**Annual Epidemiological Reports:**

Much of the epidemiological statistics received currently being necessarily of a provisional character, revised returns are received at the end of each year from the various national health services and are published for permanent record in these reports. The 1923 and 1924 reports contain only statistics for countries as a whole, the 1925 report for large towns also. These reports contain a detailed review of the more important developments throughout the world of each of the notifiable diseases.

	Price
No. 1. Eastern Europe in 1921 (French and English texts) . . . . .	1/- \$0.20

No. 4. Epidemic Diseases in Eastern and Central Europe, January-June 1922 . . . . .	1/- \$0.20
No. 5. Epidemics in Russia since 1914. Report to the Health Committee of the League of Nations by Professor L. Tarassévitch (Moscow) Part II . . . . .	1/- \$0.20
No. 6. Epidemic Diseases in Eastern and Central Europe, May-December 1922 . . . . .	1/- \$0.20
No. 7. Statistics of Notifiable Diseases in European Countries, 1922 . . . . .	2/- \$0.40
No. 8. Statistics of Notifiable Diseases for 27 European Countries, 15 African Countries, 14 American Countries, 12 Asiatic Countries and for Australasia for the Year 1923. . . . .	2/- \$0.50
No. 9. Statistics of Notifiable Diseases for 29 European Countries, 17 African Countries, 20 American Countries, 16 Asiatic Countries and for Australasia for the Year 1924 . . . . .	3/- \$0.80
No. 10. Statistics of Notifiable Diseases in 33 European, 34 African, 24 American and 23 Asiatic Countries and Australasia for the Year 1925 . . . . .	4/- \$1.00

**Statistical Handbooks:**

These handbooks describe the system of official vital statistics and the history of its development in each country. Details are given regarding the census, population registers, registration of births, still-births and deaths, the certification of causes of deaths and the notification of contagious diseases. The principal forms in use are reproduced and the relating laws and regulations in force reviewed. The Bibliography of the official statistical reports in the respective countries is given:

	Price
No. 1. The Official Vital Statistics of the Kingdom of the Netherlands (C.H. 159) . . . . .	2/6 \$0.60
No. 2. The Official Vital Statistics of the Kingdom of Belgium (C.H. 162) . . . . .	2/6 \$0.60
No. 3. The Official Vital Statistics of England and Wales (C.H. 270) . . . . .	2/6 \$0.60
No. 4. The Official Vital Statistics of the Kingdom of Spain (C.H. 271) . . . . .	2/6 \$0.60
No. 5. The Official Vital Statistics of the Republic of Austria (C.H. 348) . . . . .	2/6 \$0.60
No. 6. The Official Vital Statistics of the Scandinavian Countries and the Baltic Republics (C.H. 428. 1926. III. 8) . .	2/6 \$0.60
No. 7. The Official Vital Statistics of the Republic of Portugal (C.H. 445. 1926. III. 9) . . . . .	2/6 \$0.60
No. 8. The Official Vital Statistics of the Republic of Czechoslovakia (C.H. 524. 1926. III. 27) . . . . .	2/6 \$0.60
No. 9. The Official Vital Statistics of the French Republic (C.H. 530. 1927. III. 2) . . . . .	4/- \$1.00
No. 10. The Official Vital Statistics of the Kingdom of Hungary (C.H. 565. 1927. III. 3) . . . . .	3/- \$0.75

**Special Statistical Studies:**

CEREBRO-SPINAL MENINGITIS IN PRUSSIA, in 1923 and 1924. Third and Final Report by Professor Dr. E. Seligmann (Berlin) (C.H. 405. 1926. III. 2.) . . . . .	1/- \$0.25
TUBERCULOSIS STATISTICS. Summary of the Report addressed by Dr. S. Rosenfeld (Vienna) to the Health Committee of the League of Nations. April 1925 (C.H. 284 (1). 1926. III. 5.) . . . . .	1/3 \$0.30

**Special Studies and Investigations:**

**Malaria Commission:**

REPORT ON ITS TOUR OF INVESTIGATION IN CERTAIN EUROPEAN COUNTRIES IN 1924. (C.H. 273.) . . . . .	6/9 \$1.60
REPORTS ON THE TOUR OF INVESTIGATION OF THE MALARIA COMMISSION IN PALESTINE IN 1925. (C.H./Malaria/52) . . . . .	3/- \$0.70
REPORT ON THE FIRST RESULTS OF LABORATORY WORK ON MALARIA IN ENGLAND, by S. P. James, M.D., assisted by P. G. Shute. (C.H./Malaria/57(1). 1926. III. 6.) . . . . .	9d. \$0.25
REPORT ON THE STUDY TOUR OF THE MALARIA COMMISSION IN SPAIN (August 13th to September 7th, 1925) (C.H./Malaria/58(1). 1926. III. 14.) . . . . .	1/3 \$0.30
SECOND GENERAL REPORT OF THE MALARIA COMMISSION. (C.H. Malaria 73. 1927. III. 5.) . . . . .	3/- \$0.70

**Cancer Commission:**

REPORT ON THE RESULTS OF DEMOGRAPHIC INVESTIGATIONS IN CERTAIN SELECTED COUNTRIES. (C.H. 333. Vol. 1) . . . . .	8/- \$2.00
REPORT ON THE RESULTS OF CERTAIN CLINICAL ENQUIRIES relating to Differences of Cancer Mortality in Certain Selected Countries. (C.H. 333. Vol. II) . . . . .	1/9 \$0.40
CANCER COMMISSION: Considerations regarding the possible relationship of cancer to race, based on a study of anthropological and medical statistics of certain European countries, by Alfredo Nicerofo and Eugène Pittard (French and English texts). (C.H. 492. 1926. III. 24.) . . . . .	12/- \$3.00
Commission for the Study of Sleeping-Sickness and Tuberculosis in Equatorial Africa:	

INTERIM REPORT ON TUBERCULOSIS AND SLEEPING-SICKNESS IN EQUATORIAL AFRICA, by Andrew Balfour, E. van Campenhout, G. Martin and A. G. Bagshawe. (C. 8. M. 6. 1924. III.) . . . . .	4/- \$1.00
FURTHER REPORT ON TUBERCULOSIS AND SLEEPING SICKNESS IN EQUATORIAL AFRICA by Andrew Balfour, E. van Campenhout, G. Martin and A. G. Bagshawe. (C.H. 281.) . . . . .	2/- \$0.50

A General Catalogue and Special Catalogues of the documents prepared by the different Sections of the Secretariat will be sent free on application to:

PLAQUE AND CHOLERA CASES REPORTED IN THE PORTS SERVED BY THE SINGAPORE BUREAU IN 1926.

## INTRODUCTION

---

The *Fourth Annual Epidemiological Report of the Health Section* is presented in a different form from that of the previous reports. The tables were formerly arranged so as to show each country separately, but all information is now grouped according to disease. This enables the reader to obtain a better view of the situation of any particular epidemic disease, and a considerable saving of space is at the same time effected. The General Review is also relieved of a large number of tables as most of the figures upon which the comments are based can now be more easily found in the tabular annex. In view of this arrangement, which places all countries side by side, it becomes all the more necessary to warn the reader against unjustified comparison between the incidence of an epidemic disease in the various countries. There is a great difference in the efficiency of reporting from country to country, and also in each country a great difference in this efficiency between the different diseases. The information, however, is nearly always sufficiently reliable to show the secular and seasonal trend of each disease and gives for many diseases an approximate idea of their geographical distribution. The notes in the General Review will facilitate the use of the tables in this respect. The large amount of clerical work required to rearrange all the statistics has, unfortunately, delayed the issue of this report for three months. It is believed that, once established, the new arrangement of the tables will cause no delay in future years.

Information on the prevalence of notifiable diseases is now received by the Health Section from practically all countries where such information is collected. It is amplified by mortality statistics by cause for large towns throughout the world. Information on the occurrence of cases of plague, cholera, yellow fever, smallpox, typhus and any other epidemic disease which may temporarily constitute an international menace is published in the *Weekly Record* of the Health Section and, as far as the Western Pacific and Indian Oceans areas are concerned, in the *Weekly Fasciculus* of the Singapore Bureau. Statistics of cases and deaths attributed to all the more important or widespread epidemic diseases are shown in the *Monthly Epidemiological Reports* of the Health Section, the General Review of which brings out the outstanding epidemiological features of the month. It also contains natality and mortality statistics for large towns.

The best thanks of the League of Nations Health Organisation are due to all public health administrations and statistical offices whose generous and continuous assistance makes this service possible and universal. Special thanks are due to all administrations for having once more kindly verified, at the end of the year, the statistics for their respective countries given in the tables of this report, and in particular to the British Ministry of Health, the French Colonial Office and the United States Public Health Service for having kindly verified the information for British, French and American colonies respectively.

Geneva, October 21st, 1927.

---

DISTRIBUTION OF PLAGUE THROUGHOUT THE WORLD IN 1926.

## GENERAL REVIEW.

### PLAQUE.

Plague was on the whole more prevalent in 1926 than in 1925. The increase, which occurred in many countries and which was most marked in Northern India, appears to have been a temporary one, similar to those increases of incidence which take place with some years' interval in the case of most epidemic diseases; there was no spread of infection during the year to uninfected countries. The exceptionally low incidence in most plague centres during the first half of 1927 confirms the evidence given by statistics for the last ten years or so that, generally speaking, plague is diminishing. The few countries which form an exception to this rule have all been infected at a comparatively recent date (Madagascar, Southern Nigeria, Tunis).

The plague situation was comparatively favourable in 1926 in the eastern Mediterranean. In *Egypt*, there were 154 cases, which is the lowest figure on record since 1900 with the exception of 1925, when there were only 138 cases. Of these cases, 23 occurred at Sidi-Barrani, near the Tripolis frontier, far from the Nile valley. There were 18 cases at Suez and 8 at Alexandria, but no case of human plague was reported at Port Said for the first time for many years. The remainder of the cases were almost evenly divided between Lower and Upper Egypt. The case mortality rate for the whole country was 48 per cent, which is about normal for Egypt. Four cases which were described as pneumonic and 32 as septicæmic were all fatal.

There was no plague in *Palestine* in 1926. Seven cases were reported at Beirut in *Syria*, which is less than in previous years. No report was received from *Turkey*, but the Sanitary Maritime and Quarantine Council of Egypt received information about 15 plague cases between May and October at Constantinople. It appears that Adalia was also infected.

Twenty-seven cases were reported in *Greece*, which is less than in previous years; 8 of these occurred at Patras, 4 at Piraeus and 8 in Crete (Heracleion, Lassithion and Canea).

Plague was far more prevalent in *Tunis* in 1926 than it has ever been before; 424 cases were reported, as compared with from 6 to 31 in each of the four preceding years. The first outbreak took place in the district of Kairwan in May and June, the second in the district of Sfax in November and December. The cases occurred in the following districts: Kairwan 164, Sfax 226, Susa 25, Kef 2, Tunis 1, Military Territories 6.

Fifty-six plague cases were reported in *Algeria* in 1926; this figure has been exceeded only twice since the reintroduction of plague into the country in 1899, namely, in 1907 (57 cases) and in 1921 (203 cases). In 1921, however, 185 cases were reported in one inland locality (Aumale) and only 18 cases in two ports. In 1926, there were 43 cases at Oran, 4 at Algiers, 2 at Philippeville and 1 at Bone. The first case occurred at Algiers in June, and at Oran in September; the outbreak reached a maximum at the end of November.

Sporadic cases of plague occurred as usual in the *Azores* and the *Canaries*. Reports have not been received from *Portugal*, where there was plague at *Lisbon* at any rate up to 1924. It appears from information obtained by the Office international d'hygiène publique that there were in fact 3 cases at Lisbon in December.

*England* was free from cases of human plague between 1921 and 1925, but in August 1926 two locally contracted cases of the bubonic type occurred at Liverpool. In *France*, a few cases occurred among the ragpickers in a suburb of Paris. In the *U.S.S.R.*, plague was reported, as usual, in the Steppes on the confines of Asia, in the Governments of Astrakan and Ural-Bukajev, in the Cossack Republic and some districts of Northern Caucasus. A few cases were reported also in the Trans-Baikal Government. There were altogether 179 cases, as compared with 257 in the previous year.

Plague was more prevalent in *Senegal* in 1926 than during the previous year: 837 cases were reported, as compared with 402 in 1925. The maximum occurred in June and July. The infected area comprised the hinterland of Dakar, i.e., the districts of Rufisque, Thies, Tivaouane, Diurbel and Kaolak. The reported case-mortality rate was 57.8 per cent, which is practically the same as during the two previous years, when it was

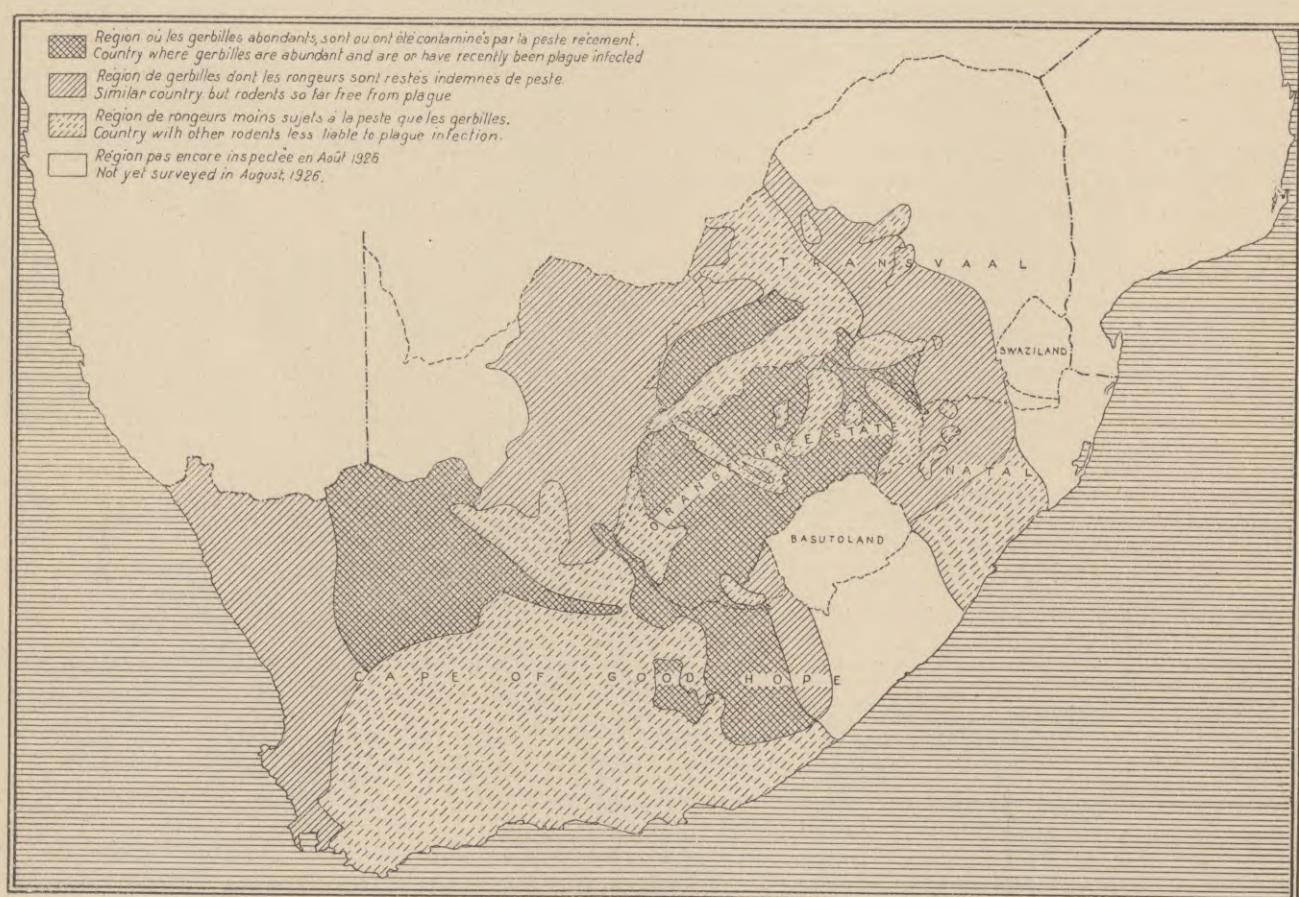

58.5 and 58.3 per cent respectively. Plague was introduced into Dakar in 1914, where it caused 1,425 deaths in the town (26,000 inhabitants), 490 in the suburbs and 479 in other districts of Senegal. The following year only 137 cases were reported, and there was apparently no human case in 1916. The disease appeared again in 1917 in the provinces; but not at Dakar until 1919. A maximum was reached in 1920, when 14,935 cases were reported in the whole colony. There was apparently no human case at Dakar from 1923 to 1926, but the disease remained prevalent in several rural districts, among which Cayor was most severely infected. A very serious outbreak occurred at St. Louis in 1918, but no human case was reported from 1921 to 1926.

Plague has spread rapidly in *Southern Nigeria* since its introduction in 1923, but only two provinces, Lagos and Ijebu, have so far been infected. There were 5 cases in 1923, 414 in 1924, 653 in 1925 and 1,402 in 1926; among the cases for which localities of occurrence are given in 1926, 491 were at Lagos and 697 in the province of Ijebu. The reported case-mortality was excessively high, 90.1 per cent; it was 75.2 and 83.1 per cent respectively in 1925 and 1924. The seasonal maximum occurred in September and October.

No plague case has been reported in the *Gold Coast Colony* since April 1925.

Fifty-one plague cases were reported in *Angola* in 1926, of which 10 were at Porto Alexandre, south of Mossamedes, 20 at Cavaco in the Benguela district and 21 at Botomono, a village in the district of Cuanza Norte. All the cases occurred during the last three months of the year. Plague appears to have decreased markedly in Angola since 1922, when 636 cases were reported.

#### SURVEY OF PLAGUE AMONG WILD RODENTS IN THE UNION OF SOUTH AFRICA IN 1926.

The plague problem in the *Union of South Africa* is closely connected with infection existing among gerbilles and other rodents of the veld. A very careful survey of these rodents which was made by the Public Health Service of the Union shows that the rodents are or have been infected in nearly the whole of the Orange Free State as well as in the adjoining districts of the Cape Colony and a few districts in the Transvaal. There was an extension westward of the infected area in 1926 in the northern districts of the Cape Colony, which is fortunately the least densely populated part of the province. The above map, which is reproduced from a report on plague made by the Chief Health Officer of the Union, shows the situation as determined by surveys up to August, 1926.

According to this report plague appeared for the first time in the country in 1899, and the first serious epidemics followed from 1901 to 1905, during which period 1,673 human cases were reported. The infection was believed to have been introduced from South America. Human cases became more rare in the following years;

a local outbreak was reported in 1907 and another in 1912. From 1914 to 1918 and again from 1920 to 1923, there were serious outbreaks on the veld, but cases were not very numerous. In 1924, the epidemic became more widespread and 400 cases were reported. In 1925, there were 70 cases, and in 1926 there were 101 cases, of which 57 were in the Orange Free State and 44 in the Cape Province. Twenty-seven of these cases were among the white and 74 among the coloured population. The case-mortality was 89 per cent among white and 59.5 per cent among coloured people. It is most unusual that the case-mortality should be so high among cases of European race; it was 50 per cent among white and 60 per cent among coloured in 1925, and 49 per cent among white and 66 per cent among coloured cases in 1924. From 1899 to 1926, altogether 509 cases and 195 deaths were reported among the white and 2,097 cases and 1,338 deaths among the coloured population, giving a reported case-mortality rate of 38.3 per cent for the former and 63.8 per cent for the latter.

The incidence of plague in *Madagascar* was higher in 1926 than in any previous year. The disease has never ceased to spread since its introduction to the island in 1921. The majority of the 2,175 cases reported occurred as usual in the province of Antananarivo (1,461 cases) outside the town itself, in which there were 156 cases. A number of localities elsewhere in Madagascar are now also infected; there were 49 cases at Tamatave, which is the seaport for Antananarivo on the east coast, 65 at Itassy and 99 at Majunga, both ports on the north-western coast, and 199 cases at Moramanga and 5 at Fort-Dauphin, ports on the south-east coast. In six inland towns in various parts of the island from 1 to 58 cases were reported. Over 90 per cent of the reported cases were fatal.

Forty-five plague cases were reported at *Mauritius*, mostly at Port-Louis, in 1926. This is the lowest return since 1920, when there was no human case. The reported case-mortality rate is very high; it averaged 87 per cent for the years 1923-26. Plague was introduced into St. Denis on *Reunion* in May 1926, and an outbreak followed later in the year; 31 cases were reported in 1926 and 12 in January 1927, after which date the outbreak ceased.

Half as many (530) plague cases were reported in *Kenya* in 1926 as in 1925; there were 39 cases at Nairobi. The port of Mombasa was free from plague, but 9 cases were reported at Kisumu, which is the terminus of the main railway line on Lake Victoria. A very intensive rat-destruction campaign has been carried on for several years in the Kavirondo district east of the lake.

Plague is very prevalent also in the districts of *Uganda* bordering on Lake Victoria; 1,886 cases were reported in 1926, as compared with 947 the previous year. There were 46 cases at Kampala and 66 and 1 respectively at Jinja and Entebbe, the two principal Uganda ports on the lake. The reported case-mortality rate is extremely high (85 per cent in 1926). No plague case was reported in 1926 from the *Tanganyika Territory*.

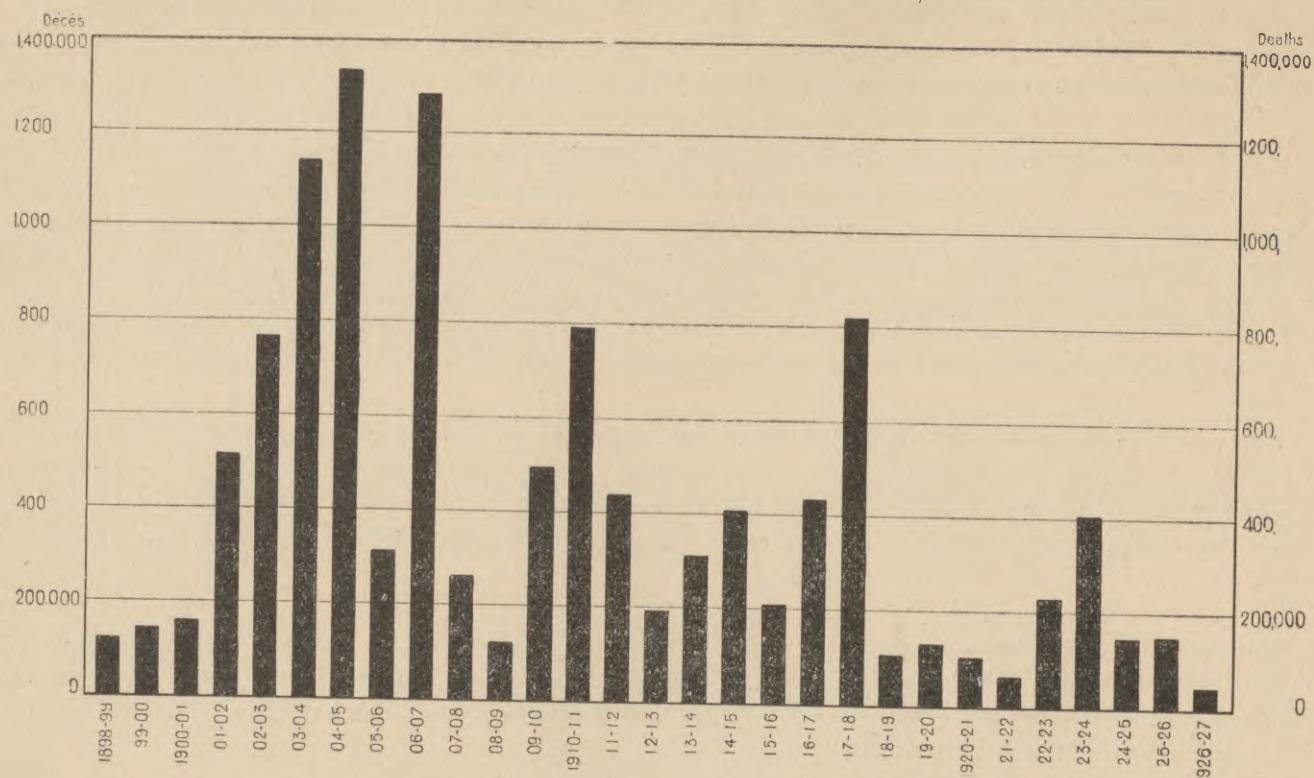

In *Iraq*, where only 20 cases were reported in 1925, plague was again more prevalent in 1926; 434 cases were reported during the year, which nevertheless shows a lower incidence than during the years 1922 to 1924. Most cases were reported at Baghdad (351). There were 22 cases in the province of Baghdad and 55 at Hillah, on the Euphrates. The remainder of the cases occurred sporadically in other provinces. Basrah was free from plague during the year. The case-mortality was 57 per cent.

The incidence of plague in *India* is always at its lowest at the end of June or early in July, and the statistics of plague cases and deaths are therefore usually compiled for plague years ending June 30th. The plague year 1925-26 was on the whole favourable as compared with previous years, except for an outbreak in the Punjab; 1926-27 was the most favourable year since the reintroduction of plague in India thirty years ago. The diagram on next page shows clearly that there is a general downward trend of plague incidence in India, although serious outbreaks, as in 1924, are still apt to occur.

Up to January 1926, the incidence of plague in northern India was only half as high as in the previous year. The rainfall, which had been deficient during the previous months, exceeded the normal in the United Provinces and the Eastern Punjab in February and March, which favoured the extension of plague. The incidence rose rapidly to more than double that of 1925, but remained below the outbreak of 1924. The centre of the epidemic was in the districts of Rohtak, Karnal, Hissar, Gurgaon, Ambala and the native states of Patiala, Jind and Nabha, which together form a compact area west of the Jumna river. The two first-named were the most severely infected. Fully one-half of the deaths reported in the United Provinces occurred in the districts of Ghazipur and Azamgarh. The number of plague deaths reported in the United Provinces did not increase between the middle of February and the middle of March, but a new increase, involving both the eastern and western plague centres, followed early in April. More plague deaths were reported in the United Provinces in April

than in March, a most unusual occurrence, which has taken place only once before, namely, in the exceptionally severe outbreak of 1907. In May, there were serious outbreaks in Northern Punjab, especially at Amritsar and Guyrat and in the Peshawar districts of the North-Western Frontier Province.

DEATHS FROM PLAGUE IN INDIA FOR YEARS ENDED JUNE 30th, FROM 1898 TO 1927.

DEATHS FROM PLAGUE IN INDIA, BY PROVINCES, 1921-27.

Provinces	Annual Average

In 1926-27, the plague situation was favourable in the whole of India and the incidence was much below the normal in the United Provinces and Punjab. The rainfall for the four months from November 1926 to February 1927 was slightly above the normal in Bihar, but from 21 to 71 per cent less than the normal in the various Punjab and United Provinces districts. The rainfall is the explanation of the greater prevalence of plague in the eastern districts of the United Provinces and the adjoining part of Bihar than in the usual centres of highest prevalence in the Punjab and in the western part of the United Provinces. The number of cases reported had already begun to decrease in the Punjab in the third week of April, and for this reason May and June returns became much lower than in any previous year. During the two four-week periods ended May 21st and June 18th, 1927, there were 3,160 and 722 deaths respectively in the whole of India, as compared with 30,069 and 11,129 deaths during the corresponding periods of the previous year.

Plague was much less prevalent in *Ceylon* than in any year since its introduction in 1913; only 16 cases were reported, as compared with 65, 453 and 230 respectively in 1925, 1924 and 1923. Twelve of these cases occurred in Colombo. Fewer cases (7) were reported at *Singapore* than during any year since 1913 and none elsewhere in the *Malacca Peninsula*.

Fewer plague cases were reported in 1926 than in 1925 in *Siam*; 81 of the 111 cases reported during the whole year occurred from January to March. The reported case-mortality rate was 69 per cent. Thirty-six of these cases occurred at Bangkok. Plague was introduced to Siam in 1904 and has persisted ever since in a few localities, but there have never been important epidemics.

The incidence of plague in *French Indo-China* was lower in 1926 than in any year since its introduction early in the century. Of 136 cases reported, 69 were in Cochin-China, 60 in Cambodia and 7 in Annam.

Tonkin has been free from plague for several years. 3,780 deaths from plague were reported in 1913 in the whole country when the incidence was at its maximum. Epidemics comparable to those from which India have suffered have never occurred in French Indo-China. *Kwang-Chow-Wan* was, as usual, badly infected (106 cases), though less than in the previous two years.

In *Java*, plague continued its gradual movement westwards; very few cases occurred in Eastern Java including Madium, which was the part of the island visited by the first epidemic of 1911-16; the disease has nearly disappeared from Samarang, and its incidence was reduced to less than one-fifth of that of 1925, in Surakarta, these being the two next provinces west of the area so far non-infected. Surakarta was last year the most severely infected province in Java. The decrease was smaller in provinces farther to the west, and in Kedu and Pekalongan there was a small increase. The two westernmost provinces, Batavia and Bantam, remained free from plague. There were 14 plague cases at Macassar, on the island of *Celebes*, as compared with 11 the previous year. There was no plague elsewhere in the Dutch East Indies.

#### MORTALITY FROM PLAGUE IN JAVA IN 1926.

In *China*, plague is endemic in the provinces of Kwangtung and Fukien, which include the southern coast to about 100 miles north of the Formosa Strait. In Fukien, which is the more northern of the two, and where Amoy and Foocho were the principal towns, both human and rat plague were prevalent throughout the year 1926 and were epidemic from May to July. In Kwangtung, the capital of which is Canton, plague was epidemic from March to May; it was not reported present after June. Plague was reported to be prevalent in October in the province of Anhwei, on the middle Yangtze. It is uncertain whether plague was present in other provinces, but it has, at any rate, not been very common elsewhere in China. Among the ports reporting to the Singapore Bureau, Amoy reported 112 plague cases, all from May to August. No plague case was reported at *Shanghai*; in 1925 there was one case, and in 1924 two cases. *Hong-Kong*, which was infected without interruption from 1894 to 1923, has remained free from plague during the last three years.

It appears that plague was prevalent in *Mongolia* in November, especially in the districts between Che-Chen-Han and Sanpeitzu, on the caravan route from Manchouli to Urga, but the particulars obtained are uncertain. Plague does not seem to have been prevalent in *Manchuria* in 1926.

Eight plague cases were reported in *Japan* in 1926, of which 6 were at Yokohama.

Plague was more prevalent in *Peru* than usual in 1926; 4,200 cases were reported during the year, while in the previous fifteen years the number varied between 400 and 900. The coastal plain is more or less infected from the Ecuador frontier in the north to the Chilian frontier in the south, while the mountain districts and the area beyond the Andes have remained free with the exception of the province of Cajamarca, in the mountains of northern Peru, where the Andes are lower. Plague infection in Peru dates from 1903, but has never given rise to very severe epidemics among human beings similar to those in India or even in Senegal. The same observation may be made for other plague-infected areas of South America. The case-mortality rate was, as usual, relatively low, 45 per cent. The seasonal maximum occurred in January.

Forty-nine plague cases were reported in *Ecuador* in 1926, all at Guayaquil, as compared with between 120 and 150 cases during each of the three previous years. The incidence was highest in January. It is remarkable that there should be so relatively few human cases in view of the very heavy infection in the rats in the town which are extremely numerous. The number of infected rats found was higher early in the year than at any time during the three preceding years (234, 172, 137, 100 and 35 infected rats during the first five months of the year, respectively, out of about 20,000 rats examined per month).

Endemic centres of plague now exist in various inland localities of the *Argentine Republic*, notably in the provinces of Cordoba and Santa Fé, as well as in the province of Salta and the territory of Chaco in the extreme north of the country. Human cases have hitherto been very few.

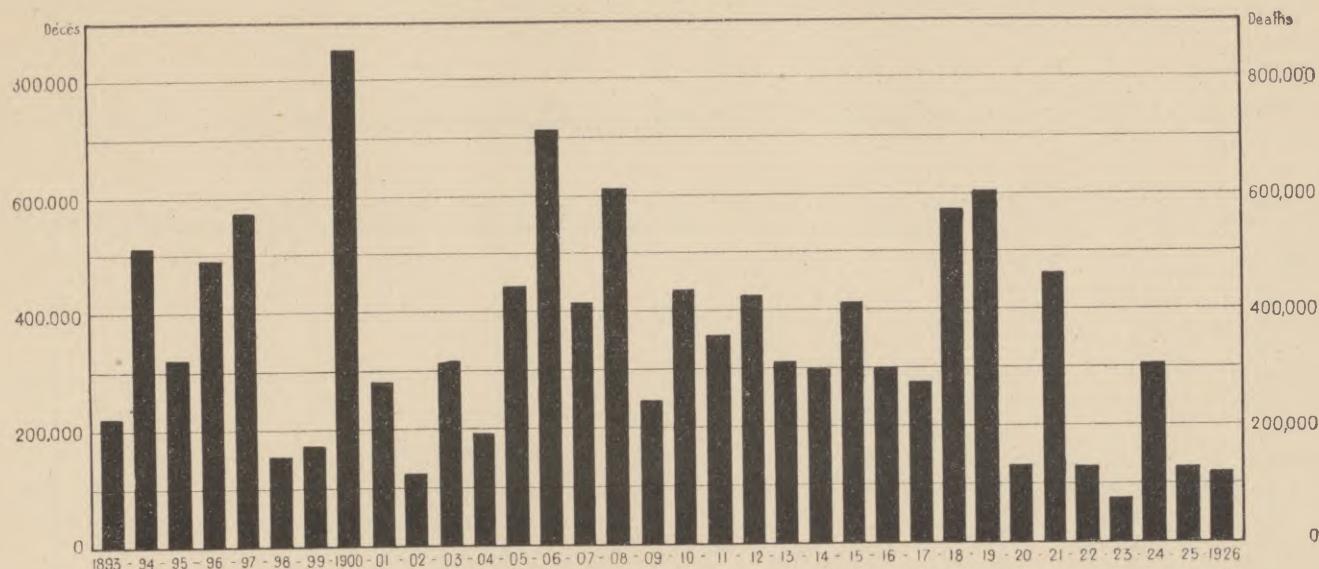

Sporadic plague cases were, as usual, reported at various maritime towns in *Brazil*: 3 cases in January at Bahia, 3 cases in November and December at Rio de Janeiro, 9 cases at São Paulo, 11 deaths in October at Paranagua, 13 deaths at Rio Grande and 1 case at Porto Alegre.

#### CHOLERA.

The geographical distribution of cholera in 1926 was similar to that of the previous year; comparative quiescence in its main centres in India, marked extension in various countries farther east, and complete absence of the disease west of India. It must be said, however, that India, even in the best years, for a long period has had more deaths from cholera than the rest of the world together. This was undoubtedly also the case in 1926, though statistical information for China is fragmentary.

In *India*, there were 127,210 deaths from cholera in 1925; provisional returns for 1926 gave 72,859 deaths attributed to this disease, but this figure will undoubtedly be increased to somewhat over 100,000 in the final returns. This large total is, however, far below that reported in epidemic years, such as 1918, 1919, 1921 and 1924, for each of which years India's death-roll from cholera was between 300,000 and 600,000. From 1905 to 1916, the annual number of deaths attributed to cholera never fell below about 300,000.

## DEATHS FROM CHOLERA IN INDIA FROM 1893 TO 1926.

The geographical distribution of the disease was characterised in 1926 by the almost complete disappearance of cholera from north-western India, its stationary situation in the important centres of the Lower Ganges plain, a marked improvement in Madras Presidency and a slight increase in Burmah and the Central Provinces. The disease seems to have entirely disappeared in Northern Kashmir, where there was a very severe epidemic in 1925. Only 83 deaths from cholera were reported in the Punjab and 54 in Bombay Presidency. Cholera seems in recent times to have an increased tendency to disappear in these areas in non-epidemic years, and there is some evidence that the movement of cholera in the United Provinces is beginning to follow the same course. In only three of the ten years from 1912 to 1921 did the number of deaths from cholera in the United Provinces fall below 30,000 and only once below 10,000. Between 1922 and 1926 it was in four years below 10,000 and in two years below 3,000. Bombay Presidency was for the second year almost free from cholera, a fact which may have some relation to its absence in the Near East. The incidence of cholera reached its maximum for the whole of India early in April; the August increase was slight.

<sup>1</sup> Provisional returns.

The cholera outbreak in *Siam*, which began in October 1925 at Bangkok, subsequent to introduction of infection from Swatow, and which caused over 3,000 cases with more than 2,000 deaths in November and December of that year, continued to spread in 1926. A temporary decrease in January and February was followed by a sharp increase in March; the maximum was reached in May, but it was only in October that the

incidence returned to a more normal level. During the year, 10,655 cases were reported, which is far in excess of the record for previous years with the exception of 1919, when 14,574 cases were reported. At Bangkok there were 540 cholera cases during the two last months of 1925 and 2,787 in 1926; the reported case-mortality rate was 57 per cent at Bangkok.

CHOLERA CASES REPORTED IN SIAM AND IN FRENCH INDO-CHINA FROM OCTOBER 1925 TO JULY 1927.

Cholera, which had been unusually rare in *French Indo-China* during the three previous years, appeared in January 1926 in Cambodia, the infection having probably been imported from Siam, where the epidemic began two or three months earlier. A severe outbreak followed, which soon spread to the whole Mekong valley, including Cochin-China and southern Laos. The maximum was passed in March in Cambodia, in April in Laos and in May in Cochin-China. This first epidemic in the Mekong valley coincided generally with the second wave in Siam. In May, cholera appeared in Tonkin and in June in Annam; the first outbreaks in the last two provinces, which lasted to September or October, did not spread so rapidly as in the first province infected. A second and more severe outbreak followed in Tonkin in November and December. In the whole of French Indo-China, 19,029 cases and 13,925 deaths were reported in 1926; the greatest number of cases previously reported was 15,183 in 1912. The epidemic became even more severe in Tonkin the following year.

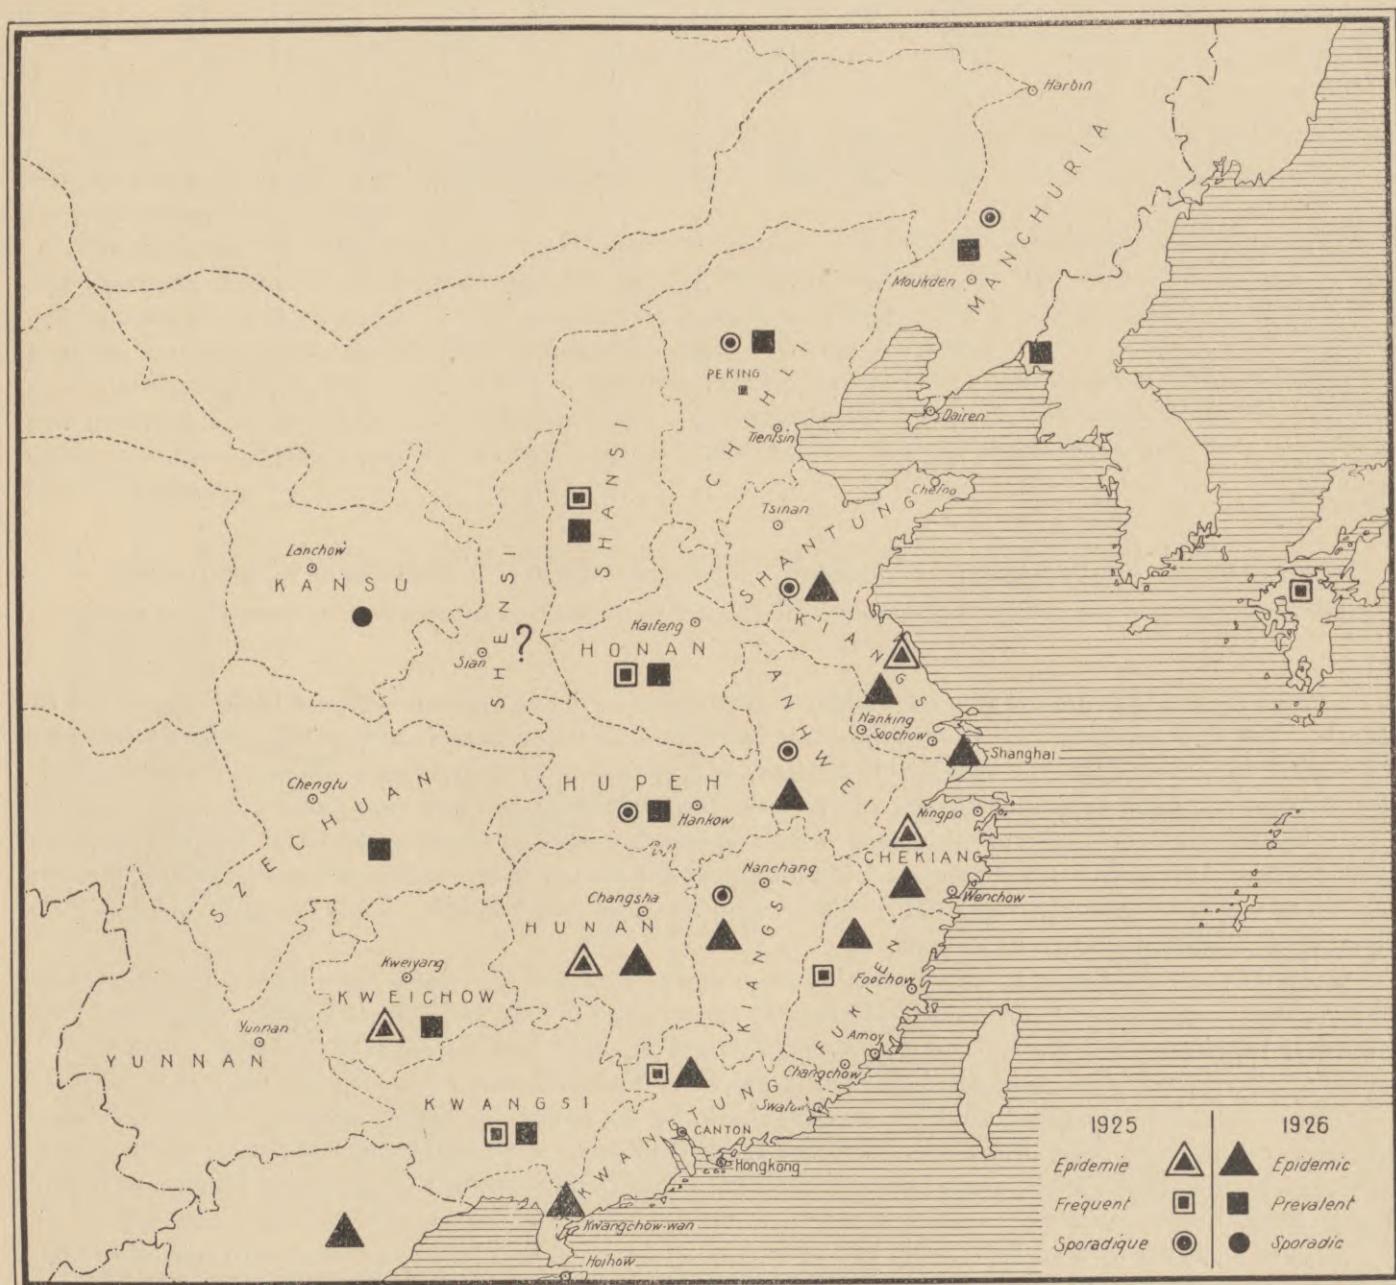

In the *Philippine Islands*, 690 cases were reported in 1926, as compared with 1,059 the previous year. These cases nearly all occurred during the first three months of the year and represented the continuation of the epidemic which began at Manila and the surrounding provinces in October 1925. Most of the cases occurred in the provinces of Pampanga and Rizal on the Manila Bay, and in the islands of Mindoro and Romblon south of Luzon Island. There were also a few sporadic cases in the neighbouring provinces and islands but no general epidemic. There were only 13 cases at Manila, as compared with 367 the previous year. The reported case-mortality rate was 55.5 in 1925 and 58.1 in 1926.

In the latter part of 1926, the National Epidemic Prevention Bureau at Pekin inaugurated a system of reports on the epidemic situation. These reports were sent each month on postcards by most hospitals, dispensaries and physicians practising Western medicine in *China*. Though figures are not yet obtainable, these reports, which are received with a fair regularity from all provinces of China, make it possible to give a monthly estimate of the situation of each epidemic disease in all parts of the country. The danger of epidemics in a country of close on 400 million inhabitants possessing an inadequate health service and in a state of civil war is clearly of great practical and scientific importance for the rest of the world. Formerly, very little reliable information could be obtained except from a few seaports and these reports may therefore be of great value. The reports, as shown in the table below, make it possible to give a general idea of the spread of cholera through China in 1926.

No province of China, with the possible exception of Yunnan in the extreme south-western part of the country, appears to have been entirely free from cholera in 1925. Epidemics occurred from July to September

in the provinces of Chekiang and Kiangsu, which include the coastal plains north and south of the Yangtze River, and in the inland provinces of Kweichow and Hunan, which include the country watered by the southern tributaries of the upper Yangtze. Cholera was also prevalent on the whole southern coast, *i.e.*, in the provinces of Fukien and Kwangtung.

CHOLERA SITUATION IN CHINA IN 1925 AND 1926.

In the early part of 1926, cholera was less in evidence in Southern China, but still of common occurrence in a belt stretching across the country from south of the lower Yangtze to Inner Mongolia in the north, and comprising the provinces of Chekiang, Anhwei, Honan and Shansi. In April, the disease reappeared on the southern coast (Kwangtung) and was qualified as epidemic there in June and the following three months. In July, cholera was epidemic in all coast provinces as far north as Kiangsu and in the inland provinces of Anhwei and Hunan. In August, the epidemic further increased and spread inland and also northward to Shantung, Chihi and Manchuria. The incidence decreased during the following months and in December remained moderately high only in the province of Kiangsu (west of Fukien). The westernmost provinces from the extreme north to the extreme south were much less affected by the epidemic (Shansi, Shensi, Kansu, Szechuan, Yunnan, Kweichow and Kwangsi), but sporadic cases occurred in all of them, except possibly in Yunnan.

††† Epidemic; †† Prevalent; † Sporadic; 0 Reported absent; ? Doubtful or No information.

Cholera appeared at *Shanghai* in the middle of July and gave rise to a serious outbreak in the last week of the month. The first case admitted to hospital came from the district of Chapei, and, of the total of 1,400 cases reported in July, 800 came from the Chinese territory and, of these, 520 from Chapei. It was found upon investigation that the water supply of Chapei, which comes from the Soochow Creek, was badly infected. Measures were taken for the chlorination of this supply and the epidemic decreased slowly in the latter part of August and in September. Altogether 1,440 cases and 443 deaths were reported in the International Settlement, a record which has not been exceeded since 1919. There were 33 cases and 7 deaths among foreign residents. The reported case-mortality was 31 per cent.

Epidemics occurred also in many other Chinese ports; at *Amoy*, 274 cases were reported in September and October. Serious outbreaks occurred in July at *Swatow*, and in May and July at *Hoihow*, where over 1,000 cases were reported. A severe outbreak at *Kwang-Chow-Wan*, which lasted from May to October, caused 1,437 cases and 801 deaths among a population of about 200,000. There were only three cholera cases at *Hong-Kong*.

The prevalence of cholera in Chinese ports was shown by the numerous cholera-infected vessels reported to the Singapore Bureau, most of which came from Chinese ports. Of 22 cholera-infected ships which arrived at Singapore and other Malacca ports between June 20th and October 18th, 13 came from China and 6 from Indian ports.

Cholera appeared in *Manchuria* early in August and about 1,500 deaths were attributed to this cause up to the end of September. This is the most extensive cholera epidemic in Manchuria since 1919, when it caused about 10,000 deaths. In the hospitals of Harbin 289 cholera patients were treated of which 226 were Chinese and 63 Russians; there were 51 deaths among the former and 33 among the latter, giving a case-mortality rate of 23 per cent for the Chinese and 52 per cent for the Russians. There were 19 cholera cases in the *Kwantung* Leased Territory in August and September, of which 8 were at Dairen and 2 at Port Arthur.

On September 9th, cholera appeared at Shingishufu in *Korea*, at the mouth of the Yalu river; it appears that the infection came from Antung on the Chinese side of the river. The disease spread to twelve districts of North Heian and one district in South Heian province. Extensive measures were taken by the Health Service; 267,200 doses of anti-cholera vaccine were distributed free of charge before the outbreak and 745,920 doses after the outbreak had begun. About 60 per cent of this vaccine was employed in the two infected provinces. The outbreak was brought promptly under control and the number of cases began to decrease after the tenth day of the outbreak; the last case occurred on October 11th. There were in all 252 cases and

159 deaths, giving a case-mortality rate of 63 per cent. Nineteen vibrio-carriers were found. The last important cholera outbreaks in Korea were in 1919 and 1920, when there were respectively 11,084 and 13,568 deaths.

Japan was more successful in keeping free from cholera in 1926 than in the previous year; only 26 cholera cases were reported, of which 18 were in January belonging to the 1925 epidemic. There were 16 cases in *Formosa*.

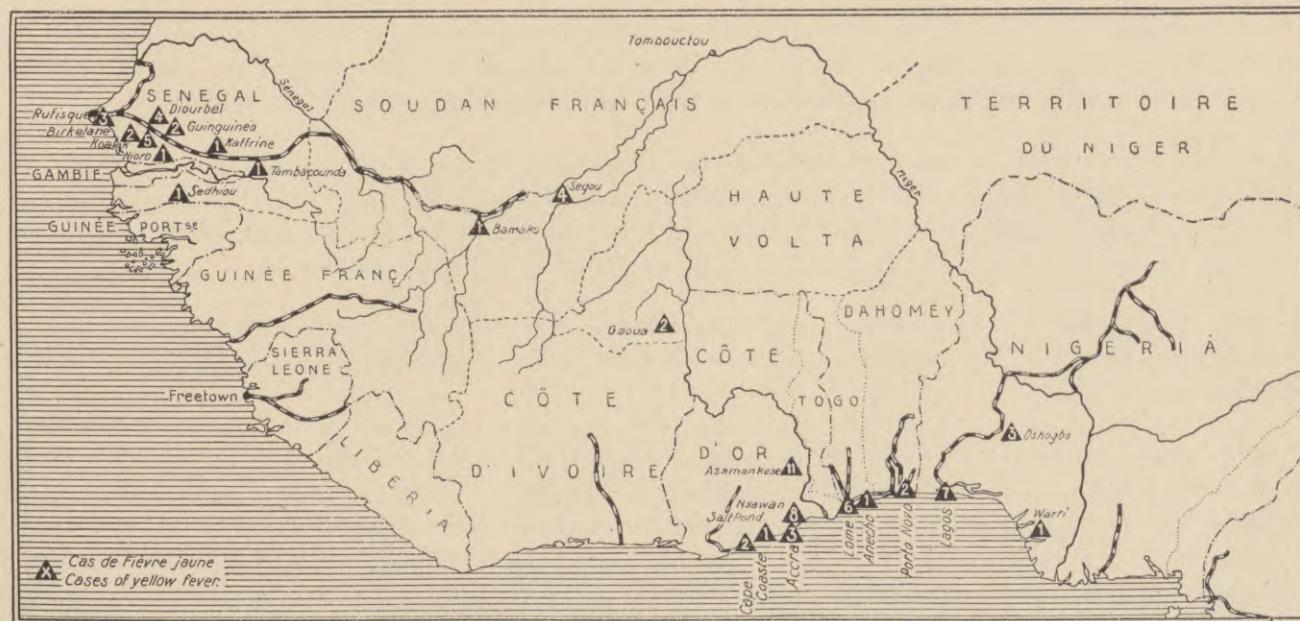

The Singapore Bureau gave prompt and reliable information regarding the movement of cholera in the ports of the Far East. The very serious exposure of maritime traffic to cholera infection in 1926 is evident from the map on page 2 and the table on page 46. The importation of a cholera case at Bangkok between October 7th and 16th, 1925, which caused 14,000 cases subsequently, shows what disastrous consequences may occur from a single imported case.

#### YELLOW FEVER.

Yellow fever, which in 1925 occurred on several points of the Guinea Coast between Monrovia in the west and Port Harcourt in the east, extended much farther north in 1926 and reached Senegal and the Niger country, where there had been no cases since 1912.

The first cases, in 1926, occurred from March to September in the *Gold Coast Colony*, mostly at Nsawam, Cape Coast and Accra, localities which had been infected the previous year. Twenty-seven cases with 13 deaths were reported. In *Nigeria*, the disease reappeared in April at Warri (1 case), in June and July at Oshogbo (3 cases), and from July to November at Lagos (7 cases); 21 cases were reported the previous year. All the cases were among Europeans, most of whom had only resided a short time in the country. None of the cases were contracted in the European residential areas. In Lagos, residence among Africans, especially near the harbour or on board ships, appears to increase the risk of infection. In September, there were 2 cases at Porto Novo in *Dahomey*.

YELLOW FEVER CASES REPORTED ON THE GUINEA COAST AND IN SENEGAL IN 1926.

The reappearance of yellow fever in *Senegal*, which occurred during the last week of October, after the arrival of a convoy of 200 Syrians, gave rise to a series of cases in widely separated localities which had not been infected for many years. Sixteen Syrians and 18 Europeans were attacked; 15 of the former and 14 of the latter died. There were further 19 suspected cases (10 Europeans and 9 Syrians), of which 12 died. All the Syrians and most of the Europeans were fresh arrivals. The first centre was in the district of Kaolak, but cases soon appeared in many localities on or near the Senegal railway; Rufisque was infected at the end of November. A case occurred at Sedhiou on the Kasamanza river, south of Gambia. On November 1st, there was a case in *French Sudan* at Bamako, which is the place where the Senegal railway joins the Niger, and several cases occurred at Segou, farther east on the same river. There were 2 cases also at Gaoua in the territory of the *Upper Volta*, near the Black Volta River.

The outbreak in French West Africa seemed to have come to an end during the first days of January, but the disease reappeared and extended in May 1927.

Several outbreaks of yellow fever occurred in *Brazil* in 1926. At Bahia 12 cases and 8 deaths were reported between May and July. In April and May, there were 41 cases at Parahyba; about 50 cases were reported in April at Natal, in the State of Rio Grande do Norte.

No yellow fever case was reported elsewhere in America.

#### SMALLPOX.

The classical type of smallpox has now become fairly rare in Europe except in the U.S.S.R., but mild smallpox continues to spread in England. Details regarding type are unfortunately not available, but it seems from mortality returns that the severe form still predominates on the Continent — at any rate, in France, southern and eastern Europe.

No case of smallpox was reported in 1926 in *Denmark, Norway, Sweden, Finland* and *Estonia*, and only 3 cases each in *Latvia* and *Lithuania*. In Central Europe, including *Germany, the Netherlands, Belgium, Luxembourg, Czechoslovakia, Austria* and *Hungary*, there were altogether 45 cases; in the Balkans and neighbouring countries, including *Roumania, the Kingdom of the Serbs, Croats and Slovenes, Bulgaria, Greece* and *Albania*, but not Turkey-in-Europe, there were 38 cases. With less than 100 cases a year of a fairly well-known disease, the gravity of which has long compelled adequate notification in most countries, in a compact area with a population of 160 millions, comprising countries endowed with modern health administrations, it should be possible to obtain very full information regarding each case. It should also be possible to locate these last sources of infection and adopt measures for their final eradication.

Only 4 smallpox cases were reported in 1926 in the *Kingdom of the Serbs, Croats and Slovenes*, where there were 1,042 cases in 1923. Only 6 cases were reported in *Roumania*, where there were 20,523 in 1919. In *Poland*, there were only 69 cases in 1926, as compared with a post-war maximum of 5,078 in 1921.

In *Switzerland*, 57 cases, of which 38 occurred in January and February, largely of the mild type, were reported. This seems to indicate the end of the extensive epidemic of mild smallpox, of which 5,440 cases were reported from 1921 to 1925, practically all in the German-speaking part of the country.

A marked reduction of the smallpox incidence has also taken place in *Italy* and in *Spain*. In *Italy*, there were 412 cases in 1926, compared with 36,365 in 1919 and 26,453 in 1920. In *Spain*, the number of deaths ascribed to smallpox decreased from 3,620 in 1919 and 1,214 in 1924 to 114 in 1926. Smallpox was, as usual, prevalent at *Lisbon* and *Oporto* in *Portugal*, but official statistics are not available.

Smallpox of severe type spread considerably in *France*, especially after September, and 554 cases were reported during the year. The case-mortality rate was 33 per cent among cases treated in the isolation hospital in Paris.

Smallpox has decreased very markedly in recent years in the *U.S.S.R.* There were 34,730 smallpox cases reported in the *Ukraine* in 1920, 3,710 in 1923 and only 278 in 1926. There has been a constant reduction of the incidence also in the remainder of the European territories of the Union since 1919, when 169,545 cases were reported, to 1926, when there were 9,946 cases. The number of deaths is unfortunately not available, and the case-mortality rate cannot be established. The incidence of smallpox is still fairly high in the eastern part of the country, while it is now quite low in the west and the centre. In 1926, there were 8,249 cases in an area formed by the *Ural*, *Viatka-Viethuga* and *Middle Volga* divisions, but only 822 in the central, south-central, western and north-western divisions, which include the great majority of the population.

The number of deaths from smallpox in Continental countries reporting both cases and deaths is so small that the case-mortality rate cannot be definitely established.

Mild smallpox continued to spread in *England* in 1926; 10,155 cases were reported, but only 18 deaths. In the case of several of these deaths it was even doubtful whether smallpox was the chief cause of death. A few cases of the severe type occurring in London were proved to have been imported from Paris. The centre of the epidemic of mild smallpox was, as in previous years, in Northern England, and cases occurred only in 14 counties, as compared with 25 counties the previous year. There were over 100 cases in the following six counties: *Durham* (6,645), *Yorkshire West Riding* (1,215), *Derbyshire* (982), *Northumberland* (843), *Nottinghamshire* (191), and *Lancashire* (139). In 1925, the following counties were most affected: *Durham* (1,438)

cases), Derbyshire (1,085), Yorkshire North Riding (934), Northumberland (711), and Nottinghamshire (599). In one urban district (Brandon and Byshottles) the incidence was as high as 3.7 per cent of the population.

The *Annual Report of the Chief Medical Officer of the Ministry of Health for 1926* states regarding the causes of this continued excessive prevalence in the county of Durham in particular:

"There was one district in that county in which all the ordinary measures necessary to limit the spread of the disease were neglected for a prolonged period, while in another neighbouring district the steps taken with this end in view were inadequate and unsatisfactory. An ill-administered district is a constant source of menace to its neighbours and to the country as a whole, as it acts as a reservoir from which the infection is liable to be carried to hitherto uninvaded areas."

The same report attributed the difficulty of control of the disease to: (1) the continued neglect of vaccination; (2) the difficulty frequently experienced in diagnosing mild cases; (3) very mild cases sometimes not seeking medical advice; (4) reluctance on the part of those exposed to infection to accept vaccination; (5) difficulty of providing sufficient accommodation for hospital isolation of the cases in the worst-infected districts.

In England and Wales, 314,325 children were vaccinated in 1926, or only 44.2 per cent of the births in the previous year; certificate of "conscientious objection" was received in 292,409 cases, or 41.2 per cent of the infants. The number of vaccinations has steadily decreased, except for 1921-24, since 1903, when 714,637, or 75.4 of the infants were vaccinated.

The table below shows clearly that vaccination conferred a complete immunity from attack for at least fourteen years. After thirty years, the amount of protection seems to be slight, cases among vaccinated outnumbering those among unvaccinated. It must be added, however, that vaccination was much more completely enforced in England forty or fifty years ago than now: in the seventies and eighties of the last century, only between 4 and 5 per cent of the children escaped vaccination. This explains the heavy excess of vaccinated over unvaccinated cases at the older ages. Only 20 cases occurred among those successfully re-vaccinated, the re-vaccination dating in all cases more than ten years back. Vaccinal condition was not known in 99 cases.

#### VACCINAL CONDITION OF CASES OF SMALLPOX IN 1926 IN ENGLAND AND WALES.

Age:	Successfully vaccinated	Unvaccin- ated <sup>1</sup>	Age	Successfully vaccinated	Unvaccin- ated

30-34 , , , , ,	125	198			
			Total	2,081	7,956

Smallpox of severe type was prevalent in North Africa in 1926 and especially so in Algeria and Egypt. In *Algeria*, 2,473 cases were reported in 1926, which is much in excess of any year since the war. The disease was most prevalent in the departments of Constantine and Algiers, where there were 1,235 and 860 cases respectively. There were 255 cases and 93 deaths from smallpox in the town of Algiers. In 1925, there were 112 deaths from smallpox at Algiers. In *Egypt*, there were 2,677 smallpox cases and 544 deaths in 1926, which is considerably in excess of any annual return between 1921 and 1925. There were 48 deaths from smallpox at Alexandria and 22 at Cairo. Smallpox was much less prevalent in *Tunis* in 1926 than in previous years: 188 cases were reported, as compared with 1,270 in 1925.

The epidemic which began on the Guinea Coast in 1925 continued, though on a less extensive scale, in 1926. Statistics for the French Colonies are incomplete, but it appears that smallpox has been more than usually prevalent in the last two years also in the districts of the *Upper Volta* and the *Niger*. There were 883 cases and 33 deaths in the *Gold Coast Colony* and 853 cases and 96 deaths in *Nigeria* in 1926. Vaccination is obli-

<sup>1</sup> Including those vaccinated during the incubation period.

gatory in the southern but not in the northern province of Nigeria. The case-mortality rate was 20.6 per cent among 257 hospitalised cases.

Smallpox has been little in evidence in the *Union of South Africa*, and the cases are usually of the mild type. In 1926, however, an outbreak of severe type occurred at Durban and vicinity, 55 cases and 16 deaths being reported. The case-mortality rate averaged, during the years 1921-25, 2 per cent (on 2,523 cases reported). This proves that the so-called Kafirpox prevails almost to exclusion of the severe form of smallpox. This appears to be the case also in *Northern* and *Southern Rhodesia*, where deaths from smallpox are rare.

Farther to the north the severe type is again met with in the *Tanganyika Territory* where an outbreak, in 1925, caused a heavy mortality. The disease was nearly absent from the territory as well as from *Kenya* and *Uganda* in 1926. A small outbreak at *Zanzibar* caused 22 deaths among 48 cases after an almost complete absence of the disease for two years. The case-mortality rate appears to be relatively low, about 5 per cent, in *Belgian Congo*, where there were 55 deaths among 1,070 cases treated in hospitals in 1925.

*Palestine* was free from smallpox and *Syria* nearly free in 1926. Smallpox was more prevalent in *Iraq* than in the two previous years, 1,221 cases being reported. The reported case-mortality rate was about 30 per cent.

Smallpox was more prevalent in *India* in 1926 than in any of the five preceding years. The death-roll will probably exceed 100,000 when final returns become available. The incidence was generally lower than in 1925 in southern India but higher in the northern provinces. The high mortality for the year was chiefly due to a very severe epidemic in *Orissa*, where the loss of life was particularly heavy in the districts of Puri and Cuttack. The case-mortality rate on the basis of reported cases is considerably higher in northern than in southern India. It is true that the records of both cases and deaths in India are frequently incomplete, but it is unlikely that the regular increase of the case-mortality rate from south to north is due merely to errors of reporting. The gradual decrease of the case-mortality rate in Madras Town from an average of between 35 and 40 to 19.9 per cent in 1926 is suggestive. In *Ceylon*, where smallpox is now relatively rare (64 cases in 1926) the case-mortality rate was even lower (4.7 per cent) than in Madras Presidency.

#### INCIDENCE AND CASE-MORTALITY RATE OF SMALLPOX IN INDIA IN 1926.

Provinces	Population (1921) in thousands	Cases	Deaths	Death Rate per 100,000 pop.	Case Mortality %
North-West Frontier . . . . .	2,251	1,084	658	29.2	60.7

Total . . . . .	295,222	218,488	54,668	18.5	23.9

Smallpox was somewhat more prevalent in *Siam*, but less widespread in *French Indo-China*, in 1926 than in the two previous years. The incidence, however, was not particularly high compared with other continental

countries of Asia (Siam 11.4 and Indo-China 11.3 cases per 100,000 inhabitants). Smallpox was, in 1926, as in the three preceding years, very rare in the *Straits Settlements* and in the *Malay States*. The number of smallpox cases reported in *Java and Madura* decreased from 5,994 in 1924 to 819 in 1926. The case-mortality rate decreased at the same time from 21.7 in 1924 to 10.6 in 1926; in earlier years it oscillated about 20 per cent.

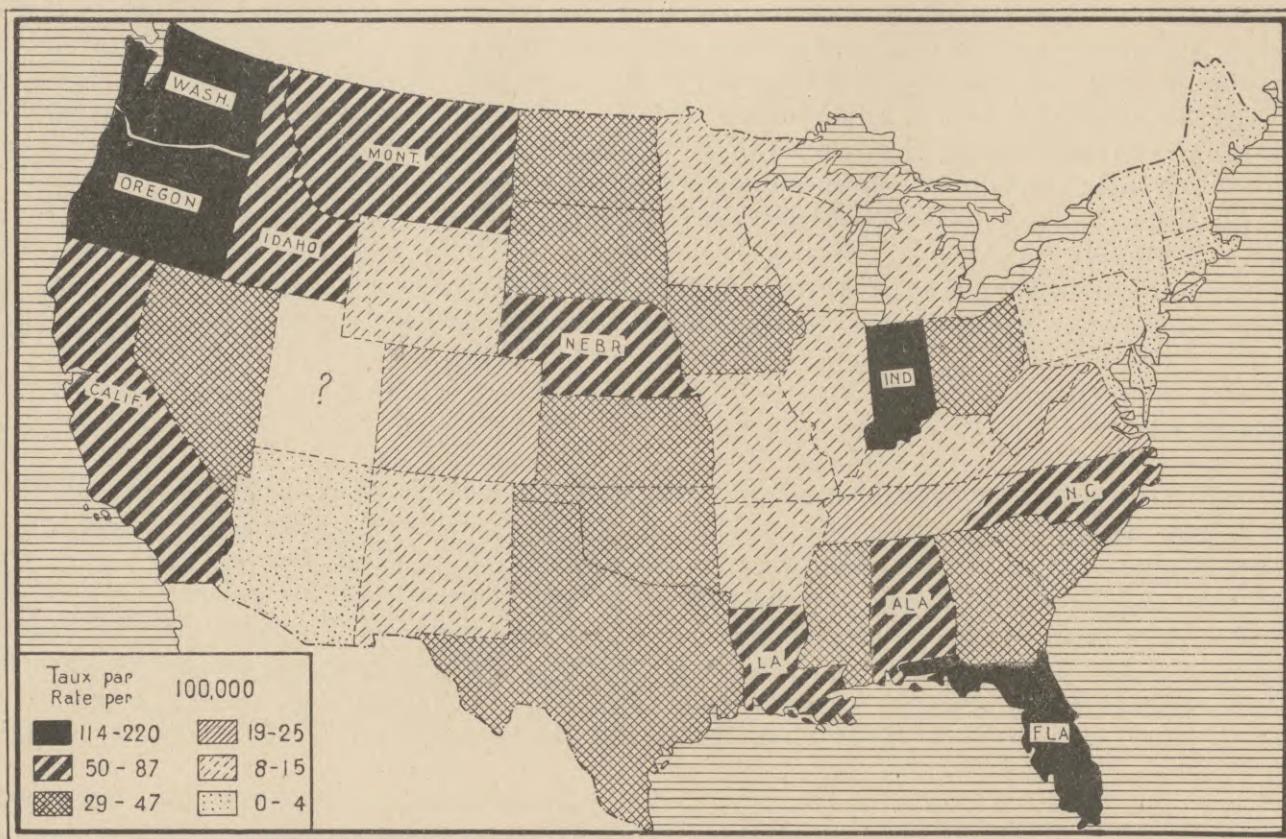

It appears from reports received by the National Epidemic Prevention Bureau in Pekin that smallpox is most prevalent in *China* between January and April; the incidence decreases rapidly after May. Epidemics causing a considerable mortality occurred in many provinces during the first half of 1926 and the disease was reported to be prevalent in all provinces. It seems to have been less widespread in the interior, especially in the most remote provinces, such as Yunnan and Szechuan. Epidemics were reported in January in Manchuria, in February in the provinces of Shantung on the Yellow Sea, and Chekiang and Fukien on the central coast, south of the Yangtze; the disease remained in epidemic state in the latter provinces in March and April. In March, the disease was reported to be epidemic also in Kweichow in the interior of southern China, and in April in Chihli and Honan in the north. In May, epidemics were reported in the provinces of Kiangsu on the central coast between the Hoangho and the Yangtze, and in Anhwei, an inland province bordering on the former. This outbreak seems to have spread further inland to Hupeh, in June. Smallpox was not particularly prevalent in Shanghai, where there were 217 deaths in the International and French Settlements, nor at Hong-Kong, where there were 25 deaths. Its incidence has decreased constantly at *Hong-Kong* since 1923, when there was a severe epidemic.

A certain prevalence of smallpox was also observed in the *Kwantung Territory* and in the *South Manchurian Railway Zone*, where 567 cases, with a case-mortality rate of 19.4 per cent, were reported. In *Korea*, there were more cases (1,010) than in the two previous years, but still much fewer than in earlier years; in 1920 for instance, there were 11,532 cases. The reported case-mortality rate was 23.5 per cent in 1926. A similar increase occurred in *Japan*, where there were 1,252 cases in 1926, as compared with 430 in the previous year. The incidence, nevertheless, is low compared with continental Asiatic countries. The increase was due to outbreaks in the southern part of the country, which came to an end in July. The case-mortality rate was 13.8 per cent, which is somewhat lower than in previous years; it was 19.8, 15.6 and 18.8 per cent in 1923, 1924 and 1925 respectively.

The *United States of America* is in much the same position as England as regards smallpox, the mild form of which has been spreading for a number of years. Vaccination laws are insufficient in many States and the proportion of vaccinated children is, over large areas, below the safety limit; neither country benefits from the re-vaccination which most men undergo in countries with compulsory military service. The situation of the United States is less favourable than that of England because the disease began to spread earlier and is now of more or less common occurrence in practically the whole of the country, while in England, so far, only a limited area in the north is infected. Outbreaks of severe type have been more frequent in recent years in the United States than in England, probably owing to the proximity of Mexico, where the severe type constantly prevails. North Africa seems now to be a source of infection of the classical smallpox type for Europe, but here France acts to some extent as a filter for England.

The danger which smallpox always represents to a partly vaccinated community is shown by the outbreaks at Detroit, Minneapolis and Los Angeles. At Detroit, there were only 17 deaths among 4,631 cases reported from 1915 to 1923, giving a case mortality of 0.4 per cent. In 1924, there were 163 deaths among 1,610 cases, the case mortality being 10.1 per cent; 124 of these cases were of the hæmorrhagic type, all but one proving fatal. During the outbreak at Minneapolis from October 1924, to March 1925, 1,182 cases and 331 deaths were reported, giving a case-mortality rate of 28.0 per cent. In December 1925, an outbreak of virulent smallpox began at Los Angeles and reached its maximum in February 1926; 1,021 cases and 186 deaths were reported up to the end of May, when the outbreak was over; the case-mortality rate was 18.2 per cent. Mild smallpox had been very prevalent at Los Angeles for a couple of years previous to this outbreak. In 1924, there were 3,380 cases and 11 deaths, and during the first eleven months of 1925 there were 1,218 smallpox cases and 23 deaths. There were but few deaths from smallpox in 1926 in other towns. No important outbreak of the severe type occurred during the second half of 1926. The total number of smallpox cases reported in the United States changed but little from 1925 to 1926; the incidence in both years was lower than in 1924. It is seen from the map on next page that the incidence was considerably lower in the New England and Middle Atlantic States, where vaccination is generally better enforced, than in the rest of the country. There was more than one case per 1,000 inhabitants in the States of Florida, Oregon, Washington and Indiana.

INCIDENCE OF SMALLPOX IN THE UNITED STATES IN 1926.

The smallpox situation in *Canada* is similar to that of the United States. Cases of mild type are prevalent in Ontario and the Prairie States, while there are very few cases in Quebec and the coast provinces. The incidence was about the same in 1926 as in 1925: 1,535 cases and 33 deaths were reported, giving a case-mortality rate of 2.1 per cent. Nearly twice as many cases were reported in 1924 as in each of the two following years.

Smallpox is practically absent from those islands of the West Indies where vaccination is properly enforced, notably in *Cuba* and *Porto Rico*. It is relatively rare in *Martinique* and *Guadeloupe*. The so-called Alastrim is common in *Jamaica*; 1,079 cases and 3 deaths were reported in 1926, numbers which do not differ greatly from those reported during each of the two previous years. The disease is much less prevalent in other British islands of the West Indies. Smallpox was less prevalent in *Mexico* than in 1925, but the deaths caused by it still numbered 2,741. Information regarding Central America is fragmentary and does not permit any conclusion regarding the incidence of smallpox. The disease has been entirely absent from the *Panama Canal Zone* since 1922.

In *Brazil*, there were several serious outbreaks, accompanied by high mortality, in 1926, the most important of which was at Rio de Janeiro. Smallpox of virulent type has been prevalent in the capital since the previous year, and a most violent outbreak occurred in July, August and September. A total of 3,717 cases and 2,172 deaths was reported during the year in the Federal District of Rio de Janeiro. Outbreaks also occurred at Manaos where there were 155 deaths, at Nictheroy (132 deaths), Belem (77 deaths) and São Paulo (32 deaths). Smallpox seems to have been rare elsewhere in South America during the year. Two cases only were reported in *Uruguay* and 4 in *Chile*, none of which were fatal. *Buenos Ayres* was free from smallpox and so were Lima and Callao in *Peru*. One case was reported at Guayaquil, *Ecuador*, 2 deaths from smallpox at Bogotá in *Colombia*, and 1 death at Asunción, *Paraguay*.

*Australia* and *New Zealand* have remained entirely free from smallpox since 1921.

TYPHUS.

Typhus fever is now, so far as Europe is concerned, of practical importance only in Eastern Europe, although endemic centres still exist in South-Eastern Europe and in a very few localities of Western Europe. On the entire territory of the U.S.S.R. 55,841 cases were reported, which give an incidence of 38 per 100,000 inhabitants, this being the lowest on record since 1907, when 52,000 cases, or 35 per 100,000 inhabitants, were reported on Russian territory. It may be added that the notification is probably not less reliable now than it was before the war. The decrease, as compared with last year, was greatest in Siberia, the Ural district and northern Russia, where it amounted to between 40 and 50 per cent. It was much smaller in western, southern and central Russia, while the situation was stationary on the Volga. There was a decrease of 15 per cent in the Ukraine. In the Black Soil districts of central Russia there was an increase. Returns for the railway and waterway services showed a substantial decrease compared with previous years.

TYPHUS CASES REPORTED IN THE UNION OF SOCIALIST SOVIET REPUBLICS, 1923-26.

Geographical Areas	1923	1924	1925	1926	Population in thousands C. 1926	Rate per 100,000 in 1926

*Lithuania, Poland and Roumania* have the highest typhus incidence among other European countries. The relative incidence of typhus in the U.S.S.R. and neighbouring countries, in 1926, is shown, with all reservations in regard to possible difference in efficiency of reporting, by the following rates: Central Industrial district of Russia, 48.4 cases per 100,000 inhabitants; White Russia, 91.0; Ukraine, 26.6; Roumania, 43.7; Poland, 12.4; Lithuania, 15.8; Latvia, 3.9; Estonia, 2.2.

More cases were reported in 1926 than in 1925 in Lithuania and Roumania, but fewer in Latvia and Poland; the difference was in no case very large. Typhus is much more prevalent in the eastern provinces of Poland and Roumania than in the remainder of the country. The case-mortality rate was slightly lower in both countries than in previous years; in Poland, it was 7.5 per cent in 1926, as against from 8.0 to 8.6 in the three previous years; in Roumania, where the case-mortality rate varied between 10.0 and 11.2 from 1923 to 1925, it was 9.3 in 1926.

The few typhus centres which still exist in *Sub-Carpathian Ruthenia (Czechoslovakia)*, in the *Kingdom of the Serbs, Croats and Slovenes*, in *Bulgaria* and in *Greece* yielded all told 672 cases in 1926, as compared with 844 cases in the previous year.

Typhus is of common occurrence in North Africa, where it has been endemic for at least a century. Its incidence, however, has decreased considerably during the last five years. In *Egypt*, there were 5,573 deaths from typhus in 1919, but only 202 in 1926; it is more prevalent in Lower than in Upper Egypt. The seasonal maximum in North Africa usually occurs between March and May.

Typhus is absent from tropical Africa but occurs again in the extreme south, where it is endemic in various parts of the *Union of South Africa* and in *Basutoland*. The incidence has constantly diminished since 1920. Typhus is far more common and more severe among the negroes (950 cases, 144 deaths, 15.2 per cent case mortality in 1926) than among the white population (35 cases, 1 death, 2.9 per cent case mortality).

In Asia, typhus cases occur sporadically in *Turkey*, *Syria*, *Palestine*, *Transjordan*, *Iraq* and *Persia*, but cases are rarely numerous. The incidence is probably about the same as in the Caucasus and Crimea, where typhus also exists but is not very prevalent. In *India*, typhus is largely confined to the mountain districts of the north and especially of the North-West Frontier Province. A few cases were reported in *Tonkin*, but none in tropical Asia except 3 cases in *Kedah* (Malay States).

Typhus is rather prevalent in *China*, particularly in the interior; it is fairly rare, however, in the southern coast provinces, Kwantung and Fukien, and in the neighbouring inland provinces, Kwangsi, Hunan and Kiangsi. It is less rare in Yunnan, and was epidemic between March and June 1926 in Kweichow, to the east of Yunnan. Typhus was very prevalent during the first half of 1926 in Szechuan, the large province east of Thibet on the upper reaches of the Yangtze and in Kansu, which includes the Chinese corridor between Mongolia and Thibet to Eastern Turkestan. Typhus was said to be prevalent in Shensi, Shansi, Chihli, Shantung, Honan, Anhwei, Kiangsu and Chekiang, which comprise northern and central China, also during two or more months of the year. It is evident, however, that there has been no general or severe typhus epidemic in China in 1926.

There has been an increase of typhus in *Chosen* in recent years; 1,239 cases were reported in 1926. The case-mortality rate was 11 per cent. The cases occurred almost entirely among Koreans. There were only 11 typhus cases during the year in *Kwantung* and the *South Manchurian Railway Zone*. Typhus is now completely eradicated from *Japan* except for a very small centre in the province of Yamagata, in northern Japan, where 36 cases were reported in 1926.

Typhus does not exist in *Australia* nor in *New Zealand*.

In *America*, typhus is endemic only in *Mexico* and in parts of the Andes of *Peru* and *Northern Chile*. In *Mexico*, 407 deaths were ascribed to typhus in 1926, as compared with 657 deaths the previous year. The disease is most prevalent on the plateau of Central Mexico. Severe epidemics occurred in 1901-02, 1906 and 1915-16, causing a heavy mortality. The death rate from typhus at Mexico City was 248 per 100,000 in 1915 and 337 in 1916; in 1926, it was 4.6 per 100,000 (28 deaths).

Typhus occurs sporadically in some of the Southern States of the *United States*; 159 cases were reported in 1926, of which 50 were in *Georgia*, 48 in *Alabama*, 16 in *Florida* and 15 in *Texas*.

A quite exceptional decrease of typhus has taken place in *Chile* during the last seven years. In 1919, 14,517 cases were reported; in 1926, only 163 cases. Statistics are not available for the mountain districts in *Peru*, where the disease also exists. Nine deaths from typhus were reported in 1926 at Bogotá, in *Colombia*. Typhus does not appear to exist elsewhere in South America.

#### RELAPSING FEVER.

Relapsing fever is now practically non-existent in Europe outside the U.S.S.R. Cases were reported in 1926 only in the following countries: *Poland*, 15; *Lithuania*, 2; *Roumania*, 6; *Germany*, 3; and the *Kingdom of the Serbs, Croats and Slovenes*, 1.

Relapsing fever is now rare also in the northern and western part of the U.S.S.R., but still fairly common in the south. In the whole territory in 1926, 14,844 cases were reported as compared with 18,640 in 1925 and 50,535 in 1924. There was a decrease in all parts of the Union except in Siberia, where the situation was stationary, and the Ukraine, Crimea and North Caucasus, where there was a slight increase. In White Russia only 74 cases were reported, while there were 1,445 cases in Ukraine, 2,183 in North Caucasus and 2,904 in the Volga area. It seems to be less prevalent in Transcaucasus and in Central Asia.

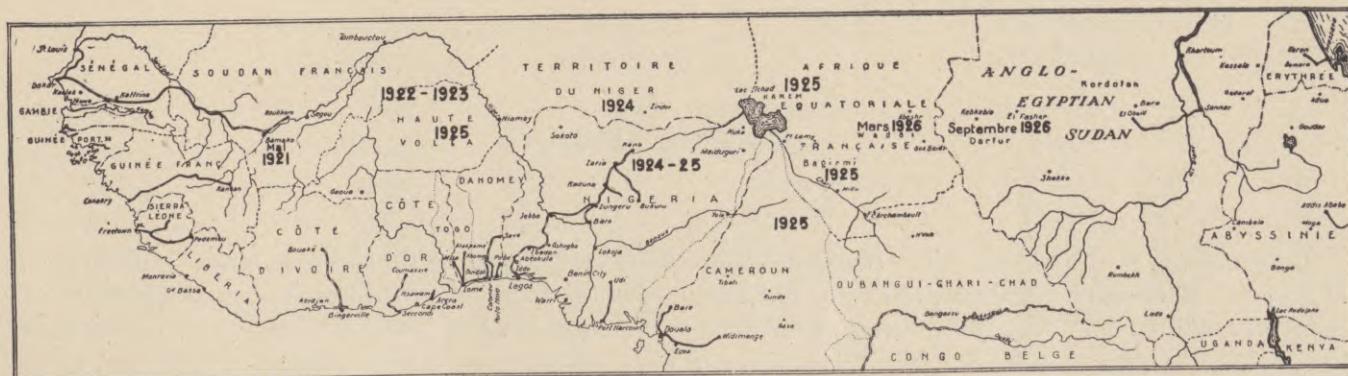

In the Near East, relapsing fever is quite rare; 12 cases were reported in *Palestine*, 2 in *Iraq* and 3 in the Protectorate of *Aden* in 1926. Relapsing fever is of greater importance in certain limited areas of *India*, especially in the Punjab and Madras Presidency. Statistics are unfortunately not available for later years than 1924. During that year 24,471 cases and 2,258 deaths were reported in the Punjab. The outbreak began in October 1923, and 773 cases and 155 deaths were reported during the last three months of that year. The maximum occurred in March and April, and the disease disappeared in August. The area affected was in the south-western part of the province on the Indus and the Chenab rivers and comprised the districts of Dera Ghazi Khan (17,373 cases and 1,611 deaths), Muzaffargarh (6,631 cases and 528 deaths) and Multan (338 cases and 106 deaths). The case mortality was 9 per cent in 1924, while it had been 23 per cent the previous year. There was a severe epidemic in *Kashmir* during the winter 1923-24, but statistics are not available. Nine districts of Madras Presidency were affected in 1924; the epidemic was most severe in Nilgiris district, in the mountainous country south of *Mysore*, where there were over 1,300 deaths. In *Bengal*, 4,034 deaths were reported chiefly in rural districts. There were in 1924, 186 deaths from relapsing fever in the United Provinces, 22 in the North-West Frontier Province, 1 in *Assam*, 24 in *Bombay Presidency* and 45 in *Coorg*.

Relapsing fever is endemic probably in the whole of *China*. There was no epidemic in 1926, but the disease was rather prevalent in the coast provinces of *Kiangsu* and *Fukien*, in *Chihli* in the north, and in the provinces of the interior, notably in *Szechuan*, where it was reported prevalent during five months of the year, but also in *Kansu*, *Kweichow* and *Yunnan*.

Relapsing fever had practically disappeared in 1926 from the Africa countries on the Mediterranean coast; 26 cases were reported in *Algeria*, 5 in *Tunis* and none in *Egypt*. In 1919, there were 3,221 cases of relapsing fever and 591 deaths in *Egypt*.

The epidemic of a most virulent type of relapsing fever which began at Bamako, on the upper Niger, in May 1921, and which during the following years passed eastward through the arid or semi-arid prairie belt south of the Sahara, decimating the population on its way, reached and passed the frontier of *Anglo-Egyptian Sudan* in 1926. In 1924, the epidemic was most severe at Zinder in the *Niger Territory*, where there were 2,600 deaths. In 1925, it was particularly the *Chad Colony* which suffered. Early in 1926, an epidemic was reported in *Wadai* which is the last French territory to the east. The disease was also prevalent in parts of the *Niger Territory* and in the *Upper Volta* but less so than in previous years. Over 1,000 cases were reported in the northern parts of the *Cameroons*. While the case-mortality rate of relapsing fever has averaged about 2 or 3 per cent in Europe, as well as in *Algeria* and *Morocco*, it was about 20 per cent in French West and Equatorial Africa. It averaged as much as 44 per cent in a number of villages in the *Upper Volta* Territory. There have been instances where up to one-half of the population of a village have died in the course of an outbreak. The causative agent of this outbreak is, nevertheless, the same as in the East European epidemics, the *Spirochæta Obermeieri* and not the *Spirochæta Dutton*, which causes the African tick fever, a similar disease, which occurs in the *Congo*, in *Uganda* and various parts of South Africa.

#### PROGRESSION OF RELAPSING-FEVER EPIDEMIC ACROSS AFRICA BETWEEN 1921 AND 1926.

In September 1926, relapsing fever appeared in *Darfur*, the westernmost province of *Anglo-Egyptian Sudan*, which on the west borders *Wadai*. *Darfur*, a country of about 150,000 square miles, with some 750,000 inhabitants, forms the watershed between the *Chad Basin* and the *Upper Nile* valleys. The rainy season lasts from the middle of June to the middle of September. *Darfur* is separated from the *Nile* country by the plateau of *Kordofan* (about 130,000 square miles, with 550,000 inhabitants). The rains cease in *Kordofan* at the end of

September and cold weather lasts from October to February. The trade from Darfur to Khartoum passes through El Obeid, the capital of Kordofan and terminus of the railway line linking this country with the White and Blue Nile.

Outbreaks of relapsing fever were first reported from two different localities, Kebkebia and Nyala, early in September, and the epidemic had covered a large area by the beginning of October. Its spread was favoured by the continued traffic to and from Zalingei, the most severely infected district, from all parts of Darfur caused by a shortage of grain and grazing over the whole country except in that particular district. The mortality has been very heavy; it is estimated that in the Zalingei district not less than 10,000 in a total population of 45,000 have died. The disease soon passed on to the eastern slopes of Gebel Marra, and was early in 1927 within 55 miles of El Fasher, the capital of Darfur, and, at other points, within 110 miles of the Kordofan border. Kordofan and Central Sudan, will be in danger from October 1927, with the coming of cold weather; the naked people farther to the south are more likely to escape. Most extensive measures have been taken by the Sudan Medical Service, but it is obviously difficult to control the wanderings of the people over so wide an area. If infection should be introduced into the more densely populated part of central Sudan, most serious results are likely to follow.

#### UNDULANT FEVER.

Undulant fever occurs in most Mediterranean countries, but is nowhere very prevalent except in Malta. It occurs also in South Africa and in Rhodesia, but is not very common there.

Undulant fever has decreased in recent years in *Malta* but 602 cases were nevertheless reported in 1926, which gives an incidence of 267 per 100,000 inhabitants. More cases of this disease were reported in the Maltese islands than of any other epidemic disease. The case-mortality rate decreased from 6.5 per cent in 1925 to 4.5 per cent in 1926.

In *Italy*, 1,085 cases were reported, as compared with 1,439 the previous year. The incidence was highest in Sicily and in Tuscany, where there were 8.6 and 8.2 cases respectively per 100,000 inhabitants, in 1926, and within these areas the incidence was highest in the provinces of Pisa, Livorno and Messina. It was between 3.6 and 4.4 in Calabria and Basilicata, in Sardinia, in Lazio and in the provinces of Ravenna and Bologna, and from 2.3 to 2.4 in Campania and in Apulia. The disease was practically absent from northern Italy, excepting the provinces of Torino and Trento, as well as from the Marches and Umbria.

In *France*, 134 cases were reported, but the notification of this disease may be incomplete. Statistics for undulant fever are not available for *Spain*. The disease seems to have been eradicated from *Gibraltar*.

The seasonal maximum occurred in April in France, in June in Italy, and in July in Malta.

#### ENTERIC FEVER.

Enteric fever is spread over the whole world, in contrast with most of the diseases hitherto dealt with in this report. Although its incidence has been much reduced in countries where sanitation and social organisation in general are in an advanced state, it has nowhere been even approximately eradicated, such as is now the case with smallpox in many countries. The fluctuations of its incidence from year to year are usually smaller than those of plague and cholera, perhaps partly because of its universality, but it remains capable of setting up very severe local epidemics, a typical example of which was furnished by the outbreak at Hanover in 1926. A general rise of the incidence may also be brought about by a simultaneous series of smaller outbreaks, the interrelation of which may be somewhat obscure; such was the case in Italy in 1926. Finally, in most tropical and subtropical countries enteric fever, on the whole, is not at all under control, running its course almost unimpeded except by the natural immunity conferred by the abundance of infection always present.

The incidence of enteric fever in Europe, in 1926, differed on the whole but little from the previous year's incidence, which means that the situation by the standard of earlier years was favourable; but it also signifies that there was no general and definite progress. There was an improvement in two large areas, one in the north comprising Denmark, Norway, Sweden, Finland, Estonia and Latvia; another in the south, including Ukraine, Roumania, part of the Kingdom of the Serbs, Croats and Slovenes, Bulgaria and Greece. The incidence also decreased in Ireland. The decrease in these areas was compensated by an increase in Italy, Malta, France, Hungary, Poland and Lithuania. The number of cases reported in other European countries was practically the same in 1926 as in 1925.

Although it is unsafe to make a direct comparison of the rates of morbidity between the various countries, owing to the different degree of efficiency with which the notification is carried out, the data show, without any doubt that enteric fever is, generally speaking, least prevalent in northern countries and increases rapidly southwards. The difference is very marked, and may amount to as much as from twenty to fifty times the incidence obtaining in the countries where it is least prevalent. Statistics of causes of death are somewhat more comparable, at any rate for countries with a good system of certification of causes of death. It must be remembered that there are differences between the case-mortality rate in the various countries, although these are not by any means so great as in the case of smallpox, relapsing fever, malaria or scarlet fever. An important source of difference in case-mortality rate arises from the varying degree in which paratyphoid fevers prevail; these are usually less severe than the typhoid infections. The relative frequency with which typhoid and paratyphoid fevers occur is shown below for countries where reliable information is available regarding the type of the infection.

CASES OF TYPHOID AND PARATYPHOID FEVERS REPORTED IN VARIOUS COUNTRIES IN 1926.

	Finland	Estonia	Denmark	Belgium	Switzerland	Austria	Japan
Typhoid . . . . .	526	544	267	801	301	4,721	43,911
Paratyphoid . . . . .	748	139	77	137	123	635	4,435

The mortality rates shown below give, undoubtedly, a good idea of the relative importance of enteric fever in various countries where climate and other conditions differ considerably. The incidence of mortality varies between 0.8 per 100,000 inhabitants in Scotland and 21.5 in Spain; still higher rates would undoubtedly be found in many other countries where the mortality statistics are not sufficiently reliable or altogether absent.

MORTALITY FROM ENTERIC FEVER IN VARIOUS COUNTRIES IN 1926.

Country	Population (in thousands)	Deaths	Rate per 100,000 pop.	Country	Population (in thousands)	Deaths	Rate per 100,000 pop.
Scotland . . . . .	4,903	39	0.8	Australia <sup>1</sup> . . . . .	5,992	170	2.8
England and Wales . .	39,067	367	0.9	Canada . . . . .	9,291	461	5.0
New Zealand . . . . .	1,408	19	1.3	United States <sup>2</sup> . . .	99,200	6,677	6.7
Denmark <sup>1</sup> . . . . .	3,442	47	1.4	Czechoslovakia . . .	14,353	1,483	8.2
Switzerland . . . . .	3,959	59	1.5	Hungary . . . . .	8,455	1,147	13.6
The Netherlands . . .	7,449	137	1.8	Japan . . . . .	59,737	9,328	15.6
Germany . . . . .	62,612	1,402	4.8	Spain . . . . .	22,128	4,747	21.5

The case-mortality rate varies in European countries between 5 and 12 per cent. It has shown a tendency to decrease in some countries; it is impossible to say whether this is due to better treatment or to improved reporting of the milder paratyphoid cases. In Austria, the case-mortality rate thus fell from 10.4 per cent in

<sup>1</sup> Data for 1925.

<sup>2</sup> Registration area for deaths in 1924.

1922 to 5.5 in 1926; in the Saar Territory, it fell from 12.4 per cent in 1922 to 6.2 in 1926. There is, however, very little change of the rate in most countries, excepting that the average type of the disease may be more severe in certain years. The case-mortality rate was 7.4 per cent in Palestine in 1926, or the same as in Central Europe. Japan seems to have a higher proportion of fatal enteric fever cases than is normal in European countries; the case-mortality rate has for at least ten years varied between 18 and 21 per cent; it seems to be just a trifle lower in Chosen. The case mortality was 20.1 per cent for typhoid fever and 10.5 per cent for para-typhoid fevers in Japan in 1926.

CASE MORTALITY RATE (PER CENT) OF ENTERIC FEVER IN VARIOUS COUNTRIES, 1924-26.

Years	England and Wales	Norway	Netherlands	Germany	Austria	Czecho- slovakia	Poland	
1924 . . . . .	12.0	5.4	13.6	13.2	7.9	7.3	8.1	
1925 . . . . .	14.0	2.9	11.8	13.6	5.0	7.9	7.8	
1926 . . . . .	13.4	5.6	11.2	8.9	5.5	7.2	7.9	
Years	Hungary	Serb-Croat- Slov. Kingd.	Bulgaria	Palestine	Java	Japan	Chosen	New Zealand
1924 . . . . .	13.0	11.2	11.4	10.6	16.1	20.8	16.3	10.1
1925 . . . . .	11.4	11.8	13.5	9.4	15.0	18.8	17.7	8.0
1926 . . . . .	11.4	10.8	10.8	7.4	16.6	19.3	15.1	12.8

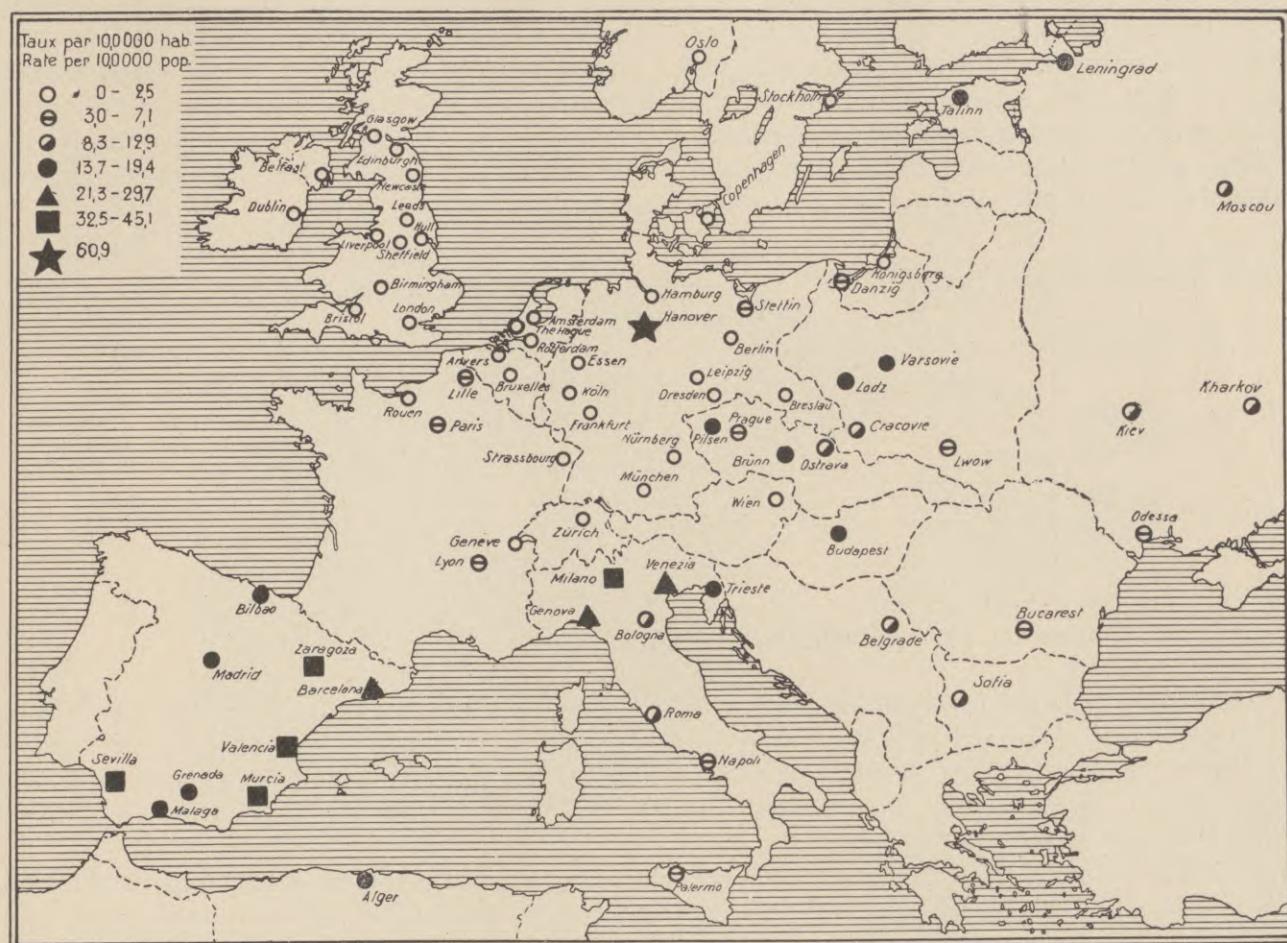

Enteric fever is usually more prevalent in rural districts than in towns. The death rates for towns shown in the table below are therefore mostly somewhat lower than for the countries as a whole; they give, nevertheless, a fairly good idea of the true incidence in countries for which complete mortality statistics are not available.

MORTALITY FROM ENTERIC FEVER IN LARGE TOWNS IN 1925 AND 1926.

	Population in thousands	Deaths		Rate per 100,000 pop.	
		1925	1926	1925	1926
107 English towns . . . . .	19,411	183	140	0.9	0.7
16 Scottish towns . . . . .	2,396	24	23	1.0	1.0
3 Scandinavian towns . . . .	1,300	41	41	0.8	0.8
48 German towns . . . . .	17,024	336	483	2.0	2.8
47 German towns <sup>1</sup> . . . . .	16,597	330	223	2.0	1.3
14 Dutch towns . . . . .	2,411	57	44	2.4	1.8
30 Swiss towns . . . . .	1,184	16	43	1.4	1.4
2 Belgian towns . . . . .	1,426	39	22	3.5	2.0
5 French towns . . . . .	3,932	222	214	5.6	5.4
7 Italian towns . . . . .	3,447	483	646	14.0	18.7
49 Spanish towns . . . . .	4,263	890	1,081	20.9	25.4
4 Czechoslovakian towns . .	1,176	97	84	8.2	7.1

<sup>1</sup> Without Hanover.

MORTALITY FROM ENTERIC FEVER IN LARGE EUROPEAN TOWNS IN 1926.

MORTALITY FROM ENTERIC FEVER IN LARGE TOWNS OF THE UNITED STATES IN 1926.

It is seen from the above table that, in Europe, the incidence of enteric fever in general increases from north to south; in England and in the Scandinavian countries, the mortality was less than 1 per 100,000 inhabitants; in German, Dutch and Swiss towns it was mostly between 1 and 2 per 100,000, except for the explosive outbreak at Hanover when the death rate rose to 60.9. In Southern and Eastern Europe, the death rates from enteric fever were mostly between 10 and 20 per 100,000 inhabitants in 1926; in certain Spanish and Italian towns they exceeded 30. At Athens the rate was 39.3 and at Salónica 44.1 in 1924. The mortality was higher in 1926 than in 1925 in Spanish, Italian, Polish and Ukrainian towns. Similarly, in the United States, the mortality from enteric fever in large towns increases from north to south.

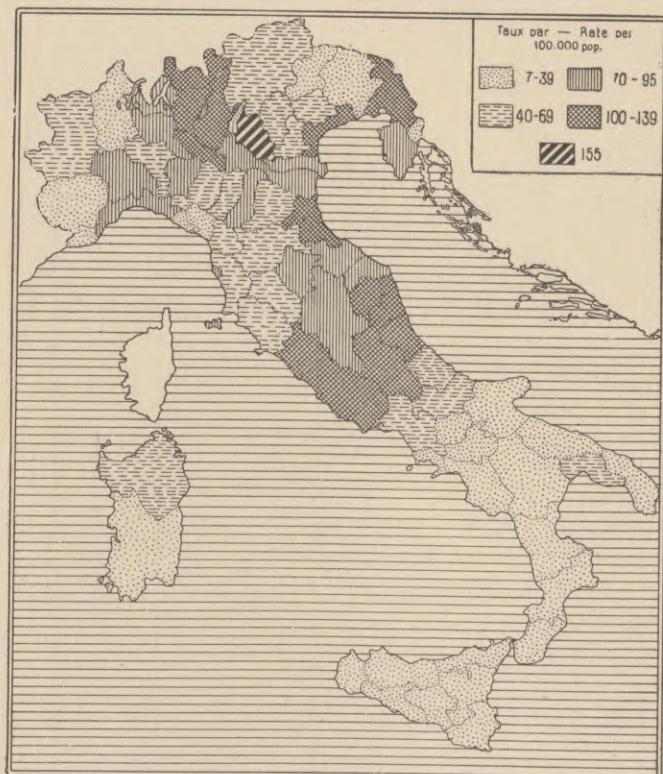

MORTALITY FROM ENTERIC FEVER IN 1926 IN LARGE TOWNS OF THE UNITED STATES GROUPED ACCORDING TO GEOGRAPHICAL DIVISIONS.

Division	Population in thousands	Deaths	Rate per 100,000
New England . . . . .	2,522	38	1.5
Middle Atlantic . . . . .	11,399	241	2.1
North Central . . . . .	10,596	192	1.8
South Atlantic . . . . .	2,226	120	5.4
South Central . . . . .	2,314	294	12.7
Pacific and Rocky Mountain . .	3,431	68	2.0

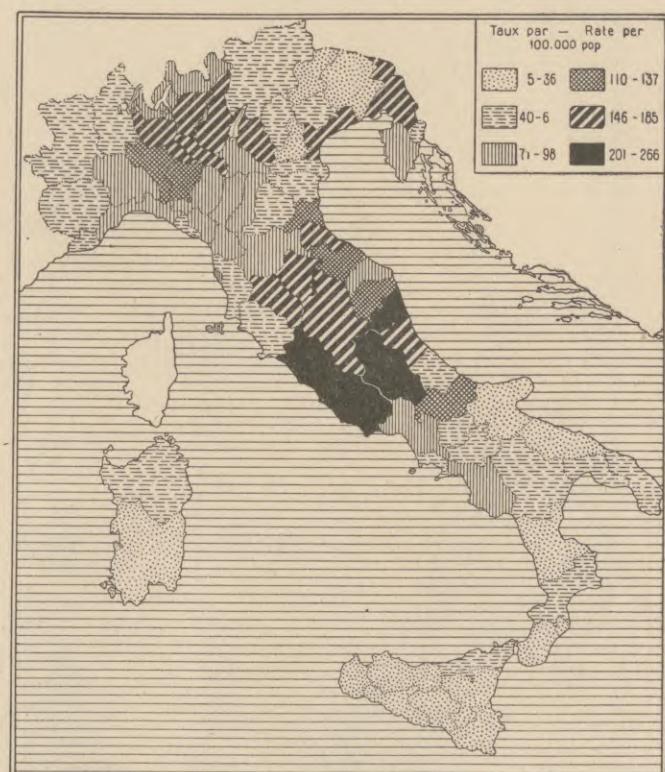

In sub-tropical and tropical countries, enteric fever is even more prevalent than in Southern Europe or in the Southern States of the United States. The mortality per 100,000 inhabitants in 1926 was 38.9 in Cairo, 82.4 in Teheran, 68.9 in Calcutta, 29.1 in Singapore, 35.9 in Batavia and 29.1 in Manila. It is probable that in several of these towns the certification of causes of death is less accurate than in European towns and the rates may therefore in some instances be too low.

In South America, the incidence of enteric fever is lowest in the southern temperate climates and generally increases northward. The death rate from this cause per 100,000 was in 1926: 4.4 at Buenos Ayres, 14.2 at Montevideo, 41.4 at São Paulo, 8.5 at Rio de Janeiro (low for the latitude), 33.7 at Lima and 92.8 at Bogotá.

INCIDENCE OF ENTERIC-FEVER CASES REPORTED  
IN ITALY IN 1925.

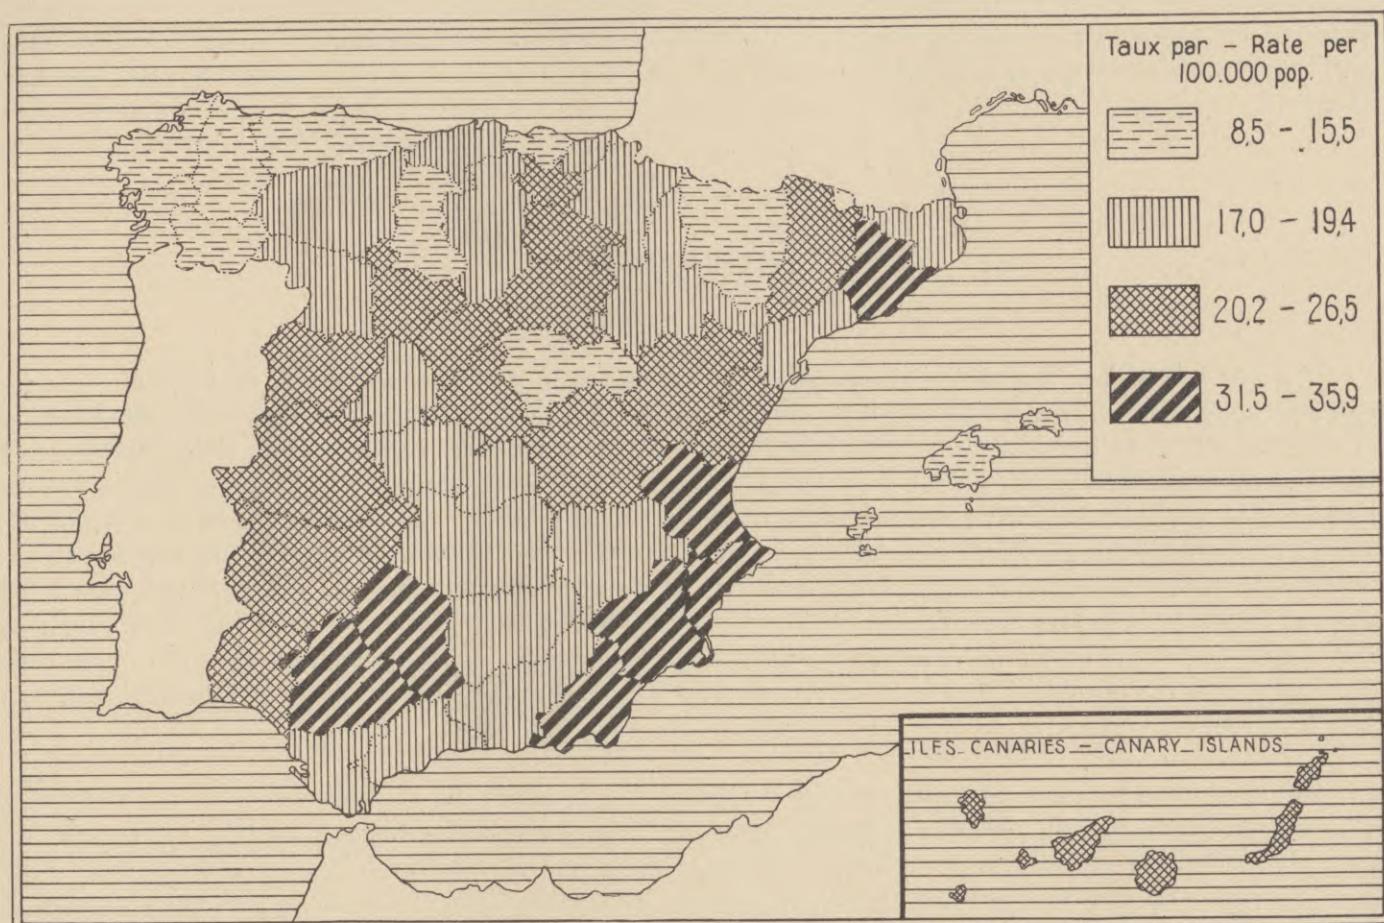

INCIDENCE OF ENTERIC-FEVER CASES REPORTED  
IN ITALY IN 1926.

The incidence of morbidity in Italy in 1925 and 1926 and the incidence of mortality from enteric fever in Spain are illustrated in the maps above and on next page. The high incidence in 1926 in Italy was mainly due to an outbreak in Central Italy and in Lombardy. In Spain, enteric fever is, generally speaking, most prevalent in

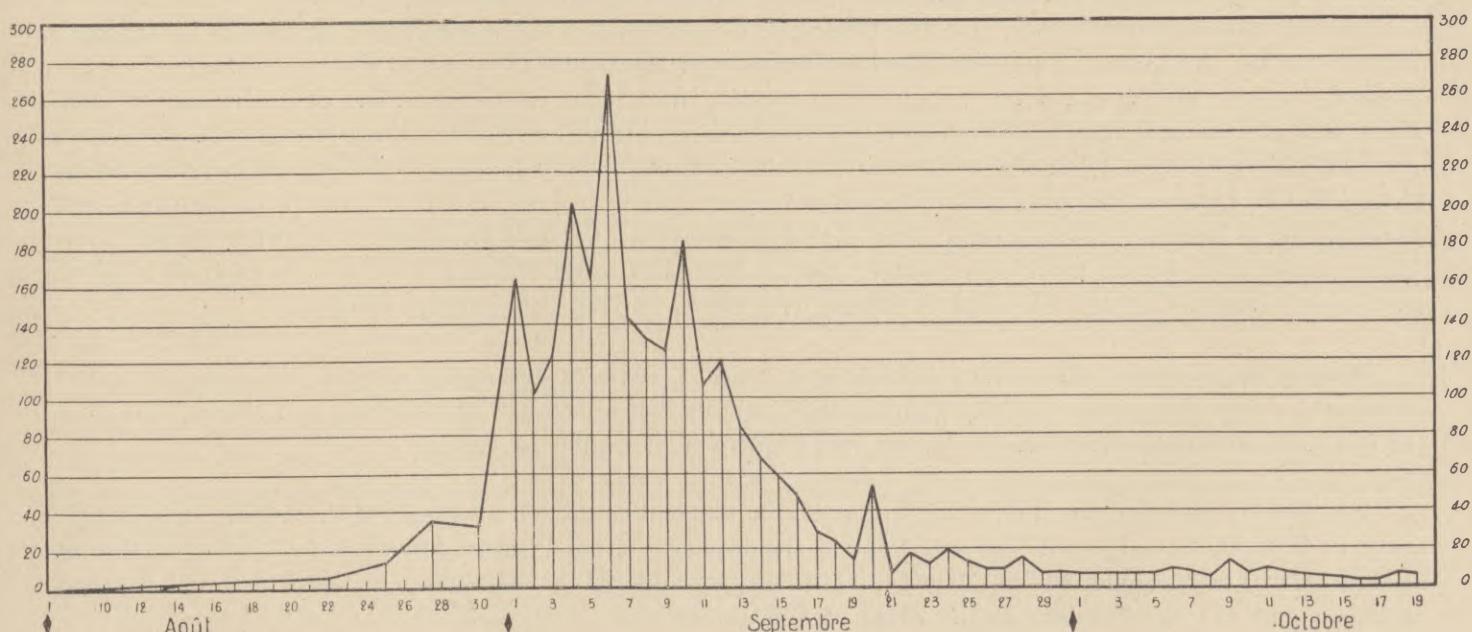

the provinces on the Mediterranean coast and least prevalent in the northern provinces on or near the Bay of Biscay.

MORTALITY FROM ENTERIC FEVER IN SPAIN IN 1926.

The most severe outbreak of typhoid fever in 1926 was the one at Hanover, in Germany, which began toward the end of August and lasted throughout September. There were in all about 2,500 cases and 260 deaths in a population of approximately 425,000. The case-mortality rate was 10.4 per cent., which may be considered as

TYPHOID-FEVER CASES REPORTED AT HANOVER FROM AUGUST TO OCTOBER 1926, THE CASES BEING TABULATED ACCORDING TO DATE OF ONSET OF ILLNESS.

about the average. The typhoid epidemic was preceded by an epidemic of probably between 20,000 and 30,000 cases of acute gastric and intestinal catarrh, which lasted to the end of August. The cases were, however, not severe and death occurred only in the case of a few children. The typhoid epidemic reached its height between September 1st and 10th, which is clearly seen when the cases are tabulated according to the date of the appearance of symptoms instead of the date of notification. The conclusions of the Government commission investigating the epidemic were that the epidemic was probably due to water-borne infection from the Ricklingen Waterworks. These works used filter galleries and filtering wells which are partly supplied by infiltrated river-water from the soil, the water-bearing gravel stratum being only protected by a weak and in some cases defective stratum of clay.

#### DYSENTERY.

The few hundred or few thousand dysentery cases reported in various tropical and subtropical countries represent only a minute fraction of the huge amount of cases which actually occur in that area. Specification of type is rarely to be had and the value of existing information is thereby further reduced, as the amoebic and bacillary dysenteries, at any rate from an aetiological point of view, are quite different diseases. The two forms usually exist together; amoebic dysentery is essentially a tropical disease while bacillary dysentery is not, although it is probably more prevalent in the tropics than elsewhere, just as typhoid fever is. But amoebic dysentery is not confined to the tropics; in *Italy*, where the differentiation between the two is made, there were 1,742 cases of bacillary dysentery and 522 cases of amoebic dysentery. The two forms occurred together throughout most of the country and were both most prevalent in southern Sardinia. Bacillary dysentery was also of frequent occurrence in Calabria and in Trento. Amoebic dysentery is reported to occur as far north as Denmark, although it is rare there.

Bacillary dysentery has decreased greatly in Central Europe since the epidemics of 1920-21. Centres of infection which continue to yield a considerable number of cases persist in *Germany* (especially in Westphalia), *Poland* (particularly in Galicia), *Roumania*, *Hungary*, *Czechoslovakia* and the *Kingdom of the Serbs, Croats and Slovenes*. The incidence was practically the same in 1926 as in 1925, except for a moderate increase in Poland. The case-mortality rate in Germany decreased from 11.8 per cent in 1924 to 8.9 in 1925 and 5.7 in 1926, it was 6.2 per cent in Czechoslovakia. It was higher in countries farther east and south: Poland 12.7 per cent; Roumania 12.6 per cent; Hungary 11.0 per cent, the Kingdom of the Serbs, Croats and Slovenes, 10.8 per cent. The seasonal maximum of dysentery in Europe occurs in August or September, generally about a month earlier than that of typhoid fever; its seasonal curve is much more concentrated in the summer and autumn than is the case with typhoid fever; dysentery is comparatively rare between January and May.

Dysentery is an important disease in the *U. S. S. R.*, where the number of cases is about double that of enteric fever. It has decreased somewhat since 1920, but much less than enteric fever. There was, on the whole, little improvement from 1925 to 1926; an increase was even reported in the south, particularly in Central Asia, Transcaucasus, the Lower Volga district, the Ukraine and the Central Black Soil district. There was a very marked decrease, on the other hand, in northern Russia, the Viatka-Vietluga and the Ural districts. A slight improvement also took place in central and western Russia and in White Russia. There was no change from the previous year in Siberia. Typhoid fever is more prevalent than dysentery in northern Russia and in White Russia; the incidence of the two diseases is about equal in western Russia and in the Crimea. In the Central Industrial District and in Ukraine there is a small excess of dysentery over typhoid fever cases; elsewhere in the Soviet Union, dysentery, judging from the reported cases, is from two to six times as prevalent as typhoid fever (on the Volga four times, in the Ural and in Siberia over twice, in Transcaucasus six times).

Among the countries where the notification of cases of bacillary dysentery is fairly well enforced may be mentioned *Java* (12,361 cases in 1926), where there was a serious outbreak in February and March, and *Japan* (17,133 cases in 1926), where the incidence was slightly higher than in 1925.

The serious problem which dysentery presents in tropical countries is shown by the death rates of many towns in Asia, Africa and South America. In 1926, the death rate from dysentery was 405 per 100,000 inhabitants in Madras, 310 in Rangoon, 187 in Calcutta, 59 in Bombay and 127 in Singapore. In tropical *Brazil*, it was 85 at Belem and 217 at Fortaleza in the State of Ceara.

The fact that bacillary dysentery is often a very serious problem in tropical Africa is shown by the occurrence of extremely severe epidemics among the labourers employed in the construction of the Congo-Ocean Railway in French Equatorial Africa in 1924-26<sup>1</sup>. Bacillary dysentery (predominance of type Hiss) was the chief cause of death, accounting for 31 per cent of all deaths. Each batch of new recruits was immediately attacked, although vaccination was practised; a state of immunity was generally acquired by the survivors after a couple of months. Among 1,417 native labourers vaccinated with two injections there were 78 cases (5.5 per cent) and 23 deaths (1.6 per cent); among 1,547 non-vaccinated there were 69 cases (4.4 per cent) and 19 deaths (1.2 per cent). In March 1926, there were in a month and a half 99 cases and 52 deaths among 655 new labourers, all of whom had been vaccinated. The total number of deaths from dysentery was 411 in two years. The case-mortality rate averaged 53.7 per cent.

## MALARIA.

Malaria is, like dysentery, most prevalent in tropical countries for which morbidity and mortality statistics are deficient. The common and most widespread forms have a low case mortality rate, and mortality statistics do not therefore give, in most cases a true idea of the importance of this source of sickness and loss of energy. Another cause of defect in the statistics is that malaria is essentially a local problem, and the total for both malarious and non-malarious districts of an infected country furnishes an average incidence which is true for neither but merely serves as a clue to the general trend of the situation. When, however, a malaria campaign produces artificially a greater number of notifications, the truth is entirely distorted by the statistics.

There are, however, a few countries in which malarial districts cover a considerable proportion of the area, where the administrations have for a sufficient number of years secured sufficiently effective notification of cases to establish records of some value. The most important of these countries are Italy, U.S.S.R., and the United States.

A considerable decrease of the malaria incidence took place in *Italy* in 1926, during which year 220,602 cases were reported, compared with 283,109 in 1925 and 250,911 in 1924. The improvement was most marked in Sardinia, where there were 108,811 cases in 1925 and 76,158 in 1926, in Latio and in Campania. The incidence was highest in Sardinia (83.1 cases per 1,000 inhabitants), Appulia, without the province of Bari (24.3), Calabria (19.3), and Basilicata (12.4). Malaria is of importance also in Sicily, but less so than in the above-mentioned districts. Malarious areas of secondary importance are found in the provinces of Latio (7.0), Grosseto in Tuscany (9.6), Ferrara in Emilia (12.1), Venezia (11.5), Rovigo in Veneto (8.4), Pola (16.6), and Zara (21.5). The following areas are entirely or practically free from malaria: the Alpine districts, Piedmont, Liguria, Emilia except Ferrara, Tuscany except Grosseto, the Marches, Umbria and the mountainous parts of the Abruzzi and the province and town of Naples. August and September are the months of maximum incidence of malaria in Italy.

The mortality from malaria has decreased constantly for a number of years in *Spain*; 1,912 deaths were attributed to this cause in 1921 and less than half that number (839) in 1926. The infection is most severe in the western and southern river valleys. The seasonal maximum occurs in August.

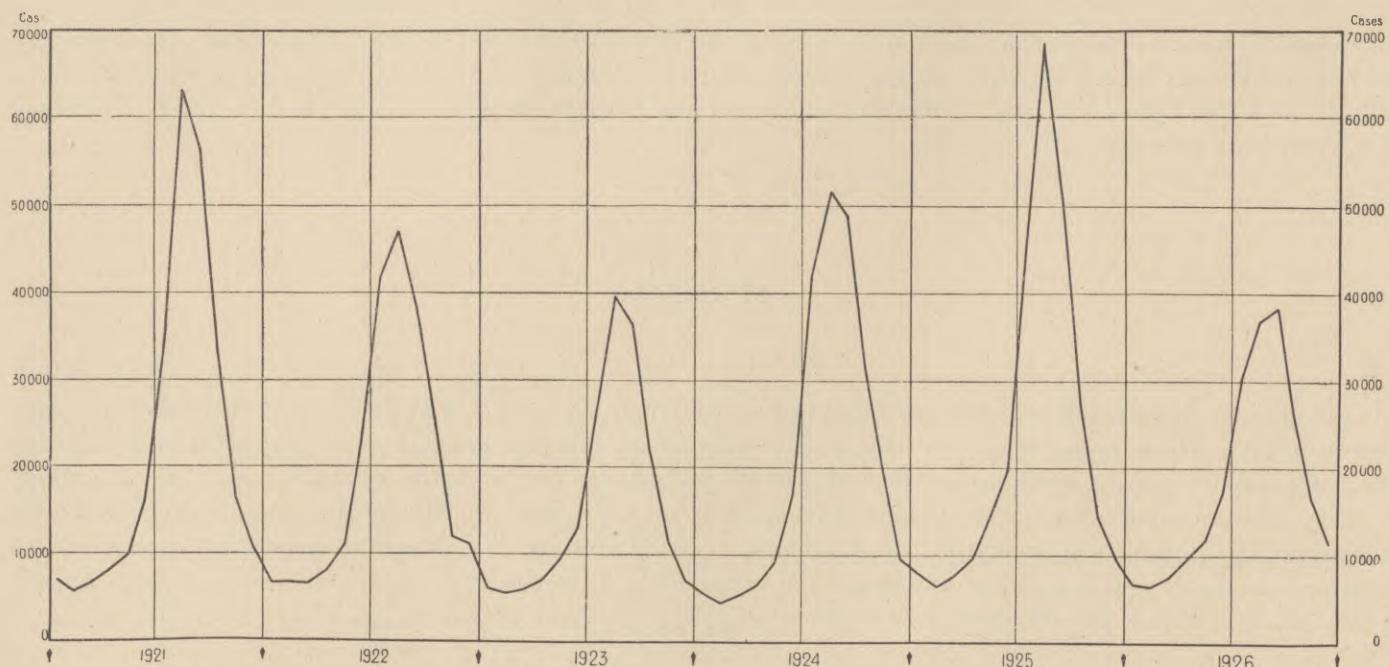

Many areas in *Greece* are intensely malarious, but the case reports are very incomplete and furnish no indication of the magnitude of the problem. The seasonal distribution appears to be of the autumnal type.

Considering the entire territory of the U.S.S.R., there was a reduction of about 670,000 malaria cases from 1925 to 1926; the corresponding reduction from 1924 to 1925 was of about 860,000 cases. There has not been a uniform reduction, however, over the entire territory; on the contrary, there was a small increase from 1925 to 1926 in Central Russia and a quite marked increase in Crimea, Transcaucasus and Central Asia.

The greatest decrease occurred in Siberia, the Ural and Volga districts, in Ukraine and in White Russia. The seasonal curve of malaria cases, which showed two distinct maxima in 1925, reverted to the type with one maximum in May and June which prevailed in earlier years. This is a favourable indication, because in the U.S.S.R. the benign tertian malaria usually has its maximum in May, while the malignant tropical form mostly occurs in autumn.

The seasonal distribution of malaria in the United States of America is of the estivo-autumnal type, the maximum occurring in August and September. The highest number of cases were as usual reported in the state of Mississippi (71,871 cases), where there was no change from the previous year. The next highest returns were, as in 1925, those of South Carolina (14,224) and Texas (13,728). The death rate from malaria in 1924 was 2.5 per 100,000 inhabitants in the entire registration area for deaths. States with a death rate from malaria over 10 per 100,000 in 1924 were: Florida (24.5), Mississippi (21.2), South Carolina (15.4), Louisiana (14.7) and Georgia (13.1). The 933 malaria cases reported the same year in Florida, the 859 cases reported in Louisiana, and the 763 cases reported in Georgia represent, therefore, only a minimal fraction of those occurring. In the state of Mississippi, where the notification is far more complete, 79,631 cases and 379 deaths were reported in 1924, giving a case mortality rate of 0.5 per cent. The mortality was higher for the coloured than for the white

population; the death rates per 100,000 from malaria in the above states in 1924 were: in Florida: white 19.7, coloured 34.6; Mississippi: white 12.9, coloured 28.7; South Carolina: white 5.2, coloured 25.7; Louisiana: white 11.3, coloured 20.4; Georgia: white 9.0, coloured 19.3.

### INFLUENZA.

The year 1926 passed without any influenza epidemics of primary importance, although the epidemics which visited Europe in the winter 1926-27 began in some countries, and especially in France, Spain and Switzerland, in December, or in some localities even in November, 1926. Apart from these outbreaks, which belong to the series of 1927, the influenza situation in 1926 was distinctly favourable in Western, Northern and Central Europe and normal in Southern Europe, compared with the two previous years. There was a moderate recrudescence, on the other hand, in Eastern Europe and North America. Every winter or spring since the reappearance of epidemic influenza in Europe in 1890 there has been a winter rise in mortality due to influenza, and still more to its complications chiefly affecting the lungs and heart. In some winters this rise has been very considerable, even apart from the 1918-19 pandemic, and it is certain that in Europe since the beginning of the twentieth century influenza has contributed more than any other single disease to the ups and downs of the general death rate. Even with its complications, it is not the chief cause of death, but its effects are much more sudden and irregular than the others, which, under modern sanitary and demographic conditions, normally combine to produce a steady death rate. Influenza outbreaks of a certain importance continue to occur at irregular intervals rarely longer than two or three years. Since the 1918-19 pandemic there have been important outbreaks in Europe in the winter 1921-22, early in 1924 and in the winter 1926-27. The average mortality caused by these outbreaks is greater than that caused by influenza in similar outbreaks between 1901 and 1917. Taking into account the decrease of deaths from most other causes, the importance of the increase of influenza is relatively even greater than suggested by the trend of its mortality alone. Together with the two epidemic diseases of the central nervous system—epidemic encephalitis and epidemic poliomyelitis—it constitutes undoubtedly the most urgent unsolved epidemiological problem.

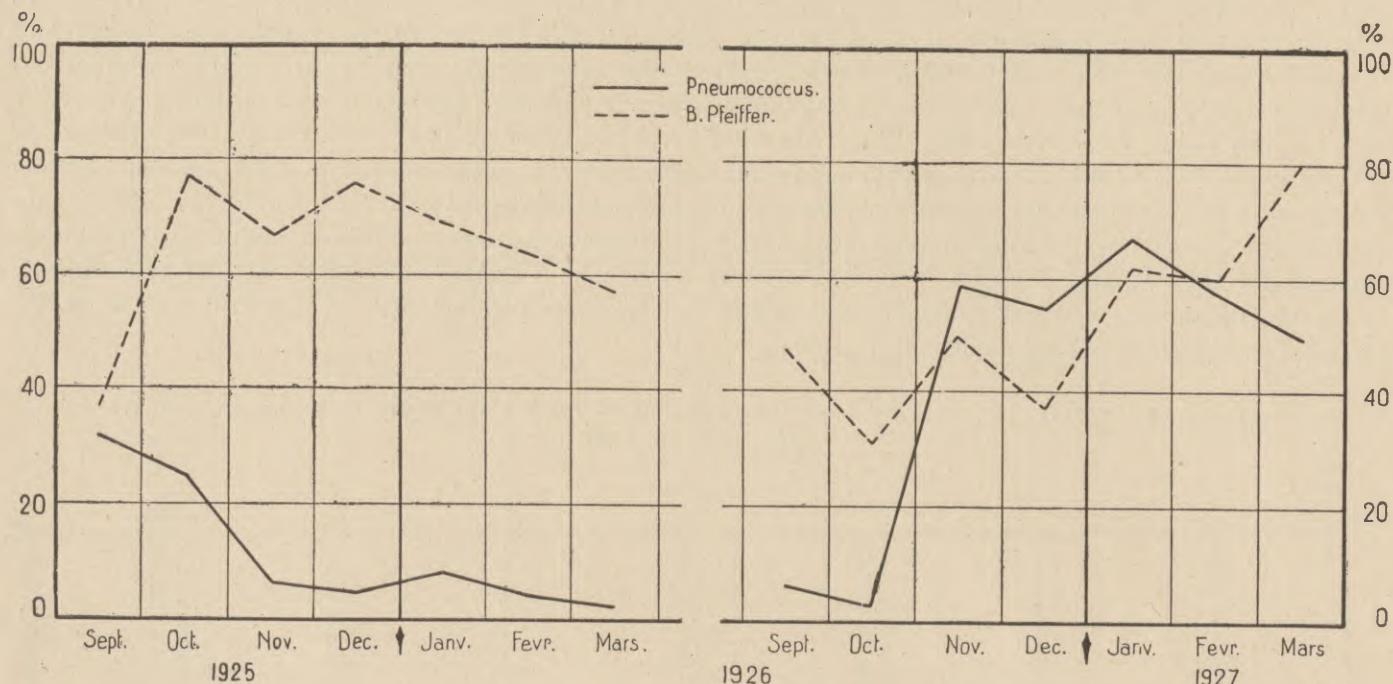

DEATH RATE PER 100,000 INHABITANTS FROM INFLUENZA AND FROM PNEUMONIA IN ENGLAND AND WALES  
FROM 1853 TO 1926.

A certain amount of work has been done on the periodicity of influenza outbreaks, and Brownlee thought that he had established a circle of 33 weeks, which in fact seems to agree with English mortality records fairly well but not with those of other countries. Influenza, except in cases of an extremely virulent epidemic as in 1918, when season is of no consequence, certainly shows a preference for the period between the middle of December to the end of March. If the epidemic comes later it is apt to be milder. Outbreaks not infrequently begin in the autumn, but they usually fail to develop; this was the case in many European countries in October and November 1926.

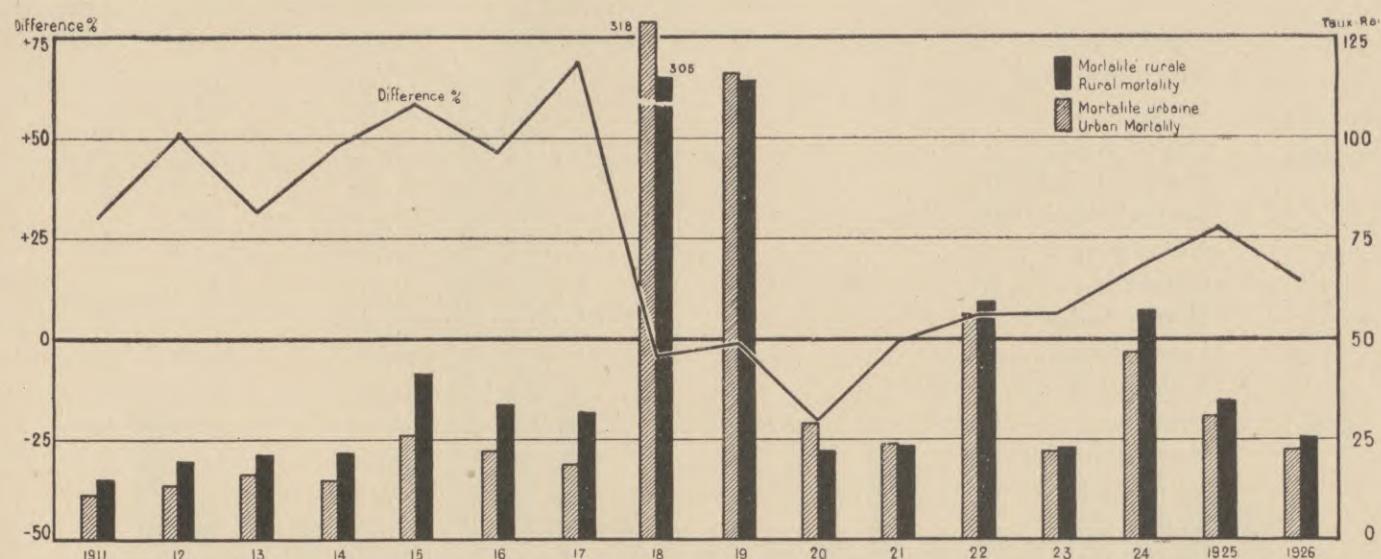

Interesting investigations of the bacterial contents of the naso-pharynx in healthy persons in non-epidemic periods have been carried out in autumn and winter 1925-26 and 1926-27 by the British Ministry of Health in London and Manchester. It was found that there was a notable increase of carriers of pneumococci in November 1926, two months before the onset of the epidemic, which in England came at the end of December. There was no corresponding increase of carriers during the winter 1925-26. It is also noteworthy that the winter rise of *B. Pfeiffer* in 1925-26 had already reached its height in October—*i.e.*, in a month in which influenza epidemics rarely occur. Haemolytic streptococcus and Gram-Negative coecus bore no relation to the absence or presence of epidemics during these two winters.

PERCENTAGE OF NORMAL ADULTS IN THE NASO-PHARYNX OF WHICH PNEUMOCOCCI AND *B. PFEIFFER* WERE FOUND BY INVESTIGATIONS CARRIED OUT AT MANCHESTER DURING THE WINTERS OF 1925-26 AND 1926-27.

The annual reports of the Registrar-General of England and Wales have long shown that the relation between influenza mortality in country districts and mortality in towns is variable. It might be advisable to investigate this question more fully in other countries. Influenza causes normally a heavier mortality in rural than in urban districts; English, American, Dutch, Swiss and Scandinavian statistics agree on this point. But this was by no means the case in the 1918-19 epidemic. In England the influenza mortality in 1911 was 30 per cent higher in the rural than in urban districts; this difference increased to 69 per cent in 1917. The excess in country districts disappeared entirely from 1918 to 1921, when urban mortality was slightly in excess, reappeared in 1922 after which it has again gradually increased to 27 per cent in 1925 but fell to 14 per cent in 1926. The simplest explanation of this excess is that the degree of immunity is higher among city dwellers than among country people, at any rate at the time when epidemics occur. This greater immunity of town dwellers (if it be a fact) disappears entirely in epidemics of extreme virulence. In the United States the rural influenza mortality was nearly twice as high as the urban mortality between 1901 and 1917, although there was a good deal of fluctuation; the rates in town and country became equal in 1918, after which the rural rate again exceeded the town. The same has occurred in the Netherlands, where municipalities under 20,000 inhabitants have now an influenza mortality twice as high as that in towns of over 100,000 inhabitants. This difference has increased since 1923, when it was less than 10 per cent.

INFLUENZA DEATH RATE PER 100,000 INHABITANTS IN URBAN AND RURAL DISTRICTS OF ENGLAND AND WALES  
AND PERCENTAGE EXCESS OF RURAL OVER URBAN RATES, 1911 TO 1926.

Statistics regarding influenza are abundant, but their value is unfortunately relatively small, and their international comparability, at any rate as far as actual incidence of morbidity and mortality are concerned, is practically nil. Notification of cases is only attempted in a few countries and only covers a high proportion of the medically assisted cases in Denmark and in the U.S.S.R. Mortality statistics lose much of their value through the lack of uniformity in classification of deaths due to complications of influenza which are of much greater importance than complications of other epidemic diseases. These differences arise not merely from differences in classification but largely from the varying degree of care and detail with which medical death certificates are made out in the different countries. The general trend of influenza mortality can nevertheless be established, because it can be ascertained in each country separately, but it is not safe to make too precise statements regarding the relative incidence of influenza in different countries.

Influenza seems to have occurred late in the season in Europe in 1926. The greatest number of deaths attributed to it occurred in February in Italy; in March in Austria, Germany, Spain and the U.S.S.R.; in April in England, Scotland, the Netherlands and Czechoslovakia; but not until May in Denmark and Ireland. In 1926 there was, as is usually the case in influenza epidemics, a complete absence of any definite geographical line of progress.

The mortality attributed to influenza in 1926 was on the whole lower than in 1925; in some localities it was very low; in Paris, where between 1,100 and 1,200 deaths were certified as due to influenza during each of the previous three years, there were only 104 deaths from influenza during the first ten months of 1926. In 30 Swiss towns there were 115 deaths from influenza during the first 11 months of 1926, as compared with 221 in 1925 and 383 in 1924. It was in these localities and in Barcelona, where also influenza was little in evidence in 1926, that the influenza epidemic of the winter 1926-27 came earliest and was most severe.

Influenza was more prevalent, on the contrary, in 1926 than in 1925 in Italy and in the U.S.S.R. Both of these countries almost entirely escaped its ravages in the following winter. In Italy, 184,499 cases were reported in 1926, as compared with 64,736 the previous year; figures which can hardly be considered complete but are nevertheless significant. A higher mortality from influenza than in the previous year was also reported in nearly all large Italian towns. The rates for these towns show, however, that the epidemic was not of more than average severity: Venice 28.4 per 100,000 inhabitants; Milan 25.4; Rome 20.9; Genoa 17.8; Naples 17.6. The distribution of the incidence throughout the country was very irregular.

4,546,907 influenza cases were reported in 1926 in the entire territory of the U.S.S.R., as compared with 2,606,494 cases in the previous year. An equal number of influenza cases and malaria cases were reported in 1926, but their geographical distribution was naturally very different. The increase was general throughout the country, as is seen from the table below. Mortality statistics for large towns show a similar increase: deaths attributed to influenza numbered, in 1926 and 1925 respectively, 451 against 208 in Moscow; 636 against 157 in Leningrad; 366 against 183 in 79 Ukrainian towns. Here also the epidemic was of average severity; the general death rate in March, when the epidemic was at its height, only rose to 17.7 in Moscow and 17.5 in Leningrad, and the death rate for the year was in both towns lower than in the previous years. In the Ukraine the death rates were hardly influenced by the epidemic.

INFLUENZA CASES REPORTED IN THE U.S.S.R. IN 1925 AND 1926.

Geographical Districts	Cases		Increase %
	1925	1926	
North-Eastern . . . . .	78,863	111,141	40.9

Railways and Waterways. . . . .	13,541 *	325,358	—
Total . . . . .	2,606,494	4,546,907	74.4

Influenza notifications are obtained in about half the states of the *United States*, but are very incomplete except in Mississippi and possibly two or three other states. These notifications together with the general mortality rates in large towns, which were higher than during the two previous years, show the prevalence of influenza in 1926. The maximum generally occurred in March; it was earliest in California (January) and latest in the south (April). The mortality attributed to influenza was highest in the South (New Orleans 95.2 per 100,000 inhabitants) and lowest in the North (Boston 7.4 and Chicago 13.3). In *Canada* the number of deaths ascribed to influenza increased from 1,916 in 1924 and 3,042 in 1925 to 5,149 in 1926; the increase was greatest in the province of Quebec, smallest in the Prairie provinces. There was also an increase in influenza mortality in *Mexico* and in some of the West-India islands but not in all. North America was not sensibly affected by the epidemic of the winter 1926-27.

Influenza was less prevalent, on the other hand, in *South America* in 1926 than in the previous years. The mortality from influenza in 1926 was lower in all South American towns for which information is available than it was in 1925.

There were no noteworthy influenza outbreaks in *Japan* in 1926; the highest mortality was at Osaka, where, however, only 8 deaths per 100,000 inhabitants were attributed to influenza. About the same number of deaths from influenza were reported in the *Philippine Islands* in 1926 as during the previous year. In *New Zealand* an influenza outbreak reached its maximum at the end of July and beginning of August; the number of deaths exceeded that of the previous two years but was lower than during the epidemics of 1920 and 1923. Such information as is available for *Africa* shows no noteworthy outbreaks, although influenza is of considerable importance in parts of South Africa.

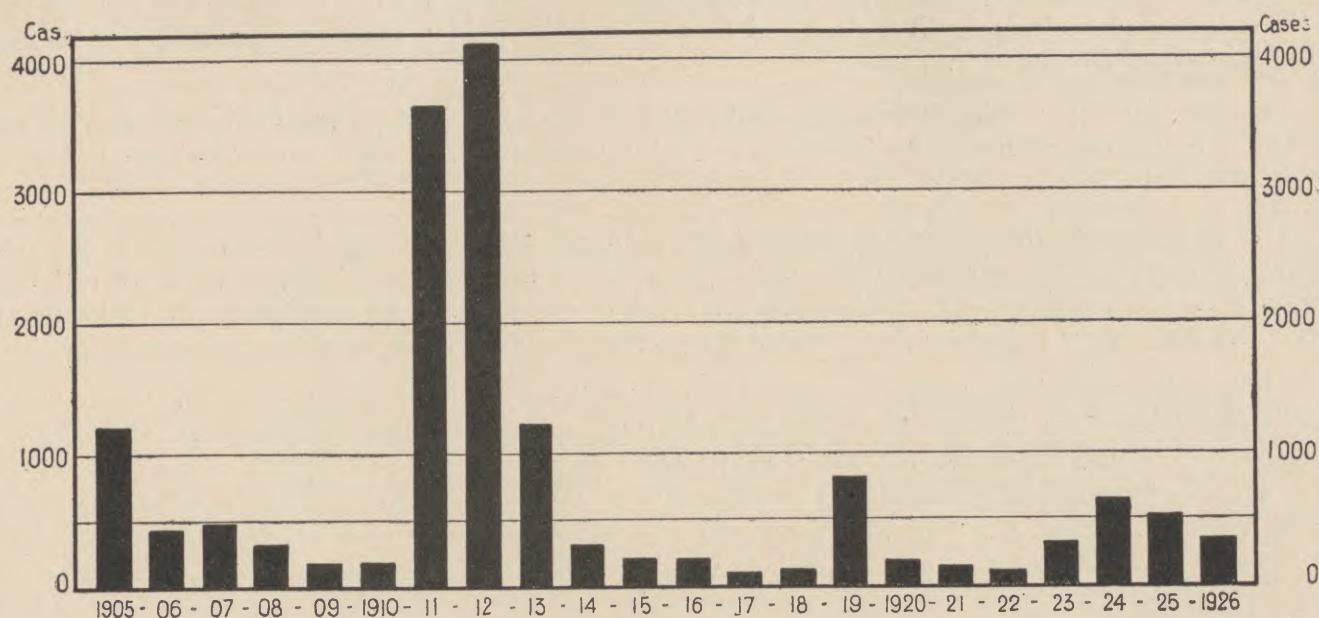

ACUTE POLIOMYELITIS.

Statistics regarding the incidence of poliomyelitis are unfortunately not available for all countries. The case notification is probably fairly complete only in a very few countries. The very incompleteness of the notification in certain countries suggests, however, that it has not hitherto been sufficiently prevalent there to warrant much vigilance on the part of the administration.

Acute poliomyelitis is far more prevalent in Europe, North America, New Zealand and Australia than elsewhere. In Europe it is less widespread in the south and east than in the centre and north.

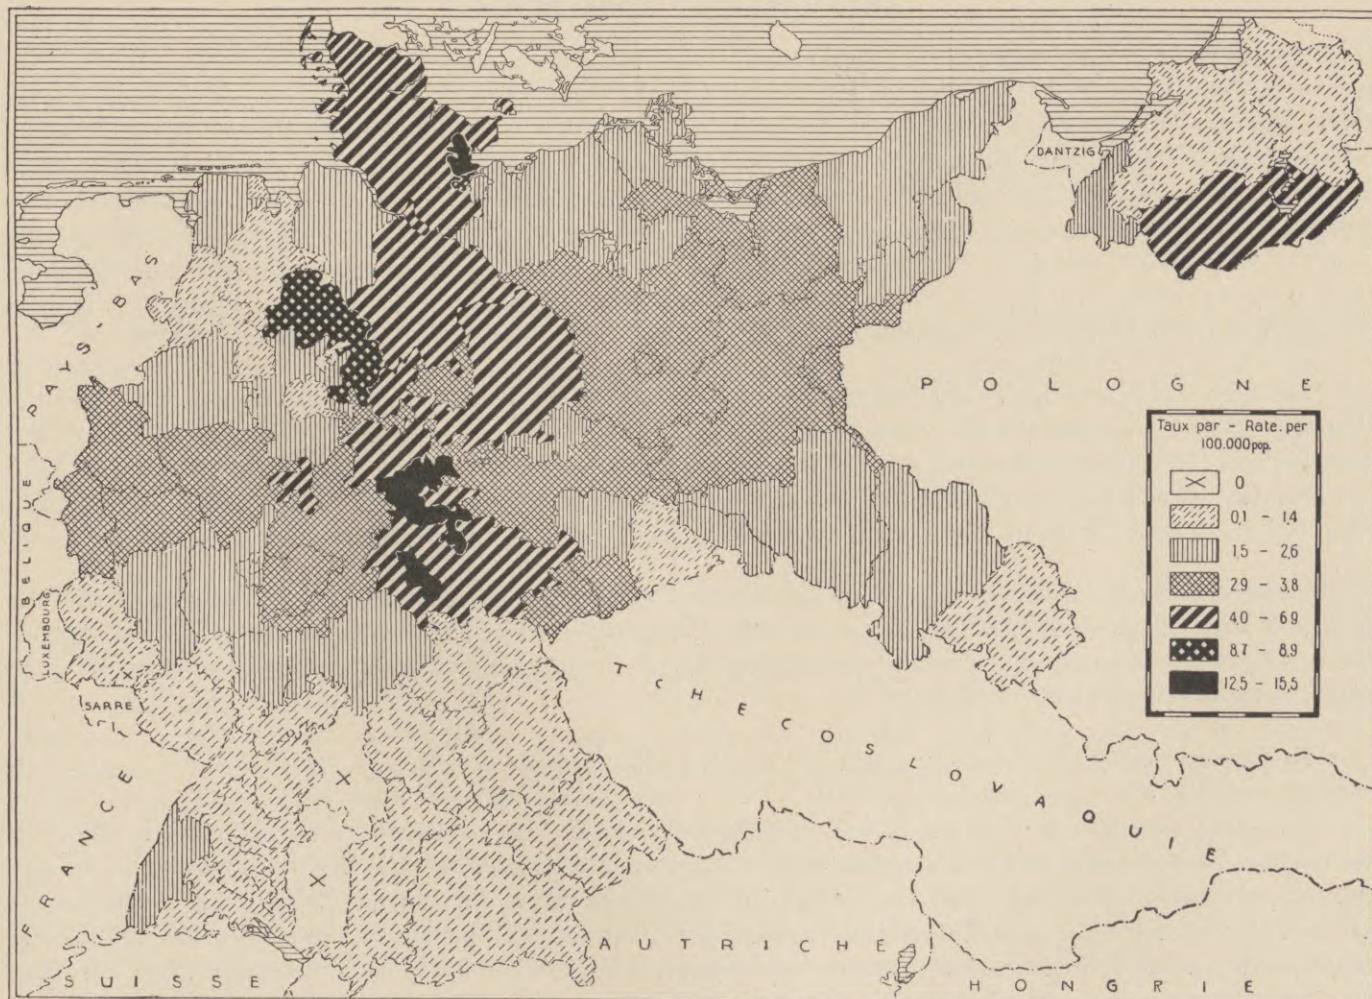

\* Incomplete records.

CASES OF ACUTE POLIOMYELITIS IN SWEDEN FROM 1905 TO 1926.

In 1926 the incidence of poliomyelitis decreased very markedly in the *United States* and *Canada*, where it had been more prevalent than usual during the two previous years. There was similarly a large decrease in the incidence in *New Zealand* (which suffered from a very serious epidemic in 1925) and in *Australia*.

INCIDENCE OF POLIOMYELITIS CASES PER 100,000 INHABITANTS REPORTED IN THE VARIOUS PROVINCES AND STATES OF GERMANY IN 1926.

In Europe there was a very marked decrease in *Norway*, *Sweden*, *Finland* and *Denmark* and an equally important decrease in *Italy*, where there had been an outbreak the previous year. There was no change in *France* and *Switzerland*, and a small increase in the *Netherlands* and *Austria*. Poliomyelitis is not notifiable in the countries of Eastern, South-Eastern and East-Central Europe, but there were probably no important outbreaks during the year in that area.

Important increases of the incidence occurred only in England and Wales, where 1,297 cases were reported in 1926, in comparison with 422 the previous year; and in Germany, where there were 1,614 cases in 1926, as against 386 in 1925.

The chief centres of the epidemic in *Germany* were in the province of Erfurt in Central Germany, and in the province of Hanover and at Lubeck in North Germany. The whole area between Thuringia in the south and Slesvig in the north was seriously affected, while the incidence was less than 4 per 100,000 in the areas east and west of this belt. Only a few cases were reported in South Germany. The case mortality rate was 10.6 per cent.

Acute poliomyelitis has never been so prevalent in *Great Britain* as in Scandinavia or in the United States; this is clearly shown by the mortality statistics, which are undoubtedly more complete than the morbidity statistics. From 1918 to 1926 the mortality from acute poliomyelitis in England and Wales was only between 0.3 and 0.7 per 100,000 inhabitants and did not exceed 0.6 in 1926 in spite of the epidemic prevalence during the second half of the year. The number of notifications began to rise in July but did not reach its maximum until late in October; the epidemic did not entirely spend itself until the end of February 1927. The disease was most prevalent in certain of the south-eastern counties (Essex and Kent), and in the Midlands, where the counties of Leicester and Rutland were specially affected. The case-mortality rate averaged 18.1 per cent for the year, but in the important outbreak at Leicester it was only 8.6 per cent. The disease was most prevalent in rural districts with the exception of the outbreak at Leicester. The age distribution of 277 cases gives 39 per cent under 5 years of age, 34.3 per cent between 5 and 9 years, 16.2 per cent between 10 and 14, 5.8 per cent between 15 and 20, 4.7 per cent between 21 and 25, and 3 per cent between 26 and 40 years of age.

#### ENCEPHALITIS LETHARGICA.

Epidemic encephalitis—which might be a better name than encephalitis lethargica, since lethargy is by no means a constant symptom of this disease—occurs all over the world, but appears to be a comparatively new disease, or at any rate a disease, which has only recently given rise to epidemics. Information on its prevalence is so far very scarce, and even moderately reliable statistics exist only for a few countries. The disease is apparently far more prevalent in Europe, North America, New Zealand and Japan than elsewhere; it is most prevalent in Great Britain and Scandinavia.

Mortality statistics which may be more reliable and comparable than the notification records give the following annual rates per 100,000 inhabitants for deaths from epidemic encephalitis: in England and Wales from 1919 to 1926: 0.8, 1.3, 1.9, 0.9, 1.4, 3.6, 3.5, 3.4; in Scotland from 1920 to 1926: 1.9, 1.2, 0.9, 2.6, 3.7, 3.4 and 3.4; the Netherlands from 1920 to 1926: 1.3, 1.2, 0.7, 0.6, 0.7, 0.8 and 0.8; the United States from 1919 to 1924: 0.7, 1.7, 1.9, 1.4, 2.0 and 1.5; Sweden from 1920 to 1923: 2.3, 6.2, 1.3 and 3.0.

Epidemic encephalitis seems to be more prevalent in towns than in the country in the United States; the death rate from this cause in 1924 was 2.2 per 100,000 inhabitants in towns and 0.8 in rural districts. In England and Wales, on the contrary, the mortality was slightly higher in the country; the corresponding figures for 1926 were: 3.3 for urban and 3.6 for rural districts.

The case mortality rate is always high but seems to have a tendency to fall when epidemics occur. In *England and Wales* it was 54.3 per cent in 1919, 53.9 per cent in 1920, 49.6 per cent in 1921, rose to 74.7 per cent in 1922 possibly owing to some of the persons falling ill during the 1921 epidemic not dying until the following year; it was 51.8 per cent in 1923, and fell to 27.9 per cent in 1924—the year of the most important epidemic hitherto experienced—and rose again to 52.1 in 1925 and 58.5 in 1926. This change has had the strange effect that, while encephalitis cases in England decreased from 5,039 in 1924 to 2,635 in 1925 and 2,267 in 1926 the number of deaths attributed to it remained nearly constant, being 1,407 in 1924, 1,372 in 1925 and 1,325 in 1926.

The case mortality rate is lower in Sweden, possibly owing to better reporting of the cases; it was 38.1 in 1921, fell to 24.5 during the severe epidemic of 1921, and was 41.1 in 1922 and 33.8 in 1923.

The seasonal maximum, which in the first epidemics of 1920 and 1921 came early in the winter, in December or January, has shown a tendency to come later and later in the year, in April, May or even later. The seasonal curve of this disease always showed up to 1924 a very sharp peak, but since that year the curve has become flatter, and the monthly variations are now no greater than for many non-epidemic diseases.

In 1926 the incidence of epidemic encephalitis was relatively low in all European countries for which reliable information is available. There was a marked decrease in *Sweden*, *Finland* and *Denmark*. In Denmark 104 cases of "epidemic hiccup" were also reported in 1926, as compared with 783 the previous year; most of the cases reported in 1926 occurred in November and December immediately before the influenza epidemic began. Epidemic encephalitis was also less prevalent in *Italy* than in 1925; its incidence was higher in the north and centre than in the south and the islands. There was a slight increase, on the other hand, in the *U.S.S.R.*.

An outbreak of encephalitis occurred in *Japan* between August and October 1926. The geographical distribution was very similar to that of the much larger epidemic which occurred during the same months of 1924. The highest incidence was found, as then, in the provinces round the Inland Sea and particularly in *Kagawa*, *Okayama* and *Tottori*, but while the case incidence in these three provinces in 1924 varied from 100 to 310 per 100,000 inhabitants, it was only from 13 to 15 per 100,000 during the last outbreak. It appears that the provinces further east and north were not affected by the epidemic. It must be remembered that these Japanese epidemics, although in some respects resembling epidemic encephalitis, show important clinical and epidemiological differences from the European and American type. The concentration in late summer and autumn is reminiscent of the typical poliomyelitis epidemics.

#### CEREBRO-SPINAL MENINGITIS.

Epidemic cerebro-spinal meningitis is probably more widespread throughout the world than epidemic encephalitis and poliomyelitis. Climatic conditions seem to be of less consequence to its development, and it is frequently more prevalent in tropical or sub-tropical countries than in the colder climates. It is a disease which attracted the attention of public health services much earlier than the two other epidemic diseases of the central nervous system and notification has therefore been compulsory for many years in most countries. Epidemics are comparatively speaking rare in spite of the wide diffusion of the infection, shown by the numerous sporadic cases reported in all parts of the world.

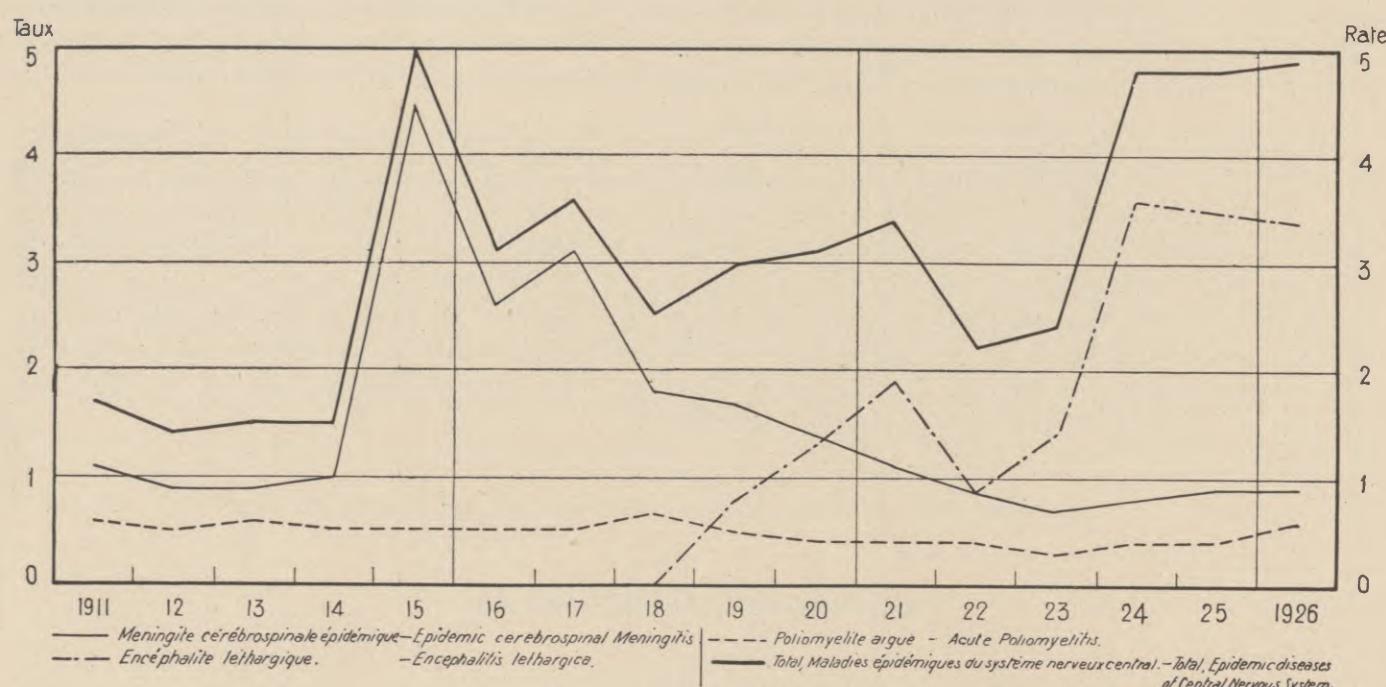

The incidence of cerebro-spinal meningitis in Europe has nowhere risen above the normal since the outbreaks in Germany of 1922 and 1923. The returns for the last three years have been remarkably steady; for instance, in *Germany* 742 cases were reported in 1924; 750 in 1925, 746 in 1926; and in *England and Wales*: 397 in 1924, 402 in 1925, 385 in 1926. Significant changes in incidence occurred only in *Czechoslovakia* (154 cases in 1925 and 220 cases in 1926) and *Poland* (396 cases in 1925 and 543 in 1926) (increase in both countries), and in *France* (653 cases in 1925 and 432 in 1926) and *Latvia* (34 cases in 1925 and 15 in 1926) (decrease in both countries). The changes were in no case very considerable.

There was a small increase in the *United States* (from 1,469 cases in 37 States in 1925 to 1,801 cases in 1926); this increase was most marked in the Pacific Coast States. There were 206 cases in California and 241 in the State of Washington in 1926, compared with 111 and 61, respectively, the previous year. There was a small increase also in *Canada*, where 167 deaths in 1925 and 206 deaths in 1926 were attributed to this cause. Statistics for other American countries did not show significant changes; neither does it seem that important outbreaks have occurred in *Australia*, *New Zealand* or in Asiatic countries. The number of notifications in *Japan* decreased slightly from 445 in 1925 to 407 in 1926.

Cerebro-spinal meningitis has in the last five years been of more serious consequences in the semi-arid country south of the North African desert belt than elsewhere in the world. In 1921 there was an epidemic in the Niamey district, in the *French Niger Territory*, which caused 3,200 deaths (77 per 1,000 inhabitants); in 1923 there were about 1,800 deaths in the same territory. In 1924 meningitis was again epidemic in the territory, causing 5,216

deaths at Zinder (248 per 1,000 inhabitants) and 1,400 deaths in other districts of the Territory. There were in that year about 1,000 deaths from this cause in neighbouring districts of *Northern Nigeria*. The following year there were 1,322 deaths in Nigeria, while the epidemic abated in the French territory. In 1926, epidemic meningitis caused 931 deaths in Nigeria, mostly during the first three months of the year. There was a small outbreak in the Niger Territory in April, during which month 160 cases were reported. Important outbreaks were reported

DEATH RATE PER 100,000 INHABITANTS FROM THE EPIDEMIC DISEASES OF THE CENTRAL NERVOUS SYSTEM  
IN ENGLAND AND WALES FROM 1911 TO 1926.

nowhere else in this area, and the situation was better on the whole than in the previous year. There were fewer cases in *Uganda* (73 cases) in 1926 than in the four preceding years. No noteworthy meningitis outbreaks were reported during the year in *Kenya* or in *Anglo-Egyptian Sudan*. The incidence was somewhat lower also in the *Union of South Africa* than during the three previous years.

#### DIPHTHERIA.

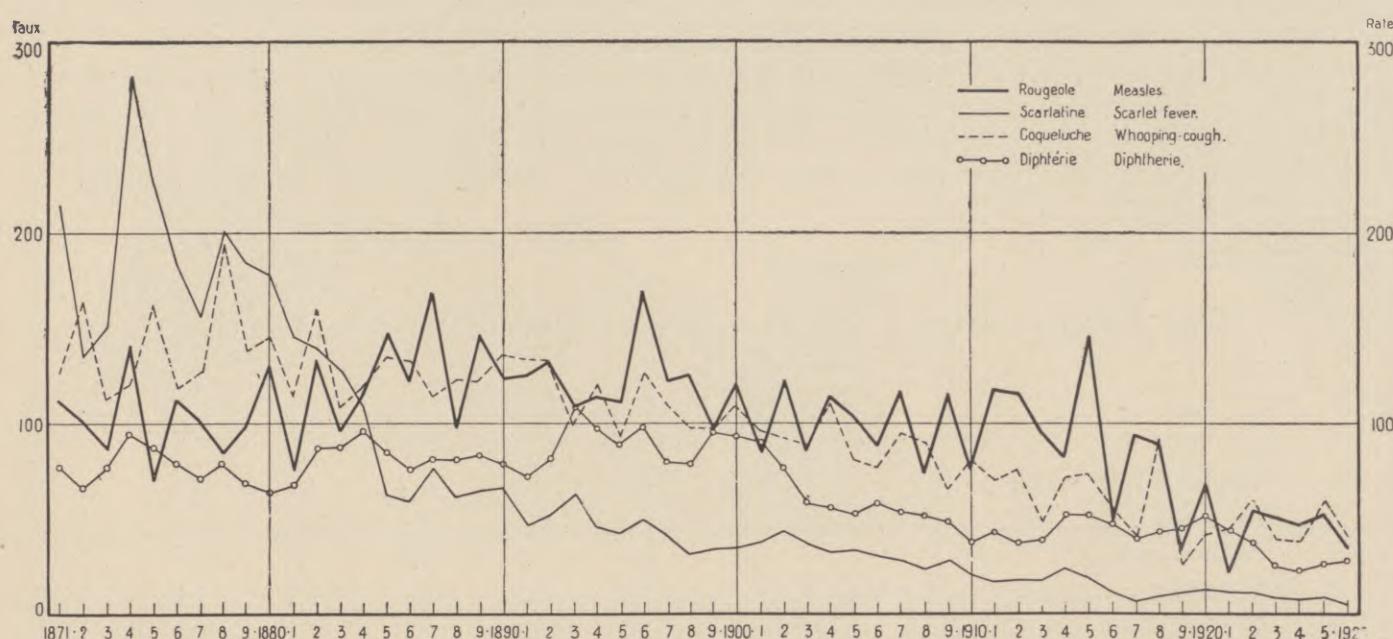

It is now generally recognised that the Schick test and toxin-antitoxin immunisation are of great value for the prevention of diphtheria. Diphtheria statistics show, unfortunately, that health officers in most countries are slow in taking full advantage of this method. The incidence of diphtheria in most countries has, in recent years, been running its normal course, with small temporary increases and decreases. The small, more permanent improvement in the incidence which can be detected in some countries, can with a few exceptions, be ascribed at least partly to the diminished proportion of children in the population due to the falling birth rate. A more permanent improvement seems to have occurred in the death rate from diphtheria, but it has, on the whole, not been so great as in the case of scarlet fever. This is best seen when comparing a long series of years, as in the diagram for 55 years' mortality from epidemic diseases of childhood in England and Wales.

In Europe, there was a moderate decrease in 1926, in comparison with the previous year, in an area covering Italy, Switzerland, Germany, the Netherlands, Belgium, Norway, Sweden, Finland, Estonia, White Russia, Western and Northern Russia as far east as the Urals. But the incidence increased in an even larger area formed by Great Britain and Ireland, France, Spain, Greece, Bulgaria, the Kingdom of the Serbs, Croats and Slovenes, Roumania, Hungary, Czechoslovakia, Poland, Lithuania, Ukraine, Crimea, Southern Russia, the Caucasus and farther on in Central Asia and parts of Siberia. All told, there were more diphtheria cases in Europe in 1926 than in the three preceding years. Mortality statistics for large towns show a similar increase.

Such information as is available for Africa and Asia indicates that there was no significant change in the diphtheria incidence in 1926. Diphtheria is much less prevalent in tropical than in temperate climates. Schick testing carried out in the Malay States and in the Philippine Islands seems to show a much higher degree of immunity among the natives of these countries than among European and American children, and the rare occurrence of diphtheria in the tropics may therefore not be due entirely to climatic causes. In the United States the death rate from diphtheria is considerably lower among negroes than among the white population; the same is the case in the Union of South Africa.

Diphtheria increased in *Australia* and *New Zealand* between 1921, when there was a serious epidemic, and 1925, when the incidence was the lowest on record. In 1926, there was a new but moderate increase in both countries; this increase did not reach Victoria, Tasmania and Western Australia.

MORTALITY PER 100,000 INHABITANTS UNDER 15 YEARS OF AGE FROM DIPHTHERIA, SCARLET FEVER, MEASLES AND WHOOPING-COUGH IN ENGLAND AND WALES FROM 1871 TO 1926.

In the *United States of America*, where the immunisation campaign is more vigorously pursued than elsewhere, there has been a steady decrease of diphtheria since 1921, during which year 204,235 cases were reported. In 1926, there were 88,714 cases in the whole Union. The decrease, which had been about 24,000 cases a year between 1922 and 1925, diminished, however, to only 3,000 from 1925 to 1926. The reason of this probably is that a new natural rise of the incidence is due but is being nearly checked by the preventive measures; even a moderate increase in 1927, if it should occur, would not prove the inefficacy of the vaccination campaign. It must also be remembered that the immunisation of school-children is by no means thoroughly carried out in all States. An increase over the previous year was reported in 1926 in California, Michigan, Ohio and several Southern States, particularly in Tennessee, Georgia, Alabama, Florida and the District of Columbia.

There was little change of the incidence from the previous year in *Canada*. In Cuba and in the Panama Canal Zone, there was a moderate increase. Such fragmentary information as is available for *South America* does not indicate more than the usual incidence. The number of deaths from diphtheria at Buenos Ayres increased, however, during the last two years from 142 to 253.

It is gratifying that the case-mortality rate in many countries has decreased in recent years. In England, it decreased to 8.7 per cent in 1913, but rose again to 11.0 in 1918, after which there was a steady decrease, only interrupted in 1922, to 5.8 in 1925 and 5.9 per cent in 1926. In London, where great care is taken to detect all cases, it was 4.0 per cent in 1926. It is hardly possible, however, to clear up how much of this decrease is due to a better notification of cases, and therefore only apparent, and how much is real. A still lower case-mortality rate is obtained in Denmark, where there were 3.8 deaths for each 100 diphtheria cases between 1921 and 1924, and only 3.0 per cent fatal cases in 1925. In Sweden, the case mortality was 4.4 per cent in 1923, and in Germany it was 4.5 per cent in 1926. The lowest case-mortality rate was in New Zealand, where it was

2.7 per cent in 1926. The case-mortality rate was higher in East-central and Eastern Europe in 1926; it was 7.4 per cent in Czechoslovakia, 8.6 per cent in Hungary, and 9.1 per cent in Poland.

#### SCARLET FEVER.

The outstanding feature of scarlet fever statistics for the last fifty years is the remarkable decrease of its mortality and the fact that its incidence has not decreased to anything like the same degree. Hence, the case-mortality rate, which usually was between 10 and 20 per cent in the eighties of last century, is now 1 per cent or less in countries of Northern, Western and Central Europe, and not much higher in the United States. Only a small part of this decrease can be explained by better notification of cases, since hospital statistics show a similar decrease of case-mortality rate. Furthermore, outbreaks of severe scarlet fever, with a high case-mortality rate, are known to have occurred locally even in countries where the milder form predominates. The case-mortality rate has decreased much less in Eastern Europe, where scarlet fever remains a serious disease causing a high mortality. It is noteworthy that the difference between the case-mortality rates in Eastern and Western Europe is not nearly so great in the case of diphtheria as in the case of scarlet fever, a fact which proves that they are not due simply to better notification in the western half of Europe. The case-mortality rate of scarlet fever during the most recent years is shown below for a few countries in various parts of the world.

CASE MORTALITY RATE (%) OF SCARLET FEVER IN VARIOUS COUNTRIES, 1921-26.

	1921	1922	1923	1924	1925	1926
England and Wales . . . . .	4.0	4.3	4.2	4.1	4.1	0.8
Denmark . . . . .	4.0	4.2	4.0	4.0	0.8	—
Netherlands . . . . .	4.5	4.0	0.8	0.8	4.0	0.8
Germany . . . . .	—	3.3	3.3	2.3	2.2	4.1
Poland . . . . .	43.9	43.2	40.9	8.7	9.5	9.5
Roumania . . . . .	43.5	44.0	42.9	8.9	7.0	6.3
Japan . . . . .	5.2	5.8	5.6	6.6	10.9	8.5
New Zealand . . . . .	4.3	0.7	4.0	4.1	0.6	0.5

The year 1926 was the second year and, in some countries, the third or fourth year in which scarlet fever had increased in most of Europe. A decrease from the previous year's incidence took place only in England, Denmark, Norway and Sweden in the north, and in an area consisting of the Kingdom of the Serbs, Croats and Slovenes, Roumania, Austria, Wurtemberg, part of northern and the whole of central Italy (there was a marked increase in Sicily and Sardinia). There was a small decrease also in the northern half or third of Russia. In all the rest of Europe there was an increase, which was very considerable in the Caucasus, Crimea, southern Russia, Ukraine, Estonia, Poland, north Germany and Spain. Scarlet fever is, on the whole, more prevalent in Europe than diphtheria, but causes fewer deaths. In the U.S.S.R., Roumania, Poland, Lithuania, Latvia and Estonia, scarlet fever is from four to six times more common than diphtheria and, as it is of a more severe type in these countries, it also causes more deaths than the latter.

Scarlet fever is rare in tropical and subtropical countries. In Egypt, for example, there were only 6 deaths from scarlet fever in 1926, compared with 617 from diphtheria and 9,149 from measles. Scarlet fever is fairly prevalent in northern China, but rare in the south; it was epidemic in the province of Chihli in July 1926. It occurs also in Chosen without being very common; it is more common among the Japanese than among Koreans. Scarlet fever has spread steadily in Japan in recent years, but it is of common occurrence only in the large towns.

The incidence of scarlet fever in the United States has changed very little during the last six years; 184,264 cases were reported in 1921 and 181,508 in 1926. Scarlet fever is less prevalent in the Southern States than in the north, and less common among the coloured than among the white population. The number of deaths

INCREASE OR DECREASE OF SCARLET FEVER INCIDENCE IN EUROPE FROM 1925 TO 1926.

caused by scarlet fever in Mexico is small in comparison with that caused by other epidemic diseases. In South America, scarlet fever does not appear to be an important cause of death except at Buenos Ayres, where it caused 128 deaths in 1926, as compared with 59 and 26 deaths respectively during the two previous years. At Rio de Janeiro, there were only 2 deaths from scarlet fever in 1926, and none the two previous years. Scarlet fever seems to be rare in Chile.

### MEASLES.

Measles undoubtedly causes more deaths throughout the world than either scarlet fever or diphtheria. It is prevalent both in cold and hot climates and among most races. There is no difference, in the United States, between its incidence among the white and the coloured population. It probably causes more deaths in Egypt and the adjoining part of Asia than any other epidemic disease. In 1926, there were again serious outbreaks in Egypt, where 9,149 deaths from measles were reported, as compared with 6,084 in 1925 and 1,750 in 1924. The case mortality increased with the coming of hot weather and the epidemic was most severe in June. There was also an increase in the reports from all the other countries on the Mediterranean coast. No important outbreaks were reported from other parts of Africa, and the incidence was somewhat lower than in the previous two years in Palestine and in Syria. There were 2,681 deaths from measles in the Philippine Islands, as compared with 478 the previous year. Measles seems to be much less prevalent both in China and in Japan.

Measles is a more typical epidemic disease than scarlet fever and diphtheria; its incidence changes much more abruptly from year to year and from season to season than does that of the other two diseases. Its seasonal incidence is also more variable, although there is, in the colder climates, a preference for the winter months, at any rate as far as the more severe cases are concerned. The outbreaks are usually of a rather local character, and it is rare

that a common upward or downward trend of the incidence can be found over very large areas, such as is frequently the case with most other epidemic diseases. In 1926 there was thus a decrease in England, but a marked increase in Scotland and Ireland. There was a very extensive epidemic in Estonia, but fewer cases in Latvia and in Lithuania than during the previous year. The severe measles epidemics which visited Russia in 1925 decreased in most districts in 1926, but the mortality was still very high in many towns. There was a decrease in 1926 also in Italy, where measles was very prevalent in 1925.

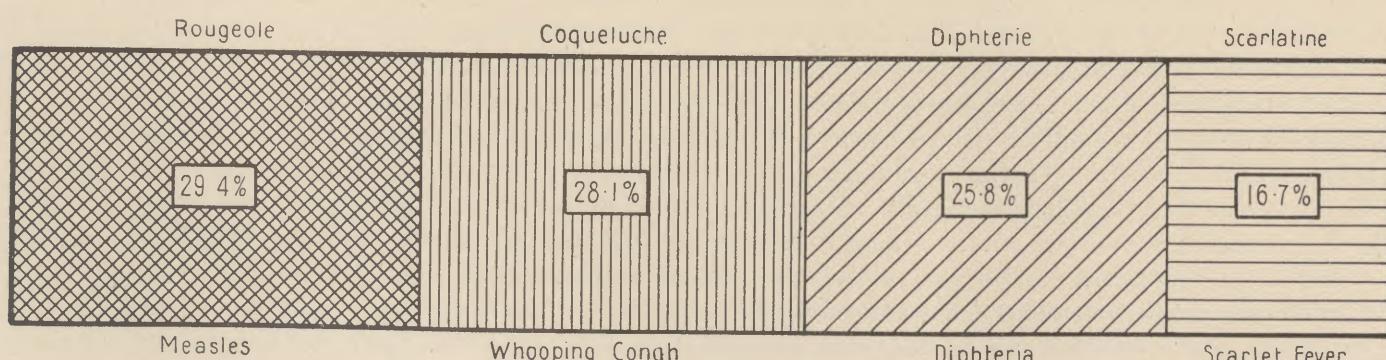

Measles was more widespread in the United States in 1926 than it had been for a number of years before; 647,605 cases were reported, compared with 222,634 the previous year. It was particularly prevalent in the States of New York and Pennsylvania, and caused 704 deaths in New York City, all but 15 during the first half of the year. The incidence increased markedly also in Canada, but there was a large decrease, compared with the previous year, in Mexico, where severe epidemics had occurred in 1925. Measles is of common occurrence also in South America, but such statistics as are available for towns showed mostly a lower incidence than in 1925.

#### WHOOPING-COUGH.

Notification of whooping-cough cases is not compulsory in very many countries, and the notification is incomplete in most countries where it is reported. The reports are probably much more complete in Denmark than elsewhere; 30,299 cases were reported in 1926, which gives 890 cases per 100,000 inhabitants. Whooping-cough is nevertheless a very important disease, which causes a considerable mortality among the very small children in most countries. Whooping-cough causes thus a greater mortality than either diphtheria, scarlet fever or measles in the Scandinavian countries, the Netherlands, Germany, Switzerland and Austria as well as in Japan. It causes a high mortality also in Great Britain and Ireland. In Mexico, there were more deaths from whooping-cough in 1926 than from the other three epidemic diseases of childhood combined.

The incidence of whooping-cough in the United States was somewhat higher in 1926 than during the previous five years. The number of deaths ascribed to this cause in Canada and in Mexico was also above the average. The highest mortality in South-American towns was at Rio de Janeiro, where there were 552 deaths from whooping-cough in 1926, compared with 208 deaths from the other three diseases combined. Whooping-cough was less prevalent in Europe, as far as can be judged from the scanty information available, in 1926 than in 1925, except in Denmark, Estonia, Italy, the Netherlands and the Ukraine. The same conclusion can be drawn from the mortality statistics of large towns, which show a slight increase also in Germany. Sardinia was more seriously affected than the other Italian provinces. In Australia, in 1925, there were 463 deaths from whooping-cough or 2 deaths more than from the other three diseases combined (diphtheria 273, measles 133 and scarlet fever 55).

RELATIVE INCIDENCE FROM THE FOUR EPIDEMIC DISEASES OF CHILDHOOD IN 344 TOWNS THROUGHOUT THE WORLD IN 1926.

The relative importance under present conditions of the four epidemic diseases of childhood may be gathered from the aggregate statistics of mortality of 344 towns distributed throughout the world. The statistics show, for 1926, 7,446 deaths from measles, 7,108 from whooping-cough, 6,522 from diphtheria and 4,215 deaths from scarlet fever. They do not include towns of tropical climates properly speaking, as the causes of infant deaths in these

are generally very unreliable; but, as scarlet fever and diphtheria are very rare in the tropics, they would only further increase the proportion of deaths from measles.

The opinion, often met with and reflected in the regulations for notification of these diseases, that whooping-cough and measles are less important than scarlet fever and diphtheria evidently dates from the latter half of the nineteenth century, when the two latter diseases caused many more deaths than they do now, and when mortality under two years of age was so heavy as to leave less in evidence such causes as measles and whooping-cough.

Note. — La déclaration des cas de fièvre jaune étant obligatoire dans tous les pays, le fait qu'un de ceux transmettant des rapports officiels ne figure pas au tableau ci-dessus signifie qu'aucun cas n'a été déclaré pendant l'année 1926.

Note. — The declaration of yellow fever cases being compulsory in all countries, the absence from the above table of any country sending official reports signifies that no case was reported during 1926.

# LEAGUE OF NATIONS

## PUBLICATIONS OF THE HEALTH SECTION

### "Monthly Epidemiological Report."

The Service of Epidemiological Intelligence and Public Health Statistics, Health Section of the Secretariat of the League of Nations, receives current official reports on the prevalence of notifiable diseases from nearly all countries where such information is available. The information at present being regularly received and published in this periodical relates to 68 per cent of the world's population.

*Yearly subscription for 12 numbers.* . . . . . 18/- \$4.50

### Yearbooks:

INTERNATIONAL HEALTH YEARBOOK 1924. Reports on the Public Health Progress of Twenty-two Countries (C.H.349)	12/-	\$3.00
INTERNATIONAL HEALTH YEARBOOK 1925 (Second Year). Reports on the Public Health Progress of Twenty-one Countries. (C.H.477.1926.III.26)	16/-	\$4.00
INTERNATIONAL HEALTH YEARBOOK 1926. Reports on the Public Health Progress of about Thirty Countries . . . . .	In preparation	

### Epidemiological Enquiries:

THE PREVALENCE OF EPIDEMIC DISEASE AND PORT HEALTH ORGANISATION AND PROCEDURE IN THE FAR EAST. Report to the Health Committee of the League of Nations by E. Norman White (C.H.130) . . . . .	6/-	\$1.40
REPORT ON AN INVESTIGATION INTO THE SANITARY CONDITIONS IN PERSIA, undertaken on behalf of the Health Committee of the League of Nations at the request of the Persian Government by Dr. John Gilmour (C.H.262) . . . . .	1/6	\$0.40
RAPPORT D'ENSEMBLE RELATIF A LA CAMPAGNE DE VACCINATION exécutée en Grèce au cours de l'année 1923, par le Docteur Aimé Gauthier, médecin principal de l'armée française, délégué de la Commission des épidémies de la Société des Nations (C.H.149) (French text only) . . . . .	1/6	\$0.40
THE PROPHYLAXIS OF DIPHTHERIA by the Determination of Susceptibles and their Active Artificial Immunisation in the United States, by Dr. Louis van Boeckel, Director of the Laboratory of the Belgian Public Health Department (C.169. M.45.1925.III) (C.H.184) . . . . .	1/9	\$0.40
A Memorandum on the EPIDEMIOLOGY OF CHOLERA, by Major A. J. H. RUSSELL, M.A., M.D., D.P.H., I.M.S., Director of Public Health, Madras Presidency, India, 1925 (C.H.339) . . . . .	1/3	\$0.30
ETUDE ÉPIDÉMIologIQUE SUR LA " LEISHMANIOSE VISCÉRALE" EN ESPAGNE, par le professeur C. Pittaluga (C.H.368) (French text only) . . . . .	9d.	\$0.20
LE FOYER ENDÉMIQUE DE CHOLÉRA DE ROSTOV-SUR-LE-DON: Etude épidémiologique par le professeur W. Barikine (Moscou) et le Docteur H. Cazeneuve (Genève) (C.H.395) (French text only) . . . . .	1/6	\$0.40
A TREATISE OF PNEUMONIC PLAGUE, by Wu-Lien-Teh (C.H.474.1926.III.13) . . . . .	20/-	\$5.00
STUDIES OF CHOLERA IN JAPAN, by Rokuro Takano, Itsuya Ohtsubo, and Zenjuro Inouye (C.H. 515.1926.III.22) . . . . .	3/-	\$0.70

### Standardisation of Sera, Serological Reactions and Biological Products:

REPORTS ON SEROLOGICAL INVESTIGATIONS presented to the Second International Conference on the Standardisation of Sera and Serological Tests, held at the Pasteur Institute in Paris on November 1922 (C.168.M.98.1923.III) . . . . .	8/-	\$2.00
REPORT OF THE EUROPEAN HEALTH CONFERENCE, held at Warsaw from March 20th to 28th, 1922 . . . . .	2/-	\$0.50
THE STANDARDISATION OF DYSENTERY SERUM, by Kiyoshi Shiga, H. Kawamura and H. Tsuychiya. The Kitasato Institute for Infectious Diseases. Tokyo.		
First Report (C.177.M.1924.III) . . . . .	1/6	\$0.40
Second Report (C.177(a).M.49(a).1924.III) . . . . .	1/6	\$0.40
INVESTIGATIONS ON THE SERODIAGNOSIS OF SYPHILIS. Report of the Technical Laboratory Conference, Copenhagen, November 19th to December 3rd, 1923, with two Annexes (C.5.M.5.1924.III) (C.H.148) (French and English texts)	3/6	\$0.80
REPORT OF THE TECHNICAL CONFERENCE FOR THE CONSIDERATION OF CERTAIN METHODS OF BIOLOGICAL STANDARDISATION. Edinburgh, July 19th to 21st, 1923 (C.4.M.4.1924.III) (C.H.147) . . . . .	4d.	\$0.05
SECOND INTERNATIONAL CONFERENCE ON THE BIOLOGICAL STANDARDISATION OF CERTAIN REMEDIES, convened by the Health Committee of the League of Nations and held at Geneva from August 31st to September 3rd, 1925 (C.532. M.183.1925.III) (C.H.350) (French and English texts)	1/-	\$0.25
THE BIOLOGICAL STANDARDISATION OF INSULIN, including Reports on the Preparation of the International Standard and the Definition of the Unit (C.H.398.1926.III.7) . . . . .	1/6	\$0.40
SUR LE TITRAGE (STANDARDISATION) DES TUBERCULINES, par le professeur A. Calmette et le Dr. de Potter. (CH.429) (French text only) . . . . .	1/6	\$0.40
REPORT OF PERMANENT STANDARDS COMMISSION (Geneva, October 11th-13th, 1926) (CH.517.1926.III.24) . . . . .	2d.	\$0.05
(A German text has been also published.)		

### Organisation of Public Health Services in Various Countries:

PUBLIC HEALTH SERVICES IN GERMANY, by Dr. Gottfried Frey, Medical Director, Reichsgesundheitsamt, Berlin (C.820. M.309.1923.III) (C.H.140) . . . . .	1/3	\$0.30
PUBLIC HEALTH SERVICES IN AUSTRIA, by Dr. Hermann Schröetter (C.825.M.314.1923) (C.H.141) . . . . .	1/3	\$0.30
ORGANISATION OF THE PUBLIC HEALTH SERVICES IN THE KINGDOM OF THE NETHERLANDS, by Dr. N. M. Josephus Jitta, President of the Health Council (C.H.209) . . . . .	9d.	\$0.20
