, or leads the music by its air; as this is the composer's design, the other parts must of necessity be accommodated to it.

Whereas in music for voices, every voice repeating the same words, that is, expressing the same sense, at the same time, or immediately succeeding; nothing can defeat the end of the music so much, which is the setting of words, or rather sentiments, to notes as expressive of the sense as inarticulate sounds can possibly do, as for one part to excel the others so much in this necessary point, as by comparison to depreciate, weaken, or alter the sense in the others.

The air, therefore, of every part in vocal music must be consulted; not only for the sake of harmony, (for a good air in each part improves even the harmony;) but also for the sentiment sake, without which the music must be absurd and disjointed.
bars, be they more or less, as it shall happen; every
tune being framed with some prevailing idea or fancy
peculiar to itself, and therefore distinguishing it from
every other.

The subjects of grand pieces of instrumental musick
are contrived with care and study; and invented with design
to enlarge or descant upon at will; not being confined to
any length, or certain number of bars. Such pieces, be-
ing the efforts of great and masterly genius, afford all the
pleasure that design and invention, carried on by every ma-
terly stroke of art, can give.

The second rule of melody is imitation. As in the
executing other arts, a similitude and proportion of the
members ought to be preferred; so imitation, or a re-
petition of the most striking passages, answers to this in
musick.

Imitation may be performed many ways. First, when
the repetition of the passage is made, beginning on the
note above the leading note of the passage; or on the
third, fifth, eighth, or any other interval.

A passage also may be imitated in any of the desce-
ding notes. A repetition on the octave below is frequent in
every good author.

In the repetition of passages, there are two varieties.
The first is, when the passage is repeated in notes be-
longing to the harmony of the key. It will seldom hap-
pen in this case, that the passage will in the repetition be
precisely the same, in respect of the intervals of the notes,
though the movement be an exact imitation.

The reason of this will be evident, if we consider that
the intervals in both flat and sharp keys respectively af-
cend by different degrees; the semitone changing the in-
tervals almost continually.

See example, No. 12, in the theory.

In these examples no more than two flat or sharp thirds
succeed each other. And where they do succeed, the
semitone is in a different place in the two like intervals
of flat thirds; it being the third of one interval, and 2d
of the next ascending 3d, or the contrary.

In the sharp key, two sharp 3ds ascend from the 4th
and 5th, and in the flat key from the 6th and 7th. The
iniquity of the 5ths, and of the few instances of their suc-
cession, is owing to the places of the semitones.

To the inequality of the 3ds is owing the inequality of
the 4ths, 5ths, and every other unequal interval in the
course of the notes; the greater necessity of partaking
of the inequality of the latter, which is included in it.

All this is evident.

Therefore, the repetition of a passage will not be pre-
cisely as the passage, except in the places above-mention-
ed; that is to say, a repetition of sharp thirds from the
4th and 5th of the sharp key; and of the same, on the
6th and 7th of the flat key. And in the sharp key,
there may be an imitation in the compass of six notes af-
cending; namely, from the key, and its 5th. We have
been particular in remarking the want of exactness in
imitation on notes belonging to the key. Not that we
mean to mark it as a defect; for it is beyond doubt, that
every passage in the harmony of the key must be pleasing,
whether it be a perfect imitation or not.

Besides, this dissimilitude, arising from the place of

Vol. III. No. 83. 2

the semitone being changed, is so far from being charge-
able with a defect, that, as hath been often said, it pro-
duces that sweet variety which is founded in the principles,
and which every artist pursuing will succeed in; as in this
he doth no other than copy after nature.

These remarks on the imitation of a passage in the notes
of the harmony of the key, will lead us to the second
manner of imitation; which is such, as that every note
in the repetition stands exactly in the same interval re-
spectively as the notes of the first passage.

This then is a perfect imitation. Which, as it cannot
take place in the harmony of the key, except in the few
cases abovementioned, it must be effected by art; that
is, by altering the places of the semitones in the key, so
as to correspond with those in the original passage, by
marking a sharp for the semitone ascending, if the repe-
tition be in notes above the passage; and a flat for the
semitone removed lower, if the repetition be in the de-
cending notes.

In this manner there can be a perfect imitation of any
passage of any length whatsoever, and of any compass:
in every instance of which, the key is changed, by in-
roducing notes not belonging to the harmony of the

As every interval of the first passage must be preferred
in the repetition: it will sometimes happen, that many flats,
or sharps, must be added to the notes in the repetition. The
rule of this practice will be well understood, when we
shall have learned the art of transposition; the repeti-
tion of any passage in this manner being no other than a
transposition of the fame into another key. In regard to
this perfect imitation, we have one remark: which is,
that if a repetition be made on the note next above, and
repeated again the note still higher, it will have a good
effect; for this will create such a novelty in the strain as
is surprising; besides that it affords the author an op-
portunity both of making new descant or enlarging on the
subject in this new key, as well as of shewing the greatest
skill by returning from that digression into the original
key with art and propriety.

This will be no difficult matter to one who understands
well the art of transposition. Now, the repetition of the
subject transposed into a key different from the original
belongs to this second rule of melody; as the repeating
the subject in its own key respects the rule of unity.

The repetition of the subject after these two manners,
and throughout the several parts, as treble, bass, tenor,
and so on successively and constantly, each part taking
it up immediately, or as soon as the repetition is finis-
hed in another, whereby the several parts seem to move in pur-
fuit of each other, is called a fugue.

Musick composed on this design is justly esteemed a-
bove all other, not only on account of its excellent con-
trivance, but for the sake of the pleasure also which it
affords.

In a just fugue is represented all the variety possible;
at the same time that an uniform progression of the parts
is preferred throughout the whole, without the least dif-
covety of the figures of art.

The reason for this may be, that the repetition of so
interesting a passage as the subject is, is so natural to the
imagination
The subject being first written in that part which the composer intends to be the leading part, the same must be set down again in the next part wherein the repetition is appointed to be made, either in unison, or on the 4th or 5th to the key or subject; the 2d, or any other interval; in which matter the composer is at liberty.

Yet the repetition on the 4th seems more natural to the flat key; as, on the 5th, it is to the sharp key.

If the music be in two parts only, the subject being written in each part in succession; the next step will be to frame descant to that part where the repetition is, and which therefore will be written in the leading part. Henceforward the parts move on at liberty, that is, nowhere repeating the subject, but expressing all the variety in descant each to the other, which the fancy, invention, and skill of the author suggest, until the subject is again repeated, either in the key, or some interval of the harmony of the key, or perhaps in a new key.

The imitation of this must immediately follow in the other part, in unison, or otherwise.

If the music be of three or four parts, let the subject be first written in every part, in succession; and in the order you intend. Then fill up with descant the second bar, or more, of the leading part; that is, as far as the subject reaches in the other part; and proceed likewise on the next repeating part with other new descant; and so on through every part, until all the spaces are equally full.

After which the parts go at liberty, as before in a two-part fugue, until another repetition of the subject.

But where, or how frequent, the repetition of the subject may be made; or on what interval, whether above or below; or by what succession of the parts, (for they need not preserve the order they began in;) is neither the business, nor in the compass of the rules of art to prescribe.

In these matters, the composer is as much at liberty as his genius and invention can furnish matter and variety. So that in some places the subject may be repeatedly, continually, in the different parts, on intervals and in a key different from the original key or order.

Sometimes, the movement of the subject being the same, the notes are changed from ascending to descending, or the contrary. Sometimes even the movement to the contrary. At other times, a new subject is introduced; and then it is called a double fugue. And lastly, for the sake of variety, the subject is repeated backwards, or inverted; so that the parts seem to pass each other by contrary motion, instead of paring.

In a word, there is no passage which expresses variety, which may not be introduced in a just fugue; while the uniformity is preferred in the imitation of the same, and retaining the original subject, and key, towards the conclusion or close of the piece.

We shall only add, that if the descant which fills up the bars be constantly written in all the parts successively and in order throughout the whole piece, the fugue is, from the exactness of this repetition, called a canon. In framing of which, observe, that if the canon consist of three or more parts; when the third part takes up the subject, the descant in the leading part must be part of the harmony of the other two.

What remains to be spoken to on this second rule of melody, or imitation, is the method of returning into the original key, after a passage in a remote one. This will lead us to consider the half-tones not belonging to the harmony of the key, or chromatic notes.

For if a passage, or repetition of a passage, be in a new key, which is the imitation we are now speaking of, the returning the key immediately will be by chromatic notes; descending if the repetition were above; and if the repetition was in notes below the passage, we may ascend into the key by chromatics likewise, or half-tones ascending.

This is evident. For every key, flat or sharp, having its semitones in their proper places, a passage is not in the key, when the semitones are out of their places.

Therefore the returning into the key, from a passage not in the harmony of the same, must be by removing the new half-tones.

This depends on the knowledge of transposition.

The new semitones introduced in a passage, or imitation of one, we have called chromatic notes; because every semitone not belonging to the harmony of the key are to be found only in the chromatic scale.

Yet this is but improperly. For two, three, or more semitones succeeding each other are properly called chromatic notes; which, to music wherein the frequent use of these is made, gives the name of chromatic music.

The use of chromatic notes is to raise the attention by the uncommon and unexpected variety they produce.

For every new half-tone ascending, being understood by the ear as the greater yth, implies a new key. Three or more semitones ascending after each other, do therefore raise the expectation of so many new keys: whereby the curiosity is greatly excited; and the expectation of the ear being gratified, in the imitation of a close, by every new semitone, the music becomes, as in all other cases where novelty takes place, truly the object of admiration. In a series of semitones ascending, the last is in the place of the key. When chromatic notes descend, the last but one is the key, for the same reason; namely, the semitone below founding as the greater 7th, every key being a semitone to its greater 7th or half-tone below relatively.

Chromatic notes ascending, by alarming the ear and imagination, elevate the soul, thereby imitating the sublime.

Chromatic notes descending, express the pathetic, which is free from any alarm or terror. The performance of these notes should always be with softness, which naturally removes the apprehension of terror. Ascending and descending semitones partake of the nature of the sharp and flat keys; as hath been said concerning the power of musical sounds to touch the passions.

Chromatic notes may be introduced in many places.

If, in a passage, the semitones of the key occur among others, they are to be accounted as chromatic. Therefore
fore flat and sharp keys are equally capable of improvement by them.

Notwithstanding chromatic notes create so much variety and elegance, it must not be underwood that they are to be introduced injudiciously, or without any address; for then they would not only be useless, but injure the musique. Chromatic notes being so affecting and expressive, as we have shewn, their place in vocal musique will easily be determined by the sentiment.

As, on the other hand, to introduce lively or pathetic sounds, where the sense is diffonant from either, is introducing contradiction and confusion.

Neither is it natural in instrumental musique to break in upon a lively strain by slowly-moving chromatic notes. Though at the end of a brisk movement, the transition is good. For music which moves in semitones, though quick notes, must appear slow to the ear, which expects the greater intervals of the diatonic scale, or whole tones.

Yet instrumental musique does properly admit the mixture of chromatic notes, when they are accommodated to the genius of the strain or subject. Neither will it be difficult to judge of this propriety. For musical sounds having a natural tendency to express our ideas, the place of chromatics will readily be found by this mark; it being in the power of the composer to imagine ideas without the help or intervention of words, and so substitute these ideas in the place of words, and make them the subject of his strain. Thus he may fill his mind with the imaginary passion of love, sorrow, anger, detestation, pity, and the like; the expressions of which will be most easily distinguished by musical sounds, and varied as the subject requires. Thus, if two or more of the passages, especially contrary ones, be represented by turns, it will form in the imagination a kind of conversation between persons, which never fails to strike the attention stronger, and make a deep impression on the hearer.

Besides this, the imagination of the composer will be assisted in the invention of variety; and the different passages of the piece will be furnished with notes proper and natural to each; for the same reason that choice and expressive words flow in upon a good writer who is master of his subject. We shall only add, that if sometimes the different passages are allotted to the bass and treble by turns, it will greatly diversify the subject, mark the sentiment stronger, and thereby cause new pleasure. So much for chromatic notes. Notwithstanding, what hath been said in this place doth not respect chromatics only; but in general the whole process of an elaborate piece, in every form and transition of the melody; wherein only there is opportunity for application of what we have here suggested.

The reason why we have given place to chromatics under this second rule of melody, or imitation, we have already assigned; namely, that the use of half-tones is necessary where there is a repetition of a passage in another key. For, whatever proportion of sounds is found in the natural order, the same may be transferred by art, and improved upon every occasion, as thereby imitating nature. And this, by the way, is likewise the reason for the resolution of dissonces by semitones; being taken from the original pattern, or refo-

The second rule of melody is order.

Order in musique is the conducting the melody or air, according to a certain rule, through several intermediate closes, from the beginning to the final close or end of the tune.

A close is the termination of a passage in a concord; which, like a period in senes, is framed with design, and from the preparation from the notes immediately preceding, which are the whole tone above, the half tone below, and the 5th (generally the bass note) is expected by the ear. This is the description of a close, which is ever the final close, especially of quick movements. This preparation is the concord of the 5th to the note on which the close is made; the basses making the great cadence, as we have taught in the rules of composition.

This preparation is in full harmony. But it must be remembered, that there is a preparation also from discord; chiefly the discord of the flat 7th, of which we have said enough in the chapter of discord or figurate defcent. In slow movements there is a preparation to a full close; which shall be described presently.

Every intermediate close has its preparation in imitation of the final close, more or less. For there is no necessity for the parts taking invariably the same member of the chord; so that the treble oft times makes the cadence from the 5th, particularly in quick passages; in which likewise, in the middle of a strain, many imperfect closes may occur, the parts taking the notes indiscriminately as they happen, without any preparation designed. It is enough to mention these.

But in order to conduct the air in each strain, if there be more strains than one, with propriety and method, there must be a close in several places in the harmony of the key. These are called proper closes.

These are also closes made by the introduction of a new semitone, by the addition of a sharp, making the greater 7th not belonging to the harmony of the key. These are rightly called improper closes.

The places and order of both these we shall now assign.

The first proper close falls naturally on the key. This is not meant of the final close; for a close may be made on the key, within a few bars of the beginning; yet this close is seldom made, as not affording variety. Again, the first strain sometimes closes on the key: yet the close of that strain is more properly on the 5th; and the close next after that on the 5th falls naturally on the key.

When a close is made on the 5th, the 4th of the key being removed a semitone higher, becomes the greater 7th by the addition of a sharp. For, in imitation of the final close on the key, there must be a semitone ascending.

Notwithstanding, a close made on the 5th, with a sharp 3d always, from the chord of the 4th in a flat key, without altering the 4th, or bringing in the greater 7th, is accounted an elegance: in which passage the basses take the flat 6th or 3d to the 4th, and thence descends by the semitone into the 5th.

This is never practised but in very slow movements.
Transposition is the removing a tune from one key into another. The use of transposition is to bring a tune within the compass of some instrument, or for the more easy performance on an instrument; some keys being more difficult to perform in than others; especially in wind instruments, as the German flute, &c. For as to instruments that are flopped, as the violin and basset-viol; and instruments with keys, as the organ and harpsichord; all keys are easy to a good performer, who is said to be master of the scale of the instrument.

Secondly, Transposition is absolutely necessary in music for voices and instruments, when it happens that the key in which the music is written is too high or too low for one or more of the voices. In this case, the music must be transposed for the instruments into the key which is nearest to and will best suit the pitch and compass of the voice. For as to the vocal performer, it matters not in what key the music is written for his part, provided he can sing in the close, (or indeed, if he can transpose, as shall be taught in the last chapter, Of singing by note, whether he can sing in the close before him, or not,) if the instrument be accommodated to his voice.

There are two ways of transposing. The first is, when the tune is written in another key, at any distance above or below the original, with the proper flats or sharps prefixed. When this is done, the performance on the instrument is easy; the half-tones of the key, and every other, keeping their due places expressed in the writing. This may be called transposition by writing.

The other method of transposing is by the close; that is to say, when the close is removed, or supposed to be removed, from the place wherein it stands prefixed to the tune.

This removal of the close at once transposes the whole, without alteration of the writing; the use of the close being, as hath been said, to ascertain the names of the notes. We shall shew both these methods of transposition; and first of transposition by writing.
Transposition, in general, is writing or playing a tune in a different key from that wherein it is written, preserving the places of all the semitones.

If the notes in the scale of music expressed no other than whole tones, transposition would be evident to sight. For a series of tones at equal intervals would, when removed to any distance or interval, preserve their places of themselves (to speak), or without the help of art. And the performance of the same on an instrument would be equally easy in all keys; no alteration happening thereby, but changing the names of the notes. And even this would be unnecessary.

The semitones therefore are the causes of any obliquity in the scale of transposition; and therefore the keeping them in their due places is the art we are now speaking of. As it is said in the theory, they are the foundation of writing the same tune in divers keys, which is transposition.

We must have recourse therefore to what hath been said in the theory concerning the essential difference of tune, or the different places of the semitone.

When the first semitone above the key is on the 4th, or 6 semitones to the key; the 3d, which is 5 semitones, is the greater, or sharp 3d; and the tune is from hence said to be in a sharp key.

Again, when the first semitone above the key is on the 3d, or 4 semitones to the key, that being the lesser or flat 3d, the tune is in a flat key. Again, the next semitone in the sharp key is the 8th; and in the flat key on the 6th.

In every sharp key, the semitone must stand in the same places, that is, the 4th and 8th; and in the flat key, in the 3d and 6th.

The name of the sharp key in the scale, whose semitones are in their places without the addition of flat or sharp, is C. Hence C is called the naturally sharp key. Its semitones are F and C.

This is the pattern for transposing in all sharp keys: chiefly by remembering the letters or names of the semitones.

The key in the scale, whose semitones are in their places without the addition of flat or sharp, is A. Hence this is called the naturally flat key. Its semitones are C and F. This is the pattern for transposing in all flat keys; remembering the names of the semitones.

It may be required to transpose from any key with a sharp 3d, into any other of the same; or likewise from any flat key respectively. Notwithstanding, we shall proceed, according to our method, to show what are the keys in the natural succession into which a tune will be transposed, beginning at C the naturally sharp key. As the properties of every key will be discovered by this method; for it will answer every thing that can be required in transposition; and by what a tune may immediately be transposed from any key into any other interval or key that may be required.

For instance, let it be required to transpose from the key of C into that which is next in the natural order of transposition. F is the first semitone in the key of C; which, by the addition of a sharp, becomes F sharp, and consequently the greater 7th to the semitone above it,...
flats, as prefixed in the example, do more methodically follow the removing the greater 7th by a flat.

The demonstration is equally certain and clear in both manners. Let it be remembered, that in transposing, by altering the greater 7th, the key is removed to the 4th above.

Let us proceed to transposition in a flat key; the general rule of which is the same as for the sharp, to remove the semitones, and thereby preserve the proportion of the key.

The different places of the semitone will cause some variation in the effect, or interval of transposition.

Let it be required, according to our method, to transpose out of the open or naturally flat key A, into that which is next by natural succession.

The first semitone in the key of A is the 3d, or C; which, by the addition of a sharp, becomes the greater 7th: wherefore, the new key, or that into which the tune will be transposed, is D. No. 104. For,

Let it be remarked, that the greater 7th which determines the new key in this as well as in the sharp key, is never prefixed to the tune; which to the sharp key always is.

The reason is, that the flat 7th is the property of the flat key. To prefix therefore a sharp to the place of this note on the stave, or beginning of the tune, would be a constant contradiction to all the flat 7ths that may occur throughout the whole air. But the sharp 7th, when brought in at a close, middle or final, or elsewhere where there is no close, is marked particularly as occasion requires.

Another reason for not prefixing a sharp on the stave to the place of the 7th of a flat key is, that, in some keys, the 6th must have its flat set on the stave, or beginning of the writing; a sharp, then, on the place of the 7th would appear a contradiction to sight, and ought therefore to be avoided.

The removal by transposition in the flat key being always to the 4th above, as in the last example, there needs no other example at length of transposition in this key, the same proportion obtaining throughout every key with a flat 3d respectively.

According, then, to this proportion, the next key after D will be G; the 3d of the former, or F natural, becoming F sharp the greater 7th, E flat its 6th.

The next will be C. Its greater 7th is B natural, with the addition of a flat to A its 6th.

The next will be F, with the addition of a flat to D its 6th.

The next would be B flat, with the addition of a flat to G its 6th; never used.

The next would be E flat, with the addition of C flat its 6th, never used.

The next would be A flat, with the addition of a flat to F its 6th, never used.

The next would be D flat, with the addition of two flats to B, never used.

The next would be F sharp, its 6th D, never used. The next is B, its greater 7th A sharp.

The next is E, from whence we ascend by a 4th into the first key A.

I C K.

Hence it is plain there are seven flat keys in use, out of the twelve semitones in the octave. Of which the following are examples, with their proper signs prefixed. No 104.

It may be observed, that by changing the place of the other semitone or 6th, by adding a sharp, the transposition is by two degrees of the former at once; as from A into G, and so on. But this is no more that what hath been done in the second step of this example; yet by putting this sharp to the 6th, it is a short way of transposing into the whole tone below.

It appears from hence, that there are in all sixteen keys in use: a fund for great variety: among which you will observe, that some sharp keys have flats prefixed, and some flat keys have sharps; which cannot by this time appear strange to one who perceives the necessity of preserving the proportion of each, and who must now understand the truth of the 3d axiom of the practice. That no tune composed in a sharp key can be transposed into a flat one, nor a flat one into a sharp; for that would be altering the permanent nature of things.

From comparison of the examples, will be seen what is most worthy of remarking; which is, That whatever sharps or flats belong to any flat key, the same are likewise the property of that sharp key, which is on the same flat key's 3d: for instance, A with a flat 3d, and C with a sharp 3d; so D and F, G and B; and so of all others respectively having the same signs belonging to and prefixed to each.

Hence we collect, that the essential difference of tunes consits in the form, that is, the position of the semitone, and not in the materials of music.

A truth which appeared before in the comparison of discord with harmony; and which will be of great service hereafter, in the art of learning to sing by note.

This inference furnishes us with a proof of the 4th of a flat key, and 6th of a sharp key, having for harmony each his own concord.

A proof which was wanting; as it could not be had from the rules of harmony, neither of these intervals being in the place of a semitone. The general theorem is this: As by axiom 3d the proportion of one single sound is to another according to the natural order of sounds; so the proportion of one chord to another will be according to the natural fucceffion of chords. For a chord is no other than an unity of sounds. But it appears that the fucceffion of chords by transposition in the flat key, is by 4ths, that is, the chord of a note, with a flat 3d; and that of the note's 4th is the same. Now, the harmony of the key or given note is the concord of itself: therefore the harmony of the 4th in a flat key is the concord of itself.

In like manner we demonstrate the harmony of the 6th of a sharp key to be the chord of the same.

And in this the proof lies nearer the truth than in the former case.

For the chord or proportion here is not only the same, but the individual sounds.

For as by comparison, as above, of any flat key with the key of its 3d (which must ever be a sharp key, the flat and sharp 3ds being the compound intervals of the 5th) the
the properties and proportions are not only like, but the same, the difference consisting in the form or place of the semitones; so the chord of one key will be to the chord of the other, not only like, but the same. Now the harmony of every flat key is, by the rule of harmony, the concord of itself: but the concord of the flat key is the relative sharp key's 6th; therefore the harmony or chord of the sharp key's 6th is the concord of itself.

Let us now apply these rules of transposition to the second rule of melody, or perfect imitation, which is the repetition of a passage in notes not belonging to the harmony of the key; by which notes we understand all that have a sharp or flat added, which was not prefixed to the beginning of the same.

The general rule of which is, first name the key in which the passage is written, whether the same be the original key, or that of the tune, or some other; then name the interval of the first note of the passage to the same key.

Whatever interval the imitation begins on, whether a 2d, 3d, 4th, 5th, or any other above or below the passage, it bears the same proportion to the key of the imitation as the first note of the passage to its key. Thus:

- G is to C as A is to D, or
- G : C :: B : E, or again
- D : A :: B : F, or
- D : B :: E : C.

The leading note and key being thus expressed, both of the passage and imitation, shews the proportion of the imitation above or below passage.

If the passage be in a sharp 3d, as the imitation must be so too, the signs, as prefixed to one of the examples of the sharp keys, will be required to be added to the notes of the imitation; and if the passage move with a flat 3d, the examples of the flat key discover the marks wanting in the repetition.

Thus G, the leading note of a passage in C, with a sharp 3d, repeated in the note above; as A and D require two sharps, namely on F and C, the property of D with a sharp 3d.

And the same passage in C with a flat 3d, will in the note above require B marked flat, the property of D with a flat 3d:

And G C sharp 3d, transposed into a 3d, or B E, requires four sharps, on F, C, G, and D, the property of E with a sharp 3d.

The same passage with a flat 3d, or any other passage, will, when transposed into E, require but one sharp on F:

And D B, with a sharp 3d repeated in E C the natural sharp key, require neither sharp nor flat.

But the same, or any other passage with a flat 3d, will, when transposed into C, have three flats on B, E, and A, the property of C with a flat 3d: and if there be no leading note, as it may often happen, nothing more is to be considered than the key.

Thus the use of transposition in perfect imitation is evident.

The second method of transposition is by the cliff.

The use of the cliff is to ascertain the names of the notes. Therefore, the names of the notes will be changed by removal of the cliff.

Now as, in transposing, it is necessary that every interval be preferred, or that the semitones keep their due places; so by altering the name of the first note of the tune, by removing the cliff, all the other notes are altered in proportion.

Thus the removal of the cliff effects at once what was done in the other method by the transposition of every single note of the tune by writing.

This way is easier for the writer, but much more difficult to the performer.

Inasmuch as a confirmed habit in any thing is harder to be changed for a new method, than it is to learn by a certain rule at first.

Therefore the performance in transposing by the cliff can no otherwise be attained, than by constant and repeated practice in all the cliffs, and in all such places as they are used to be set for convenience.

Every one therefore who desires to become a master in performance, after he is well acquainted with the three cliffs in their usual places, ought to accustom himself to perform in every cliff, in whatever place it may be set. This knowledge will not only render the performance convenient to his private amusement, by the variety with which he can furnish himself, by playing the same air in whatever key he pleases; but will also make him an useful member in a concert, by transposing at sight, whenever it may be required to accommodate the instrument to the voice. For let it be understood, that to him who is so well acquainted with the places of the cliffs, as to perform in any of them at sight, nothing more is wanting to his transposing by the cliff at sight than to imagine the cliff is prefixed to such or such a place, and commit to his memory the name of the key in which he is to perform, by transposing according to the removal of the cliff which may be most convenient.

This will fix the places of the semitones, or assign the sharps or flats belonging to the new key, as they are set in the example in the first method of transposing by the writing.

Any of the cliffs may be removed; yet the C cliff or tenor is most commonly in use for this purpose.

The general rule for transposition by the cliff is this.

To transpose into any interval above the key, remove the cliff by the same interval descending. And if the instrument be too high for the voice, to transpose into a lower key, remove the cliff to a convenient interval higher.

For, raising the cliff depresses the notes; and, contrary, setting the cliff lower raises the notes, or transposes them into a higher key, in proportion.

**CHAPTER VI. OF SINGING BY NOTE.**

The art of singing by note is founded on the principles and practice of music. Therefore we have reserved this subject to the last.

To sing by note seems in some respects more difficult to attain than performance on some instruments. In other respects, it is easier and sooner acquired.
The more time is laid out on the practice on some instruments, the more difficult the execution grows, in some cases, that is, according to the construction and compass of the instrument. On the contrary, all the difficulties in learning to sing by note present themselves in the beginning, in appearance greater than they really are; and which a knowledge of the principles of music, and a little of the practice, with a tolerable good ear, will with ease overcome.

Besides, a little time and experience will convince any one of what compasses his voice is, and what degree of performance he is capable of attaining. The principles of singing therefore being well understood, there remains no further difficulty; no one having a right to expect he can execute more than what is within his natural powers.

If this art is not so commonly understood, or the knowledge of it sought, it may be owing to this, that the precepts for learning, or the manner invented, and constantly used, are more perplexed than the subject demands.

How far this may be true, will appear from an observation or two which we shall make on the method now in use.

The art of singing by note rolls on these two principles; the finding the places of the semitones, and tuning them and the whole tones of the octave aright.

The first of these has been delivered in the theory; and also in the practice, under the last article Transposition. The tuning the notes is the subject we are now engaged in.

Let us first examine how far these have been prosecuted in the present method.

The notes of the octave, besides their names in the scale, have been used to be distinguished by these four syllables, Sol, la, mi, fa; accommodated to the purpose of singing by note, in the following order.

Fa, fol, la, mi, fa, fol, la.

Whereof Sol being thrice repeated in the octave, La twice, Fa twice, and Mi once; four syllables express the 8 notes.

The art of tuning by these, or assigning the places of the semitones, is by appointing to Mi the place of the greater 7th; and then Fa immediately following expresses the semitone or key, and the other Fa the 4th. How well forever this may answer the purpose of tuning the half-tones in a sharp key; yet in a flat key, the places of the half-tones being the 3d and 6th, will, according to this order, be expressed by La, the semitone syllable Fa consequently expressing whole tones.

To obviate this difficulty, and reduce things to order, another place of Mi must be assigned, which is the 2d of a flat key: for this Fa will express the semitones on the 3d and 6th.

It is evident then, that before any half-tone or whole-tone can be tuned, the first business must be to find out the place of this mi: now how this can be done by virtue of the sound, or name, or order of these syllables, is not so easy to comprehend.

But admitting the place of mi, or the key, to be known by some previous precept, as indeed ought to be; yet tuning the key as the first semitone in a sharp 3d, and the 3d as the first semitone in a flat key, is beginning at the wrong end in the first case, and thereby not marking the essential difference of tone, which consists in the flat and sharp 3ds, the order of which is disturbed by this variation of the place of mi.

From this want of marking the essential difference in tuning by these syllables, and wherein the beginning and ending is not on the key, some confusion and much trouble and untunableness must arise. And indeed it cannot be imagined, that this or any other essential difference of things can be marked by the same invariable artificial signs, if they be not exactly accommodated to the nature of things. An invention that fails in this, however ingenious it may be in speculation, not being a just representation of nature, doth not merit the name of art.

For instance, if you tune eight notes, whose key hath a sharp 3d beginning on the 5th, your seventh note, which is the 4th of the key, and therefore a whole tone from the succeeding note, will sound like the flat 7th. Again, if you begin to tune on the 2d, your 3d, which is the 4th of the key, is flat; and the found in this succession will appear as if you were tuning in a flat key.

And again, if you tune from the 6th, the deception of a flat 3d is the same as in the last case.

Secondly, if you tune 8 notes whose key hath a flat 3d, and begin on the 7th, your 3d, which is the 2d of the key, is sharp, and your tuning will be as if in a sharp key.

The same deception will appear if you begin to tune on the 3d or 6th.

In a word, whatever other interval you begin on, to tune either with flat or sharp 3d except the key, some semitones will be out of their places: This is rendering what is at first sight attended with some difficulty, more perplexed and obscure.

The ear, the judge of sounds, is deceived, and the judgment misled.

But on the other hand, the ear will naturally and easily distinguish the flat and sharp key, when the key and its 3d are ascertained by beginning and ending on the key.

But otherwise, and where these marks are promiscuously used, the difference of tune, or invariable sign, will appear neither to the ear nor understanding.

We shall end these remarks with one general observation; which is, that by assigning the place of mi to the greater 7th or 2d, in order to find out the key, is resolving one difficulty by a greater, and requiring to do a thing without any means of information offered to compass it.

For as it is true that when the greater 7th or 2d is known, the key is known also, and again, the key being given, you have consequently the 7th or 2d; yet to do either of these, without some intermediate helps, is taking for known the thing fought, which is directly contrary to reason.

Proceed we now to our method of singing by note.

The first principle of singing, is the finding the places of the two semitones in the octave, in any given key.
This hath been pointed out in general, in the theory, where are shown the places of the semitones in the sharp key to be the 4th and 5th, and in the flat key the 3rd and 6th.

But the particular names of the notes, on which the semitones fall in any key whatsoever, and which it is evident must depend on the name of the key, are demonstrated, and examples given, in the practice, under the article of Transposition.

We shall therefore transfer only the examples into this place, in a concise order, which will fully answer our inquiry into the names and places of the semitones.

The nine sharp keys. No. 106.
The seven flat keys. No. 107.

By these examples the particular names of all the semitones are known at sight; as they depend on the name of the key.

Therefore in the example of the sharp keys; the first key being C, the semitones are F and C.
The second G; the semitones C and G.
The third D; the semitones G and D, the 4th and 5th of each respectively.

In the example of the flat keys; the first being A, the semitones are C and F.
The second D; the semitones are F and B flat.
The third G; the semitones B flat and E flat. And so on, the 3d and 6th respectively.

To apply this to the purpose of tuning the notes by the voice: At sight of the sharps or flats prefixed to the tune to be sung, and looking at the key-note, you have of course the places of the semitones, by referring these to the original in the examples set above.

Having thus discovered the difference of tune, you are at the same time determined whether you are to tune the notes of the octave with a flat or sharp 3d.

This tuning of the eight notes, tones and semitones, in their due order, is the first step or principle of tuning all other intervals, or of finging by note.

It will most readily be learned by imitating another voice, or following the notes of an instrument; this is the only safe wherein there is need of any foreign assistance to singing by note.

The instrument we would recommend for this purpose is the organ or harpsichord; as the 4 or 5 semitones, which ascertain the flat or sharp 3d, succeeding each other, being visible on the keys of that instrument in any part, the learner can in this case assist himself, by striking the notes of the octave in either flat or sharp key, on any part of the instrument which will best suit the pitch of his voice, and distinctly repeating them by turns, until his ear is become a perfect judge of the difference of the flat and sharp 3d, as well ascending as descending, and his voice perfect in tuning both.

As musical sounds will be best expressed in tuning by articulate ones; we shall, to answer this convenience, take the four syllables already in use.

As we shall apply them to another purpose than they serve at present; so the order or manner we shall dispose them in, will be altogether different from that.

In tuning, then, the notes of the octave with the instrument, let the syllables be expressed with the notes, in the order of the following examples.

In G sharp. No. 108.

Now, since the flats or sharps adjusting the semitones of any sharp key are exactly the same which belong to the flat key respectively on the 6th, as we have said before in comparing the examples of flat and sharp keys in transposition; therefore the eight notes ascending in a flat key will have the syllables annexed to each, as in the following example on the 6th, without disturbing or departing from the order of the sharp.

In E flat. No. 109.

The semitones and the tones below them being distinguished by the syllables fa and mi, in their respective places in both keys, for descending as well as ascending notes, is the sole use we intend by these syllables; the tuning of the notes, which is to be learned by the instrument, being entirely independent of them.

For tuning the descending notes, then, there need no other examples than the two above written; for reading the same backwards will serve this purpose.

When the ear becomes well acquainted with tuning the notes of the octave by the instrument, it will then be proper to sing the same looking on the notes written on the book; and this should be done in every example of both keys. And let it be remembered, that tuning the notes thus in the natural order, should be to a beginner the prelude to singing any song proposed.

The next step will be, before the learner attempts to sing any part of a song, to tune by the notes the greater intervals, both concord and discord.

The general rule for which is, Tune all the notes of the interval in the natural order, ascending if the interval ascend, and descending if the intervals descend. Then immediately tune both notes of the interval, beginning with the concords.

Thus. No. 110.
Concord in succession.
The concords are. No. 111.
The semitone being the distance between the 3d and 4th, is already known by tuning the notes of this interval.

Note, The name of every greater 7th introduced by a sharp prefixed, is mi.

Next tune the concords of the thirds in succession. In this manner. No. 112.
The 4ths and 5ths being all perfect and like, except one of each, need no repetition.
The 6ths in succession are tuned thus. No. 113.
Lastly, mix the discords and concords as they stand in the natural order; than which nothing will better confirm the just tuning of the intervals, when these rules are to be applied to future practice.

In this manner. No. 114.
This line may be tuned various ways; as, secondly, beginning still on the left hand, tune the 3d and 2d notes, reading backwards; and so on, each two under the flor.

Again, beginning on the right hand, tune the uppermost note and second downwards; then the first and third; and 4 T
so on, still missing one, and omitting constantly the G, or key not below.

And lastly, beginning still on the right hand, tune the second and first, the third and first, the fourth and first, and so on, omitting the G or key note constantly.

The practice of tuning the notes descending of all these examples, is by reading the same backwards.

The tuning the greater intervals in the flat key depending in like manner on tuning the eight notes in succession, according to that series; it is unnecessary to set examples of the same.

The same method of practice equally serving this key, except that the syllables annexed to this key must be repeated, as in the proper example 109.

As in this example of the intervals of the 3d, 6th, and 7th, wherein this key differs from the sharp. No. 115.

The general rule of tuning the intermediate notes of each interval first likewise taking place here.

In order to establish these rules in the memory, and render them of immediate service to the practicioner, especial notice must be taken of the flat and sharp thirds, as also of the flat and sharp sixths, in what places they stand, or how they succeed each other in the order of the key.

The not attending to these differences being the only obstacle that can stand in the way of singing at sight, see them set down at large in the theory, and in the examples of this chapter, No. 112, 113.

When these are well recorded in the memory, together with the sharp 4th or flat 5th, the art of singing by note will not appear so mysterious. This knowledge of the intervals at sight will render the syllables of little or no use, as hath been observed, and especially if words be set to the airs you intend to practice; which we would advise.

When the interval of each note is known at sight by constant practice, and the found of every interval become familiar to the ear, and thereby distinguished immediately upon hearing the name, the learner may make an easy to sing by note some plain song; which is no more than tuning the same intervals, with which he is supposed to be well acquainted in the foregoing lessons.

For as to any other article of knowledge requisite to the performance of the song; as the time of the movement, and lengths of the notes, and the like; if the practicioner hath not been acquainted with them by practice on some instrument beforehand, the principles of them have been delivered in few words in the introduction to this essay.

But besides that this is not the place for speaking of these matters, so neither is there occasion for this knowledge in the very beginning, in strictness of speaking; it being advisable for a beginner to study the tuning the intervals of the song, without respect to any other affection of the sounds; and when he is master of this, to add the practice of the lengths of the notes, as a second consideration.

We shall here set the notes of a plain song, in order to make such application of the rules as may be an introduction towards the further execution of them. No. 116.

First, find out the key, by looking at the last or key note; then see whether it hath a flat or sharp 3d.

The key of this example being G, with one sharp prefixed, is a sharp key; being the second instance in the examples of the nine sharp keys.

Therefore tune the notes of the octave ascending and descending, in a sharp 3d. Immediately after tune the concords in succession. After that, tune the concords of the 3ds, ascending and descending. This will be prelude enough for fixing your attention and ear to the 3ds of the key, and for pitching your voice. Having repeated this two or three times, begin the song in the same pitch or key wherein you sung the prelude. For nothing contributes more to singing in tune, than frequent repetition of notes in one key. Therefore, if your voice be rightly pitched in the prelude, seek not to change it in the song.

The two first notes in the example are Fa, Mi: which interval, it is presumed, you can tune at sight. If otherwise, you must have recourse to the general rule, and tune the intermediate note of that interval ascending, thus, Fa, sol, mi; immediately repeating the interval you want to sound, thus, Fa, Mi.

The next note is the 2d, or Sol, which may be tuned from Mi, the last note, by descending; or from the key, as it hath an equal reference to both. We have laid before you this choice in consideration of your first attempt. But when from experience you are become more perfect in tuning the intervals, the most approved way will be; to make the last note you sung relative to the succeeding one, whose interval you are to tune. Whereby your singing an air will be no other than tuning the intervals as they succeed each other in the movement of the song; which you practiced often before in the natural order, and with which you are supposed to be well acquainted.

The fourth note in the example being Sol, and a 4th to the last note you sung, you will now tune a perfect 4th; not considering this note in relation to the key, to which it is a 5th; but in relation to the last sound note Sol, to which it is a 4th.

This is the method you will pursue in every interval after some improvement gained by practice. Notwithstanding, it will be convenient sometimes to have recourse to the key, by founding it, and taking the interval from the same; whereby you will sing better in tune by keeping to the pitch or key you began in; particularly if the interval from the last note be a great one, or discord, or lie near the key, above or below.

To sum up all; every new note introduced; or not belonging to the harmony of the key, bearing the proportion of some concord or discord, to the preceding note or to the key, will come within the rules laid down, and therefore needs no repetition.

On the principles of the theory and practice of music, we shall now demonstrate the art of transposing with the voice, or singing in any cliff at sight, where with it may happen a person is not acquainted; and this from the knowledge of singing in any other cliff.

MUS

**Theorem.** The intervals of the notes of all sharp keys and flat keys respectively, are proportional. Therefore, the singing at sight in an unknown cliff will be by transposing out of the given cliff, into that you are acquainted with.

This is done by naming the key in the cliff you are to transpose into, and distinguishing whether the song hath a flat or sharp 3d, compared to the examples of the nine sharp and seven flat keys in use, knowing the name of each cliff. Now, the name of the bass cliff is F, of the tenor C, and of the treble G.

Let it be required to sing the notes in the following example in the bass cliff unknown; transposed into the treble with which you are acquainted. No. 117.

The notes in the uppermost line, in the bass cliff, are in C.

In the second line and treble cliff, they are in E.

Demonstration. By the rules of transposition they are the second and fifth instances in the sharp key; then they are proportional; if proportional, the semitones are preferred in their proper places: but keeping or sing the semitones in their places, is tuning the notes of the octave right; therefore this transposition from the bass cliff into the treble is singing by note right.

The same example in the tenor. No. 118.

The notes of the tenor are in F; those of the treble in E. But they are the third and first instances of Sharp keys, therefore proportional; and if proportional, C.

Again, let the treble be the unknown cliff. No. 119.

MUSK, a dry, light, and friable substance, of a dark blackish colour, tinged with purple; it is a kind of perfume of a very strong scent, and only agreeable when in a very small quantity, or moderated by the mixture of some other perfume. It is found in a kind of bag or tumour which grows under the belly of the musk moshiferous. See Moschus.

Musk is brought to us sewed up in a kind of bladders or casks of skin of the bigeef of a pigeon's egg, or larger, each containing from two or three drams to an ounce of musk. These are covered with a brownish hair, and are the real capsules in which the musk is lodged while on the animal. That which is unacclimated appears in mufhes, of loose and friable granules, which are soft to the touch, and easily crumble between the fingers, feeling somewhat smooth and uncruous.

Musk taken inwardly produces ease from pain, quiet sleep, and a copious diaphoresis; hence it has been found of great use in spasmodic disorders, petechial, malignant, putrid fevers, the jail diftemper, hiccoughs, &c. and Dr Wall observes, that it has been found useful in spasmodic disorders, given by way of crifter. The operation of musk in some respects resembles that of opium; but it does not leave behind it any flupor or languidness, which the latter often does. Musk likewise seems likely to answer in those low cafes where sleep is much wanted, and opiates are improper. It is said to be best given in a bolus, in which form those who are moll averfe to perfumes may take it without inconvenience. Fifteen grains or more are now given in a dofe with great success.

MUSKET, a fire-arm born on the shoulder, and used in war. The length of a musket is fixed at three feet eight inches from the muzzle to the pan, and it carries a ball of fourteen to the pound.

MUSKEETOON, a kind of short thick musket, whose bore is the thirty-eighth part of its length; it carries five ounces of iron, or seven and a half of lead, with an equal quantity of powder. This is the shortest fort of blunderbusses.

MUSLIN, a fine fort of cotton cloth, which bears a downy knap on its surface. There are several forts of muslins brought from the East Indies, and more particularly from Bengal; such as dorcas, betelles, muls, tanjeets, &c.

MUSSENDA, in botany, a genus of the pentandria monogyia class. The corolla is funnel-shaped; it has two thickish stigmata; the berry is oblong, and the seeds are disposed into four series. There is but one species, a native of India.

MUSSELBOROUGH, a port-town of Scotland, in the shire of Lothian, six miles east of Edinburgh.

MUSTARD, in botany. See Sinapi.
MUSTELLA, in zoology, a genus of quadrupeds of the order of fere. There are fix erect, sharp, distinct teeth in the upper jaw, and an equal number in the under jaw, but blunter and clover together, and two of them are situated a little farther within the mouth; and the tongue is smooth. There are 11 species, viz. 1. The lutra, with the hind-feet palmated, and the tail about one fourth of the length of the body. It is found in Asia and North America. 2. The lutra, or otter, has palmated feet, and a tail about one half of the length of the body. This animal is exceedingly voracious; but is tender of fish than of flesh. He seldom quits the banks of rivers, and can remain a considerable time below water. The female comes in season in the winter, and brings forth three or four young in March. This animal is found in most countries of Europe and North America. 3. The lutreola has hairy palmated feet, and a white mouth. It is a native of Finland, and feeds upon frogs and fishes. 4. The barbata, is of a reddish colour; and the toes are not connected with a membrane. It is a native of Brazil. 5. The gulo of a dusky red colour, and blackish on the middle of the back. It is found on the woody mountains of Lapland, Russia, and Siberia. The gulo is a very voracious animal, and devours hairs, birds, &c. He has an abominable odor; but his fur is very precious. 6. The martes, or marten, is of a blackish yellow colour; and the toes are not connected. This animal is a native of the southern parts of Europe; it frequents the woods, and feeds upon squirrels, mice, and birds. 7. The putorius, or pole-cat, has unconnected toes, is of a dirty yellow colour, with a white mouth and ears. This animal is very destructive to birds and poultry. He conceals himself during the day; but fleals into barns, dovecotes, hen-houses, &c. in the night, in order to catch his prey. He is a native of most parts of Europe. 8. The furo, or ferret, has red eyes, and unconnected toes. This animal is easily tamed, and frequently employed to hunt rabbits out of their holes. The female is less than the male, and brings forth twice in the year, 5 or 6 at a litter. It is a native of Africa. 9. The zibellina has divided toes; the body is of a dusky yellow colour, with a white forehead, and an ash-coloured throat. It is found in Tartary, and the northern parts of Asia. 10. The reminea has divided toes; and the point of the tail is red. The skin of this animal is a valuable fur, and of a fine white colour. It is a native both of Europe and Asia, and particularly of the northern climates. It feeds upon mice, eggs, &c. and has a very offensive smell. 12. The nivalis has divided toes, and a white body. It is very similar to the ermine, but about one half less in size. It is found in Russia and the northern parts of Europe. See Plate CV. fig. 1, 2, 3, 4.

MUTE, in a general fenfe, signifies a perfon that cannot speak, or has not the ufe of speech.

Mute, in grammar, a letter which yields no sound without the addition of a vowel. The fimple confonants are ordinarily distinguished into mutes and liquids, or semi vowels.

MUTILATION, the retrenching or cutting away any member of the body.

MUTILATION, in Scots law. See Law, Tit. xxxiii.

MUTULE, in architecture, a kind of square modillion set under the corniche of the Doric order.

MUTUM, or Loan, in Scots Law. See Law, Tit. xx. 7.

MUZZLE of a gun or mortar, the extremity at which the powder and ball is put in; and hence, the muzzle ring is the metallic circle, or moulding, that surrounds the mouth of the piece.

MYAGRUM, in botany, a genus of the tetrandria filiculosa class. The pod is terminated with a conical stylus, and generally contains but one seed. There are nine species, only one of which, viz. the fatim, or gold of pleasure, is a native of Britain.

MYCONE, one of the islands of the Archipelago, about twenty-five miles in circumference, Situated in E long. 25° 6', N. lat. 27°.

MYLOGLOSSUM, in anatomy. See Anatomy, p. 304.

MYLOHYOIDÆUS, in anatomy. See Anatomy, p. 304.

MYOLOGY, that part of anatomy which treats of the muscles of the human body. See Anatomy, Part II.

MYOPIA, short-sightedness, a species of vision, wherein objects are seen distinctly only at small distances. See Optics.

MYOSOTIS, in botany, a genus of the pentandria monogynia class. The corolla consists of 5 emarginated segments. There are four species, only one of which, viz. the scorpionides, or mouse-ear scorpion-gras, is a native of Britain.

MYOSURUS, in botany, a genus of the pentandria polygynia class. The calyx consists of 5 leaves connected at the base; it has five fribulated, petal-shaped nectaries; and the seeds are numerous. There is but one species, viz. the minimus, or mouse-tail, a native of Britain.

MYRIAD, a term sometimes used to denote ten thousand.

MYRICA, in botany, a genus of the dicocia tetrandria class. The amentum of the male has alunulated scales; the corolla is wanting both in the male and female; the female has two stili; and the berry contains only one seed. There are five species, none of them natives of Britain.

MYRIAD, a term sometimes used to denote ten thousand.

MYRICA, in botany, a genus of the dicocia tetrandria class. The calyx of both male and female consists of four leaves, and none of them have a corolla: the male has eight lamina, and the female four pellia; and there are four naked seeds. There are two species, both natives of Britain, viz. the ficcatum, or spikewort millfoil; and the verticillatum, or verticillated millfoil.

MYRMECOPHAGA, in zoology, a genus of quadrupeds belonging to the order of bruta; the characters of which are these: There are no teeth in the mouth; the tongue is long and cylindrical; the head terminates in a long snout or muzzle; and the body is covered with
with pretty long hair. There are 4 species, viz. 1. The didaòyla, or white American coati of Seba, has

two toes on the fore-feet and four on the hind feet. This animal is about 7 inches long; the head is two

inches in length; the snout is not fo long as that of the other species; the tail is about an inch longer than

the body, and covered with pretty long hair; the legs are not made for walking, but jumping. He climbs trees,

and hangs on the branches by the extremity of his tail. In this situation he swallows his long tongue in the holes

or fissures of trees, and brings it out covered with ants or other insects. He can live long without nourishment

of any kind, sleeps generally in the day, and searches for food in the night. 2. The tridàyla, tamandua-guaca, or tamanour, has three toes on the fore-feet, and five on the hind-feet, and long hair on the tail.

This animal is about four feet long, and the head and snout about fifteen inches: It is a native of the East

Indies, and feeds upon ants, &c. in the same manner as the didàyla. See Plate CXVI. fig. 4.—3. The ju-

bata, has four toes on the fore-feet and five on the hind ones, and a very hairy tail. This animal resembles the

tridàyla, and is found at the Cape of Good Hope. 4. The tetraòyla, has four toes on the fore feet and five on the hind, with a tail naked at the extremity. It is a native of south America.

MYROBALANS, a kind of medicinal fruit brought from the Indies, of which there are five kinds: 1. The citrine, or Indian myrobalan, of the size of a date, round, of the size of an ordinary prune, less angular, and covered with pretty long hair; the legs are not made for walking, but jumping. He climbs trees, and hangs on the branches by the extremity of his tail. In this situation he swallows his long tongue in the holes or fissures of trees, and brings it out covered with ants or other insects. He can live long without nourishment of any kind, sleeps generally in the day, and searches for food in the night. 2. The tridàyla, tamandua-guaca, or tamanour, has three toes on the fore-feet, and five on the hind-feet, and long hair on the tail. This animal is about four feet long, and the head and snout about fifteen inches: It is a native of the East Indies, and feeds upon ants, &c. in the same manner as the didàyla. See Plate CXVI. fig. 4.—3. The ju-bata, has four toes on the fore-feet and five on the hind ones, and a very hairy tail. This animal resembles the tridàyla, and is found at the Cape of Good Hope. 4. The tetraòyla, has four toes on the fore feet and five on the hind, with a tail naked at the extremity. It is a native of south America.

MYRRH, a vegetable production of the gum or resin kind, issuing by incision, and sometimes spontaneously,

from the trunk and larger branches of a tree growing in Egypt, Arabia, and Abyssinia. The incisions are made twice a-year, and the myrrh oozing out is received on rush-mats dispersed underneath. Myrrh is sent over to us in loose granules of various sizes, from that of a pepper-corn, to the bigness of a walnut. The generality of them, however, are from the size of a pea, to a little more than that of a horse-bean: these are sometimes roundish, but often irregularly long and contorted. The colour of myrrh is a reddish-brown, with more or less of an admixture of yellow, and in the purest pieces it is somewhat transparent. Its taste is bitter and acrid, with a peculiar aromatic flavour, but very nauseous: but its smell, though strong, is not disagreeable. It is to be chosen in clear pieces, light, friable, and of the bitterest taste. Myrrh is of great use in medicine; it powerfully resolves and attenuates thick and viscid blood, and concreted bile, and glutinous humours, and is good in ob-

MYRTUS, the Myrtle, in botany, a genus of the Jaceo-

MYRTIFORM, in anatomy, an appellation given to several parts, from their resembling myrtle berries.

MYRTLE, in botany. See Myrtus.

MYRSINE, in botany, a genus of the pentandria monogynia class. The corolla consists of five segments; and the berry has five cells and five seeds. There is but one species, a native of Ethiopia.

MYRTIFORM, in anatomy, an appellation given to several parts, from their resembling myrtle berries.

MYRTLE, in botany. See Myrtus.

MYRTUS, the Myrtæ, in botany, a genus of the pentandria monogynia class. The calyx consists of five segments, and the corolla of five petals; and the berry contains two or three seeds. There are 13 species, none of them natives of Britain.

MYRIA, the ancient name of a province in Asia, being the north-west part of Nattolia or Asia Minor.

MYTHOLOGY. The word mythology is a Greek compound, that signifies a discourse on fables; and comprehends, in a collective sense, all the fabulous and poetic history of pagan antiquity. It follows therefore, that this science teaches the history of the gods, demi-gods, and fabulous heroes of antiquity; the theology of the pagans, the principles of their religion, their mysteries, metamorphoses, oracles, &c. By this definition, it appears sufficiently what are the objects of which we are to treat in this article.

If we well consider the matter, we shall find, that there were, in pagan antiquity, three different religions. First, That of the philosophers, who treated metaphysically of the nature, the attributes, and of the works of the Supreme Being. They endeavoured to discover the true God, and the manner in which he ought to be worshipped. It is not wonderful, that these men of exalted genius should in some degree ridicule, in their works, the two other positive religions, and those gods on whom they were founded; at the same time that they outwardly professed the established religion, in order to preserve the peace of society, and to avoid the perfections of the legislature, and the insults of the populace. For in fact, was it possible for them to believe the pagan fables? Must they not foresee, that their religion would one day give place to another, while their own works would pass with their names to the latest posterity? And could they suffer the thought, that their reputation would be tarnished in the eyes of that posterity, by having it imagined they believed such idle tales as were broached by the priests of their times? Could Plato, Socrates, Seneca, and Cicero, be unconcerned for their fame among future generations, or hypocritical, as to have entirely concealed their sentiments with regard to these matters?

The second religion was that of paganism, which was the established religion of all the ancient nations except the Jews. This was the doctrine that was taught by the priests, and protected by the sovereigns. Its dogmas were demonstratively false, but not always so absurd as may at first appear, especially if we annex to the divinities, and to the religious ceremonies of the pagans, a feme that is frequently mystic, and always allegoric; if we remember,
that the first heathens deified those great men to whom the rest of mankind were indebted for any signal benefits, as Jupiter, Apollo, Ceres, Bacchus, Hercules, Æsculapius, &c. in order to induce others, as well of the present as future ages, to reverence and to imitate them. Would not an ancient pagan, if he were to return upon the earth, have specious arguments, at least, to support his religion, when he saw weak mortals beautify or canonize, merely by their own authority, other weak mortals (frequently mere pedants,) and place them in heaven, without the permission or approbation of the Supreme Being? Happy is it for mankind, when at different times sagacious pontiffs purge the calendar, and the brains of the people, from a herd of pretended saints, and prevent them, at least after their death, from doing injury to society, by interrupting the industry of the laborious inhabitants with keeping their festivals.

The third religion was idolatry, or the religion of the populace. For the common people, born to be deceived in every thing, confounding in their imaginations the statues of the gods, the idols of their divinities, the emblems of their virtues and of religious worship, with the gods, divinities, virtues and worship themselves, adored these images, and proceeded to extravagancies the most ridiculous, and frequently most criminal, in their ceremonies, feasts, libations, sacrifices, &c. It is to be feared, that, as long as there are upon the earth men of our limited capacities, this triple religion will constantly subvert under different forms; and we are much deceived, if it may not be found under the empire of Christianity itself, notwithstanding the purity of its doctrine. It will be easily conceived, that it is not of the religion of philosophers, nor that of the populace, of which we are to treat in this article of Mythology; but of that which subsisted under the authority of the magistracy and the priesthood, and consequently of paganism in general.

As far as we are able to judge by all the ancient authors we have read, the pagans adored the sovereign Lord of the universe under the name of Fate or Destiny, which we must not confound with Fortune, who was regarded as a subaltern divinity. Jupiter himself, all the gods, every animating being, the heavens, the earth, the whole frame of nature, was subfervient to Destiny, and nothing could reverse its decrees. This divinity was so highly adorable, as to be above all rank; and was regarded as too supreme to be represented under any finer image or statue, or to have any temple erected for its worship. We do not remember to have read, that any sacrifice was ever offered to this Destiny, or that any temple or city was ever dedicated to its name. We are almost inclined to think, that the pagans were fenfible, that the temple and the worship of the God of gods ought to be in the heart of man. Mention is made, indeed, of a temple that was dedicated to the Unknown God, but we are ignorant whether or not Destiny were thereby meant. We must not confound this Destiny, moreover, with the goddesfs of chance, of which there are some antique statues that represent her in a recumbent posture, and playing with little bones; for this was nothing more than an invention of some flautary.

After this general and philosophical idea of the Supreme Being, comes the positive religion of the pagans. This was entirely founded on fable, which took its rise either from ancient traditions, or historical events, altered or augmented by the imaginations of the poets, by superstitition, or by the credulity of the people; or else it consisted of allegoric or moral fictions. A crowd of writers, among the rest N. de Comte, Natalis Comes,) the abbots Binner and Pluche, &c. have made many researches into the origin of fable: and they think they have discovered its source, 1. in the vanity of mankind; 2. in the want of letters and characters; 3. in the delusive eloquence of orators; 4. in the relations of travellers; 5. in the fiction of poets, painters, flautaries, and dramatic writers; 6. in the diversity and uniformity of names; 7. in the ignorance of true philosophy; 8. in the foundation of colonies, and the invention of arts; 9. in the desire of having gods for our ancestors; 10. in the imperfect or false interpretation of the holy scriptures; 11. in the ignorance of ancient history; 12. in a like ignorance of chronology; 13. in that of foreign languages; 14. in the translation of the religion of the Egyptians and Phœnicians into Greece; 15. in the ignorance of geography; and, 16. in the belief that the first people had of the intercourse of gods with men. It is certain, that all these matters taken together are sufficient to produce many thousands of fables; are more than sufficient to enable us to deceive ourselves and others, and to give rise to infinite reveries. But we should take care how we draw from these sources demonstrations that might be used, by infidels, as arguments to overthrow the history of the Jews; a people the most stupid, most credulous, and oftentimes of all others. In the mean time, the pagan philosophers themselves asserted, that it was a god who invented the fable: so much they were convinced of its ingenuity, and of its strong tendency to instruct mankind in their duty.

Mythology therefore, when properly treated, begins with making learned researches into the real origin of fable, of paganism, and of that idolatry which was its consequence. It recurs for this purpose even to the beginning of the world; and after finding that Laban, the father-in-law of the patriarch Jacob, was a maker of idols; and that he had his little images, or household-gods, which he formed of baked earth, and which shews that idolatry existed in the greatest antiquity; it then explains cosmogony, and theogony, or the belief that the first inhabitants of the earth entertained of the creation of the universe, and what the pagan theology taught of the genealogy of their false gods. It begins with the tradition of the Chaldeans, a people so ancient, that Nimrod was their first king; but at the same time so credulous and superflitious, that we may regard them as the authors of all those fables, and the propagators of all those visions, that have since blinded human reason. According to this tradition, a monster named Ænemos, or Oer, half fish and half man, sprang from the sea, before the chaos was completely dispersed, and gave laws to the Chaldeans. A woman called Omorka, reigned over all the earth. Bel custer in two, and made of one moiety the heavens, and of the other the earth. They likewise invented the two primitive beings, of which the good one, who was named Ærmasdes, had the direction.
tion of heaven; and the other, called Ariminus, that of hell.

The science of mythology then teaches the theology of the Phenicians; concerning whom it draws great lights from Sanchoniathon, a priest of Beryt, who lived before the Trojan wars, more than four hundred years before Hefiod and Homer, and of whom Eusebius has preserved considerable fragments. From thence it passes to the theology of the Egyptians; of whom Thot or Thaut, the founder of that nation, was likewise, they say, their first historian; that Sanchoniathon even copied from him; and of whom we find many relations in the Greek historians, especially in Herodotus, Diodorus Siculus, and in Eusebius of Caesarea. It then examines the theology of the Atlanteens, who dwelt on the western part of Africa, and of whom Diodorus alone has preserved any account. From thence it proceeds to the theology of the Greeks, which is far better known to us, as we find accounts of it, more or less particular, in numberless Greek and Latin writers. This theology had the same foundation as that of the Romans; the latter having only extended it, by adding to the Greek divinities certain gods or demi-gods, formed of their heroes, and certain symbolic and allegorical divinities, which mythology explains at the same time: and it is on this occasion that it enters into a particular explication of the cosmogony and theology of Ovid; whose book of metamorphoses contains as copious descriptions as we could desire of the fables of the ancients: what was their belief concerning the habitations of the blessed after their death, or of the Elysian fields; as well as of their hell or tartarus; of the dog Cerberus; of the ferryman Charon; of the furies; of the four rivers, Cocytus, Lethe, Phlegethon, and Styx, which water the tartarian regions, &c. The learned have likewise made many inquiries, and many ingenious discoveries, concerning the theology of the ancient Germans, Celts, the Scythian and Hyperborean nation. In the latter place, this science furnishes great lights on the theology of the Brahmins, the Troglovides, the Indians, the Chinese, and even the Americans; all which it concludes with a regular and minute examination of the pagan theology, and particularly that of the poets.

All these matters being well digested in the minds of those who would make a regular study of pagan theology, they continue their researches into the time, the epoch and place of the real origin of paganism and idolatry; and they prove that the pagans began by adoring the heavenly bodies, the stars and planets. They next examine into the progress of idolatry: what were the temples of the pagans, their altars, their inclosures, their sacred groves, their asylums, the idols and statues of their deities; in what manner they were represented; what were their sacrifice, the victims that were offered; what were the sacred vessels, the censers and other instruments that were used in the sacrifices, libations, and other religious ceremonies: concerning the priests, priestesses, and other attendants on the service of each divinity: what were the festivals that were celebrated among the Greeks and Romans, as well as among the orientals; what the days of penitence and supplication, the feasts or the gods of lec- tillery, their invocations or incantations, and exorcisms, the religious ceremonies observed at laying the foundations of cities, &c.

Divination, or the prediction of future events, a weakness that has at all times possessed the human mind, forms also an important article of pagan theology. It is therefore in this place, that mythology considers the nature of Oracles; and in particular, 1. The oracle of Delphi, the most ancient of Greece; 2. That of Jupiter, Hammon or Ammon, in Libya; 3. That of Jupiter Philus; 4. That of Apollo, both of Heliopolis; 5. That of Apollo of Delphi; 6. That of Trophonius in Boeotia; 7. That of Venus of Aphaca, a country between Byblos and Heliopolis, situated on a small lake; and a great number of other oracles of less note, dispersed over Greece and other countries. It also examines in what manner these oracles gave their answers, the ceremonies that were observed in consulting them, the frantic emotions of the priestess Pythia on her tripod; and those of other priests. It then endeavours to determine, if there ever were in fact any Sibyls, which, whatever has been said, is still very doubtful: it draws, however, from all the sources of antiquity, a kind of history of these Sibyls, and of their prophecies. It next passes to the examination of the nature of auguries, auspices, haruspices, prefages, prodigies, and phenomena, of expiations and abolutions, of the magic and astrology of the ancients, &c. Whoever has thoroughly studied all these objects, is fully provided with the preliminary knowledge that is necessary to enable him to proceed steadily and securely through the darkness of ancient mythology, and he may thereby advance more confidently to the examination of the nature of the pagan divinities themselves.

The celebrated treatise of Cicero De natura Deorum will here furnish great lights: but modern authors who have treated on these matters, have not been contented with this alone: they have, to our eye, extracted the essence of all antiquity, of which they have formed systems; but unskilfully scarce ever agree with each other. As philosophers, it is of very little importance for us to know what was the nature of these gods, seeing we know that they were merely fabulous: but as historians and antiquaries, it concerns us to know what was the nature that was attributed to them in general; and, in particular, what were the origin, genealogy, rank, functions, authority, and operations, that were attributed to each divinity; and it is on these matters that we have still some remarks to make.

The gods of the ancient Greeks and Romans were all either Dii majorum gentium, or Dii minorum gentium; that is, of the first or second order. The former were all called consentes, magni consiltores, &c. According to Ennius they were twelve in number, and are included in these verses:

Juno, Vesta, Minerva, Ceres, Diana, Venus, Mars, Mercurius, Jovis, Neptunus, Vulcanus, Apollo.

To these were added eight others under the title of dei latiri, which were Sol, Luna, Tellus, Genius, Janus, Saturnus, Liber, and Pluto. The second order, or minorum gentium, were called Adepti, Memoximi, Minufeciarii, Putatitii, Indigetes, Semones, &c. the principal of which were Aëliculapius, Bacchus, Calfor, Fauna, Hercules.
According to the second division, all their deities were classified into:

1. Celestial gods.
2. Terrestrial gods.
3. Sea gods.
4. The Infernal deities, or inferi.
5. The Pales, Pan, Pomona, Priapus, the Satyrs, Silenus, Silenus, the god Terminus, Vesta or Rhea, Bercynthia, Vulcan, Harpocrates, &c.
6. The sea-gods were Neptune, Amphitrite, Thetis, Canopus, Gaucus, Ino, the Nereids, Nereus, Oceanus, Paolon, Triton, &c.
7. The inferior gods were Pluto, Proserpine, Charon, Minos, Aeacus, Rhadamantus, the Furies, Death, Night, the Fates, Plutus, &c.
8. The third division ranged the deities according as they presided over:
   a. Over the pregnancy of women (Pregnantia).
   b. At parturitions (Parturienti).
   c. At births (Nascientium).
   d. At adulteries.
   e. At marriages.
   f. To which they added, Dii morales, or moral gods.
   g. Funeral gods.
   h. The gods of parturition, Juno, Lucina, Diana, Egerio, Profa, Poltvera, Menagenata, Latona, the gods that were called Nixi, or of labour, &c.
9. The gods of birth were Janus, Opis, Nacion, Cunia, Carmenta, Vagina, Ruma, Rumia, Potina, Educa, Ollago, Carnea, Nundina, Statilinus, Fabulius, Paventia, &c.
10. The gods of adultery were Juvenus, Agenoria, Streuna, Stimula, Horta, Quius, Murcia, Adeona, Aboena, Volupra, Orbena, Pellonia, Numeria, Camocna, Sentia, Angerca, Heres, Martea, Laverna, the god Averruncus, Confus, Catus, Volumnus and Volumna, Honorius, Aius Locuti, &c.
11. The nuptial gods were Diana, Domiduca, Domitius, Hymenzeus or Hymen, Jugatimis, Jupiter perfectus, Juno perfecta, Juno cynthia, Juna unxia, Lucina, Mantutia, Muinitus, Dea Mater prima, Suada, Thalaffis, Venus, &c.
12. The moral gods were called Virtus, Honus, Fides, Spec, Justitia, Pietas, Misericordia, Clementia, Publicitia, Veritas, Mens, Concordia, Pax, Salus, Felicitas, Libertas, Pecunia, Ritus, Invidia, Contumelia, Impudentia, Calumnia, Frans, Difcordia, Furor, Fama, Fortuna, with all their epithets good or bad, Febulis, Pavor and Palor, Pauperitas, Nesperitas, Tempelitas, Silentium, &c.
13. The funeral gods were Pluto, Libitina, Nenia, Death, the Fates, &c.

Hermod indeed pretends that all these gods derived their origin from chaos; but we have already pointed out more just sources. It is almost incredible to what a prodigious number the superflitious and weakens of the Greeks and Romans multiplied these deities; there have been thirty thousand of them enumerated. It will not be expected that we should here attempt to describe them, nor will it be remarkable if we have forgotten to mention even some of the first rank: Although, vail as this company of gods is, mythology does not omit to trace the history of the greatest part of them, as is taught by paganism; and they who are defirous of particular information in these matters may consult with advantage the theogony of Hesiod, the catalogue of Apollodorus, the metamorphoses of Ovid, the fables of Hyginus, Lylif Gregorii Gyraldi Synthagma de Dios Gentilium, the mythology of Natalis Comes, the books of Gerard Volius de Idolatria Gentilium, Johannes Boccattii Genealogia Deorum, the Pantheon of Pomey, the history of heaven by Abbe Pluche, the historic explanation of fables by Abbe Bannier, and numberless other works of the same kind in all languages.

There were still many other divisions, of which the pagans made use to mark the rank, the functions and nature of their several deities. For example, the gods called Vealta, or the mother of all the gods, was adored by all people in general. Mars, Bellona, Victoria, Fortunata, &c., assisted all parties. The topical gods, on the contrary, were adored in particular countries only; as Astarte in Syria, Derceto and Semiramis among the Assyrians, Isis and Osiris by the Egyptians, Quirinus at Rome, &c.

The title Semones, which was given to a certain class of deities, was doubtless derived from the Homunculi, that is, demi-men; and signified the same as semi-di or demi-gods. These were monarchs and illustrious heroes, or those great men who were the founders of cities and nations, that were deified by way of apotheosis. Pythagoras had taught the Chaldeans the doctrine of transmigration; and that, after their death, those who were virtuous would be elevated to the rank of deities. This doctrine was adopted by all the pagan world. The apotheosis, after they had erected temples and altars to the new gods, was celebrated with much solemnity. In the last ceremony, an eagle was fixed on the catafalque, or funeral pile, on which was placed the image of the hero; and when the pile began to burn, the eagle was let loose, who, mounting into the air with the flames, seemed to carry the soul of the departed hero up to heaven.

Mythology informs us also, who those persons were that antiquity regarded as the children of the gods, such as Thefeus, Hippolytus, Paris, &c.; what the pagans believed with regard to the nature of their Genii and Demons, of their Dryades, Hamadryades, Nymphs, Tritons, Sirens, Fauns, Sylvans, Centaurs, and other subaltern deities; and in this manner it explains all the systems of the positive religion of the Greeks and Romans. They who are desirous of extending their knowledge of paganism still further, of knowing the dogmas of each particular people, what were their gods, and the various manners in which they were worshipped, such as Apis, Isis, Osiris, &c., the adoration of crocodiles and onions, &c., among the Egyptians, must study the different theogonies of these people; and notwithstanding all the informations which ancient and modern authors afford, this study is yet bountiful, and attended with many difficulties and uncertainties. Though it appears demonstrative, that the origin of paganism, and of idolatry in general, was derived from the Chaldeans, from whom the Egyptians drew that doctrine which they after transmitted to all other nations; and consequently that the primordial divinities were the same, under different denominations, among all the Idolatrous nations of the earth.

The nature of this work will not permit us to descend to further particulars. But to give our readers an idea...
of the manner in which mythology treats its subjects, and of the method that should be observed in studying fable, or the history of the gods of antiquity, which we shall here give, by way of example, a carftory description of Parnassus and its inhabitants.

Parnassus was a mountain of Phoebis, that had two summits, one of which was called Tithorea, and the other Hyampeus. Others say, that one of these hills was named Helicon, and the other Cytheron; and that it is an error to imagine, that Helicon was a mountain of Boreas. However be that, this double hill was consecrated to Apollo and the Muses, who there held their usual residence. According to fable, there had been a remarkable combat on this hill, between Helicon and Cytheron. Whoever slept on Parnassus, when he waked, became a poet. Apollo had there a temple. There also was the fountain Caflalia, into which Apollo had metamorphosed a nymph that he loved, and had given to its waters the power of making all who drank of them poets. At the foot of Parnassus flowed the river Hippocrene, that had the fame virtue; and the source of which was opened by a stroke of the foot of the horse Pegafus. This river nourished a great number of swans, that were regarded as sacred. Pegasus was a winged horse, that belonged to Apollo, and grazed on the summits of Parnassus. He sprang from the blood of Medufa, when Perseus cut off her head, which was placed among the stars. Such was the delicious abode of Apollo, the fon of Jupiter and Latona, who was born, with his twin sister Diana, in the island Delos. He killed the Cyclopes, who forged the thunderbolts which Jupiter had overthrown his son, Eclathapius; but for that presumption, he was forced to leave heaven, and become an inhabitant of the earth. He guarded the oxen of Admetus; he aided Neptune to build the walls of Troy, and Alcmeius in forming the labyrinth. He killed the dragon or serpent Python. He invented music and physic; and was honoured as the god of poets and physicians. He was represented as a young man without a beard, his head surrounded with rays, and bearing in his hand a bow, or a lyre. As the ancients denoted the sun by the name of Apollo, they sometimes represented him also as seated in a chariot, drawn by two white horses, preceded by Aurora and the star Venus: Phaeton his son, being desirous of conducing these horses, was thrown into the sea. Apollo was also called Phæbus, Titan, and Sol. He is known to have had amours with Ares, Cybele, Μελενη, Μυλνεα, Μανθο, Μινος, Κυλλοπε, and others; by whom he had Delphæ, Naxæ, Miletus, Arcæ, Garamas, Sirus, Linus, Orpheus, and other children. He had peculiar honours paid him in the Pythian games at Delphos, and in the secular games at Rome.

The Muses were the companions of Apollo in his rural abode. They were likewise called the learned sibyls; as also the Cinaeis, Heliocinon, Parnassian, Aonian, Pierian, Pegasean, Aganippian, Theopian, Libethrian, and Caflalian sibyls. They were the daughters of Jupiter and Mnemosyne, and were regarded as the goddesses of sciences and arts in general. There were nine of these Muses; to whom they attributed, 1. to Clio, history, 2. to Melpomene, tragedy, 3. to Thalia, comedy, 4. to Euterpe, flutes and other pneumatic instruments of music, 5. to Terpsichore, the harp and the dance, 6. to Erato, the lyre and the lute, 7. to Calliope, heroic verse, 8. to Urania, astronomy, and 9. to Polyhymnia, rhetoric and eloquence. The Graces also sometimes quitted Venus to pay their court to Apollo.

Such was the idea they entertained of Parnassus and its inhabitants. There is no doubt but that, under these fabulous representations, these sensible images, were concealed allegoric and moral meanings; nor can it be denied but that their method of cultivating the arts and sciences, by this manner of expressing their ideas, was as ingenious and pleasing as it is possible to imagine. Every other subject that paganism embraced, it treated with the same genius, and in a manner equally pleasing; and though that religion was altogether fallacious, yet we must allow that it was extremely well calculated to promote the polite arts, by those refined, noble, graceful, brilliant images, by those charming subjects, which it constantly prefented, and which it still offers to the poet, painter, sculptor, and every other artificer.
