In Scotland, the opening up of the country by the construction of practicable roads, and the enclosing and subdividing of farms by hedge and ditch was now in active progress. The former admitted of the general use of wheel-carriages, of the ready conveyance of produce to markets, and in particular, to the extended use of lime; the application of which was immediately followed by a great increase of produce. The latter, besides its more obvious advantages, speedily freed large tracts of country from stagnant water, and their inhabitants from ague; and prepared the way for the under-ground draining which soon after began to be practised.

Historical Summary.

Remarkable progress from 1795 to 1815.

The agriculture of the country was thus steadily improving, when suddenly the whole of Europe became involved in the wars of the French Revolution. In 1795, under the joint operation of a deficient harvest, and the cutting off of foreign supplies of grain by the policy of Napoleon, the price of wheat, which, for the twenty preceding years, had been under 50s. a quarter, suddenly rose to 81s. 6d., and in the following year, reached to 96s.

Bank Restriction Act.

In 1797, the fear of foreign invasion led to a panic and run upon the banks, in which emergency the Bank Restriction Act, suspending cash payment, was passed and ushered in a system of unlimited credit transactions. Under the unnatural stimulus of these extraordinary events, every branch of industry extended with unexampled rapidity. But in nothing was this so apparent as in agriculture; the high prices of produce holding out a great inducement to improve lands then arable, to reclaim others that had previously lain waste, and to bring much pasture-land under the plough. Nor did this increased tillage interfere with the increase of live stock; as the green crops of the alternate husbandry more than compensated for the diminished pasturage. This extraordinary state of matters lasted from 1795 to 1814; the prices of produce even increasing towards the close of that period. The average price of wheat for the whole period was 89s. 7d. per quarter; but for the last five years it was 107s., and in 1812 it reached to 126s. 6d. The agriculture of Great Britain, as a whole, advanced with rapid strides during this period; but nowhere was the change so great as in Scotland. Indeed, its progress there, during these twenty years, is probably without parallel in the history of any other country. This is accounted for by a concurrence of circumstances. Previous to this period, the husbandry of Scotland was still in a backward state as compared with the best districts of England, where many practices, only of recent introduction in the north, had been in general use for generations. This disparity made the subsequent contrast the more striking. The land in Scotland was now, with trifling exceptions, let on leases for terms varying from twenty to thirty years, and in farms of sufficient size to employ at the least two or three ploughs. The unlimited issues of Government paper, and the security afforded by these leases, induced the Scotch banks to afford every facility to landlords and tenants to embark capital in the improvement of the land. The substantial education supplied by the parish schools, of which nearly the whole population could then avail themselves, had diffused through all ranks such a measure of intelligence as enabled them promptly to discern, and skilfully and energetically to take advantage of this spring-tide of prosperity; and to profit by the agricultural information now plentifully furnished by means of the Bath and West of England Society, established in 1777; the Highland Society, instituted in 1784; and the National Board of Agriculture in 1793; of which, however, more anon. As one proof of the astonishing progress of Scottish husbandry during this period, we may mention that the rental of land which in 1795 amounted to L.2,000,000, had in 1815 risen to L.5,278,685, or considerably more than doubled in twenty years.

But of the causes which have influenced the agriculture of the period under review, none have been so powerful as the extraordinary increase of our population, which, in round numbers, has twice doubled during the past seventy years. Not only are there four times as many people requiring to be fed and clad now as there was then, but from the increased wealth and altered habits of the people, the individual rate of consumption is greater now than formerly

Historical Summary.

This is particularly apparent in the case of butcher-meat, the consumption of which has increased out of all proportion with that of bread-corn. To meet this demand, there behoved to be more green crops and more live stock; and from that has resulted more wool, more manure, and more corn. While this ever-growing demand for farm-produce has stimulated agricultural improvement, it has also operated in another way. The productiveness of the soil has been greatly increased, and will no doubt be still more so in future; but the area of the country cannot be increased. Land—the raw material from which food is produced—being thus limited in amount, and in increasing demand, has necessarily risen in price. So much is this the case, that whereas the average price of wheat for the five years preceding 1852, has been L.2, 8s. $7\frac{3}{4}$d. per quarter, or L.2, 13s. 10d. less than during the five years preceding 1815, the rent of land is actually higher now than it was then. The raw material of the food-grower having thus risen in price, his only resource has been to fall upon plans for lowering the cost of producing his crops and for increasing their amount. To such an extent has he succeeded, that the produce-market has been kept full, and prices have decreased. The business of farming has in the main been a less prosperous one than most other branches of national industry, and yet agriculture, as an art and as a science, has made steady progress. We believe it is only in this way that the contemporaneous existence of two things apparently so incompatible as a steady rise in the rent of land, and a steady decrease in the price of its produce, can be satisfactorily accounted for.

From 1815 to present time.

The abundant crop of 1813, and restored communication with the continent of Europe in the same year, gave the first check to these unnaturally exorbitant prices and rents. The restoration of peace to Europe, and the re-enactment of the Corn-Laws in 1815, mark the commencement of another era in the history of our national agriculture. It was ushered in with a time of severe depression and suffering to the agricultural community. The immense fall in the price of farm-produce which then took place was aggravated, first, by the unpropitious weather and deficient harvest of the years 1816, 1817; and still more by the passing in 1819 of the Bill restoring cash payments; which coming into operation in 1821, caused serious embarrassment to all persons who had entered into engagements at a depreciated currency, which had now to be met with the lower prices of an enhanced one. The much-debated Corn-Laws, after undergoing various modifications, and proving the fruitful source of business uncertainty, social discontent, and angry partisanship, were finally abolished in 1846, although the Act was not consummated until three years later. Several other Acts of the Legislature, passed during this period, have exerted an important influence on agriculture. Of these, the first in date and importance is the Tithe Commutation Act of 1836. All writers on agriculture had long concurred in pointing out the injurious effects on agriculture, of the tithe system as it then stood. The results of the change have amply verified the anticipations of those who were instrumental in procuring it. Since the removal of this formidable hindrance to improvement, it has been stimulated by those acts under which the Government has been empowered to advance money on certain conditions, for the draining of estates. An important feature in these advances is, that the $6\frac{1}{2}$ per cent. of interest charged upon them, provides a sinking fund by which the debt is extinguished in 22 years. Additional facilities have also been granted, by the Act passed in 1848 for disentailing estates, and for burdening such as are entailed with a share of the cost of certain specified improvements.

Sir Robert Peel's Bill restoring cash payments.

Corn-Laws

Act commuting tithes into a rent charge.

Drainage Acts.

Another class of outward events, which has had an important influence upon agriculture, requires our notice. We refer to those mysterious diseases affecting both the animal and vegetable kingdoms, the causes and remedies for which, we have alike failed to discover. The murrain, or "vesicular epizootic" appeared first in 1841; having been introduced, as is supposed, by foreign cattle. It spread rapidly over the country, affecting all our domesticated animals, except horses, and causing everywhere great alarm and loss, although seldom attended by fatal results. It has prevailed ever since, in a greater or less degree. It was soon followed by the more terrible lung-disease, or pleuro-pneumonia, which continues to cause such mortality among our herds. But these have been as nothing in comparison with the dreaded potato-disease, which first appearing in 1845, has since pervaded the whole of Europe, and in Ireland especially has been the sad precursor of famine and pestilence. This seemingly insignificant blight, has already wellnigh withdrawn from cultivation one of our most esteemed field crops; it influences the business of farming in a way that baffles the shrewdest calculators, and is producing social changes of which no man can predict the issue.

Historical Summary.

Cattle Murrain.

Potato-disease.

We can here do little more than enumerate some of the more prominent improvements in practical agriculture which have taken place during the period under review. Before the close of the past century, and during the first quarter of the present one, a good deal had been done in the way of draining the land; either by open ditches, or by Elkington's system of deep-covered drains. This system has now been superseded by one altogether superior to it both in principle and practice. In 1835, James Smith of Deanston (honour to his memory!) promulgated his now well-known system of thorough draining and deep ploughing. It has been carried out already to such an extent, as to have altered the very appearance and character of whole districts of our country, and has prepared the way for all other improvements. The words "Portable Manures," indicate at once another prominent feature in the agriculture of the times. Early in the present century, ground bones began to be used in the eastern counties of England as a manure for turnips; whence the practice spread, at first slowly, and then very rapidly, over the whole country. It was about 1825 when it began to be generally used in Scotland. In 1841 the still more potent guano was introduced in Great Britain; and about the same time, bones, under the new form of superphosphate of lime. By means of these invaluable fertilizers, a stimulus has been given to agriculture which can scarcely be overrated.

Smith of Deanston's system of Draining.

Bone Dust.

Guano and Superphosphate of Lime.

The labour of agriculture has been greatly lightened and its costs curtailed, by means of improved implements and machines. The steam-engine has taken the place of the jaded horses, as a thrashing power. This was first done in East Lothian, by Mr Reid at Drem, who in 1820 erected such an engine at a cost of L.600. It would be tedious to particularise other instances in this department, as it will be treated of fully in its proper place. It is especially in this department that the influence of the ever-memorable Exhibition of the Industry of all Nations in 1851, has told upon agriculture. Reaping by machinery, may virtually be regarded as one of the fruits of that great gathering.

Thrashing by Steam.

The railways, by which the country is now intersected in all directions, have proved of great service to farmers, by conveying their bulky produce to distant markets cheaply and quickly; and by making lime and other manures available to the occupiers of many inland and remote districts. In nothing has this benefit been more apparent, than in the case of fatted live stock, which is now invariably transported by this means, with manifold economy to all concerned.

Railways.

During the whole of this period, there has been going on great improvements in all our breeds of domesticated ani-

Historical Summary.

Improved live stock and field crops.

mals. This has been manifested, not so much in the production of individual specimens of high merit—in which respect the Leicesters of Bakewell, or the short-horns of Colling, have perhaps not yet been excelled—as in the diffusion of these and other good breeds over the country, and in the improved quality of our live stock as a whole. The fattening of animals is now conducted on more scientific principles. Increased attention has also been successfully bestowed on the improvement of our field crops. Improved varieties, obtained by cross-impregnation, either naturally or artificially brought about, have been carefully propagated, and generally adopted. Increased attention is now bestowed on the cultivation of the natural grasses. The most important additions to our list of field crops during this period, have been Italian ryegrass, winter beans, white Belgian carrot, and sugar beet.

Agricultural Societies.

Let us look now at the means by which, during this period, agricultural knowledge has at once been increased and diffused. Notice has already been taken of the institution of the Highland Society and National Board of Agriculture. These patriotic societies were the means of collecting a vast amount of statistical and general information connected with agriculture, and by their publications and premiums made known the practices of the best-farmed districts of the country and encouraged their adoption elsewhere. These national associations were soon aided in their important labours by numerous local societies which sprung up in all parts of the kingdom. After a highly useful career, under the zealous presidency of the amiable Sir John Sinclair, the Board of Agriculture was dissolved, but has left in its Statistical Account, county surveys, and other documents, much interesting and valuable information regarding the agriculture of that period. In 1800, the original Farmer's Magazine entered upon its useful career under the editorship of Robert Brown of Markle, the author of the well-known treatise on "Rural Affairs." The Highland Society having early extended its operations to the whole of Scotland, by and by made a corresponding addition to its title, and as the *Highland and Agricultural Society of Scotland* continues to occupy its important sphere with a steadily increasing membership, popularity, and usefulness. As its revenue and experience increased, it gradually extended its operations. In 1828, shortly after the discontinuance of the Farmer's Magazine, its "Prize Essays and Transactions" began to be issued statedly in connection with the "Quarterly Journal of Agriculture," a periodical which still occupies a prominent place in our professional literature. This Society early began to hold a great annual show of live stock, implements, &c., the popularity of which continues unabated. In 1842, Mr John Finnie at Swanstone, near Edinburgh, having suggested to some of his neighbours the desirableness of obtaining the aid of chemistry to guide farmers in many departments of their business, the hint was promptly acted upon, and these Mid-Lothian tenant-farmers had the merit of originating an Agricultural Chemistry Association (the first of its kind), by which funds were raised, and an eminent chemist engaged, for the express purpose of conducting such investigations as the title of the Society imports. After a successful trial of a few years this association was dissolved, after transferring its functions to the Highland and Agricultural Society, which has ever since devoted much of its attention to this subject. The accompanying article on Agricultural Chemistry from the pen of its present accomplished chemist, Dr Anderson, shows the nature and importance of the labours in which he, and his predecessor, Professor Johnston, have been engaged. This society has of late years established itself on a broader basis, and imparted new energy to its operations by lowering its admission-fee in behalf of tenant-farmers, who have in consequence joined it in great numbers, and now take an important part in the conduct of its business. The practice adopted by it, about the same time, of holding periodical meetings for the discussion of important practical questions, by means of essays from selected individuals, is doing good service to the cause of agricultural progress.

Farmer's Magazine.

Quarterly Journal of Agriculture.

Agricultural Chemistry Association.

Royal Agricultural Society of England.

The obvious success of this National Scottish Society has led to the formation of similar ones in England and in Ireland. The former instituted in 1838, and shortly afterwards incorporated by Royal Charter, at once entered upon a career of usefulness, the extent of which cannot well be overrated. Its membership—comprising the most influential persons in the kingdom—and its revenues are now so large as to enable it to conduct its proceedings on a scale befitting its position and objects. These are of a varied character, but its efforts are concentrated upon its journal and annual show. The former, published twice a-year, is chiefly composed of the essays and reports to which the liberal prizes of the society have been awarded, and undoubtedly stands at the head of our present agricultural periodicals. At its annual shows, a prominent place is assigned to implements and machines. Such as admit of it, are subjected to comparative trials, which are conducted with such skill and pains that the awards command the entire confidence of exhibitors and their customers. The extent and rapidity of the improvement in agricultural machinery which the society has been the means of effecting, is altogether extraordinary.

Farmers' Clubs.

There are few market-towns of any importance that have not their organised club or occasional gathering of the farmers in their neighbourhood, for the discussion of professional topics. We have now also a goodly list of agricultural periodicals, both weekly and monthly, most of them ably conducted, which are extensively read, and are the means of collecting and diffusing much valuable knowledge, which, but for them, would often, as in former times, perish with its authors, or be confined to corners. The facilities now afforded by railways for cheap and expeditious travelling, induce most farmers to take an occasional peep at what is going on beyond their own neighbourhood. This, more than anything, deals deathblows to prejudices, and extends good husbandry.

In reviewing the history of our national agriculture for the past fifty years, it is pleasing to note the growing intelligence displayed by our agriculturists in the prosecution of their calling. It is curious, also, to observe the analogy betwixt the order of that progress, and that which is usually observed in individual minds. For a length of time we see agricultural societies and writers occupying themselves chiefly about the practical details and statistics of husbandry, and attaching much importance to empirical rules. Gradually, however, we observe, along with a zealous collecting of facts, a growing disposition to investigate the *causes* of things, and to know the *reason* why one practice is preferable to another. When, therefore, the Royal Agricultural Society adopted as its motto "Practice with Science," it expressed not more the objects to be aimed at in its own proceedings, than the characteristic feature of our present stage of agricultural progress.

## CHAPTER II.

### PRACTICE OF BRITISH AGRICULTURE.

Practical Agriculture. Plan of Treatise.

We shall now endeavour to present a picture of British Agriculture in its present state. In doing this, we shall take much the same course which we should pursue, if we were asked to conduct a visitor over our own farm, and to give him a detailed account of its cultivation and management. In the case supposed, we should, first of all, explain to him

Practical Agriculture.

that the farm comprises a great diversity of *soils;* that its fields are very variously circumstanced as regards altitude, exposure, and distance from the homestead; and that in its tillage, cropping, and general management, regard must be had to these diversities, whether natural or artificial. Having thus premised, we should then conduct him through the homestead, pointing out the position and uses of the various FARM BUILDINGS, and of the MACHINERY and IMPLEMENTS contained in them. From thence we should proceed to the fields, examine their FENCES and the TILLAGE OPERATIONS. With some observations about the SUCCESSION OF CROPS, and the MANURES applied to them, there would follow an examination of the CULTIVATED CROPS, PASTURES, and MEADOWS; of the LIVE STOCK of the farm; and of the measures adopted in reclaiming certain WASTE LANDS belonging to it. This survey being completed, there would naturally follow some discussion about the TENURE of land, the CAPITAL required for its profitable cultivation, the condition of FARM LABOURERS, the necessity for devoting more attention to the EDUCATION of the agricultural community, and the duty of the legislature to remove certain OBSTRUCTIONS to agricultural improvement. In the sequel we shall give, from authentic sources, some examples to illustrate the British husbandry of the present day.

Soils.

The soil constituting the subject-matter on which the husbandman operates, its character necessarily regulates to a large extent the nature of his proceedings. The soil or surface covering of the earth in which plants are produced is exceedingly varied in its qualities. Being derived from the disintegration and decomposition of the rocks which constitute the solid crust of the globe, with a mixture of vegetable and animal remains, soils take their character from that of the rocks from which they have chiefly been derived. There is hence a generally prevailing resemblance betwixt the soils of a district and the rocks over which they lie, so that a knowledge of the composition of the one affords a key to the character of the other. But this connection is modified by so many circumstances that it is altogether impossible by the mere study of geology to acquire an easy and certain rule for determining the agricultural character of the soil of any particular district or field, as it has been the fashion with some writers of late years to assert. "When indeed, we regard a considerable tract of land, we can for the most part trace a connection between the subjacent deposits and the subsoil, and consequently, the soil. Thus, in a country of sandstone and arenaceous beds we shall find the soil sandy; in one of limestone, more or less calcareous; in one of schistose rocks, more or less clayey. But even in tracts of the same geological formation, there exist great differences in the upper stratum, arising from the prevalence of one or other member of the series, or from the greater or less inclination of the strata, by which the debris of the different beds are more or less mixed together on the surface. The action of water, too, in denuding the surface at one part, and carrying the debris in greater or smaller quantity to another, exercises everywhere an important influence on the character of soils. Thus the fertility of a soil on the higher ground from which the earthy particles are washed, is found to be very different from that of the valley to which these particles are carried. It is seen accordingly, that within the limits of the same geological formation, soils are greatly varied, and that the mere knowledge of the formation will not enable us to predicate the character of the soil of any given tract, either with respect to its texture, its composition, or its productiveness."[1] Even a very limited acquaintance with the geology of Great Britain serves, however, to account for the exceedingly diversified character of its soils. The popular definitions of soils, and to which it is safest for practical farmers to adhere, have respect to their most obvious qualities. Thus they are designated from their composition, as *clays, loams, sands, gravels, chalks, or peats;* or from their texture, in which respect those in which clay predominates are called *heavy, stiff,* or *impervious;* and the others *light, friable,* or *porous.* From the tendency of the former to retain moisture they are often spoken of as *wet* and *cold*, and the latter, for the opposite reason, as *dry* and *warm.* According to their measure of fertility they are also spoken of as *rich* or *poor.* The particular crops for the production of which they are respectively considered to be best adapted, have also led to clays being spoken of as *wheat* or *bean soils*, and the friable ones as *barley* and *turnip soils.* This latter mode of discriminating soils is however becoming every day less appropriate; as those of the lighter class, when sufficiently enriched by suitable manuring, are found the most suitable of all for the growth of wheat; while the efforts of agriculturists are now successfully directed to the production of root crops on those so strong as heretofore to have been reckoned unfit for the purpose. But still, such extreme diversities as we everywhere meet with in our soils, must necessarily lead to a corresponding diversity in their agricultural treatment, and hence the necessity for keeping this fact prominently in view in every reference to British agriculture as a whole.

Popular definition of soils.

Influence of Climate.

But if diversity of soil necessarily modifies the practice of the husbandman, that of climate does so far more powerfully. The soils of the different parts of the globe do not very materially differ from each other, and yet their vegetable products vary in the extreme. This is chiefly owing to difference of temperature, which decreases more or less regularly as we recede from the equator, or ascend from the sea-level. Places in the same latitude and at the same elevation, are found however to vary exceedingly in temperature, according to their aspect, the prevailing winds to which they are exposed, their proximity to seas or mountains, and the condition of their surface. The different parts of Great Britain are accordingly found to possess very differing climates. In passing from south to north its mean temperature may be taken to decrease one degree Fahrenheit for every 80 miles, and the same for every 300 feet of elevation. The temperature of the west side of our island also differs materially from that of the east, being more equal throughout the year. This is owing to the prevalence of mild westerly winds charged with moisture, which, while they equalise the temperature, cause the average fall of rain on the west side of Britain to be in many cases the double, and in some nearly the triple, of that on the opposite side. In the central parts of England cultivation is carried on at 1000 feet of elevation, but 800 may be taken as the ordinary limit. In Scotland the various crops are usually from two to three weeks later in coming to maturity than in England. In both divisions of the island the western counties, owing to their mild and humid climate, are chiefly devoted to pasturage, and the eastern, or dry ones, to tillage. As compared with the continent of Europe our summers are neither so hot, our winters so cold, nor our weather so steady. We want therefore many of its rich products, but on the other hand, our milder winter and moister climate are eminently favourable to the production of pasturage and other cattle crops, and admit of agricultural operations being carried on more regularly throughout the year. Indeed, looking to the immense varieties of the products of our soil, there is probably no other country so favourably circumstanced for a varied and successful agriculture.

[1] Low's Practical Agriculture, p. 42.

Practical Agriculture.

Agriculture influenced by distribution of population.

Besides those variations in the agricultural practice of this country which arise from diversities of soil and climate, there are others which are due to the distribution of the population. The proximity of cities and towns, or of populous villages, inhabited by a manufacturing or mining population, implies a demand for dairy produce and vegetables, as well as for provender and litter, and at the same time, affords an ample supply of manure to aid in their reproduction. Such commodities, from their bulk or perishable nature, do not admit of long carriage. The supplies of these must therefore be drawn from comparatively limited areas, and the character of the husbandry there pursued is determined apart from those general influences previously referred to. From these and other causes there is a diversity in the practice of British agriculture which increases the difficulty of describing it accurately. Indeed, it is so well known that there are peculiarities of character attaching to almost every individual field and farm, and still more to every different district or county, which demand corresponding modifications of treatment in order to their successful cultivation, that a prudent man if required to take the management of a farm in some district greatly inferior in its general system of farming to that which he may have left, will yet be very cautious in innovating upon specific practices of the natives. To such peculiarities it is obviously impracticable to refer in such a treatise as the present. They are referred to now because they suggest an explanation of some of those discrepancies in the practice and opinions of farmers, equally successful in their respective localities, which we constantly meet with; and because, in proceeding to delineate the practice of Berwickshire, where our personal experience has been gained by twenty years of actual farming, we would deprecate the idea of claiming for its modes a superiority over those of other districts. Its geographical position, and the mixed husbandry pursued in it would justify, in some measure, its being referred to as a fair sample of the national agriculture. But it is on the specific ground that it is best to speak from actual experience as far as that will serve, that we vindicate this selection.

Farm-Buildings.

In pursuance of the plan already indicated, let us now refer for a little to *Farm-Buildings*. We have spoken of the soil as the raw material upon which the farmer operates: his homestead may, in like manner, be regarded as his manufactory. That it may serve this purpose in any good measure, it is indispensable that the accommodation afforded by it be adequate to the extent of the farm, and adapted to the kind of husbandry pursued upon it. It should be placed upon a dry, sunny, sheltered site, have a good supply of water, and be as near as possible to the centre of the farm. The buildings should be so arranged as to economise labour to the utmost. It should be constructed of substantial materials, so as to be easily kept in repair, and to diminish, to the utmost, risk from fire. The most cursory examination of existing homesteads will suffice to show that in their construction these obvious conditions have been sadly neglected. For one farm really well equipped in this respect, hundreds are to be met with in all parts of the kingdom, and more especially in England, most wretchedly deficient. Wherever this is the case it is impossible that the farmer, however skilful or industrious, can make the most of his materials, or compete on equal terms with his better furnished neighbours. As the agricultural community becomes more generally alive to the importance of economising labour by a judicious arrangement of buildings, and of reducing the cost of the production of beef (and adding to the amount and fertilizing power of the home-made manure) by the manner in which the live stock is housed, we may hope that improvement in this department will make rapid progress. Tenants will refuse to embark their capital, and waste their skill and labour on farms unprovided with suitable apparatus for cultivating them to the best advantage. Landlords, and their agents, will by and by find that until this is done, they must put up with an inferior tenantry, an antiquated husbandry, and with lower and worse-paid rents.

Evils of defective Homesteads.

Economy of consulting a competent architect.

In erecting new homesteads, or in making considerable additions to or alterations upon existing ones, it is of much importance to call in the aid of an architect of ascertained experience in this department of his art, and then to have the work performed by contracts founded upon the plans and specifications which he has furnished. A reasonable sum thus expended will be amply returned in the cost, trouble, and disappointment which it usually saves to both landlord and tenant. It is to be hoped that in future a greater number of thoroughly qualified architects will devote themselves to this department of their profession, and that they will meet with adequate encouragement. It is not, therefore, with the view of superseding their services, but simply to illustrate our references to existing practices, that we subjoin a plan of farm-buildings.

While protesting against the utter rudeness and inadequacy of the great majority of homesteads, we must also deprecate the hurtful expenditure sometimes lavished in erecting buildings of an extent and style altogether disproportionate to the size of the farm, and out of keeping with its homely purposes. When royalty or nobility, with equal benefit to themselves and their country, make agriculture their recreation, it is altogether befitting that in such cases the farm-yard should be of such a style as to adorn the park in which it is situate. And even those intended for plain everyday farming need not be unsightly; for ugliness is sometimes more costly than elegance. Let utility, economy, and comfort first be secured, and, along with these, as much as possible of that pleasing effect which arises from just proportions, harmonious arrangement, and manifest adaptation to the use they are designed for.

Much has recently been written on this subject, in the journals of our national agricultural societies, and other agricultural periodicals; and plans in great variety have been offered to public notice. Indeed, there is at present so much diversity of opinion about the best plan of farm-buildings, that most practical farmers, if offered a new homestead, would have considerable difficulty in deciding upon that which should be adopted in their own case. That now given has been designed by an experienced Roxburghshire farmer, Mr Hardie, Harrietfield, near Kelso. It is calculated for a farm of 600 acres of good arable land, cultivated on the system presently pursued in Berwick or Roxburgh shires. It expresses very fairly the present state of opinion in these counties on the question of housing fattening cattle, as provision is made in it for using at once yards, stalls, and boxes.

Principles to be attended to in the arrangement of Farm Buildings.

The barn, with its thrashing machinery, and other appurtenances, naturally forms the nucleus of the homestead, and regulates the distribution of the other buildings. The command of water-power will often determine the exact site of the barn, and indeed of the whole buildings. The cheapness and safety of this motive-power render it well worth while to make considerable sacrifices to secure it, when a really sufficient and regular supply of it can be had. But the difficulty of securing this when the adjoining lands are thoroughly drained, with the great efficiency, and facility of application of steam-power, are good reasons why precarious supplies of water-power should now be rated very differently than when a horse-wheel or windmill were the only alternatives. A very usual and suitable arrangement is to have the whole buildings, forming a lengthened parallelogram, facing south or south-east. The barn being placed in the centre of the north range, with the engine-house behind it, and the straw-house at right angles in front, with doors on both sides for the ready con-

Practical Agriculture.

veyance of litter and fodder to the yards, &c. It is always advantageous to have the barn of sufficient height to afford ample accommodation to the thrashing and winnowing machinery. When the disposition of the ground admits, it is a great convenience to have the stackyard on a level with the upper barn, so that the unthrashed corn may be wheeled into it on barrows, or on a low-wheeled truck drawn by a horse. Failing this, the sheaves are usually pitched in at a wide opening from a framed cart. The space on which the cart stands while this is going on is usually paved, that loose ears and scattered grain may be gathered up without being soiled; and it is a further improvement to have it covered by some simple roof, to protect the sheaves from sudden rain.

Rickyard Railways.

In several recent instances stackyards have been laid with rails, and the stacks built on low platforms set on wheels, so that each stack, as required, can be pushed close up to the barn, and the sheaves pitched from it directly to the side of the feeding-board. A friend who recently visited the farm of Mr Favell at Stockeld near Harrowgate, where this plan has been adopted, has kindly furnished the following notice of it. The rails for the stackyard are laid 7 feet 3 inches apart. On these are ranged a series of trucks, each on two pairs of wheels, the axles of which are 11 feet apart, and having a platform 20 feet long and 7½ feet wide formed of planks placed close together to prevent the ascent of vermin. On this the stack is built to the height of 16½ feet above the truck. The stacks are ranged on one set of rails only, which lead directly to the door of the thrashing machine. Mr Favell admitted the inconvenience of having his wheat, barley, beans, and oats, all on one line, and stated his intention of having a series of rails radiating from the door of the barn.

On a farm near Hull the stackyard is fitted with rails and turn-tables in a more complete manner. Where this expedient has been adopted, the rails, trucks, &c., have usually been second-hand railway materials.

It is a good arrangement to have the straw-barn fitted up with a loft, on the level of the opening at which the straw is discharged from the thrashing-mill, so as to admit of fodder being stored above and litter below. A sparred trap-door in front of the shaker retains the straw above, or lets it fall to the ground as required. This upper floor of the straw-barn

Place for Chaffcutter

is the most convenient place for fixing a chaff-cutter to be driven by the thrashing-power. The granary should communicate with the upper barn, that the dressed grain may be raised to it by machinery.

Grinding Mill, &c.

A loft over the engine-room, communicating with the upper barn and granary, forms a suitable place for fixing a grinding-mill, bruising-rollers, and cake-breakers, as it affords opportunity for having these machines easily attached to the steam-power. It suits well to have the house in which cattle food is cooked attached to and under the same roof as the engine-house. One coal store and chimney thus serves for both. The small boiler can even be built in so close to the large one as to derive some benefit from its waste heat; and meal, &c., can be conveyed by spouts from the grinding loft above. An open shed outside the barn, for the accommo-

Circular Saw.

dation of a circular saw, is also a desideratum. By the aid of the latter machine and a handy labourer, the timber required for ordinary repairs on the farm may be cut out at trifling expense.

The cattle-housing of whatever description, where there are the largest and most frequent demands for straw, is placed nearest to the straw-house, and in communication with the turnip-stores, and the house (if any) in which food is cooked or otherwise prepared. Where cattle are bred, the cow-house and calf-house are kept together. A roomy working court is always a great convenience, and it suits well to have the stable opening to it, and the cart-shed and tool-house occupying another side. Costly machines, such as corn-drills, require to be kept in a locked place, to preserve them from the collisions, and the loss or derangement of their minute parts, to which they are exposed in an open cart-shed.

Water.

An abundant supply of good water is a most important matter. The best source is from springs, at such an elevation as to admit of its being brought in a pipe, with a continuous flow. Failing this, a well and pump is the usual alternative, although it is sometimes necessary to collect the rain-water from the roofs, and preserve it in a capacious and carefully-made tank. In every case it is desirable to have a regulating cistern, with ball-cock, from which it is distributed by pipe to every part of the homestead where it is required. It is, in every case, of importance to have the eaves of the whole buildings spouted, and the rain-water carried off to where it can do no mischief. Where fattening cattle are kept in open yards with sheds, by spouting the eaves, and slightly hollowing the yards towards their centres, the whole urine is absorbed by their litter, and retained in the manure. If stall feeding is practised, a pit is required, into which the solid dung is wheeled, and the liquid conveyed by drains.

Tanks for Liquid Manure.

Liquid manure tanks are at present in universal repute, but we shall endeavour to show, when treating of manures, that they are not such an indispensable appendage to a farm-yard as is generally asserted. In Scotland, it is customary to carry the dung from the byres into a yard in which young cattle are kept, where it is daily spread about and subjected to further treading, along with such quantities of fresh litter as are deemed necessary. That from the stables is carried into the adjoining feeding-yard, and it is usually remarked, that the cattle occupying it make more rapid progress than their neighbours.

Labourers' Cottages.

An important part of the buildings of a farm are the cottages for its labourers. It is in all cases expedient to have the people required for the ordinary working of a farm resident upon it; and it is always much better to have families, each in their own cottage, than a number of young people boarded in the farm-kitchen, or with the farm-overseer. These cottages are usually a little removed from the other farm-buildings, and it is, on various accounts, better to have them so. There is, however, an advantage in having the cottages of the farm-steward and cattleman either within the court-yard, or close to its entrance, that these responsible functionaries may at all times be near to their charge, and especially that they may be at hand when any of the live stock require night attendance. As there are manifold advantages in having but one main entrance to the homestead, and that closed by a gate which can be locked up at night, it will be obviously necessary to have the keeper of the key close at hand to open the gate by night if required. Much more attention than formerly is now paid to the construction of cottages. The apartments are better floored, higher in the roof, and so arranged as to secure comfort and decency. Besides a small garden, each cottage is usually provided with a pig-sty and ash-pit, and in some cases with a coal-place and privy besides.

Farm-House.

The position and style of the farmer's dwelling also claims a remark here. The approved mode used to be, to place it either directly in front or rear of the farm-yard, on the ground that the farmer would thus have his premises and cattle under his eye even when in his parlour or bedroom. As has been well remarked, "The advantages of this parlour-farming are not very apparent, the attendant evils glaringly so. If the condition of ready communication be obtained, the farm-house should be placed where the amenities of a country residence can be best enjoyed."[1] On all hands

[1] For further information on Farm Buildings, see Appendix (B.) to this article, *infra;* see also *Morton's Cyclopædia of Agriculture*, article "Farm Buildings."

Fences.

we now hear it urged, that it is only by men possessed of capital and intelligence that the business of farming can be rendered remunerative. Those who desire to have such men for tenants, will be more likely to succeed by providing a commodious and comfortable Farmery, pleasantly placed among trees and shrubs, than by setting it down in the precincts of the dung-heap.

### FENCES.

The fences by which farms are generally enclosed and subdivided, form another part of what may be termed their fixtures, and may therefore be suitably noticed here. When lands are let to a tenant, the buildings and fences are usually put into sufficient repair, and he is taken bound to keep and leave them so, at the issue of his occupancy. Although there are some persons who advocate the total removal of subdivision fences, it is admitted on all hands, that the farm as a whole, and the sides of public thoroughfares which may intersect it, should be guarded by sufficient fences of some kind. The general belief has hitherto been, that there is a farther advantage in having the land subdivided by permanent fences into enclosures of moderate size. The use of such partition fences is not only to confine the live stock to particular fields, or restrain them from trespassing on the other crops; but to afford shelter from cutting winds. It is now frequently urged, that the heavier cattle should never be turned to pasture at all, but kept on roots and green forage the whole year round; and that sheep can be managed satisfactorily by means of moveable hurdles. It is highly probable that the practice of soiling will become more general, as it undoubtedly deserves to do. Still this does not necessarily call for the total removal of subdivision fences, which we cannot but regard as an imprudent proceeding. It is probable that those who have adopted it have done so very much owing to the prevalence of the opposite extreme. There are large portions of the finest land in England so encumbered with hedges and hedgerow trees, as to be utterly incapable of profitable cultivation. In many cases the fields are so small and the trees so large, that their roots actually meet from the opposite sides and pervade the entire surface soil of the area enclosed by them. When manure is applied to such fields, it is monopolised by these freebooters from the hedges, and the crops of grain or hay, such as they are, are so screened from the sun and wind, that there is great risk of their being spoiled in the harvesting. If drains are made in such fields they are speedily filled up by the rootlets, and thus rendered useless.[1] In such circumstances, it is no wonder that zealous agricultural improvers should look upon hedgerows much as American settlers do upon their forests; and, like them, be sometimes indiscriminate in their clearings. We believe that there is an advantage in having land, whether for pasture or tillage, subdivided into parallel-sided fields of from 10 to 40 acres each, according to the size of the farm, by means of permanent fences of a kind adapted to the locality. When the soil and climate are favourable to the growth of the common *white thorn*, hedges formed of it combine efficiency, economy, and ornament, in a greater degree than any other fence. But to have a really efficient thorn hedge, much attention must be paid to its planting, rearing, and after management. In proceeding to *run* a new line of thorn hedge, care must be taken that the soil is clean and in good heart; and that the subsoil is porous and dry. When these conditions do not obtain, they must be secured by fallowing, manuring, draining, and trenching. The young quicks should be stout and well rooted; not taken indiscriminately as they stand in the nurseryman's beds, but of uniform stoutness. Such selected plants are always to be had for a small additional price, which will be found to be well repaid in the superior progress of such plants, when contrasted with that of others taken as they chance to come to hand. The embryo fence must be kept free of weeds, and secured from the encroachments of cattle by a line of rails on both sides. Some persons advise that the young hedge should from the first be trimmed into line by using the pruning hook after each year's growth. It is certainly better not to touch it with the knife, or, at least, only to restrain an occasional shoot that unduly overtops its neighbours, until the centre stems are at least a couple of inches in diameter. If the plants are then headed over fence-high, and the lateral shoots pruned to a straight line, a close fence with a substantial backbone in it is secured; whereas by pruning annually from the first, a fence is obtained that pleases the eye, but which, consisting only of a mass of spray, presents no effectual barrier to cattle. When a thorn hedge has reached the stage just referred to, the protecting rails may be removed, and the hedge kept in a neat and efficient state by annual pruning. On good, deep soil, thorns will stand this constant removal of the annual growth of spray for many years without injury. In less favourable circumstances, it is found necessary from time to time to withhold the pruning knife for a few years together. When the hedge has been reinvigorated by such periods of unrestrained growth, it can again be cut back to the centre stems, and subjected anew to a course of annual pruning. To insure a close fence, the bottom of the hedge must at all times be kept clear of tall weeds. The constant use of the weeding-iron is however objectionable; for, besides being expensive, it injures the bark of the thorns, and thereby impairs their health. It is quite sufficient to cut the weeds close to the surface, twice a year, by means of a reaping hook or short scythe.

Benefit of fences.

Evils of very small enclosures.

Thorn hedges.

In arable lands, by this plan of keeping hedges about four feet high, and cutting down the weeds as required, an efficient and ornamental fence is maintained at comparatively small cost, and with little injury to the adjoining crops from shading, or the harbouring of weeds and vermin.

Although the white thorn forms a better hedge than any shrub yet tried for the purpose in this country, there are many upland situations where the beech or hornbeam grow more freely, and are to be preferred either alone or in mixture with it. These plants, and also crab or sloe, are sometimes useful in filling a gap occasioned by the removal of a hedgerow tree, or the death of a portion of thorn hedge.

Stone walls.

In exposed situations where thorns do not thrive, *dry-stone walls* are the most usual substitute. When carefully constructed, of stones suitable for the purpose, they last a long time, and form an excellent fence. Their durability is much enhanced by having the cope-stones set in lime-mortar. A layer along the centre of the wall, and an external pointing, of lime-mortar will also repay the additional first cost thus incurred. A wall of this kind, four feet high, exclusive of the cope, while quite sufficient to restrain cattle and the heavier kinds of sheep, is no barrier to the mountain breeds, which can easily clear a six-foot wall. A simple and very effective fence has however come much into use of late

[1] It has been computed that not less than 1¼ million acres are occupied by hedge-rows in England and Wales, and that, if the land overshaded and plundered by roots be included, the amount is 3 millions. In Devonshire one-fourth of the enclosures in many parishes are under *two* acres; more than one-third under *three* acres, and nearly two-thirds under *four* acres. Two millions, at least, of these acres might be redeemed, and what a margin is here available for increased production. The land thus wasted would probably yield a sum equal to county and poor rates, and perhaps malt-tax too. *See Farmers' Magazine for March* 1852, p. 253.

Fences.

Wire fences.

years. It is composed of iron wire, (No. 8 being the size most commonly used,) which is attached by small staples to common stakes such as are used for wooden railings, driven firmly into the ground about five feet apart. The wire is drawn out of the coil, and the ends of the various lengths or *threads* are neatly joined by first heating them and then twisting the one into the other, until the quantity required for the stretch of fence is run out. It is then attached to every third or fourth stake by a staple, which must not be driven home. The other lines of wire are then treated in the same manner, each being attached to the stakes at such width apart as has been determined upon, and marked upon the stakes. A ready way of doing this is by stretching along the stakes a common gardener's line which has been previously rubbed with chalk, or a charred stick, and striking it against the stakes at the required heights in the way that sawyers mark a plank. When the requisite number of wires has thus been loosely attached, they are pulled as tight as possible by the hands of the workmen, after which a screw or lever is applied to each in turn until it is made perfectly tight. As the efficiency of this kind of fence is wholly dependent on perfect tightness being obtained, a stout straining-post must be fixed securely in the ground at the end of each line of fence. This serves the double purpose of furnishing a fulcrum for the stretching instrument, and a secure attachment for the ends of the wires. When the straining is accomplished, each wire is stapled to each stake. The gates are usually hung upon these straining posts. Although wooden straining-posts are commonly used, some persons prefer iron ones, fixed into large blocks of stone. Five wires thus stretched, at an average width of six inches, form an effectual fence for the wildest sheep. They could indeed easily clear it so far as height is concerned, but they are afraid to leap at an object which they cannot see until they are close upon it. They may be seen at first walking along the line anxiously looking for an opening, and if one more bold than the others makes a run at it, he is sure to catch such a fall as effectually deters him from repeating the attempt. A cwt. of No. 8 wire costs at present 16s., and when drawn out, yields a line about 620 yards in length. Staples cost 1s. 8d. per gross; stakes ready for driving, from one penny to twopence each. With these cheap and portable materials, which any labourer of ordinary intelligence can easily put together, a fence admirably adapted for enclosing or subdividing mountain pastures, is now quite attainable by every sheep-farmer, and will well repay its cost. It is equally available for protecting young thorn hedges, and generally for all purposes for which wooden railing is used. As a fence for cattle or horses, it is advisable to add a single rail of wood nailed *flat* along the tops of the stakes, which must be sawn off evenly for this purpose. As compared with wooden railing, wire is much cheaper and more durable, and more easily kept in repair. It is cheaper also than stone walls, available in many situations where they are not, and a more certain barrier to agile sheep; but it is less durable and affords no shelter.

The latter defect can in some situations be remedied by raising a low mound of turf, running the wire-fence along the top of this mound, and sowing on it the seeds of the common whin.

Fences should be maintained at mutual expense of Landlord and Tenant

We have already noticed, that the fences of a farm are usually erected by the landlord, and kept in repair by the tenant. The latter is at least usually taken bound in his lease to keep and leave them in good order; but as this obligation is often very indifferently performed, and much damage and vexation occasioned in consequence, it is always expedient that a person should be appointed by the landlord to attend to the fences, and the half of his wages charged against the tenant. By such a course, dilapidation and disputes are effectually guarded against, and the eyesore of defective, ill-kept fences is wholly removed.

Machines and Implements.

### MACHINES AND IMPLEMENTS OF HUSBANDRY.

That the cultivation of the soil may be carried on to the best advantage, it is necessary that the farmer be provided with a sufficient stock of machines and implements of the best construction. Very great improvement has of late years taken place in this department of mechanics. The great agricultural societies of the kingdom have devoted much of their attention to it; and under their auspices, and stimulated by their premiums and exhibitions, manufacturers of skill and capital have embarked largely in the business. In many instances the quality of the article has been improved and its cost reduced. There has hitherto been a tendency to produce implements needlessly cumbrous and elaborate, and to introduce variations in form which are not improvements. The inventors of several valuable implements, the exclusive manufacture of which they have secured to themselves by patent, appear to have retarded their sale, and marred their own profits by the exorbitant prices which they have put upon them. Some, however, have become alive to the advantages of looking rather to large sales with a moderate profit on each article, and of lowering prices to secure this. A most salutary practice has now become common of inventors of implements of ascertained usefulness granting license to other parties to use their patent-right on reasonable terms, and thus removing the temptation to evade it by introducing some alteration which is trumpeted as an improvement, although really the reverse.

The lower price and extended use of iron in the construction of agricultural implements is materially adding to their durability, and generally, to their efficiency, and is thus a source of considerable saving. While great improvement has taken place in this department, it too commonly happens, that the village mechanics, by whom a large portion of this class of implements is made and repaired, are exceedingly unskilled, and lamentably ignorant of the principles of their art. They usually furnish good materials and substantial workmanship, but by their unconscious violation of mechanical laws, enormous waste of motive power is continually incurred, and poor results are attained. This can probably be remedied only by the construction of the more costly and complex machines being carried on in extensive factories, where, under the combined operation of scientific superintendence, ample capital, and skilled labour, aided by steam-power, the work can be so performed as to combine the maximum of excellence with the minimum of cost.

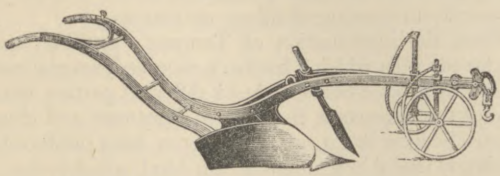
We begin our brief notice of the implements of the farm, with those used for the tillage of the soil. Of these the first place is unquestionably due to the plough. A history of this implement, tracing its gradual progress from the ancient Sarcle to its most improved form at the present day, is necessarily a history of Agriculture. So much is this the case, that a tolerably correct estimate of the progress of the art in any country, whether in ancient or modern times, may be formed by ascertaining the structure of the plough. Much attention has been paid to its construction in Britain for the last 100 years, and never more than at the present day. After all that has been done, it is still, however, an unsettled point, which is the best plough for different soils and kinds of work; and, accordingly, many varying forms of it are in use in those parts of the kingdom which have the reputation of being most skilfully cultivated. Ever since the introduction of Small's improved swing-plough, the universal belief in Scotland, and to a considerable extent in England, has been, that this is the best form of the implement. Wheel-ploughs have accordingly been spoken of by

Ploughs.

Wheel-plough.

Machines and Implements.

Scottish Agriculturists in the most depreciatory terms, and yet it turns out that this has been nothing better than an unfounded prejudice. For when subjected to careful comparative trial, as has been frequently done of late, the balance of excellence is undoubtedly in favour of the plough with wheels. Its advantages are, that it is easier of draught

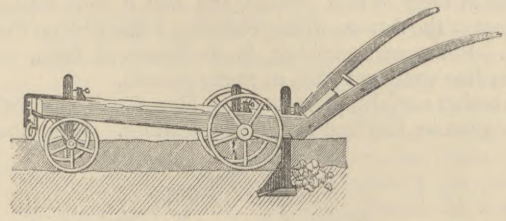


RANSOME'S PATENT TWO-WHEELED PLOUGH.

—that the quality of its work is better and greatly more uniform than can be produced by a swing plough—that in land rendered hard by drought, or other causes, it will enter and turn over even furrows where its rival either cannot work at all, or at best with great irregularity and severe exertion to the ploughman; and lastly, that its efficiency is independent of skill in the ploughman. This last quality has indeed been usually urged as an objection to wheel-ploughs, as their tendency is said to be to produce an inferior class of workmen. Those who know the difficulty of getting a field ploughed uniformly, and especially of getting the depth of furrow specified by the master adhered to over a field, and by all the ploughmen, can best appreciate the value of an implement, that when once properly adjusted, will cut every furrow of an equal width and depth, and lay them all over at exactly the same angle. The diversity in the quality of the work at those ploughing competitions, to which only the picked men of a neighbourhood are sent, and where each may be supposed to do his very best, shews conclusively how much greater it must be on individual farms, even under the most vigilant superintendence. In every other art the effects of improved machinery is to supersede manual dexterity; and it does seem absurd to count that an objection in agriculture which is an advantage in everything else. There is more force in the objection that wheel-ploughs are inferior to swing ones in ploughing cloddy ground, or in crossing steep ridges, and that they cannot be used for forming drills for turnip or other crops. This objection vanishes when it is known that in the most improved wheel-ploughs, the wheels can be laid aside at pleasure, and that they can then be used in all respects as swing-ploughs. A mould-board, somewhat higher and wider behind than that best adapted for ordinary work, is required for forming turnip-drills. This, however, is easily managed by having two distinct mould-boards for each plough. An important feature in the English ploughs is, that they are fitted with cast-iron shares, which being case-hardened on their under surface, wear unequally, and so preserve a sharp edge. The necessity for daily recourse to the smithy is thus removed, and along with it, that irregularity in the quality of the work and draught of the plough, which so often arises from witting or unwitting alterations being made in the *set* of the share in the course of its unceasing journeys thither. It remains to be seen whether these more brittle shares will withstand the collisions to which they are liable in our stony Scottish soils. A good implement of this kind should therefore be sufficient for all usual kinds of ploughing. When it is desired to turn a very deep furrow, a plough differing from the common one only in being somewhat larger and stronger in all its parts is used, with four horses to draw it.

Subsoil-plough.

Ploughs which break and stir the subsoil, without bringing it to the surface, by following in the wake of the common plough, are now much used. The first of the kind—the invention of the late Mr Smith of Deanston—is a ponderous implement, requiring at least four good horses to draw it. It is well adapted for displacing and aiding in the removal of earth-fast stones. The inventor has happily described its operation by terming it a "horse pick." Read's subsoil-plough is a much lighter implement, which can usually be drawn by two horses. Since the introduction of thorough

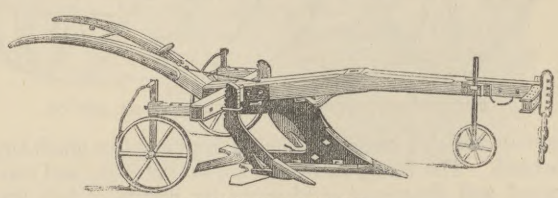


READ'S SUBSOIL PULVERIZER, AS MADE BY BARRIT AND CO.

draining, it is found beneficial to loosen the soil to much greater depth than was formerly practicable, and this class of implements is well fitted for the work.

Paring-plough.

Broadshare or paring ploughs are much used in various parts of England in the autumn cleaning of stubbles. A broad-cutting edge is made to penetrate the soil to the depth of one or two inches, so as to cut up the root-weeds which at that season lie for the most part near the surface.



BENTALL'S BROADSHARE.

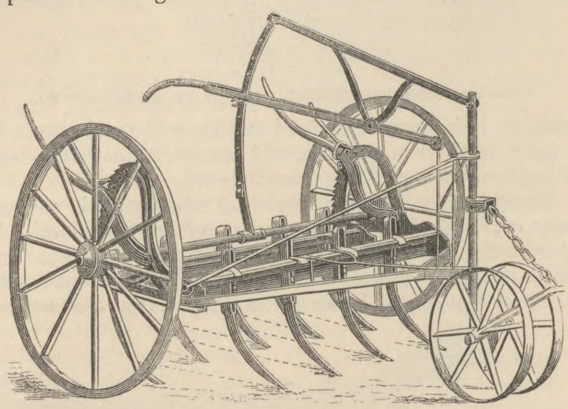
These, as well as the stubble, being thus detached from the firm soil, are removed by harrowing and raking; after which, the land is worked by the common plough. An implement of this kind is frequently used in carrying out the operation of paring and burning.

Various implements of the plough type, so modified as to adapt them for particular processes, have from time to time been offered to public notice, but have failed to meet with general favour. We limit our notice to those of ascertained utility, and refer the reader who desires fuller information, to "Ransome's Implements of Agriculture," and similar works, where he will find descriptions of the most interesting of them.

## GRUBBERS, &c.

Next in importance to the plough, is the class of implements variously called grubbers, cultivators, or scarifiers. To prepare the soil for the crops of the husbandman, it is necessary to pulverize it to a sufficient depth, and to rid it of weeds. The appropriate function of the plough is to penetrate, break up, and reverse the firm surface of the field. This, however, is only the first step in the process, and does but prepare for the more thorough disintegration which has usually been accomplished by harrowing, rolling, and repeated ploughings. Now, however excellent in its own place, the plough is a cumbrous and tedious pulverizer, besides needlessly exposing a fresh surface at each operation, and cutting the weeds into minute portions, which renders their removal more difficult. These defects were long felt, and suggested the desirableness of having some implement of intermediate character betwixt the plough and harrow, which should stir the soil deeply and expeditiously without reversing it, and bring the weeds unbroken to the surface. The whole tribe of grubbers, &c., has arisen to meet this demand, and we shall now consider the comparative merits of the more prominent of the group. The first notice is due to Finlayson's harrow, which, as improved by Scoular, was, until recently, the best implement of its kind. Its faults—and they attach equally to Kirkwood's and Wilkie's—are, that it is severe work for two horses; is liable to choke in turfy or foul ground, and that it consolidates the bottom of the furrow, while producing a fine tilth on the surface. Finlayson's grubber, in its improved form, weighs about five cwt., and costs as many pounds.

Another useful implement of this class which enjoys a large reputation in England is Biddle's scarifier. It is mounted

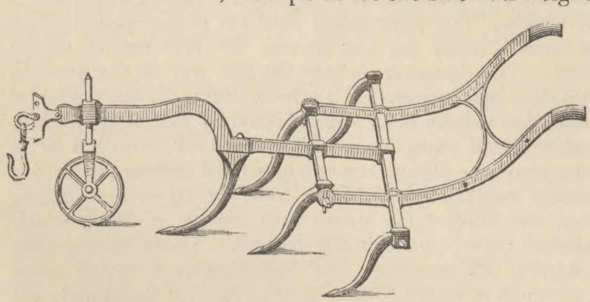


BIDDLE'S SCARIFIER, AS MADE BY RANSOME AND CO.

on four wheels; two small ones in front and two much larger behind. The frame and tines are of cast-iron, and can be raised and depressed at pleasure by means of two levers which regulate the depth to which the tines shall penetrate. The tines are prepared to receive case-hardened cast-iron points of different widths, or steel hoes of nine inches width, so that the implement can be used for breaking up and paring the surface, or for grubbing out weeds and pulverising the soil, as may be required. An important feature in this scarifier is, that it keeps its hold of a hard surface much better than a plough. It weighs half a ton, is drawn by four or six horses, and costs about L.18.

The Ducie or Uley cultivator has many features in common with Biddle's, and although brought forward as an improvement upon it, has not established its title to be so regarded. The great weight, high price, and amount of horse-power required to work them, are serious objections to both of these implements.

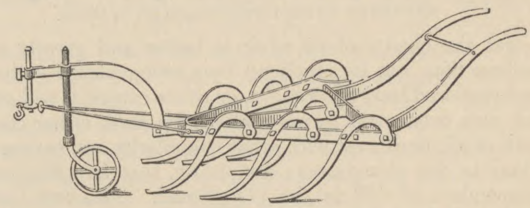
Of more recent notoriety than either, and contrasting with them favourably in these respects, is an implement invented by Mr John Tennant, at Shields, near Ayr, and now popularly known as Tennant's grubber. Its construction, as the annexed cut will shew, is simple in the extreme. Its weight



TENNANT'S GRUBBER.

is about 2 cwt., its price L.4, 10s., and its draught easily overcome by two horses. The depth at which it works is regulated by raising or lowering the shank which supports its single wheel in front. Its tines can be easily moved on their supporting bars, and it may be worked with five or seven as desired. By substituting a shorter hind-bar, and setting the tines more closely together, it makes a most efficient drill grubber. We shall have occasion to refer to this implement frequently in treating of tillage operations.

Since the introduction of Tennant's grubber, and from the favour with which it has been received, several variations on its form have been made by different parties, but all retaining the important features of lightness and cheapness. Messrs Scoular & Co., of Haddington, have produced an exceedingly useful implement of this kind, which is also in very



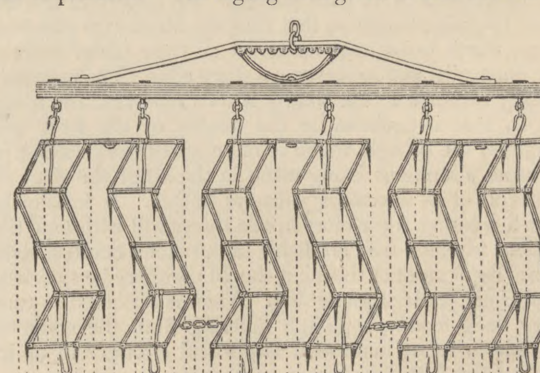
SCOULAR'S GRUBBER.

general use. There seems no reason why these light grubbers should not have their tines so constructed as to have the working parts moveable (as in Biddle's scarifier), so that sharp points for grubbing, or broad hoes for paring, could be used at pleasure.

## HARROWS.

When a field has been broken up by the plough, it is usually next operated upon by the harrow, whether the object be to prepare it for and to cover in seeds, or to bring clods and roots to the surface. It is virtually a rake dragged by horses. In its most ordinary form, the frame-work is of wood with iron tines, of which each harrow contains twenty. Formerly each horse dragged a single harrow, although two or more were worked abreast. Under this arrangement the harrows had too much independent motion, and were liable to get foul of each other. This has been remedied, first partially, by coupling them loosely by riders, and then more effectually by a hinge-like joining, which allows a separate vertical motion, but only a combined horizontal one. A rhomboidal form is also given to this *pair* of harrows—usually called *brakes*—so that when properly yoked, no two tines can work in the same track. This description of harrow is now frequently made entirely of iron.

Howard's patent harrows are a further improvement on this implement. The zigzag form given to each section ena-



HOWARD'S PATENT HARROW.

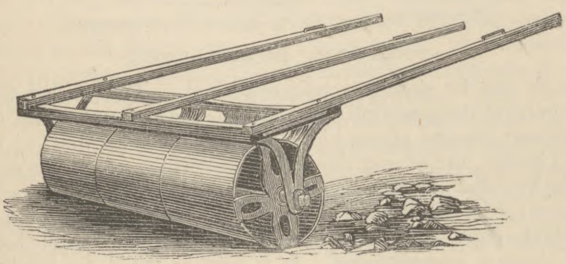
bles the whole so to fit in, that the working parts are equally distributed over the space operated upon. The number of tines is 75, instead of 40, as in the form last noticed, and yet from

Machines and Implements.

the form of frame and manner of coupling, the tines are well apart, and have each a separate line of action. Practical farmers speak very highly of the effective working of this implement. By an exceedingly simple contrivance the centre part when turned on its back forms a sledge on which its fellows can be piled, and drawn along from one field to another. A light description of harrows with smaller and more numerous tines, is sometimes used for covering in grass-seeds. If a harrow is to be used at all for this purpose, Howard's is a very suitable kind, but a much better implement is the chain-web with discs, the invention of Smith of Deanston. The old-fashioned ponderous break harrow is now entirely discarded, and the more efficient cultivator used in its stead. A form of the latter, from its close resemblance to harrows, is noticed now rather than before. It is a very strong iron harrow, with the tines made longer and very considerably curved forwards. An iron rod with a loop handle is fixed to the hind bar, by means of which the driver can easily hitch it up and get rid of weeds, &c. Two such harrows are coupled together and drawn by four horses. Its pulverizing power is very considerable. But when clods have been brought to the surface they are most effectually reduced by various kinds of

ROLLERS.

Those formerly used were solid cylinders of timber or stone attached to a frame and shafts, for which hollow ones of cast-iron are now generally substituted. The simplest form of these has a smooth surface, and is cast in sections to admit of more easy turning. They are made of diverse weights,

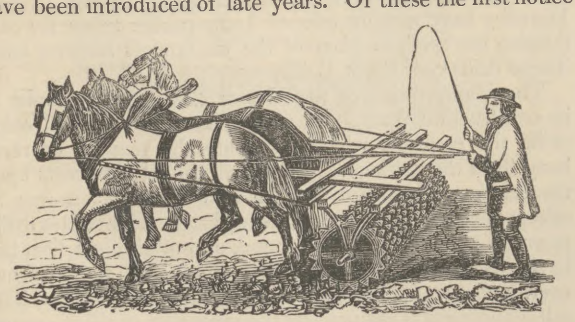


SMOOTH CAST-IRON FIELD ROLLER.

so as to be adapted for the draught of one or two horses as required. Those of the former description, weighing in all 6 cwt., and costing as many pounds sterling, are exceedingly useful for all purposes where expedition rather than heavy pressure is wanted. From their greater durability, smoother surface, and less liability to clog, the readiness with which they can be cast of any weight that is required, and their moderate price, it is probable that cast-iron cylinders will speedily supersede all others.

Crosskill's clod-crusher.

Several important variations on the common smooth roller have been introduced of late years. Of these the first notice

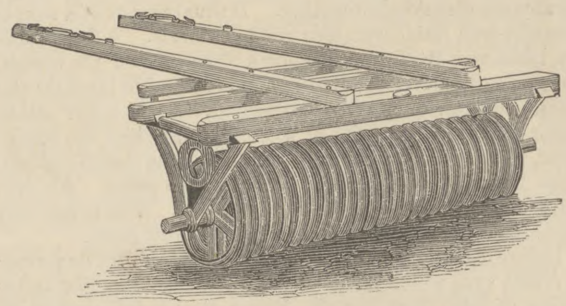


CROSSKILL'S CLOD-CRUSHER.

is due to Crosskill's clod-crusher. It consists of cast-iron discs $2\frac{1}{2}$ feet in diameter, with serrated edge and a series of side-way projecting teeth. Twenty-three of these discs are strung loosely upon a round axle, so as to revolve independently of each other. The free motion thus given to each disc, and which has latterly been increased by casting each alternate one wider in the eye, adds at once to the pulverizing and self-cleaning power of the roller. Three horses yoked abreast are required to work it. The axle is prolonged at each end sufficiently to receive travelling wheels, on which it is transported from place to place. Although primarily designed and actually much used for breaking clods, it is even more in request for consolidating loose soils, checking the ravages of wire-worm, and covering in clover and grass seeds. For the latter purpose, its action is perfected by attaching a few bushes to it, which fill up the indentations and leave a surface so beautifully even, as to rival the accuracy and neatness of a well-raked border. We have long thought that it would be an improvement in this valuable implement to reduce its weight so far as to suit it to the draught of two horses.

Cambridge's roller.

Cambridge's roller possesses several features in common with Crosskill's, and is used for similar purposes. It consists of discs with fluted instead of serrated edges.



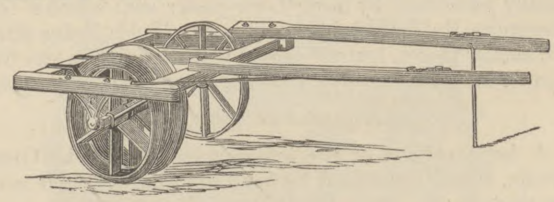
CAMBRIDGE'S PRESS-WHEEL ROLLER.

Gibson's clod-crusher.

Gibson's clod-crusher has a double row of smooth discs on separate axles, the projecting edges of which work into each other. Both implements have this advantage over Crosskill's, that they do not so readily clog on a damp surface.

Land-presser.

Under this head may be noticed press drills, which, by means of a series of narrow cylinders with conical edges, form corresponding grooves in loose soil. Seeds sown broadcast over a surface thus treated come up in rows. The land-presser is a modification of the press-roller. It is made with

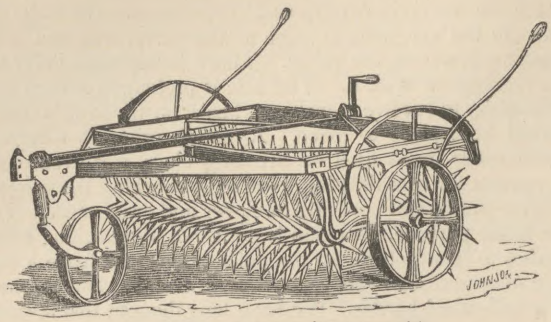


LAND-PRESSER.

two or three conical edged cylinders to fit into the seams of the same number of plough furrows, the other end of the axle on which they are fixed being supported by a plain carriage-wheel. It is drawn by one horse, and follows in the wake of two or three ploughs, according to the number of its cylinders. When wheat is sown after clover lea, this implement is found exceedingly useful in closing the seams, and forming a uniform seed-bed.

Norwegian harrow.

The Norwegian, or as it should rather be called, the Swedish, harrow is strictly a clod-crushing implement. From its radiating spikes penetrating the surface over which it is drawn, it has been called a harrow; but its revolving motion entitles it rather to be classed with rollers. In its usual form it consists of three rows of cast-iron rowels arranged upon parallel axles fixed in an iron frame, which is supported on three wheels,—one in front and two behind. The outline and arrangements are in fact the same as in Finlayson's grubber,



NORWEGIAN HARROW (CROSSKILL'S).

only substituting parallel rows of rowels for tines. There is also the same leverage for raising and depressing the frame. But this implement has recently been constructed on a much simpler and cheaper plan, in which the wheels and lever apparatus are discarded altogether. It thus consists of a simple wrought-iron frame with four rows of rowels. A few boards are laid across the frame, forming a platform over the rowels, on which the driver stands when it is wished to increase the weight and efficiency of the implement. On the upper side at either end, is fixed a piece of wheel-tire, on which the implement, when turned on its back, can slide along, sledge-fashion, when it is wished to move it from place to place. As thus constructed, it can be made for about L.5. This is the best implement yet introduced for breaking *moist* clods.

Breast-plough and trenching-fork.

Before leaving the implements of tillage, it may be proper to notice two, which have been a good deal brought under notice of late years, viz. the breast-plough and trenching-fork. The former is extensively used in carrying out the process of paring and burning. It is the implement so well known in Scotland as the flaughter-spade. In using it the workman guards his thighs with a piece of board, fastened on apron-wise, and with this presses against the cross-head of the implement, and urges forward its cutting edge. When a thin turf has thus been severed from the surface, he throws it topsy-turvy by a jerk of his arms. The fork is used in giving a deep autumn digging to land, in preparation for root crops. Both operations can ordinarily be more economically performed by using horse-power with suitable implements. But for clearing out corners of fields, hedge sides, and similar places, manual labour with these tools can frequently be made to supplement the plough to good purpose.

IMPLEMENTS FOR SOWING.

Broadcast sowing.

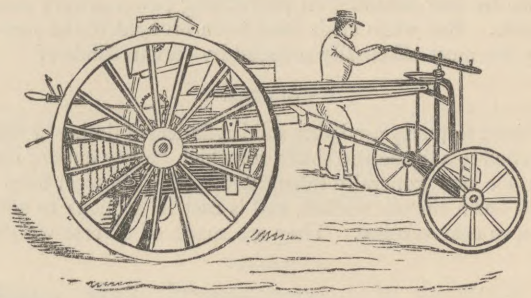
A large portion of the grain annually sown in Great Britain, is still distributed by hand from the primitive sowing sheet.

> "The sower stalks
> With measured step, and liberal throws the grain
> Into the faithful bosom of the ground."

In Scotland, a decided preference is still given to broadcast sowing, for which purpose a machine is used which covers from 15 to 18 feet, according to the width of ridges adopted. It consists of a long seed-box carried on a frame mounted on two wheels. From these, motion is communicated to a spindle which revolves in the seed-box, and expels the seed by means of cogs or brushes, through openings which can be graduated to suit the required rate of seeding. It is drawn by a single horse, is attended by one man, and can get over 30 acres a-day. It is peculiarly adapted for the regular distribution of clover and grass seeds. In one exhibited at the Highland Society's Show at Perth in 1852, by an ingenious apparatus on the principle of the odometer, the machine itself is made to register the space which it travels over, and thus to indicate the rate per acre at which it is distributing the seed. Excellent results have been, and still are, obtained from broadcast sowing. But as tillage becomes more perfect, there does arise a demand for greater accuracy in the depth at which seeds are deposited in the soil, for greater precision in the rate and regularity of their distribution, and for greater facilities for removing weeds from amongst the growing crop. These considerations led, at a comparatively early period, to the system of sowing crops in rows or drills, and hence the demand for machines to do this expeditiously and accurately. We accordingly find in our best cultivated districts, the sowing and after-culture of the crops now conducted with a precision which reminds the spectator of the processes of some well-arranged factory. This is accomplished by means of a variety of drilling machines, the most prominent of which we shall now notice.

Suffolk drill.

The Suffolk drill is the kind in most general use. It is a complicated and costly machine by which manure and



SUFFOLK DRILL. (GARRETT AND CO.)

seeds can be simultaneously deposited. That called the "general purpose drill," can sow 10 rows of corn, with or without manure, at any width between the rows, from 4½ to 10 inches, and at any rate per acre betwixt two pecks and six bushels. It can be arranged also to sow clover and grass seeds—the heavier seeds of clover being thrown out by minute cups—and the lighter grass seeds brushed out from a separate compartment. It is further fitted for sowing beans and turnips—the latter either two drills at a time on the ridge, or three on the flat. This drill, as most recently improved by Messrs Hornsby of Granthan, and Garrett of Leiston, has an apparatus for preserving the machine in a level position when working on sloping ground. As a main object in drilling crops at all. is to admit of the use of the hoe, it become an important point to accomplish the drilling with undeviating straightness, and exact parallelism in each successive course of the drill. This is now obtained by means of a fore carriage, which an assistant walking alongside so controls by a lever as easily to keep the wheel in the same rut down which it had previously passed. Messrs Hornsby have also introduced India-rubber tubes for conducting the seed, in place of the tin funnels hitherto used. These drills cost about L.42.

Woburn drill.

The Woburn drill of the Messrs Hensman, is simpler in its construction than those already noticed. "In all other drills, the coulters, which distribute the manure or seed, hang from the carriage. In this drill the carriage rests upon the coulters, which are like the iron of skates; it may be said, indeed, to run on four pairs of skates. Hence this drill's power of penetrating hard ground, and of giving a firm bed to the wheat-seed in soft ground. Each drill coulter, however, preserves its independence as when suspended. This self-adjustment is required by the inequality of tilled ground, and is thus obtained: each pair of coulters is fixed to the end of a balance beam, these again to others, and they to a central one. Thus each coulter, in well-poised rank, gives its independent share of support. It varies from the generality of drills, as it is drawn from the centre by whipple-trees instead of shafts; and the drill-man behind can steer or direct the drill with the greatest nicety. The corn-box of the drill is entirely self-acting, and delivers the seed equally well going either up or down hill. It is also capable of horse-hoeing, by attaching hoes to the levers instead of the coulter-shares. It is drawn by a pair of horses, and the price from L.18 to L.20."[1]

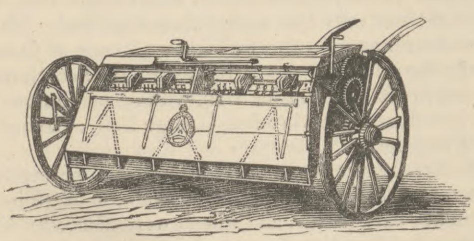
Turnip drill.

Turnip Drill. In Scotland, and in the north and west of England, turnips are usually sown on the ridge by a machine which sows two rows at a time. In the south-eastern parts of England, which are hotter and drier, it is found better to sow them on the flat, for which purpose machines are constructed which sow four rows together, depositing manure at the same time. Both kinds are adapted for sowing either turnips or mangold-wurzel seeds as required. With the view of economising seed and manure, what are called drop-drills have recently been introduced, which deposit both—not in continuous streams—but in jets, at such intervals apart in the rows as the farmer wishes the plants to stand. What promises to be a more useful machine is a water-drill invented by a Wiltshire farmer—Mr Chandler, of Market Lavington. "His water-drill pours down each manure-coulter the requisite amount of fluid, mixed with powdered manure, and thus brings up the plant from a mere bed of dust. Having used it largely during three years, I may testify to its excellence. Only last July, when my bailiff had ceased turnip-sowing on account of the drought, by directing the use of the water-drill, I obtained from this latter sowing an earlier and a better show of young plants than from the former one with the dust-drill. Nor is there any increase of expense, if water be within a moderate distance, for we do not use powder-manures alone. They must be mixed with ashes, that they may be diffused in the soil. Now the expense and labour of supplying these ashes are equal to the cost of fetching mere water; and, apart from any want of rain, it is found that this method of moist diffusion, dissolving, instead of mingling only, the superphosphate, quickens its action even upon damp ground, and makes a little of it go further."[2]

Chandler's water-drill.

The practice of top-dressing wheat, vetches, clover, or meadows, with guano and various light manures, has now so much increased, and the inconvenience of scattering them over the surface by hand is so great, that various machines have recently been invented for distributing them. That by Holmes of Norwich has obtained the prize offered for such a machine by the Royal Agricultural Society of England.

Holmes' manure distributor



MANURE DISTRIBUTOR. (J. HOLMES AND SONS, NORWICH.)

It can also be used for sowing such manures over turnip drills, covering three at once. Such machines will probably be more used in future for distributing lime, which can thus be done much more regularly than by cart and shovel, especially when it is wished to apply small quantities for the destruction of slugs or for other purposes. It seems quite practicable to have this or a similar machine so constructed as that it could be readily hooked on to the tail of a cart containing the lime or other substance which it is desired to distribute by it. The top-dressing material could by such an arrangement be drawn into the hopper of the distributor, as it and its tender move along, and the cart, when emptied, be replaced by a full one with little loss of time.

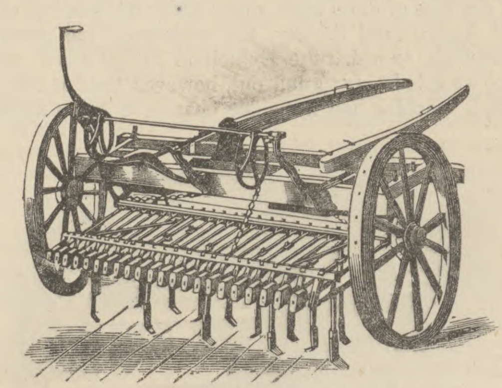
A cheap and effective machine, capable of being in a similar manner attached to a dung-cart, and which could tear asunder fold-yard manure, and distribute it evenly in the bottoms of turnip drills, would be a great boon to farmers, and seems a fitting object to be aimed at by those possessed of the inventive faculty.

### HORSE-HOES.

It has already been remarked, that the great inducement to sow grain and green crops in rows is, that hoeing may be resorted to, for the double purpose of ridding them of weeds and stimulating their growth by frequent stirring of the soil. It is now upwards of a century since Jethro Tull demonstrated in his books and on his fields, the facility with which horse-power could be thus employed. His system was early adopted in regard to turnips, and led, as we have seen, to a complete revolution in the practice of agriculture. The peculiar manner in which he applied his system to grain crops, and the principles on which he grounded his practice, have hitherto been for the most part repudiated by agriculturists, who have thought it indispensable to drill their grain at intervals so narrow as to admit, as was supposed, of the use of the hand-hoe only. But the accuracy with which corn-drills perform their work, has been skilfully taken advantage of, and we now have horse-hoes, covering the same breadth as the drill, which can be worked with perfect safety in intervals of but seven inches wide. By such a machine, and the labour of a pair of horses, two men, and a boy, ten acres of corn can be hoed in as many hours. Not only is the work done at a fifth of the expense of hand-hoeing, and far more effectually; but it is practicable in localities and at seasons in which hand-labour cannot be obtained.

Garrett's horse-hoe.

Garrett's horse-hoe is admitted to be the best implement of its kind. It can be used for hoeing either beans, turnips,



GARRETT'S HORSE-HOE.

or corn, as the hoes can be adapted to suit any width betwixt rows, and the axle-tree being moveable at both ends, the wheels, too, can be shifted so as to be kept betwixt the rows of plants. The shafts can be attached to any part of the frame to avoid injury to the crop by the treading of the horses. Each hoe works on a lever independent of the others, and can be loaded with different weights on the same prin-

---

[1] See Mr Pusey's Report on Implements.—*Journal of the Royal Agricultural Society of England*, vol. xii. p. 604.

[2] Ib., p. 607.

ciple as the coulters of the corn-drill to accommodate it to uneven surfaces and varying degrees of hardness in the soil.

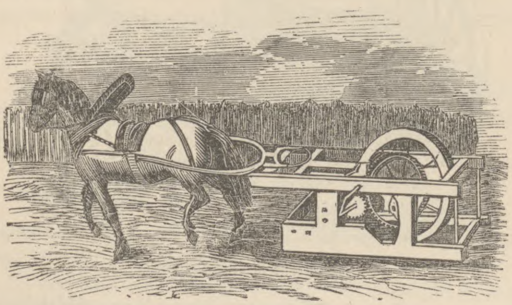
A great variety of implements under the general names of horse-hoes, scufflers, scrapers, or drill-grubbers, fitted for the draught of one horse, and to operate on one drill at a time, is in use in those parts of the country where root crops are chiefly sown on ridgelets from 24 to 30 inches apart. With considerable diversity of form and efficiency, they in general have these features in common, viz., provision for being set so as to work at varying widths and depths, and for being armed either with hoes or tines, according as it is wished to pare the surface or stir the soil more deeply. A miniature Norwegian harrow is sometimes attached to drill-grubbers, by which weeds are detached from the soil, and the surface levelled and pulverized more thoroughly. Tennant's grubber with its tines set close together, and two horses yoked to it abreast by a tree long enough to allow them to walk in the drills on either side of that operated upon, is the most effective implement for cultivating betwixt the rows of beans, potatoes, turnips, or mangold, that we have yet seen used for this purpose. The next class that claims attention is

HARVESTING IMPLEMENTS.

These, until recently, comprised only the reaping-hook and scythe. An implement, by means of which horse-power could be made available for this important operation has long been eagerly desired by farmers. Repeatedly during the past 50 years have their hopes been excited by the announcement of successful inventions of this kind; but, after much fair promise, have hitherto always met with disappointment. These hopes have recently been revived, and raised to a higher pitch than ever, by the appearance, in the Great Exhibition of the Industry of all Nations, of two reaping-machines, known as M'Cormick's and Hussey's, from the United States of America, where, for several years past, they have been used extensively and successfully. These implements were subjected to repeated trials in different parts of England, on crop 1851, but never in circumstances which admitted of their capabilities being tested in a thoroughly satisfactory manner.

American reaping-machine.

At the first of these trials, made under the auspices of the Royal Agricultural Society, the preference was given to M'Cormick's, to which the Exhibition Medal was in consequence awarded. It turned out, however, that at this trial Hussey's machine had not a fair chance, it being attended

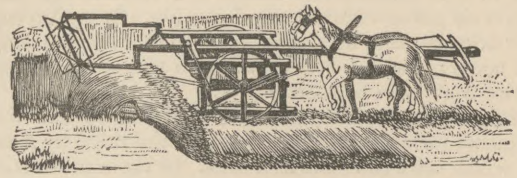


HUSSEY'S REAPING MACHINE, BY GARRET AND CO.

by a person who had never before seen it at work, for, when a further trial took place before the Cleveland Agricultural Society, with Mr Hussey himself superintending his own machine, an all but unanimous decision was given in his favour. Hussey's machine was in consequence adopted by the leading implement makers, such as Messrs Garrett, Crosskill, &c.

Early in 1852, a very important communication from the pen of Mr James Slight, curator of the museum of the Highland and Agricultural Society, appeared in the Transactions of the Society, by which the attention of the public was recalled to a reaping machine of home-production, viz., that invented by the Rev. Patrick Bell, now minister of the

Machines and Implements.



BELL'S REAPING MACHINE, BY CROSSKILL.

Bell's reaping-machine.

parish of Carmylie in Forfarshire, and for which a premium of L.50 had been awarded to him by the Highland Society so long as 26 years ago. This machine attracted much attention at that time. Considerable numbers were made and partially used, but from various causes the invention was lost sight of, until by the arrival of these American machines, and the notoriety given to them by the Great Exhibition, with concurring causes about to be noticed, an intense interest was again excited regarding reaping by machinery. From Mr Slight's report, the public learned that the identical Bell's machine to which the prize was awarded, had for the last 14 years been statedly employed on the farm of Inch-Michael in the Carse of Gowrie, occupied by Mr George Bell, a brother of the inventor, who, during all that period, and on the average of years, succeeded in reaping four-fifths of his crop by means of it. Mr Slight further stated, that at least *four* specimens of it had been carried to America, and that from the identity in principle betwixt them and those now brought thence, with other corroborating circumstances, there is little doubt that the so-called American inventions are after all but imitations of this Scottish machine. When it became known that Bell's machine was to be exhibited, and if possible, subjected to public trial, at the meeting of the Highland and Agricultural Society at Perth, in August 1852, the event was looked forward to by Scottish farmers, with eager interest. On that occasion, it was accordingly again brought forward, with several important improvements made upon it, by Mr George Bell, already referred to, and was fully tested in competition with Hussey's, as made by Crosskill. To the disappointment of many, Mr M'Cormick did not think fit to enter the lists either at this or at subsequent opportunities. The following is the report of the judges who acted upon that occasion:—

"Out of five reaping machines exhibited, four were on the principle of Hussey's, and one on that of the Rev. Patrick Bell. Of these only two were entered for trial. The Hussey machine was from the well-known house of Crosskill of Beverly, the other was the early constructed Scotch machine, invented in 1828 by Patrick Bell, with certain improvements lately introduced by his brother, George Bell, of Inch-Michael farm, Perthshire.

"As has already been stated, arrangements were made by the secretary to conduct the trial on the farm of Muirton, and three fields, oats, barley, and wheat, were placed by Mr Morton, the tenant, at the disposal of the society, for the experiment.

"The following judges were appointed to superintent the trial:—Laurence Oliphant of Condie; Henry Stephens, author of The Book of the Farm; James Stirling, civil engineer, Edinburgh; John Finnie, farmer, Swanston; John Dickson, farmer, Saughton Mains; John Gibson, farmer, Woolmet; James Steedman, farmer, Boghall; William Watson, millwright, Errol; John Young, engineer, Newton-upon-Ayr.

"A space was first cut by the sickle along the ends of the fields, so as to enable the machines to commence. Hussey's,

Machines and Implements.

from being *drawn* by the horses, requires a further clearance along the sides sufficiently broad to allow the horses to walk. Bell's, on the other hand, being *propelled* by the horses, and having the power of delivering the grain to the right or left, opens a passage for itself at any point, whether at the side or in the centre of a field; hence in each trial it took precedence in starting. Each machine was worked by two horses.

"The first essay was in a field of oats. The crop was standing, and nearly ripe, consequently in a favourable condition for machine-cutting, although it stood rather thin on the ground. Bell's machine at first created an impression, from the slow movement of its shears (making only about 110 strokes per minute), that it might pass over and crush the grain. A second or two, however, sufficed to dispel this; and as the implement progressed, it left a stubble about four inches high, cut with the most perfect regularity, and so clean, that scarcely a straw or a grain was observable on it. A stoppage occurred, to allow some adjustment to the height of stubble, and during the five or six turns made by the machine, two or three stoppages took place in crossing deep furrows and unequal ground; but, on the whole, the work was well and continuously performed. The cutting was perfect throughout, and the corn laid with great regularity in an unbroken swathe, the straw lying at an angle of 30 degrees with the line of progress. The breadth of the cut, when shut on both sides, is 6 feet, but cutting with an open side, the breadth seems not to exceed 5½ feet. In the present case the average of four turns was only 5 feet.

"Hussey's machine next came into operation on the oats. The rapid vibration of its cutters, which gave about 570 strokes per minute, produced a feeling of confidence at the start that it would leave nothing uncut; and the first turn, though not performed without stoppage, was satisfactory with respect to cutting. The grain, however, was not so well laid as by Bell's, and the stubble was higher and not so clean. The succeeding cuts were less satisfactory, frequent stoppages occurred, and when there was any undergrowth of grass, the machine was greatly baffled. While the operation of cutting was fairly performed, it was evident that the radical defect of the machine lay in the want of sufficient and regular means for removing the grain when cut. This division of the process depended exclusively on the rakeman, and when he missed the proper moment for removal, the cutters were immediately choked. In point of economy a most important defect was observable, —the breadth cut by Hussey's did not, on an average, exceed 3¼ feet.

"The barley crop was much heavier than the oats, and partially laid, thus presenting greater difficulties to the machines. The superiority of Bell's was here decided in every respect, while the more frequent stoppages of Hussey's from choking, seemed to be caused partly by the greater weight of the crop, but mainly by the inability of the rakeman to perform his duties under the combined difficulty of a partially matted and a heavy crop.

"In the wheat field the crop was of great weight and strength, estimated at a produce of six quarters the imperial acre; and here the decided superiority of uniformly continued mechanical action over intermitting muscular force was strikingly illustrated. Bell's machine, at the outset, cutting a breadth of 5½ feet along the edge of a ditch, had a stoppage, from inequality of surface, after which it proceeded almost without intermission, cutting its regular breadth, and laying the wheat with great regularity, three or four straws only being seen out of the proper angle on the top of the swathe. Under this ordeal, Hussey's had still some merit. It cut a fair stubble, though higher than desirable. It began with its usual breadth, but even that (small compared with Bell's) was beyond the powers of the rakeman to remove; the machine, consequently, became choked at intervals of a few yards, and it ultimately appeared necessary to reduce the breadth of cut to about two feet. In the wheat, therefore, the comparative failure of this machine was, under any economical view, obvious and decided. The action of the fan in Bell's machine, in gathering and depositing the crop upon the web, induced an apprehension that the grain might to some extent be beaten out. This the judges carefully investigated and found to be groundless.

Machines and Implements.

"Taking into consideration all the circumstances of these trials, the judges unanimously felt warranted in awarding the premium to Mr Bell, for the following reasons:—

"1*st*, For the decided superiority of his machine in economising time and expense, owing to the greater breadth cut by it with the same horse-power, the difference being as 10 to 6½.

"2*d*, For the character and quality of the work performed by it, as being cleaner cut, producing less waste or shake, and laying the swathe with a regularity better suited for binding in sheaves, than when laid off in unequal bundles.

"3*d*, For being less liable to choke, and to the consequent stoppages.

"4*th*, For being mechanically adapted to deposit the grain in rows, performing the operation in a superior manner, and saving, in the opinion of the judges, the labour of two men, as compared with Hussey's.

"5*th*, For the advantages arising from its having the means of laying off the grain to the right side or the left, this feature, combined with that of being propelled instead of being drawn, enabling it to enter on either side, or into the centre of a field, without any previous clearing, and to continue the cutting without interruption, while the cut portion of the crop was lying on the ground.

"6*th*, For greater efficiency when operating on a crop partially lodged."[1]

Subsequent to this, Bell's machine, besides being seen at work by many visitors on his own farm at Inchmichael, was publicly exhibited at four different places,—viz., Phantassie in East Lothian; in the neighbourhood of Dunfermline in Fife; in Ireland, at the special invitation of the Royal Society, who handsomely paid the expense of transporting it thither; and last of all, at Keillor in Forfarshire, on which occasion a challenge was given by public advertisement to all other reaping machines to compete with Bell's for a sweepstakes of L.50 a side. The subject is so important that we shall here quote from the report of the last of these trials:—

"KEILLOR, *September* 4, 1852.

Trial of reaping-machine at Keillor.

"We, the undersigned, having been requested to act as Judges at the trial of reaping machines, which took place this day at the above farm, pursuant to a challenge given by Hugh Watson, Esq., and Mr George Bell, for a sweepstakes of Fifty Sovereigns each, to test the merits of the different machines which are now attracting public attention in this country, and, if possible, to decide upon the best before next season,

REPORT

"That only three reapers appeared upon the field, viz.:—

"1*st*, An American machine, known by the name of Hussey's, constructed and improved under the superintendence of Mr Crosskill, of Beverley, and worked by his agent, Mr Love.

[1] Transactions of the Highland and Agricultural Society of Scotland, Oct. 1852, p. 419.

Machines and Implements.

"2*d*, A similar machine, with some important improvements, exhibited by Lord Kinnaird; and,

"3*d*, The old original reaping machine, invented by the Rev. Mr Bell of Carmylie, Forfarshire, and which, it appears, has been worked by his brother, Mr George Bell, on his farm of Inchmichael, in the county of Perth, for upwards of twenty years.

"Another machine, constructed by an ingenious mechanic at Invergowrie, near Dundee, was also expected, but met some accident on trial the previous evening, which was the cause of much disappointment.

"It was understood that Mr M'Cormick, from America, was also on the ground, but the machine which bears his name did not appear.

"Mr Love, on the part of Mr Crosskill, stated before the trial commenced, that, after the decision of such a high and competent authority as the Highland Society, at Perth, and after witnessing a trial of the machine itself at Phantassie, Mr Crosskill considered it would be useless to contend against Mr Bell's any longer, which he considered a far superior and more effective machine than any he had yet seen; but that he (Mr Love) would give every assistance in his power to work Hussey's that day for the satisfaction of the large and influential body who were then present.

"As it was desirable that the merits of the machines should be tested in every possible way, it was deemed advisable that the locality should not be too favourable to their easy working, but should possess all the average difficulties of an ordinary corn crop, so as to ascertain the working powers of each. Accordingly the ground selected for the trial was a large field of barley, on the slope to the south of Keillor House; and three lots of one imperial acre each having been measured off, Bell's machine was started first, and performed its work steadily and well in 45 minutes. We examined the stubble carefully, both up and down hill, and it was cut much to our satisfaction, though some difference of opinion existed as to which way the machine worked best. It appeared that the breadth cut each time was something over six feet, and the corn was delivered at the side of the machine in one uniform long line, and most convenient for the binders. Mr Bell concluded by driving a transverse cut obliquely across the field, and right through the centre of the grain, which appeared to show off the merits of the machine to much advantage.

"The other two machines were then set to work on similar lots of ground, and Hussey's, under the superintendence of Mr Love, cut about two-thirds of the prescribed quantity within the 45 minutes, while, from some reason not explained, the other did not complete its task. As these two machines were nearly similar, with the exception of that exhibited by Lord Kinnaird, which had an endless cloth revolving directly in the track of the machine, and intended to facilitate the delivery of the corn in a straight line behind it, the work performed by them was nearly alike. We found on examination that the breadth cut was about three feet and a half each time; and though the stubble was well cut up hill, and when the machine worked against the inclination of the barley, yet it was quite the contrary down hill, where the stalks were often dragged and left uncut. Indeed, so strongly did the director of Hussey's machine feel this difficulty, that, after the first round, he avoided cutting down hill at all, and confined himself to working up hill exclusively, by which nearly one half the time was lost. The stops of these two machines were also much more frequent than with Bell's, arising from stones and other impediments, as well as from the cutters driving into the ground, which not only caused great delay, but also ran much risk in damaging the machines irreparably. From the shortness and peculiar construction of the cutters, it appeared to us that they were much too liable to choke or clog, particularly when they came in contact with anything green, or lying at an angle from them, which rendered it often necessary to stop the machines, in order to have the teeth cleared, and the impediments otherwise removed.

"When the trial at the barley was completed, the parties adjourned to the wheat field, and Bell's machine first charged directly into the centre, and cut a large lane for itself, upwards of six feet in breadth, laying the wheat, which was an exceedingly heavy crop, in a perfectly straight line, and peculiarly well placed for the binders. The reaping of this heavy crop appeared to be comparatively easy work after the barley, and the easy, masterly way in which it was cut down, without any apparent difficulty or noise, gave general satisfaction. Three-quarters of an acre was cut within the half-hour, or at the rate of an acre within the three-quarters, while the stubble appeared beautifully clean and well cut, and no delay whatsoever took place in the performance by Bell's. A lane having been thus cleared, the two other machines set to work, and completed half an acre each in shorter time, and with greater ease than with the barley, and the stubble exhibited none of those inequalities which marked the down-hill work at the other crop.

"With regard to the relative merits of the different machines, it is evident that two of them are imitations, but not improvements, of Mr Bell's original one; and, with the exception of their being somewhat lighter and more portable, when not actually at work, and more easily turned, they do not retain what we consider the leading and important features of his; while, though doing only two-thirds of the work, they appear to be as distressing to the men and horses that work them." . . . . . . . .

(Signed) George A. Grey, Millfield Hill, Northumberland; Charles Chambers, Aberdeenshire; John Garland, Kincardineshire; Andrew Archer, Forfarshire; William Blackadder, C.E., Glammis; Archibald Turnbull, Perthshire, *Judges.* John Ogilvy, Bart., Baldovan; Edward Bullen, Dublin, *Stewards.* Alexander Geekie, Baldowrie, *Timekeeper.*[1]

Since these trials, Mr Bell has informed the public that he has committed the manufacture of his machine, now secured to him by patent, to Mr Crosskill of Beverley, and that he has added to it a contrivance, by means of which he anticipates that it will deposit the cut corn in quantities ready for sheaving, instead of a continuous swathe as hitherto.

Before leaving this subject a remark is due in connection with the strange neglect of this machine for 25 years, and the enthusiasm with which it has now been hailed on its reappearance. The first is so far accounted for by the fact recently noticed by Mr George Bell, that such specimens of his brother's machine as formerly got into the hands of farmers were so imperfectly constructed that they did not work satisfactorily and thus brought discredit on his invention. The true explanation seems to be, that at that date the country was not ready for such a machine. Not only was manual labour then abundant and cheap, from the number of Irish labourers, who annually, as harvest drew near, flocked into the arable districts of Great Britain; but thorough draining had made little progress, and the land was everywhere laid into high ridges, presenting a surface peculiarly unfavourable for the successful working of a reaping machine. Now, however, the conditions are reversed. Under the joint operation of a famine at home pressing out, and the gold discoveries in Australia alluring, emigration from Ireland and elsewhere

[1] North British Agriculturist, 8th September 1852.

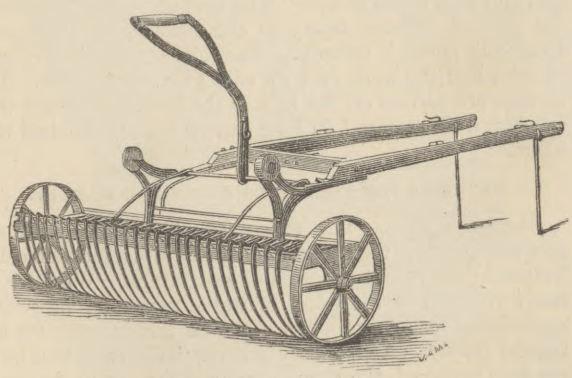
Machines and Implements.

has so thinned the population as already to tell seriously on the supply of labour. The lower price of farm produce consequent on free-trade, urgently demands a reduction in the rate of producing it; and from the extent to which thorough draining has now been carried, high ridges and deep furrows are not merely useless, but positively hurtful. In these altered conditions lies the true explanation of the former apathy and present enthusiasm manifested by our farmers towards this invention. In America, where reaping by machinery has already become a well-established agricultural practice, much progress appears to have been made during 1851-52 in improving this class of machines. At a meeting of the New York State Agricultural Society, in July 1852, no less than eight to ten different mowing and reaping machines were subjected to public trial, all of which accomplished their work in a more or less satisfactory manner. The report of this trial in the *American Cultivator* concludes thus—"On the whole, the trial was a complete triumph of machinery over hand-work, for both mowing and grain-cutting; and, when machines shall be perfected, simplified, and rendered much cheaper than at present, mowers and reapers must become as indispensable on all farms of moderate size, as horse-rakes, ploughs, and thrashing machines."[1]

Now that our leading agricultural mechanists have set themselves in good earnest to the task, and with such eager demand from their customers to stimulate them, we may with some confidence anticipate that really efficient reaping machines will, ere long, be available to British farmers. The trials which have recently been made, suffice to shew that we have already several machines by which the mere reaping is upon the whole performed in a satisfactory manner. What we now want is to have the cut grain deposited out of the track of the machine, and in parcels ready for sheafing. So long as the gatherers and binders must work *in column*, each hurrying past the other, to clear the course for the next round of the reaper, there must necessarily be much loss of time and unnecessary waste. With a machine thus improved, starting so long beforehand as to admit of the same number of people working *in line*, each with a ready parcelled swathe to himself, proper superintendence, economical arrangement, and accurate work will be attainable.

### HORSE RAKES.

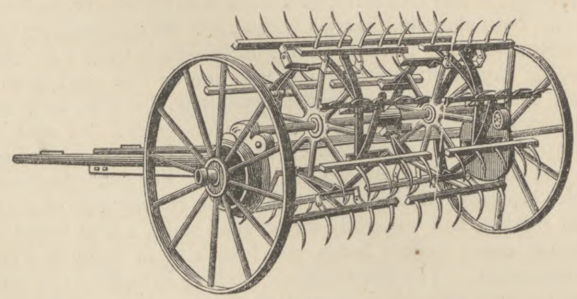
Horse-rakes are in frequent use for gathering together the stalks of corn which are scattered during the process of



HORSE-RAKE (SMITH'S).

reaping; for facilitating the process of haymaking, and also for collecting weeds from fallows. By an ingenious contrivance in the most improved form of this implement, the teeth are disengaged from the material which they have gathered without interrupting the progress of the horse.

Haymakers are valuable implements, and well deserving of more general use. They do their work thoroughly, and



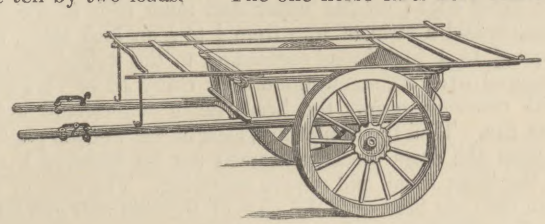
HAYMAKER.

enable the farmer to get through a great amount of it in snatches of favourable weather. Where manual labour is scarce, or when, as in Scotland, haymaking and turnip-thinning usually come on hand together, the haymaker and horse-rake render the horse power of the farm available for an important process which cannot be done well unless it is done rapidly and in season.

We seem to be verging on the time when, by means of reaping, haymaking, and raking machines worked by horse power, farmers will be enabled to cut and carry their grass and corn with little more than the ordinary forces of their farms.

### WHEEL CARRIAGES.

The cartage of crops, manure, &c. upon an arable farm, is such an important part of the whole labour performed upon it, (equal, as shown by a recent estimate, to one-half,)[2] that it is a matter of the utmost consequence to have the work performed by carriages of the most suitable kind. It was for a long time keenly debated by agriculturists, whether waggons or carts are most economical. This question is now undoubtedly settled. Mr Pusey says, "It is proved beyond question, that the Scotch and Northumbrian farmers, by using one-horse carts, save one-half of the horses which south-country farmers still string on to their three-horse waggons and three-horse dung-carts, or dung-pots, as they are called. The said three-horse waggons and dung-pots would also cost nearly three times as much original outlay. Few, I suppose, if any, farmers *buy* these expensive luxuries now; though it is wonderful they should keep them; for last year at Grantham, in a public trial, *five* horses with five carts were matched against five waggons with *ten* horses, and the five horses beat the ten by two loads."[3] The one-horse carts here referred



HARVEST-CART.

to are usually so constructed as to be easily adapted to the different purposes for which wheel-carriages are needed upon

Machines and Implements.

a farm. For each pair of wheels and axle there is provided a close-bodied cart, and another with sparred sides and broad shelvings, called a long-cart, or harvest-cart, either of which can easily be attached to the wheels, according to the nature of the commodities to be carried. Such a cart, weighing from 7 to 8 cwt., with iron axle and oak shafts, costs at present, in Berwickshire, from L.10 to L.11, when complete, with both close and harvest bodies, &c. Sometimes a simple moveable frame is attached to the close-body to fit it for carrying hay or straw; but although one or two such frames are useful for casual purposes throughout the year, they are inferior for harvest work to the regular sparred cart with its own shafts. In some districts the whole of the close-bodied carts used on the farm are made to tip. For many purposes this is a great convenience; but for the conveyance of grain to market, and generally for all road work, a firm frame is much easier for the horse, and less liable to decay and derangement. The Berwickshire practice is to have one pair of tip-carts on each farm, and all the rest firm or dormant-bodied, as it is sometimes called.

Many farms are now provided with a water or tank cart, for conveying and distributing liquid manure.

A plan for lessening the expenditure of horse-labour in the carriage of roots, &c. and accomplishing it with less injury to the land, by means of a portable railway, has been introduced by R. Neilson, Esq., of Halewood, near Liverpool, and tried by others in various parts of the country. When we first heard of this portable farm railway, we confess to having regarded it as a mere toy for amateurs, to whom expense was no object. Further inquiry and reflection have led us to a different conclusion, and we now regard it as likely ere long to come into general use. In the Agricultural Gazette, of 22d March 1851, Mr Neilson, after stating that his farm consists of heavy clay land, on which the difficulty of carting off root crops, or carting on manures, &c. was so great as to lead him to invent a rude sort of railway of wood, which so well answered the purpose, that for the last nine or ten years he had used it always for taking off his root crop, and frequently in putting on manure, thus describes his contrivance:—" The sides are of the common deal, 18 feet long, or shorter if thought more desirable, nearly 3 inches deep and $2\frac{1}{2}$ thick. A balk of timber 18 feet long and 12 inches by 13 square, will cut up into 20 of them. They are connected by means of wooden sleepers of tougher material (slabs or thinnings of oak, ash, beech, &c.), 2 feet 5 long, 3 inches broad by 2 inches thick, and morticed through the side pieces about 4 feet; the tenon is left in the upper side of the cross piece, and the mortice is cut in the side piece, so as to allow the bottom of it and the cross piece to be on a level, so that the flange of the wheel will travel above. The tenons are fastened by a half-inch wooden pin driven through the side piece $\frac{3}{4}$ of an inch from the outer edge; on the upper and inner edge of the side piece is laid a strip of iron from $\frac{1}{4}$ to $\frac{1}{2}$ an inch thick, and from $\frac{3}{4}$ to 1 inch broad (according to the weight of work required over it), screwed down at every 15 or 18 inches with two-inch screws, the heads being countersunk in the iron rim. Thus the iron strip is clear of the wooden pin that fastens the cross pieces, and need not be removed if any of the latter break and require renewing. The ends of the iron strip are bent over the ends of the side rails and let in flush, and are secured by a band of hoop-iron covering the mortice hole outside, passing round the end, and for six inches along the inside of the side rail, and through this plate is fastened the joint for attaching to the next rail. After many contrivances, I have found the following the best and most convenient mode of connecting two consecutive rails together: a pin three inches long, of half-inch square iron, turned with a half-inch eye at one end, and driven nearly home in each end of each side piece. Care must be taken that these pins are fixed half an inch on the inside of the centre on one end, and half an inch on the outside of the centre on the other end of the same rail, so that when two rails are brought together, the two pins of the one rail are both inside or both outside the two pins of the other rail, which prevents them separating sideways, and the eyes being level, are fastened by a half-inch pin or plug put through them, and which forming a joint, enables the railway to be laid more easily over undulating ground. These pins or plugs are secured to the side pieces by a small piece of light jack chain. Though this description is but an imperfect one, I trust that with the accompanying sketch it may be sufficiently understood to be tried; and where the surface is suitable and not too hilly, I'll answer for it, that on heavy land it will not readily be discontinued. Of the waggons and turn-tables I presume no description is needed; the latter is very simple, adapted to the length of the former, and costs about L.10. The former will hold about ten or twelve cwt. of turnips, and discharges sideways over the wheel, which is about 18 inches high. Cost about L.2, 15s., or L.3. My arrangement for getting off my turnips is to deliver the rails, waggons, and turn-tables in proper working order to the labourers who contract to deliver the turnips at the field-gate at so much per acre, and to restore the rails, &c. in good order, or pay for breakage and damage." [1]

Mr Caird, who visited Mr Neilson's farm in October 1850, thus notices the invention:—" A light tramway with waggons is made use of for taking the turnip crop off the ground in moist weather. The tramway is readily shifted, and the crop is thrown into the waggons, which are then each pushed along by a man, so that the entire crop may be removed from the ground, which thus receives no injury from the feet of horses. The tramway can be constructed for 1s. 4d. per yard, and might be very advantageously introduced on all heavy farms where it is found difficult to take off the turnip crop in moist weather. A gang of men are at present employed on a considerable field of Mr Neilson's in taking off the turnip crop, which they draw from the ground, fill into the waggons, and convey outside of the gate at the rate of 6s. an acre, shifting the tramway at their own cost. At this work they earn 2s. 3d. a-day." [2] On the Home farm of Earl Grey at Hawick, he found the same contrivance in use, and thus refers to it,—" The root crops are taken from the ground, without injury to the surface, by the use of Crosskill's portable railway. The rails are found very easy to shift, and the work goes on with great expedition. The Swedes are carried on the rails to the headland, where they are stored till required, in long narrow heaps, thatched with straw." [3]

### MACHINES FOR PREPARING CROPS FOR MARKET.

*Steam Engines.*—The extent to which steam power is now employed for the purposes of the farm is another marked feature in the recent progress of agriculture. We have already referred to the value of water power for propelling agricultural machinery when it can be had in sufficient and regular supply. As it is only in exceptional cases that farms are thus favoured, the steam-engine is the power that must generally be reckoned upon; and accordingly its use is now so common that a tall chimney has become, over extended districts, the prominent feature of nearly every homestead. It has been satisfactorily shewn that grain can be thrashed

[1] See Agricultural Gazette for 1851, p. 186.

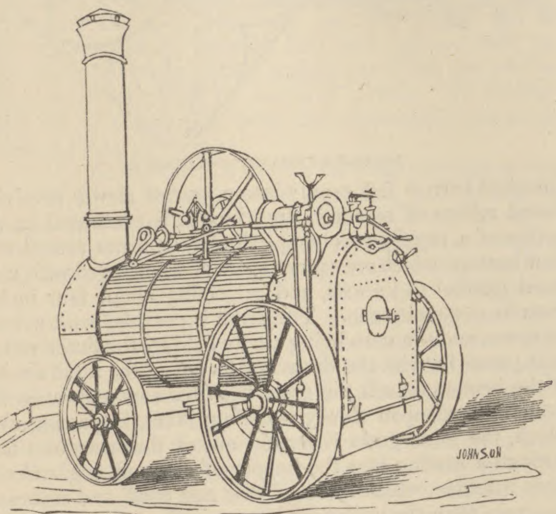
[3] Ibid. p. 375.

Machines and Implements.

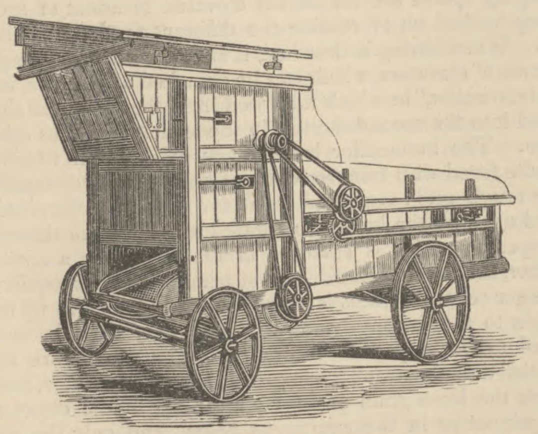
and dressed by well-constructed, steam-propelled machinery, at one-fourth the cost of thrashing by horse power and dressing by hand-fanners. So great indeed is the improvement in steam-engines, and so readily can the amount of power be accommodated to the work to be done, that we find them everywhere superseding the one-horse gin, and even manual labour, for pumping, churning, coffee-grinding, &c. Wherever, then, a thrashing-mill is used at all, it may be safely asserted that, next to water, steam is the cheapest power by which it can be propelled. The *portable* engine is the form which has hitherto found most favour in the southern parts of the kingdom. Mr Pusey thus states the reasons for

Portable *versus* stationary engine.



PORTABLE STEAM-ENGINE. (CLAYTON, SHUTTLEWORTH AND CO.)

which he regards them as preferable to fixed engines,—"If a farm be a large one, and especially if, as is often the case, it be of an irregular shape, there is great waste of labour for horses and men in bringing home all the corn in the straw to one point, and in again carrying out the dung to a distance of perhaps two or three miles. It is therefore common, and should be general, to have a second outlying yard. This accommodation cannot be reconciled with a fixed engine.



PORTABLE THRASHING-MACHINE. (CLAYTON, SHUTTLEWORTH AND CO.)

"If the farm be of a moderate size, it will hardly—and if small will certainly not—bear the expense of a fixed engine: there would be waste of capital in multiplying fixed engines to be worked but a few days in the year. It is now common, therefore, in some counties for a man to invest a small capital in a moveable engine, and earn his livelihood by letting it out to the farmer.

"But there is a further advantage in these moveable engines, little, I believe, if at all known. Hitherto corn has been thrashed under cover in barns; but with these engines and the improved thrashing-machines we can thrash the rick in the open air at once as it stands. It will be said, how can you thrash out of doors on a wet day? The answer is simple. Neither can you move your rick into your barn on a wet day; and so rapid is the work of the new thrashing-machines, that it takes no more time to thrash the corn than to move it. Open-air thrashing is also far pleasanter and healthier for the labourers, their lungs not being choked with dust, as under cover they are; and there is, of course, a saving of labour to the tenant not inconsiderable; but when these moveable steam-engines have spread generally, there will arise an equally important saving to the landlord in buildings. Instead of three or more barns clustering round the homestead, one or other in constant want of repair, a single building will suffice for dressing corn and for chaff-cutting. The very barn-floors saved will be no insignificant item. Now that buildings are required for new purposes, we must, if we can, retrench those buildings whose objects are obsolete. Open-air thrashing may appear visionary: but it is quite common with the new machinery; nor would any one perform the tedious manœuvre of setting horses and men to pull down a rick, place it on carts, and build it up again in the barn, who had once tried the simple plan of pitching the sheaves at once into the thrashing-machine."[1]

To us these reasons are inconclusive. A fixed engine can be erected and kept in repair at greatly less cost than a portable one of the same power. It is much easier to keep the steam at working pressure in the common boiler than in the tubular one, which, from its compactness, is generally adopted in portable engines. It is no doubt very convenient to draw up engine and machinery alongside a rick and pitch the sheaves at once upon the feeding-board, and very pleasant to do this in the sunshine and "caller air," but we should think it neither convenient nor pleasant to have engine and thrashing gear to transport and refix every time of thrashing; to have grain and chaff to cart to the barn, there to undergo a separate process of dressing by some other power; the thrashed straw to convey to the respective places of consumption, and all this in circumstances unfavourable to accurate and cleanly disposal of the products, and excessive exposure to risk of weather. Sudden rain will no doubt interrupt the carrying in of a rick in the one case as the thrashing of it in the other; but there is surely a vast difference betwixt merely re-covering the partially carried rick, having machinery, work-people, and products safely under cover, and engine and people ready by a slight change of gearing for other work, such as bruising, grinding, or chaff-cutting. Mr Favell and others have also now shown, that it is quite as practicable and much less laborious to bring the rick to the engine as to take the engine to the rick.

The fact that in the best modern machines, the grain is not merely separated from the straw, but riddled, winnowed, sacked, and weighed ready for market as the thrashing proceeds, at no more expense of time, fuel, or wages, than by the portable engine is expended on thrashing only, makes it very evident to us that the former is in every point of view the preferable machine. It is urged on behalf of the protable engine that in districts where the farms are generally small, one may serve a good many neighbours. Now, not

[1] Mr Pusey's Report on Implements.—Journal of the Royal Agricultural Society of England, vol. xii., p. 621.

Machines and Implements.

to dwell on the expense and inconvenience to small occupiers of frequently transporting such heavy carriages, and of having as much of their crop thrashed in a day (there being manifest economy in having at least a day's work when it is employed) as will meet their demands for fodder and litter for weeks to come, we are persuaded that on farms, of even 80 or 100 acres, a compact fixed engine of two or three horse-power will thrash, bruise grain, cut chaff, work a churn, and cook cattle-food, &c. more economically than such work can be done in any other way. It is very usual to find on such farms, especially in dairy districts, an apparatus for cooking cattle-food by steam, or by boiling in a large copper, where as much fuel is used every day, and as much steam generated, as would work such an engine as we have referred to, and do the cooking over and above. Even a small dairy implies a daily demand for boiling water to scrub vessels and cook food for cows. How manifestly economical, then, when the steam is up at any rate, to employ this untiring, obedient agent, so willing to turn the hand of anything, in performing the heavy work of the homestead with a power equal perhaps to that of all the men and horses employed upon the farm.

The prices of portable engines by the best makers, are, for 4-horse power, with tubular boiler, four wheels, double shafts, &c. about L.200. For a 6-horse power, from L.250 and upwards.

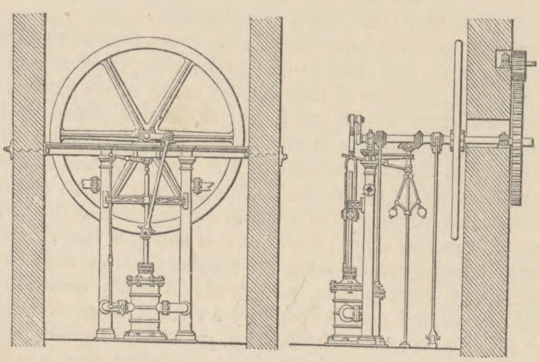
Fixed over-head crank steam-engine.

The kind of fixed engine most approved for farm-work in the north of England and south of Scotland is the over-head crank-engine, attached by direct action to the spur-

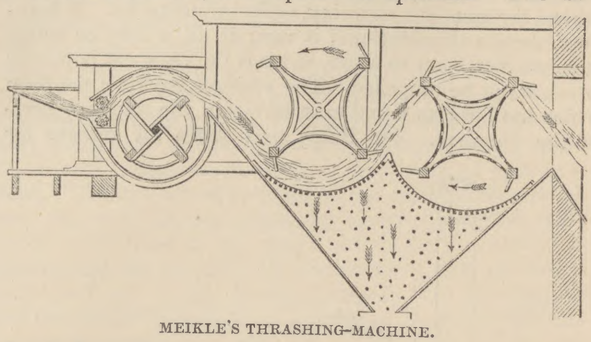


wheel, and sometimes even to the drum-shaft of the thrashing-machine. Their cheapness, simplicity of construction, easy management, and non-liability to derangement, fit them in an eminent degree for farm-work.

(*See article on "comparative advantages of fixed and portable steam-power for the purposes of a farm." By Robert Ritchie, Esq., C.E., Edinburgh, in Transactions of Highland Society for March* 1852, p. 281.)

THRASHING-MACHINE.

It is now 65 years since an ingenious Scotch mechanist, Andrew Meikle, produced a thrashing machine so perfect, that its essential features are retained unaltered to the present day. Indeed, it is frequently asserted that, after all the modifications and supposed improvements of the thrashing machine, which have been introduced by various parties, the mills made by Meikle himself have not yet been surpassed, so far as thorough and rapid separation of the grain from the straw is concerned. The annexed sketch presents a section of Meikle's machine, and explains its operation. The un-



MEIKLE'S THRASHING-MACHINE.

thrashed corn is fed evenly into a pair of slowly revolving fluted rollers of cast-iron, by which it is presented to the action of a rapidly revolving cylinder or drum armed with four beaters, which are square spars of wood faced with iron, fixed parallel to its axis, and projecting about four inches from its circumference. The drum is provided with a dome or cover, and the corn being partly held by the fluted rollers as it passes betwixt the drum and its cover, the rapid strokes of the beaters detach the grain from the ears and throw the straw forward upon slowly revolving rakes, in passing over which, the loose grain is shaken out of the straw and falls through a grating into the hopper of a winnowing and riddling machine, which rids it of dust and chaff, and separates the grain from the unthrashed ears and broken straw, called *roughs* or *shorts*. The grain and roughs are discharged by separate spouts into the apartment below the thrashing loft, where the corn is fed into the rollers, and the thrashed straw falls from the rakes into the straw-barn beyond. Since Meikle's time, further additions have been made to the machinery. In the most improved machines driven by steam or a sufficient water-power, the grain is raised, by a series of buckets fixed on an endless web, into the hopper of a double winnowing machine, by which it is separated into clean corn, light, whites or capes, and small seeds and sand. The discharging spouts are sufficiently elevated to admit of sacks being hooked on to receive the different products as they fall. When barley is thrashed, it is first carried by a separate set of elevators, which can be detached at pleasure, into a "hummeller," in which it is freed from the awns, and then raised into the second fanners in the same manner as other grain. The hummeller is a hollow cylinder, in which a spindle fitted with transverse blunt knives revolves rapidly. The rough grain is poured in at the top, and after being acted upon by the knives, is emitted at the bottom through an opening which is enlarged or diminished by a sliding shutter, according to the degree of trimming that is required. A larger set of elevators is usually employed to carry up the roughs to the feeding-board, that they may again be subjected to the action of the drum. The roughs are not emptied directly on the feeding-board, but into a riddle, from which the loose grain passes by a canvass funnel direct to the winnower in the apartment below, and only the unthrashed ears and short straw are allowed to fall upon the board.

Barley-hummeller.

The alterations that have been made upon the thrashing-machine since Meikle's time chiefly affect the drum. Meikle himself tried to improve upon his beaters by fixing a projecting ledge of iron on their outer edges so as to give them a scutching action similar to that of flax-mills. This strips

Machines and Implements.

off the grain from oats or barley very well, when thinly fed in; but its tendency is to rub of the entire ears, especially of wheat, and also to miss a portion of the ears, whenever there is rapid feeding in. More recent trials with drums on the scutching principle show it to be on the whole inferior to the plain beater.

Scutching-drum.

We have already referred to the general use of portable thrashing-machines in the eastern counties of England. These, for the most part, have drums with six beaters upon a skeleton frame, which revolve with great rapidity (about 800 times per minute, hence often called high-speed drum), within a concave, or skreen, which encloses the drum for about one-third its circumference. This skreen consists alternately of iron ribs and open wire-work, and is so placed that its inner surface can be brought into near contact with the edges of the revolving beaters, and admits of this space being increased or diminished by means of screws. No feeding-rollers are used with this drum, the unthrashed corn being introduced directly to it.

High-speed drum.

Another form of drum, acting on the same principle as that just referred to, but cased with plate-iron, and having for beaters, eight strips of iron projecting about one-fourth of an inch from its surface, and which works within a concave which embraces it for three-fifths of its circumference, is in use when it is desired to preserve the straw as straight and unbroken as possible. These are made of sufficient width to admit of the corn being fed in sideways, and are called *bolting* machines, from the straw being delivered in a fit state for being at once made up into *bolts* or bundles for market. Although the term *beaters* is retained in describing these drums, it is evident that the process by which the grain is separated from the ears, is rubbing rather than beating. This necessarily requires that only a narrow space intervene betwixt drum and concave, and that the corn be fed in somewhat thinly. Such machines thrash clean, whether the ears are all at one end of the sheaf or not, and deliver the straw straight and uninjured; but it is objected to these by some that they are slower in their operation than the common beating-drum,—are liable to choke if the straw is at all damp, —that the grain is sometimes broken by them,—and that they require greater power to drive them.

Bolting-drum.

Peg-drum.

A further and more recent modification is the peg-drum. In this case the drum is fitted with parallel rows of iron pegs, projecting about $2\frac{1}{2}$ inches from its surface, which in its revolutions pass within one fourth of an inch of similar pegs fixed in the concave, in rows running at right angles to the drum. Great things were at first anticipated from this invention, which, however, it has failed to realise. But iron pegs have more recently been added to the common beater-drum with apparent success. The beaters in this case are made one half narrower than usual, and have stout iron pegs, formed of square rods, driven into their faces, angle foremost, and slightly reflected at the points. These act by a combination of beating and rippling, and are said to thrash clean, and to be easily driven.

There is thus a great variety of thrashing-machines to be found in different parts of the country, the comparative merits of which are frequently and keenly discussed by agriculturists. The extraordinary discrepancies in the amount and quality of the work performed by different machines, and in the power required to effect it, are quite as much due to the varying degrees of skill with which their parts are proportioned and put together, as to varying merit in the respective plans of construction.

In the best examples of six-horse power stationary steam-engines and thrashing machinery, as found in the Lothians, fifty quarters of grain, taking the average of wheat, barley, and oats, are thrashed, dressed, and sacked up ready for market in a day of ten hours, with a consumption of $7\frac{1}{2}$ cwt. of good coals, and a gross expenditure for wages, value of horse-labour, fuel, and wear and tear of machinery, of 9d. per quarter.

Machines and Implements.

The Royal Agricultural Society of England have done much towards ascertaining the real merits of the various thrashing-machines now in use, by the carefully conducted comparative trials to which they have subjected those which have been presented in competition for their liberal prizes. The accuracy of these trials, and the value of the recorded results, have been much enhanced by the use of an ingenious apparatus invented by Mr C. E. Amos, consulting engineer to the Society, which is figured and described at p. 479 of Vol. xi. of the Society's Journal. A pencil connected with this apparatus traces a diagram upon a sheet of paper recording every variation of the power employed during the experiment to work the machine under trial. For reasons already stated, we regard it as unfortunate that the patronage of this great Society has hitherto been so exclusively bestowed upon portable machines.

### WINNOWING MACHINES.

We have already referred to the fanners, which, except in portable machines, are almost invariably found in combination with thrashing machinery, so as to deliver the grain into the corn-barn in a comparatively clean state; and we have also noticed the further contrivances by which, when there is a sufficient motive power at command, the complete dressing of the grain goes on simultaneously with the thrashing. The winnowers used in such cases do not differ in construction from those worked by hand. Indeed, it is usual to have one at least that can be used in either way at pleasure. In these machines the separation of the clean from the light grain, and of both from dust, sand, and seeds of weeds or other rubbish, is effected by directing an artificial blast of wind upon a stream of grain as it falls from a riddle. There is thus a combination of fanning and sifting, which is used in different degrees according to the views of the mechanist. In some forms of this machine, the benefit of the artificial blast is in a great measure lost through an injudicious excess of sifting apparatus. In the principal corn districts of Scotland, these machines have recently been much improved by the Messrs Elsey from Wisbeach, who lay most stress on the proper management of the fan.

The now frequent use of various kinds of grain in the fattening of live-stock creates a necessity for machines to prepare it for this purpose, either by breaking, bruising, or grinding. A profusion of these, to be worked by hand, is everywhere to be met with. Such machines are always most economically worked by steam or water power. When that can be had, a set of rollers for bruising oats or linseed, and millstones to grind the inferior grain of the farm, form a most valuable addition to barn machinery. Machines for breaking linseed-cake into large pieces for cattle, or smaller for sheep, are now in general use. The breaking is performed by passing the cakes between two serrated rollers, by which it is nipt into morsels. These are usually driven by hand; but it is always expedient to have a pulley attached to them, and to take advantage of mechanical power when available.

Corn-bruiser and grinding-mill.

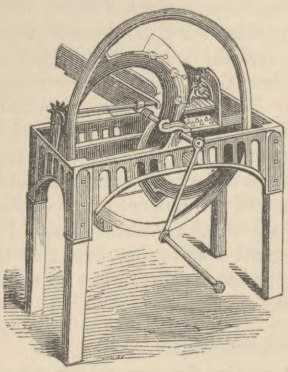
Cake-crusher.

### CHAFF-CUTTERS.

The use of this class of machines has increased very much of late years. Fodder, when cut into lengths of from half to whole inch, is somewhat more easily masticated, but the chief advantages of this practice are, that it prevents waste, and admits of different qualities—as of hay and straw, or straw and green forage,—being so mixed that animals cannot pick out the one from amongst the other, but must eat the mixture as it is presented to them. Such cut fodder

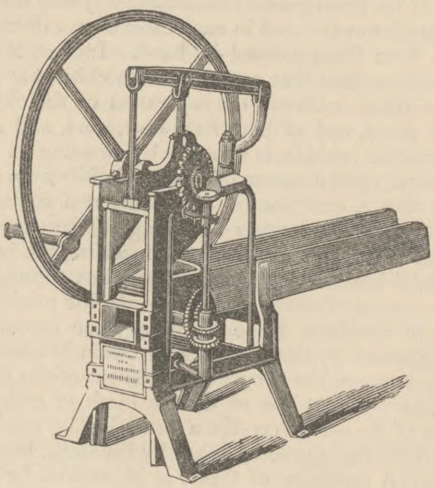
Machines and Implements.

also forms an excellent vehicle in which to give meal or bruised grain, either cooked or raw, to live-stock. This is peculiarly the case with sheep when feeding on turnips, as they then require a portion of dry food; but waste it grievously when not thus prepared. They are constructed on a variety of plans; but the principle most frequently adopted is that of radial knives bolted to the arm of a fly-wheel, which work across the end of a feeding-box fitted with rollers which draw forward the straw or hay, and present it in a compressed state to the action of the knives. A machine on this principle, made by Cornes of Barbridge, has gained the first premium, in its class, at recent meetings of the Royal Agricultural Society of England. Gillets' guillotine chaff-cutter is an exceedingly ingenious and efficient machine, performing its work with great accuracy and without frequent sharpening of its one double-edged knife. These



CHAFF-CUTTER, BY RICHMOND AND CHANDLER.

Guillotine chaff-cutter.

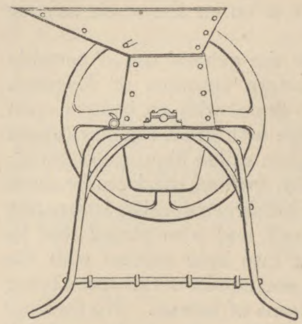


CHAFF-CUTTER, BY GILLET.

machines are most economically worked by the power used for thrashing. The most convenient site for them is in the upper loft of the straw-barn, when the straw can be supplied with little labour, and the chaff either shoved aside or allowed to fall as it is cut, through an opening in the floor, into the apartment below, and at once conveyed to other parts of the homestead. The practice, on some farms where there is a fixed steam-engine is, to thrash a stack of oats in the forenoon, and to cut up the straw, and bruise or grind the grain simultaneously in the afternoon.

### TURNIP-CUTTER.

Cattle and sheep which have arrived at maturity are able to scoop turnips rapidly with their sharp gouge-like front teeth, and so can be fattened on this kind of food without an absolute necessity of slicing it for them. Even for adult animals there is, however, an advantage in reducing turnips to pieces, which they can easily take into their mouths, and at once get between their grinders without any preliminary scooping; but for young stock, during the period of dentition, it is indispensable to their bare subsistence. It is largely through the use of slicing-machines that certain breeds of sheep are fattened on turnips, and got ready for the butcher at 14 months old.



TURNIP-SLICER, (GARDENER'S,) BY SAMUELSON.

Gardener's turnip-cutter.

It seems to be admitted on all hands that Gardener's patent turnip-cutter is the best that has yet been produced for slicing roots for sheep. It is now made entirely of iron, and is an exceedingly useful machine.

In cattle feeding it is not usually thought necessary to divide the roots given to them so minutely as for sheep. A simple machine, fashioned much on the principle of nut-crackers, by which, at each depression of the lever handle, one turnip is forced through a set of knives which divide it into slices each an inch thick, is very generally used in Berwickshire for this purpose. Many persons, however, prefer to have the turnips put into the cattle-troughs whole, and then to have them cut by a simple cross-bladed hand-chopper, which, at each blow, quarters the piece struck by it. The mode of housing fattening cattle largely determines whether roots can be most conveniently sliced before or after being put into the feeding-troughs. A recent writer[1] urges the advantage of rasping or crushing roots into minute fragments, and mixing them with chaff before giving them to cattle, as this not only renders them of easy mastication, but prevents, in wintry weather, the chilling effects of a bellyfull of such watery food as turnips alone. A machine by Moody, resembling a bark mill, is said to per form the crushing very satisfactorily.

### STEAMING APPARATUS FOR COOKING CATTLE FOOD.

We have several times alluded to the cooking of food for cattle. This is performed either by boiling in a common pot, by steaming in a close vessel, or by infusion in boiling water. A variety of apparatus is in use for these purposes. A convenient one is a close boiler, with a cistern over it, from which it supplies itself with cold water by a self-acting stop-cock. This is alike suitable for cooking either by steaming or infusing.

### WEIGHING MACHINES.

It is of course indispensable for every farm to be provided with beam and scales, or other apparatus, for ascertaining the weight of grain, wool, and other commodities, in quantities varying from 1 lb. to 3 cwt. But, besides this, it is very desirable to have a machine by which not only turnips, hay, manures, &c, can be weighed in cart-loads, but by which also the live weight of pigs, sheep, and bullocks, can be ascertained. Such a machine, conveniently placed in the homestead, enables the farmer to check the weighing of purchased manure, linseed-cake, coal, and similar commodities, with great facility. It affords the means of conducting various experiments for ascertaining the comparative productiveness of crops, and the quantities of food consumed by cattle, and their periodic progress, with precision and facility. To persons unable to estimate the weight of cattle

[1] Rev. Mr Huxtable in his "Present Prices."

Machines and Implements.

by the eye readily and accurately, such a machine is invaluable.

Concluding remarks on implements.

We have thus enumerated, and briefly described, those machines and implements of agriculture which may be held to be indispensable, if the soil is to be cultivated to the best advantage. The list does not profess to be complete; but enough is given to indicate the progress which has recently taken place in this department. We have already referred to this department of the proceedings of the Royal Agricultural Society of England, and would earnestly recommend to all engaged in agriculture, the careful study of the reports on implements contained in the 9th, 10th, 11th, and 12th volumes of their Journal. The care with which they have selected their judges, and the skilful manner in which those entrusted with the difficult and responsible office have discharged their duties, are truly admirable. A few extracts from these reports will serve to show the extent and value of this department of the Society's labours. In the report for 1847, Mr Thomson of Moat-Hall says, " The Society's early shows of implements must be viewed chiefly in the light of bazaars or expositions. Neither stewards nor judges had yet acquired the experience requisite for the adequate discharge of their office, so that such men as Messrs Garrett, Hornsby, Ransome, and a few others, would have laughed in their sleeves had they been told that they could learn anything in the Society's show-yard. In spite, however, of a creditable display on the part of a few leading firms, the majority of the implements exhibited at these early shows were of inferior construction and workmanship, and the general appearance of the exhibitions meagre and unsatisfactory.

" The attention of some of the leading members of the Society (especially of the late lamented Mr Handley), was earnestly directed to the improvement of this department, and they soon perceived that little was gained by collecting implements in a show-yard for people to gaze at, unless an adequate trial could be made of their respective merits. To attain this end great exertions were made, and every improvement in the mode of trial was followed by so marked an increase in the number and merit of the implements brought forward at subsequent shows, as to prove the strongest incentive to further effort.

" At the Cambridge and Liverpool meetings, when these trials were in their infancy, their main attraction consisted of ploughing-matches on a large scale, which gratified sightseers, but gave no results that could be depended upon, and therefore disappointed all practical men. It would occupy time unnecessarily to trace the gradual changes which have led to the discontinuance of these showy exhibitions, and the substitution in their place of quiet, business-like trials in the presence of stewards and judges alone. Suffice it to say, that what they have lost in display, they have gained in efficiency, and consequently in favour with those classes for whose benefit they were designed. At the York meeting, the improved mode of trying the thrashing-machines supplied a deficiency which, until that time, had been much felt, viz., the absence of any means of ascertaining the amount of power expended in working the machines under trial; and it may now be asserted, with some confidence, that, with the exception of an occasional error or accident, the best implements are uniformly selected for prizes.

" It now remains to answer the question proposed for consideration, viz., to what extent the great improvement made of late in agricultural implements is due to the exertions of this Society, and with this view a tabular statement is subjoined, which shows the relative extent and importance of the Society's two first and two last shows of implements:—

| | No. of Exhibitors. | Awards. Money. | Medals. |
|---|---|---|---|
| 1839 Oxford,............ | 23 | £5 | 4 |
| 1840 Cambridge,......... | 36 | 0 | 7 |
| 1848 York,............... | 146 | 230 | 21 |
| 1849 Norwich,............ | 145 | 364 | 13 |

From this it will be seen that at Cambridge, where the trial of implements was confined to one day, and was, in other respects, so immature as to be of little practical value, the number of exhibitors was only thirty-six, and the judges, in whom a certain discretionary power was vested, awarded no money and but seven medals, in consequence of the scarcity of objects deserving of reward; whilst at York, eight years after, when trials lasted several days, and had attained a considerable degree of perfection, the number of exhibitors had increased four-fold. The additional amount offered in prizes at the later meetings has undoubtedly assisted in creating this great increase of competition, but it cannot be considered the principal cause, since the implement-makers are unanimous in declaring that, even when most successful, the prizes they receive do not re-imburse them for their expenses and loss of time. How, then, are the increased exertions of the machine-makers to be accounted for? Simply by the fact that the trials of implements have gradually won the confidence of the farmer, so that, when selecting implements for purchase, he gives the preference to those which have received the Society's mark of approval. This inference is corroborated by the makers themselves, who readily admit that the winner of a prize, for any implement of general utility, is sure to receive an ample amount of orders, and that the award of a medal is worth on an average L.50."

In reporting upon the agricultural implement department of the Great Exhibition, Mr Pusey says, " The yearly shows and trials of the Royal Agricultural Society have certainly done more in England for agricultural machines within the last ten years, than had been attempted anywhere in all former time. . . . . It seems proved that since annual country shows were established by Lord Spencer, Mr Handley, and others yet living, old implements have been improved, and new ones devised, whose performances stand the necessary inquiry as to the amount of saving they can effect. To ascertain that amount precisely is difficult; but, looking through the successive stages of management, and seeing that the owner of a stock-farm is enabled, in the preparation of his land, by using lighter ploughs, to cast off one horse in three, and by adopting other simple tools, to dispense altogether with a great part of his ploughing,—that in the culture of crops by the various drills, horse labour can be partly reduced, the seed otherwise wanted partly saved, or the use of manures greatly economised, while the horse-hoe replaces the hoe at one-half the expense,—that at harvest the American reapers can effect thirty men's work, whilst the Scotch cart replaces the old English waggon with exactly half the number of horses,—that in preparing corn for man's food, the steam thrashing-machine saves two-thirds of our former expense,—and in preparing food for stock, the turnip-cutter, at an outlay of 1s. adds 8s. a-head in one winter to the value of sheep; lastly, that in the indispensable but costly operation of draining, the materials have been reduced from 80s. to 15s.—to one-fifth, namely, of their former cost; it seems to be proved that the efforts of agricultural mechanists have been so far successful, *as in all these main branches of* farming labour, taken together, to effect a saving, on outgoings, of little less than one-half."

Scottish agriculturists, in reading these reports, will probably note with self-gratulation, that some of the improvements referred to as of recent introduction in England, viz. two-horse ploughs and one-horse carts, have long been established among themselves. Indeed, they will find graceful

Machines and Implements.

notice of the fact on the face of these reports. Unless altogether blinded by prejudice they will, however, see that our brethren south of the Tweed have already outstripped us in many particulars, and that unless our national society, our mechanists, and farmers, exert themselves with corresponding judgment and zeal, we must henceforth be fain to follow, where we at least fancy that we have hitherto been leading. But we have more important motives and encouragements to exertion than mere national emulation. The extent to which the cost of production of farm produce has been lessened by recent improvements on the implements of husbandry, and in the details of farm management, is greater than many are aware of. It seems to be in this direction mainly that we are to look for outgate from our present embarrassments. If by further improvements we are enabled to keep fewer horses, and to get our harvest work accomplished by the ordinary forces required throughout the year, the saving of money and anxiety will be really important. Believing, as we do, that on every farm enormous waste of motive power, mechanical, animal, and manual, is continuously going on through the imperfection of the implements and machines now in use, we would urge upon all concerned to look well to this; for, with all our improvements, there is undoubtedly yet a large margin for retrenchment here.

Besides the bulky and costly implements now enumerated, every farm must be provided with a considerable assortment of hand-implements and tools, all of which it is of consequence to have good of their kind. Although not individually costly, they absorb a considerable capital in the aggregate. When not in use, they require to be kept under lock, and at all times need to be well looked after. Without waiting to describe these in detail, let us now see how the work of the farm is conducted.

## CHAPTER III.

### TILLAGE OPERATIONS.

When the natural green sward, or ground that has been cleared of a cultivated crop, is to be prepared for the sowing or planting of further crops, the plough leads the way in breaking up the compact surface, by cutting from it successive slices, averaging about ten inches in breadth by seven in depth, which it turns half over upon each other to the right-hand side. This turning of the slices or furrows to one side only, renders it necessary to square off the space to be ploughed into parallelograms, half the slices of which are laid the one way and the other half the other, by the going and returning of the plough. These parallel spaces are variously termed *ridges*, *stetches*, *lands*, or *feirings*, which, in practice, vary in width from a few furrows to 30 yards. When very narrow spaces are used, a waste of labour ensues, from the necessity of opening out and then re-closing an extra number of index or guiding furrows; while very wide ones involve a similar waste from the distance which the plough must go empty in traversing at the ends. The spaces thus formed by equal numbers of furrow-slices turned from opposite sides have necessarily a rounded outline, and are separated by open channels. In a moist climate and impervious soil, this ridging of the surface causes rain-water to pass off more rapidly, and keeps the soil drier than would be the case if it was kept flat. Hence the cultivated lands of Great Britain almost invariably exhibit this ridged form of surface. Until the art of under-ground draining was discovered, this was indeed the only mode of keeping cultivated ground tolerably dry. But it is at best a very defective method, and attended by many disadvantages. When land is naturally dry, or has been made so by thorough drainage, the flatter its surface is kept the better for the crops grown upon it. We are not forgetful that there are in various parts of Great Britain, clays so impervious, that probably no amount of draining or disintegration of the subsoil will render it safe to dispense with ridging. These, however, are exceptional cases, and as a rule, such a condition of soil and subsoil should be aimed at as will admit of this rude expedient of ridging being altogether dispensed with. Unless land can absorb the whole rain which falls upon it, its full range of fertility cannot be developed; for the same showers which aggravate the coldness and sterility of impervious and already saturated soils, carry down with them, and impart to those that are pervious ever fresh supplies of genial influences. Instead, then, of this perennial source of fertility being encouraged to run off by surface channels, or to stagnate in the soil and become its bane, let provision be made for its free percolation through an open stratum several feet in thickness, and then for its escape by drains of such depth and frequency as each particular case requires. When this is attained, a flat surface will generally be preserved, as alike conducive to the welfare of the crops, and to the successful employment of machinery for sowing, weeding, and reaping them.

Tillage operations.

Importance of retaining a flat surface.

In all existing treatises on agriculture, we find great stress laid on the proper formation of the ridges, careful cleaning out of the separating channels, or water-furrows, and drawing and spading out of cross-cuts in all hollows, so that no water may stagnate on the surface of the field. As thorough under-draining makes progress, such directions are becoming obsolete. But whether ridging or flat work is used, the one-sided action of the plough renders it necessary, in setting about the ploughing of a field, to mark it off into parallel spaces by a series of equidistant straight lines. Supposing the line of fence, at the side at which he begins, to be straight, the ploughman takes this as his base line; and measuring from it, erects his three or more feiring poles perfectly in line, at a distance from the fence equal to half the width of the ridges or spaces in which it is proposed to plough the field. This operation—called in Scotland *feiring* the land—is usually entrusted to the most skilful ploughman on each farm, and is regarded as a mark of honour. Having drawn a furrow in the exact line of his poles, which practice enables him to do with an accuracy truly admirable, he proceeds, using always the last furrow as a fresh base from which to measure the next one, until the field is all marked off. When this is done, it presents the appearance of a neatly ruled sheet of paper. Besides the poles just referred to, the ploughman is frequently furnished with a cross staff, by means of which he first of all marks off two or more lines perpendicular to the straight side at which he commences, and along these he measures with his poles, which are graduated for the purpose, in laying off his parallel lines. This feiring is only required when a process of fallowing, in preparation for green crop, has obliterated the former ridges. In breaking up clover lea or older sward, the ploughman begins at the open furrows, which afford him a sufficient guide.

In ploughing for a seed-bed, the furrow-slice is usually cut about five inches deep. In the case of lea, it should be turned over unbroken, of uniform thickness, and laid quite close upon the preceding one, so as to hide all green sward. The improved wheel-plough already referred to does this work very beautifully, cutting out the slice perfectly square from the bottom of the furrow, and laying it over upon one corner, so as to leave a triangular space under each slice, forming an air-drain from end to end of the ridge, which aids much in keeping the land dry, and in bringing it sooner into proper condition for harrowing in spring. The perfect

Tillage operations.

uniformity in the width and depth of the slices cut by it, permits the harrow to act equally upon the whole surface. When the slice is cut unevenly, they draw the loosened soil from the prominences into the hollows, so that one part is scraped bare, and the other remains untouched and unbroken. This must necessarily yield a poor seed-bed, and contrasts unfavourably with the uniform tilth produced by harrowing after such work as these wheel-ploughs invariably produce. In the Lothians and west of Scotland, a form of plough is much used for ploughing lea, which cuts out the slice with an acute angle at the land side. This, when turned over, stands up with a sharp ridge, which looks particularly well, and offers a good subject for harrows to work upon. But if a few of these furrow-slices are removed, the firm earth below exhibits the same ribbed appearance as the newly ploughed surface, instead of the clear level sole on which the right-sided slice cut by the wheel-plough is laid over so as to rest upon its lower angle. This ribbing of the unstirred subsoil is exceedingly objectionable in all kinds of ploughing.

In the autumn ploughing of stubble-ground in preparation for the root-crops of the following season, a much deeper furrow is turned over than for a seed-furrow. In ordinary cases, it should not be less than nine inches, while in very many, if ten or twelve can be attained so much the better. In all deep soils, this bringing up and mixing with the surface of fresh material from below, is highly beneficial. It must not, however, be practised indiscriminately. Silicious and peaty soils need compactness, and to have the soil that has been artificially enriched kept a-top. For such deep work as we have noticed above, three or even four horses are frequently yoked to the plough. When a field slopes considerably one way, it is good practice to work the plough down the slope only, and return it to the top empty. A pair of horses working in this way, will turn as deep a furrow, and get over as much ground, as three will do taking a furrow both ways, and with less fatigue to themselves and to the ploughman. After bringing a heavy furrow downhill, they get recruited in stepping briskly back with only the empty plough to draw. This mode of ploughing one furrow *down* the slope, tends less to gather the soil toward the bottom than by using a turn-wrist plough *across* the slope. It is while giving this deep autumn furrow that the subsoil-plough is used. It follows in the wake of the common plough, and breaks and stirs the subsoil, but without raising it to the surface. This is a laborious operation, and engrosses too much of the horse-power of the farm to admit of large breadths being overtaken in any one season. In all indurated subsoils, however, it repays its cost; for when once thoroughly done, it diminishes the labour of ordinary ploughings for several succeeding rotations, aids the drainage, and adds to the fertility of the soil.

The harrow, cultivator, and roller, are all more simple in their action, and easier managed than the plough. Harrowing is most effective when the horses step briskly along. The tines are then not merely drawn through the soil, but in their combined swinging and forward movement, *strike* into it with considerable force. It is with reference to this that a single application of this implement is called a *stroke* of the harrows. Rollers are used to aid in pulverizing and cleaning the soil by bruising clods, and lumps of tangled roots and earth, which the other implements have brought a-top; in smoothing the surface for the reception of small seeds, or the better operation of the scythe and other implements; and for consolidating soil that is too loose in its texture. Except for the latter purpose light rollers are much superior to heavy ones. When it is wanted, for example, to bruise clots of quickens, that the after harrowing may more thoroughly free the roots from the adhering earth, a light cast-iron roller, say of 5 cwt., drawn by one horse, effects this purpose as thoroughly as one double the weight drawn by a pair; and does it, moreover, in much less time, at less than half the expense, and without injuriously consolidating the free soil. These light rollers are conveniently worked in pairs; the ploughman driving one horse and leading the other. With a pair of active horses, and such rollers, a good deal more than *double* the space can be rolled in a day, than by yoking them both to one heavy one of the same length of cylinder. For mere clod-crushing, provided the clods are moist, the Norwegian harrow is superior to any roller: and for tightening a loose surface or checking wire-worm, serrated or smooth-edged discs, such as Crosskill's or Gibson's, are better than smooth cylinders of the same weight, so that the heavy smooth roller, requiring two or more horses to draw it, is superseded by better implements for all purposes where rollers are used at all.

As a general rule, none of these tillage operations can be performed to advantage when the soil is wet. When rain falls inopportunely there is a strong temptation to push on the field operations, before the soil has recovered the proper state of dryness. When this is done the farmer almost invariably finds in the issue that he has made more haste than good speed. Soils with a good deal of clay in their composition are peculiarly susceptible of injury in this way. Nice discrimination is needed to handle them aright. They require, moreover, a full stock of well-conditioned horses, that the work may be pushed rapidly through whenever the tide favours. To manage such soils successfully, especially when root crops are grown, tries the skill of the farmer to the utmost.

### PREPARATION OF THE LAND FOR CROPS.

Beside those simple tillage operations which are necessary in every instance of committing seeds and plants to the earth, there are more costly and elaborate processes of preparation which must be encountered in certain circumstances, in order to fit the soil for bearing cultivated crops. It is now only in exceptional cases that the British agriculturist has to reclaim land from a state of nature. The low-country farmer does occasionally meet with a patch of woodland, a bank covered with gorse or brushwood, which he sets about converting into arable land. It is in the higher districts that, from the facilities now afforded for readily enriching poor soils by portable manures, the plough still frequently invades new portions of muir and bog, and transforms them into fields. The occupiers of land in these upland districts are accordingly still familiar with the processes of paring and burning, trenching, removing earth-fast stones, and levelling inequalities of surface. In breaking up land that has been for a course of years under pasturage, paring and burning is also frequently resorted to in all parts of the country. The grand improvement of all—thorough underground drainage—is common to every district and class of soils. After all these operations have been successfully performed, and the land has been subjected to a continuous course of culture, it is found necessary, from the accumulation of weeds, or undue consolidation of the soil, to subject it from time to time to the process of *Fallowing*. We shall now notice these preparatory operations in order.

*Draining.*—From the moist climate of Britain, draining is undoubtedly the all-important preliminary operation in setting about the improvement of the soil. As this subject is treated of at large in a separate article under the title "Draining,' it is superfluous to enter here into details of the process. The facilities for carrying it out are now very great, from the excellence and cheapness of the tiles or pipes of burnt clay, which have nearly superseded every other material for the purpose of forming underground drains. So recently as

Preparation of the land for Crops.

twelve years ago, when only the common hand-moulded horse-shoe tile was in use, the writer had much difficulty in obtaining these (about $12\frac{1}{2}$ inches long by 3 wide) at 40s. per thousand, and soles at half as much more. Whereas now, beautifully moulded and well-burned pipes of 2-inch bore, and 15 in length, can be had in any quantity at 18s. per thousand. Formerly, when a large receiving or main drain was wanted, the only resource was a costly conduit built with stone; now a strong description of tiles, varying from 3 to 12 inches diameter, to suit any anticipated flow of water, can be had at very moderate prices. This improvment in the quality, and lowering of the cost of draining materials, has arisen not merely from the increased number and better construction of the kilns used in their production, but chiefly from their being moulded by machinery.

Before the introduction of tiles, covered drains were usually made of considerable depth, and were directed rather to the cutting off of springs, and intercepting the flow of water from higher to lower grounds than to the removing of redundant moisture from the whole area of a field. This was provided for by furrows, cross-cuts, and open ditches. With the use of tiles, the system of furrow draining, as it is often called, has rapidly extended. By this plan provision is made over the entire field for carrying off rain underground as fast as it falls. This is done by converting the whole furrows of the field into drains; the deeper main drains occupying the place of the ditches and cross-cuts, the shallower parallel ones that of the ridge furrows. The number of channels for the escape of the water thus remains the same, but instead of being on the surface they are sunk to depths varying from 20 inches to 4 feet, according to the nature of the soil, and are filled with tiles or pipes of a size adapted to the greatest anticipated flow of water. By such a system of draining, not the surface merely, but the entire stratum of soil and subsoil, to the depth of the drains, is at all times kept free from stagnant water and its inseparable evils. For a time these furrow drains were too generally made so shallow as not to secure the full benefits of the system. It is now known that by deeper drainage the temperature of the subsoil is considerably raised, to the great benefit of plants growing above it, and care is therefore taken to make the drains at least three feet in depth.

In executing this work, the first step is to ascertain that there is sufficient outfall to admit of the drains being cut to a proper depth. In a majority of cases, the natural flow of the water determines this point beyond any risk of mistake; but when this is not the case, recourse must be had to the spirit-level, lest money be wasted in making drains that will not run. This work can be carried on at all seasons, but is usually best done in summer or early autumn, and when the land is in grass. The digging is usually paid for by task work, and the setting of the pipes by day's wages. A thoroughly trust-worthy and experienced workman is usually selected for the latter work, with instructions to set no tiles until he is satisfied that the depth of the drains and level of the bottoms are correct. When the soil is returned into the drains, all defects are of course buried, and it therefore behoves the owner or his substitute, whether tenant or bailiff, to exercise a vigilant superintendence over draining operations. Unless carefully executed they cannot be efficient; and without efficient drainage all other agricultural operations are carried on under grievous disadvantages. The extent of land in Great Britain naturally so dry as not to need draining, is very much less than even practical farmers who have not studied the subject are at all aware of.

*Removal of Earthfast Stones.*—Newly reclaimed lands, and even those that have long been under tillage, are frequently much encumbered with earth-fast stones. This is particularly the case in many parts of Scotland. Their removal is always desirable, though necessarily accompanied with much trouble and expense. In our personal practice we have proceeded in this way. In giving the autumn furrow preparatory to a fallow crop, each ploughman carries with him a few branches of fir or beech, one of which he sticks in above each stone encountered by his plough. If the stones are numerous, particularly at certain places, two labourers, provided with a pick, a spade, and a long wooden lever shod with iron, attend upon the ploughs, and remove as many of the stones as they can, while yet partially uncovered by the recent furrow. Those thus dug up are rolled aside upon the ploughed land. When the land gets dry enough in spring, those not got out at the time of ploughing are discovered by means of the twigs, and are now dug up. Such as can be lifted by one man are carted off as they are, but those of the larger class must first be reduced by a sledge hammer. They yield to the hammer more easily after a few days' exposure to drought than when attacked as soon as dug up. Before attempting to break very large boulders, a brisk fire of dried gorse or brushwood is kept up over them until they are heated, after which a few smart blows from the hammer shivers them completely. Portions of otherwise good land are sometimes so full of these boulders, that to render them available, the stones must be got rid of by trenching the whole to a considerable depth. Should ploughing by steam-power ever become general, a preliminary trenching of this kind will in most cases be requisite before tillage instruments thus propelled can be used with safety.

*Paring and Burning* has, from an early period, been resorted to for the more speedy subduing of a rough uncultured surface. It is still the most approved method of dealing with such cases, as well as with any tough old sward which is again to be subjected to tillage. In setting about this operation, which is usually done in March or April, a turf, not exceeding an inch in thickness, is first peeled off in successive stripes by a paring-plough drawn by two horses, or by the breast-plough already described. These turves are first set on edge and partially dried, after which they are collected into heaps and burned, or rather charred. The ashes are immediately spread over the surface, and ploughed in with a light furrow. By this process the matted roots of the pasture plants, the seeds of weeds, and the eggs and larvæ of innumerable insects, are at once got rid of, and a highly stimulating top-dressing is supplied to the land. A crop of turnips or rape is then drilled on the flat, and fed off by sheep, after which the land is usually in prime condition for bearing a crop of grain. This practice is unsuitable for sandy soils, which it only renders more sterile; but when clay or peat prevails, its beneficial effects are indisputable. We shall, in the sequel, give an example of its recent successful application.

Use of levelling-box.

Land, when subjected to the plough for the first time, abounds not unfrequently with sudden hollows and protuberances, which impede tillage operations. These can be compendiously levelled by means of a box shaped like a huge dust-pan, the front part being shod with iron, and a pair of handles attached behind. This levelling-box is drawn by a pair of horses. Being directed against a prominent part, it scoops up its fill of soil, with which it slides along sledge-fashion to the place where it is to discharge its load, which it does by canting over, on the ploughman disengaging the handles.

Straightening crooked ridges.

In all parts of Great Britain, abundance of pasture land, and often tillage land also, is to be met with lying in broad, highly raised, serpentine ridges. These seem to have originated when teams of six or eight bullocks were used in ploughing; and it has been suggested that this curvature of the ridges at first arose from its being easier to turn these

Preparation of the land for Crops.

long teams at the end of each land by sweeping round in a curve than by driving straight out. The very broad headlands found in connection with these curved ridges point to the same fact. A theory still lingers among our peasantry, that "water runs better in a crooked furrow than in a straight one," and has probably been handed down since the discovered awkwardness of curved ridges was first seen to need some plausible apology. These immense, wave-like ridges are certainly a great annoyance to the modern cultivator; but still the sudden levelling of them is accompanied with so much risk, that it is usually better to cut drains in the intervening hollows, and plough aslant them in straight lines, by which means a gradual approximation to a level surface is made. We are at present engaged in preparing for turnips a field which was levelled, by cleaving down the old crooked ridges, upwards of forty years ago, and where every succeeding crop still shows, by alternate curving bands of greater and less luxuriance, the exact site of the crowns and furrows of the ancient ridges.

Trenching.

But for its tediousness and costliness, trenching two or three *spits* deep by spade or fork is certainly the most effectual means for at once removing obstructions, levelling the surface, and perfecting the drainage by thoroughly loosening the subsoil. For the reasons mentioned, it is seldom resorted to on a large scale. It is becoming a more common practice, with careful farmers, to have those patches of ground in the corners, and by the fences of fields, which are missed in ploughing, gone over with the trenching-fork. The additional crop thus obtained may fail to compensate for this hand-tillage, but it is vindicated on the ground that these corners and margins are the nurseries of weeds which it is profitable to invade and abolish.

*Fallowing.*—When, by those operations that have now been described, land has been reclaimed from its natural state, and rendered fit for the purposes of the husbandman, it is everywhere so charged with the germs of weeds, most of which possess in a remarkable degree the power of reproduction and multiplication, that it is only by the most incessant and vigorous efforts that he can restrain them from encroaching upon his cultivated crops, and regaining entire possession of the soil. He can do much towards this by ordinary tillage, and by sowing his crops in rows, and hoeing in the intervals, during the early stages of their growth. But if his efforts are restricted to such measures only, the battle will soon go against him. Besides this, all arable soils in which clay predominates, particularly when undrained, have such a determined tendency to become compact and soured, that under ordinary efforts they fail to yield a genial seed-bed. There is a necessity, therefore, for having recourse, from time to time, to that ameliorating process of lengthened tillage called fallowing. This process begins in autumn, immediately after the removal from the ground of the cereal crop, which had been sown upon the land newly broken up from clover lea, or natural sward, and extends either to the time for sowing turnips and analogous crops in the following spring, or is continued during the entire summer in preparation for autumn-sown wheat. We shall first describe that modification of the fallowing process by which the soil is prepared for the sowing of drilled green crops, and then the more prolonged form of it usually called *summer* or *naked* fallow.

The object aimed at being the thorough disintegration and cleaning of the soil, the usual practice is to begin by ploughing as deeply as is found practicable. This first or autumn furrow is accordingly turned over to a depth of 8 or 9 inches; or by using a stronger plough drawn by three or four horses, it is carried to 12 inches in depth; and in some cases, by following with a subsoil-plough in the wake of the common one, the soil is stirred to the depth of 14 or 16 inches. All cultivators are agreed as to the importance of thus deeply and effectually disintegrating all soils that are naturally dry or thoroughly drained. In the case of undrained lands, and even of very unctuous clays, although well drained, such deep stirring of the soil in autumn does but increase its capacity of retaining the rains of winter, and of being thereby more effectually soured, and is therefore to be avoided. Assuming, however, that we have to do with soil thoroughly drained and moderately friable, it is undoubtedly beneficial to loosen it deeply and thoroughly at this stage. But before this deep ploughing is set about, it will be worth while to consider well its bearing upon the cleaning part of the process. On carefully examining the fields at the time of reaping the grain crops, and from week to week thereafter, the roots of the couch-grass are found at first lying close to the surface; but instantly, on their getting the ground to themselves, they begin to send out fresh fibres, and to push their shoots deeply into the soil. In these circumstances, to proceed at once, according to the customary practice, to plough deeply, allows these weeds much time to increase, while this laborious and tedious operation is going on; and although, when performed, it gives some present check to their progress, by burying them under a mass of loosened soil, it not only increases the difficulty of their after removal, but places them out of the reach of frost, and in the best possible position for pervading the entire soil, on the first recurrence of mild weather. The consequence is, that fallows so treated are invariably found in spring more fully stocked with quickens than they were at the time of the autumn ploughing. The observation of this suggested the practice, now very common in England, of *cleaning fallows in autumn before giving the first deep furrow.* For this purpose, such implements as Biddle's scarifier, or the broad-share paring-ploughs, are set to work as fast as the grain-crops are reaped, and the whole surface is rapidly pared at a depth of two or three inches. This completely loosens the yet shallow-lying roots of the couch-grass, which are then freed from the adhering earth by the harrow and light roller, raked together and burned, or carted off. This pulverizing of the surface-soil, in early autumn, is usually followed by the springing up of an abundant crop of annual weeds, which are thus got rid of by the subsequent ploughing. So great and manifold are the advantages of this modern practice, that in those districts where it is most in use, other autumn work, even wheat-sowing, is comparatively neglected until it is accomplished. When the weeds have been got rid of in this summary and inexpensive manner, deep ploughing is then resorted to with unalloyed benefit.

Autumn cleaning.

In the case of farms that have for a lengthened period been carefully cultivated, the stubbles may be found so clean as not to require their whole area to be scarified in the manner now described. Instead of this, it may suffice to have them carefully examined, and such patches or stray plants of couch-grass, or other perennial weeds, as are met with, forked out. By this means the fallows are kept clean at little expense, and when spring arrives, those repeated ploughings, and other tedious and costly operations, are wholly avoided, in performing which, the condition of the soil is marred, and the best seed-time often missed. When fallows are thus cleaned in autumn, it is highly advantageous to cart on to them at once, and cover in with a deep furrow all the farm-yard dung that is on hand up to the completion of their first ploughing. From the length of time which must elapse before the land can again be touched, it is quite safe, or rather, it is highly advantageous, to apply all the recently made dung, although in a very rough state. In doing this, it is necessary that a person precede each plough, and trim the rank litter into the previous furrow, that it may be properly covered up and re-

Removal of weeds by forking.

Autumn manuring.

Preparation of the land for Crops.

gularly distributed. Unless this precaution is observed, the ploughs are constantly choked and impeded, the manure is drawn together into unsightly hassocks, and the whole operation is imperfectly performed. The recommendations to this practice are, *first*, An important saving of labour, for the manure being carted direct from the yard, &c. on to the land, and evenly spread over it, there is no forming, covering up, and turning, of dunghills, or refilling and carting in spring. This heavy work is accomplished at a season when time is less pressing than in spring, and the sowing of the crop can be proceeded with more rapidly when the time for it arrives, and while weather favours. *Second*, There is a saving of manure by burying it at once in its rough state, instead of first fermenting it in large heaps; and a large portion of the fallow break can thus be dressed with home-made manure. *Third*, The rough dung thus ploughed in decomposes slowly, its virtues are absorbed and retained by the soil, with the whole mass of which it is thoroughly incorporated by the spring tillage, and which, in consequence, is found, after such treatment, in a peculiarly mellow and favourable condition for receiving the seed.

The advantages of autumn cleaning and manuring of land in preparation for green crops are so great that the utmost exertions should be made to secure them. Over a large portion of England the harvest is usually so early as to leave ample time for accomplishing the cleaning process before being arrested by bad weather. From the later harvest-season and more humid climate of Scotland, it is there more difficult to carry it out to the whole extent of the fallow-break; but still, with promptitude and energy, much can be done. One of her shrewd and intelligent sons, Mr Tennant, the inventor of the grubber which bears his name, has, however, introduced a system of autumn tillage, founded upon the same principle, and accomplishing virtually the same end, but less expensive and better adapted to the climate of Scotland than that just described. So soon as the grain crops are harvested, Mr Tennant sets his light grubbers agoing, and by working them over the whole field several times, and in opposite directions, stirs the whole surface soil to the depth of six or eight inches, tears up and brings to the surface all root-weeds, where, after being knocked about and freed from adhering soil by repeated harrowings, they are left for the winter. A field thus treated presents for a time a singularly untidy and unpromising appearance; but the ultimate effects of the practice, as well in the cleaning as the disintegrating of the soil, are very remarkable. When roots of couch-grass, &c. are freed from the soil, and fully exposed to the vicissitudes of the weather, at a season when their vital force is at the lowest point, they are unable to resist its effects, and gradually die. If placed in similar circumstances in spring, with their vital energy in full play, the merest point of a root embedded in, or even in contact with pulverised soil, enables them to push down fresh fibres, to re-establish their connection with the soil, and to grow as lustily as ever. But so completely is the destruction of these pests secured by this simple process of winter exposure, that on the return of spring they may be ploughed in with impunity. Mr Tennant assures us, that ever since he adopted this practice, now twelve years ago, he has been enabled to dispense with the removal of these weeds. Having recently had an opportunity of inspecting his farm, we are enabled to testify to its cleanness and high state of fertility. On this plan, then, the cleaning of fallows is accomplished by tillage operations alone, without any outlay for raking or hand-picking, burning or carting off. Nor is this done at the expense of the pulverising part of the process. On the contrary, Mr Tennant asserts, and we have so far verified his assertion by actual experiment, that by disintegrating the soil in autumn, as is done by this grubbing and harrowing, it receives far more benefit from the alternation of frost and thaw, rain and drought, than when merely ploughed and left lying during winter in compact furrow-slices. This plan affords the same facilities as the other for autumn manuring, by raking off the weeds at once from so much of the fallow-break as it is wished to manure before winter. When the remainder is ploughed in April following, more of it may then have the farm-yard dung applied to it in the same way. Agriculturists owe a large debt of gratitude to Mr Tennant for the invention of his beautifully simple and efficient grubber, and for this scientific application of it to the fallowing process.

Mr Tennant's system of winter-fallowing.

The autumn tillage of the fallows having been accomplished in one or other of the ways described, the land is left untouched till the return of spring. If it is infested by annual weeds, it is expedient, as soon as it is dry enough to bear treading with impunity, to level and stir the surface by a turn of the harrows. This slight moving of the mellowed surface-soil induces the seeds of weeds to germinate more quickly than they would otherwise do, and thus a crop of them is got rid of by the next tilling. This preliminary harrowing is useful also in affording a level course for the tillage implements. By the time that the labour connected with the sowing of spring crops is over, the fallows are usually dry enough to be stirred with safety. This point must, however, be well seen to, as irreparable mischief is often done by going upon them too soon. And now it is, that, instead of rigidly following any customary routine of so many ploughings, harrowings, and rollings, the skilful cultivator will regulate his procedure by the actual circumstances of his soil, and the object which he has in view. What is needed for the successful growth of drilled green-crops, is to have the soil free from weeds, thoroughly disintegrated to the depth of six or eight inches, and yet moist enough to ensure the ready germination of seeds deposited in it. Where such autumn cleaning and manuring, as we have described have been successfully carried out, all that is needed in order to obtain a proper tilth, is to go to work with light grubbers, first in the line of the previous furrows and then across them, and then to harrow, roll, and remove any weeds that have been missed in autumn, after which the soil will be in the best possible condition for drilling. On friable soils, this method of performing the spring tillage by means of the grubber instead of the plough, is perfectly practicable, and has manifold advantages to recommend it. The saving of labour is very great, as a man and pair of horses will more easily grub four acres than plough one acre. Weeds are more easily removed, as the grubber pulls them out unbroken, whereas the plough cuts them in pieces. The soil that has been all winter subjected to the mellowing influences of the weather, and which, in consequence, is in the best possible condition to yield a genial seed-bed, is retained a-top, whereas ploughing buries it and brings up clods in its stead. And lastly, the soil being merely stirred, without having its surface reversed, its natural moisture (*or winter sap*) is retained, whereby the germinating of seeds sown in it becomes almost a certainty. The importance of this last point in the cultivation of such crops as the turnip, whose seeds must usually be sown during hot and dry weather, can scarcely be overrated. This practice is peculiarly appropriate for soils of loose texture, which are invariably injured by repeated ploughings. But it is also resorted to successfully on soils of the opposite extreme. Many farmers in the Lothians now grow abundant and extensive crops of turnips on strong clay soils by spreading a liberal dressing of dung on the stubble in autumn, ploughing it in with a deep furrow, leaving the land untouched until sowing-time has fully arrived, and then stirring the mellowed surface soil by the grubbers, removing weeds,

Substitution of light grubbers for the plough.

Preparation of the land for Crops.

and drilling and sowing at once without any ploughing. When this system is adopted on tenacious soils, it is prudent to operate upon portions of the field in detail; taking in only so much at a time as can be grubbed and drilled the same day, for if rain should intervene betwixt the grubbing and the drilling, the soil would set like mortar, and the tide be lost. When once the ridglets are made up in good condition, they can withstand a fall of rain with comparative impunity; and hence the occurrence of a course of fine weather, when the season is yet too early for sowing, is sometimes taken advantage of by preparing the land and making it up into ridglets, although it should require to remain in this state weeks, or even months, before sowing takes place. In such a case, immediately before sowing, the ridglets are first partially levelled by harrowing lengthwise, in order to loosen the soil and destroy annual weeds, and then again made up by using a double-breasted plough. It is sometimes objected to this system of spring-tillage, that it fails to rid the land of thistles and other tap-rooted weeds; but it is surely easier to fork these out as they appear, than to plough a whole field merely to destroy as many thistles as a man, it may be, would dig up in a day. By taking advantage of the tilth obtained by the action of the elements, instead of first ploughing down the mellowed surface, and then attempting laboriously to reduce the obdurate furrows by mechanical means, skilful and energetic farmers now succeed in preparing even tenacious soils for drilled green-crops, at little expense, and with a good measure of certainty.

On these opposite classes of soils, then—the very loose, and the tenacious—spring tillage, in preparation for root-crops, is performed to better purpose by means of the grubber than the plough. Betwixt these extremes, however, lies the most valuable class of soils—the strong fertile loams—on which the heaviest crops, and best quality of Swedes, are grown. With these it is usually expedient to have recourse to at least one spring ploughing, as soon, but only as soon, as the soil is dry enough to crumble freely to the very bottom of the furrow. As this usually occurs from four to six weeks before the time of sowing the crop, it is advisable to plough the entire field, and leave it so until rain falls, when a moderate use of the grubber, harrows, and light roller, usually suffice to produce a good tilth for ridging. When operations are not thus facilitated by a seasonable fall of rain, it is necessary to proceed somewhat differently. The field is lying as it was left by the plough, with a rough dried surface. If harrowed while in this state, an abundant crop of clods is brought to the surface, which quickly harden, when thus fully exposed to drought. To avoid this inconvenience, the field is *first* rolled with a heavy roller, and then grubbed across the direction in which it was last ploughed. By this means the clods being pressed down amongst the loose earth resist the grubber, and are crumbled by it, instead of being merely raked out and left entire on the surface, as would happen, but for this preliminary rolling. The grubbers are followed closely by harrows and a light roller, and these again by the grubbers; but this time with *seven* tines on instead of five, after which a sufficient tilth is usually obtained. All this is on the supposition that the land is clean when these spring operations are commenced; for should it be otherwise, it is usually better to begin with the grubber on the stale winter furrow, and to get rid of the weeds, before using the plough. Let it ever be borne in mind, that if the soil is cleaned, and sufficiently disintegrated, the less working it gets at this stage the better.

### SUMMER OR NAKED FALLOW.

Having thus described at length that modification of the fallowing process by which the soil is prepared for the sowing of green crops, we shall now, as proposed, speak of that prolonged form of it called a *summer* or *naked* fallow. From the facilities now afforded, by means of tile-training and portable manures, for an extended culture of green crops, this laborious and costly process, which in its day was justly regarded as the very key to good and profitable farming, is now restricted to the more obdurate clay soils, or to cases where draining and other modern improvements are neglected. The manifold advantages of having abundant crops of turnips, or mangel wurzel, instead of naked fallow, sometimes tempt the occupiers of clay soils to push the cultivation of these crops beyond due bounds. We know of cases where, after large expenditure in draining, the cultivation of turnips has been carried to such an extent, and conducted so injudiciously, that the land has got foul and soured, and its gross produce has been reduced below what it was while the land was undrained, and under a regular system of all but exclusive naked fallows. However thoroughly drained, clay soils retain their ticklish temper, and are so easily disconcerted by interference during unfavourable weather, that the preparing of them for the cultivation of root-crops, and still more, the removing of these crops when grown, is at best a hazardous business, and requires to be conducted with peculiar tact. Judicious farmers, who know by experience the difficulties that have to be overcome in cultivating such soils, are of opinion, that all that can yet be ventured upon with safety, is to prolong the period of the naked fallow's recurrence, rather than entirely to dispense with it. After a series of alternate grain and cattle crops, it is accordingly still their practice to wind up with a summer fallow, by which they rectify unavoidable defects in the tillage of preceding years, and put their land in good humour for entering again upon a fresh course of cropping.

This process is begun by a deep ploughing in autumn, in performing which the land is gathered into ridges, that it may be kept as dry as possible during winter. When the more urgent labours of the following spring are so far disposed of as to afford leisure for it, a second ploughing is given to the fallow—usually by reversing the furrows of autumn. This is followed at intervals by two cross-ploughings, which are made to reverse each other, in order to keep the land level. As it is the nature of these soils to break into lumps, under the action of the plough, rather than to crumble down, the clods thus produced get so thoroughly parched in dry weather, that root-weeds inclosed in them are killed by sheer desiccation. To further this cheap mode of getting rid of them, the land is not rolled, but stirred by the grubber and harrow as frequently as possible, so as to expose the clods freely to the drought. We know by experience that fallows can be cleaned effectually by thus taking advantage of the tendency in clay soils to bake excessively under exposure to the hot dry weather which usually prevails in June and July. Should the season happen to be a showery one, this line of tactics must needs be abandoned, and recourse had to the judicious use of the grubber, Norwegian, and common harrow, in order to free the weeds from the soil, and then to clear them off by raking or hand-picking. This is more costly, and, as we believe, less beneficial to the soil than the simple method first noticed, which should therefore be attempted in the first place. As in haymaking, much can here be done in a few favourable days, by keeping grubbers and harrows at work, and turning the clods frequently. When farm-yard dung is to be applied to such fallows, it is desirable that it should be carted on and ploughed in before July expires. In applying it, two methods are followed. That usually adopted is, after marking off the ridges, to put down the dung in small heaps, at regular distances, and forthwith to spread it and plough it in. In the other, the land is formed into ridglets, running diagonally across the

Succession of Crops.

intended line of the ridges, and the dung is enclosed in them in the manner to be hereafter described in treating of turnip culture. In either way, after the lapse of several weeks, the surface is levelled by harrowing, and the land is gathered into ridges by the last of this series of ploughings, hence called the seed-furrow. When lime is to be applied to such land, this is the stage of the rotation which is usually chosen for doing so. It is spread evenly over the surface, immediately before the last ploughing. In finishing off this fallowing process, it is necessary, on undrained lands, to be careful to clean out the ridge-furrows and cross-cuts, in anticipation of wintry rains. But if such land is worth cultivating at all, it is surely worth draining, and this operation once thoroughly performed, puts an end to all further solicitude about furrows.

## CHAPTER IV.

### SUCCESSION OF CROPS.

There are few agricultural facts more fully ascertained than this, that the growth, year after year, on the same soil, of one kind of plants, or family of plants, and the removal from it, either of the entire produce, or at least of the ripened seeds of such plants, rapidly impairs the general fertility of that soil, and, in particular cases, unfits it for bearing further crops of the kind by which it has been exhausted. The explanation of the causes of this phenomenon belongs to the agricultural chemist, or vegetable physiologist, to whom we willingly leave the task. What we have to do with is the fact itself, and its important bearing on agricultural practice. There is no natural tendency in the soil to deterioration. If at any time, therefore, the earth fails to yield its increase for the use of man, it is owing to his own ignorance and cupidity, and not to any defect in the beneficent arrangements of the Creator. The aim, then, of the agriculturist, and the test of his skill, is to obtain from his farm abundant crops at a remunerative cost, and without impairing its future productiveness. In order to this, two conditions are indispensable; 1st, that the elements of fertility abstracted from the soil by the crops removed from it be duly and adequately restored; and, 2d, that it be kept free from weeds. The cereal grains, whose seeds constitute the staple food of the human family, are necessarily the most important and valuable of our ordinary crops. The stated removal from a farm of the grain produced on it, and its consumption elsewhere, is too severe a drain upon its productive powers to admit of these crops being grown every year on the whole, or greater part of it, without speedily impairing its fertility. Supposing, however, that this waste could be at once repaired by the annual return to the soil of manure equivalent in constituent elements to the produce removed, the length of time which grain crops occupy the soil, and their habit of growth, interpose peculiar difficulties in the way of cleaning it thoroughly, either before they are sown, or while they occupy the ground. Again, although bread-corn is the most important product of our soil, other commodities, such as butcher-meat, dairy produce, vegetables, wool, and flax, are indispensably required. The economical culture of the soil demands the employment of animal power, which, to be profitably used, must be so distributed as to fill up the year. The maintenance of the working cattle, and of other live stock, implies the stated culture of a large amount of herbage and forage. Now, these varied conditions are duly met by cultivating grain and cattle crops alternately, and in about equal proportions. In carrying out these general principles, much discrimination is required in selecting the particular plants best adapted to the soil, climate, and other circumstances, of each farm; and in arranging them in the most profitable sequences. For not only is it necessary duly to alternate grain and green crops, but, in general, there is a necessity, or at least a high expediency, in so varying the species or varieties of the latter class as to prolong, as much as possible, the periodic recurrence of any one of them on the same field. In settling upon a scheme of cropping for any particular farm, regard must be had to its capabilities,—to the markets available for the disposal of its products,—and to the command of manure. When these things have been maturely considered, it is always beneficial to conduct the cropping of a farm upon a settled scheme. The number of men and horses required to work it is regulated chiefly by the extent of the fallow-break, which it is therefore desirable to keep as near to an average annual breadth as possible. When the lands of a farm vary much—as regards fertility, fitness for particular crops, and proximity to the homestead,—they must be so apportioned as to make the divisions allotted to each class of crops as equal as possible, in all respects, taking one year with another. Unless this is done, those fluctuations in the gross produce of farms which arise from varying seasons, are needlessly, it may happen ruinously aggravated; or such an accumulation of labour is thrown on certain years which may prove unfavourable ones as to weather, that the work is neither done well nor in due season. No better rotation has yet been devised for friable soils of fair quality than the well-known four-field or Norfolk system. By this course half the arable lands are in grain crops, and half in cattle crops, annually. It is indeed true, that, in the way in which this course has hitherto been usually worked, both turnips and clover have recurred so frequently (every fourth year) on the same fields, that they have become subject to disease, and their produce excessively precarious. But the excellence of this course is, that its main features can be retained, and yet endless variation be introduced in its details. For example, instead of a rigid one-fourth of the land being each year under turnips, barley, clover, and wheat, or oats, respectively, half only of the barley division is frequently in practice, now sown with clover seeds, and the other half cropped in the following year with beans, peas, potatoes, or vetches. On the same set of fields, coming round again to the same point, the treatment is reversed by the beans, &c. and clover being made to change places. An interval of *eight* years is thus substituted for one of *four*, so far as these two crops are concerned. Italian rye-grass, unmixed with any other plant, is now frequently taken in lieu of clover, on part of the division usually allocated to it, and proves a grateful change both to the land and to the animals which consume it. In like manner, instead of sowing turnips unvaryingly every fourth year, on each field, a portion of the annual division allotted to this crop, can advantageously be cropped with mangel-wurzel, carrots, or cabbages, and taking care to change the site occupied by each when the same fields again come in turn. The same end is even so far gained by alternating Swedish with yellow or globe turnips. It is also found expedient, either systematically or occasionally, to sow a field with clover and pasture grasses immediately after turnips, without a grain crop, and to allow it to remain in pasture for four years. A corresponding extent of the other land is meanwhile kept in tillage, and two grain crops in succession are taken on a requisite portion to equalize the main divisions, both as respects amount of labour and the different staple products. A closer cover of grasses and a better pasture is obtained in this way than by first taking the customary grain crop after turnips; the land is rested and invigorated for future tillage,—the outlay on clover and grass-seeds somewhat diminished,—and the land better managed for the interests of all concerned than by a rigid adherence to the customary rotation. It is common enough for landlords, or their agents, to tie down the ten-

Succession of Crops.

antry over large estates to the rigid observance of some pet rotation of their own. In an unimproved state of agriculture, and for a tenantry deficient both in capital and intelligence, such trammels, kindly enforced, may be as beneficial to them as to their landlord. But, when the culture of the soil is undertaken by men of good education, who bring to the business ample capital, and skill to use it to the best advantage, such restrictions are much more likely to do harm than good to both parties. It is to be observed, in regard to those restrictive clauses usually inserted in farm-leases,—such as, that two grain crops shall never be taken in immediate succession; that no hay, straw, or turnips, shall be sold from the farm; that only certain limited quantities of potatoes or flax shall be grown; that land shall be two or more years in grass, &c.; that they all proceed on the supposition that the farm is to maintain its own fertility. They obviously do not contemplate the stated purchase of large quantities of guano, bones, and similar extraneous manures, or the consumption by live stock of linseed-cake, grain, or other auxiliaries to the green crops produced on the farm. Now, not only are such clauses incompatible with such a system of farming as we have just now indicated, but their direct tendency, if enforced, is to hinder a tenant from adopting it even when disposed to do so. We hear now-a-days of tenants who are annual purchasers of these extraneous fertilising substances to the extent of 20s. to 30s. worth for every acre occupied by them. To enforce the same restriction on such men as on others who buy none at all, is obviously neither just nor politic; and we believe that any practical farmer, if he had his choice, would rather be the successor of a liberal manurer, however he may have cropped, than of one who has farmed by rule on the starving system. We are quite aware that, in regard to the first-mentioned of these restrictions (viz. that which forbids taking two grain crops in immediate succession), the contrary practice is still asserted by agricultural authorities to be necessarily bad farming. Now, we do not concur with this opinion, but believe, on the contrary, that when land is kept clean, and is as highly manured and well tilled as it must be to grow cattle-crops in perfection, the second successive crop of grain will usually be better than the first, its production nowise injurious to the land, and the practice, *in such circumstances*, not only not faulty, but an evidence of the skill and good management of the farmer. A frequent encomium applied to a particularly well-cultivated farm is, that "it is like a garden." The practice of market-gardeners is also frequently referred to as a model for farmers. Now, the point with them is to have every inch of their ground under crop of some kind at all seasons, and to carry everything to market. Under such incessant cropping, the fertility of the soil is maintained only by ample manuring and constant tillage. By these means, however, it is maintained, and the practice is extolled as the perfection of management. Such a system must therefore be as true in farming as in gardening when the like conditions are observed. Undoubtedly he is a good farmer, who, while keeping his land clean and in good heart, obtains the greatest produce from it at the least proportionate outlay; and it is no valid objection to his practice merely to say, that he is violating orthodox rotations.

Some curious information has been afforded regarding the effects of growing successive crops of one kind of plant on the same field, by two examples of it that have recently attracted much attention. We refer to the experiments of Mr Lawes at Rothamstead, and of the Rev. Mr Smith at Lois Weedon. It is well known that Mr Lawes has now for a number of years devoted a considerable extent of land to the prosecution of a series of interesting experiments, one field being allotted to those upon wheat, another to turnip, and another to beans. One acre in the wheat-field has now borne ten successive crops of wheat without any manure whatever. The land is annually scarified and thoroughly cleaned so soon as the crop is removed, whereupon it is ploughed and again drilled with wheat, which is then hoed in spring. Now with occasional variations due to the character of particular seasons, Mr Lawes finds that the average annual produce of this acre is 16 bushels of grain and 16 cwt. of straw, below which he has as yet failed to reduce it by ten successive crops. His soil is a strong clay loam, resting at a depth of five or six feet upon chalk. In the case of turnips, he has found that when treated in the same way they cease after a few years to grow larger than radishes, nor can he by the application of any amount or variety of manure which he has yet tried, obtain a second successive crop equal to the first. With the wheat, on the contrary, the addition of four cwt. of Peruvian guano at once doubles the produce. Mr Smith's experiments, as is well known, are a revival of Jethro Tull's system of growing wheat continually on the same field, by a plan of alternate strips of wheat and bare fallow, which are made to change places annually. He has so far improved upon Tull's practice, inasmuch as his land is thoroughly drained, and his fallow spaces are deeply trenched every autumn, as well as ploughed and hoed during the growing season. The result is, that his land thus treated, has yielded an average annual produce of 34 bushels per acre for six or seven successive crops. Now it is not our intention to offer any opinion on this as a system of wheat-growing. We refer to it along with Mr Lawes's, for the purpose of shewing that, notwithstanding the prevalent opinion that grain crops exhaust the fertility of soils more rapidly than green crops, this is true only in a very restricted sense. Green crops judiciously interposed do undoubtedly serve a most important purpose in the means which they furnish for maintaining the fertility of a farm, but it is worthy of note, that whereas by the addition of suitable manure, thorough tillage, and diligent removal of weeds, clay soil at least will stand an indefinite succession of grain crops, the same means entirely fail to yield the same results with our most popular green crops. Our personal experience quite accords with this; for we suppose it will be admitted, that the corn crops of the country are at the present day superior both in quality and quantity to these of any preceding period; whereas potatoes, turnips, and clover, which we have so long regarded as our sheet anchor, have become increasingly precarious, and threatened to fail us altogether. We offer these facts for the consideration of those who out-and-out condemn the practice of sowing two white crops in immediate succession. In stating this opinion, we must, however, guard misapprehension. Unless the land is highly manured and kept thoroughly clean, we are just as much opposed to the practice as any one can be; but when mischief is done by it, we believe that it is due rather to the presence of weeds than to the second grain crop. Neither do we plead for the absolute removal of restrictive clauses from farm leases. Human nature being what it is, men who do not see it to be for their own advantage to farm well, will, through ignorance or greed, impoverish their land unless they are restrained. Clauses as to cropping should, however, be prohibitory rather than prescriptive—have reference rather to what is removed from the farm than to what is grown upon it—and they should be contingent upon the other practices of the tenant. So long as he continues by ample manuring and careful tillage to maintain the fertility and general good condition of the farm rented by him, it can be no advantage to his landlord to hinder him from cropping it at his own discretion. It will be seen from these remarks, that we attach more importance to those general principles which should regulate the succession of crops, than to the laying down of formulæ to meet supposed cases. The man who cultivates by mere routine, is unprepared for emergencies, and is sure to lag in the race of improvement; while he who studies principles is still guided by them, while altering his practice to suit changing circumstances. Illustrations of this will be found in our closing notices of the farming of selected districts.

## CHAPTER V.

### MANURES.

In our remarks on tillage operations, and on the succession of crops, we have seen how much the practice of the husbandman is modified by the kinds and amount of manures at his disposal. In describing the crops of the farm and their culture, frequent reference will also necessarily be made to the use of various fertilising substances; and we shall, therefore, before proceeding to that department of our subject, enumerate and briefly remark on the most important of them. In such an enumeration, the first notice is unquestionably due to

*Farm-Yard Dung.*—This consists of the excrements of cattle, their litter, and the refuse of their fodder; usually first trodden down in successive layers, and partially fermented in the farm-yard, and then removed to some convenient place and thrown together in heaps, where, by further fermentation and decay, it is reduced to a dark-coloured, moist, homogeneous mass, in which state it is usually applied to the land. It is thus the residuum of the whole products of the farm, *minus* the exported grain, and that portion of the other crops which, being first assimilated in the bodies of the live-stock, is sold in the form of butcher-meat, dairy-produce, or wool. In applying farm-yard dung to land there is thus a returning to it of what it had previously produced, *less* the above exceptions, and such waste as may occur during the process of decay by gaseous exhalation or liquid drainage. It is obvious that the value of such dung as a fertilising agent must depend much on two circumstances; viz., 1*st*, the nature of the food consumed by the animals whose excrements are mingled with it; and 2*d*, the success with which waste from drainage and exhalation has been prevented. When cattle used during the winter months to be barely kept alive on straw and water, and were confined in an open yard, which, in addition to its own share of rain, received also the drip from the eaves of the surrounding buildings—which, after percolating the litter, flowed unchecked into the neighbouring ditch—it is needless to say that the dung resulting from such a process was all but worthless. It is much to be regretted that, from the faulty construction of farm-buildings, farmers still find it impossible to guard their dung-stores from injury and waste. When cattle-yards are slightly hollowed towards their centre, and the surrounding eaves are spouted, the litter absorbs the whole of the urine and the rain which falls upon the uncovered area, while the treading of the cattle goes far to prevent undue fermentation and escape of gases. The same remark applies still more strongly to covered boxes, the dung resulting from this mode of housing fattening cattle being of the best quality. In the case of byres and stables it is certainly desirable to have a covered depot, into which the litter and solid excrements may be wheeled daily, and to have the urine conveyed by proper drains and distributed over this mass of solid matter. As there is usually more liquid than these can at once absorb, it is well to have a tank at the lowest part of this depot in which to store the surplus, that it may from time to time be returned upon the adjoining mass, or conveyed to heaps in the fields. Advantage is usually taken of frosty weather to cart out to the fallow division of the farm the dung that was accumulated in yards and boxes. It is formed into large square heaps about four feet deep, in situations most convenient for ready application to the land when the season for sowing the crops arrives. It is desirable to prepare a site for these heaps by carting together and spreading down a quantity of earth (or peat, when that can be got), for the purpose of absorbing the ooze from the fermenting mass laid upon it. At the beginning of winter, the loaded dung-carts are driven on to the heaps, and their contents are spread evenly over it, layer above layer, both to equalise the quality of the dung-heap as a whole; and, by the compression thus applied, to prevent a too rapid fermentation. When the heap has attained the requisite bulk, a covering of earth or peat is spread over it to keep it moist, and to prevent the escape of its ammonia. When this home-made manure was the only kind statedly at the command of the farmer, it was considered necessary, and we believe truly, to have it in an advanced state of decomposition before putting it into the turnip-drill. There was a waste of manure by this practice, but unless it was in a state to supply instant nourishment and stimulus to the young turnip plants, the crop was certain to be a deficient one. The application, along with farm-yard dung, of guano, superphosphate of lime, and other portable manures, quite does away with the necessity of having the former much rotted. These concentrated manures stimulate the growth of the plants during their early stage, and put them in the best condition for making gradual use of the slowly dissolving dung. Excessive decomposition of farm-yard dung is now therefore avoided, and pains rather bestowed to improve its quality by protecting it from the weather, and retaining its ammonia and natural juice. The cheapest, and perhaps also the best, way of doing this is to cart the dung direct from the cattle-yards to the fields, and at once to plough it in.

*Liquid Manures.*—We have spoken of the importance of carefully retaining the urine of the housed live-stock, by having it absorbed in the solid matter of the dung-heap, and of collecting the surplus into a suitable tank, where it may be available for moistening the heap from time to time, and especially when about to be applied to the land. A system has, however, recently attracted much notice, by which pains are taken not only to preserve every drop of urine and ooze from dung-heaps, but, as far as practicable, to apply the whole manure produced on the farm in a liquid form. It is in Ayrshire, and especially on the farm of Myremill, that this system has been carried out most fully. Our reference will be best explained by quoting at length from the "Minutes of Information" issued by the General Board of Health regarding sewage manure.

"The next farm visited was in the immediate vicinity of Glasgow, where the supply of liquid manure is derived from another source, and distributed in a different manner. The supply is from a dairy of 700 cows, attached to a large distillery: the entire drainage from the former flows in a full continuous stream into a tank containing 30,000 or 40,000 gallons, whence it is pumped up immediately by a 12-horse power engine, and forced through 4-inch iron pipes, laid about 18 inches under ground, into large vats or cisterns placed on the highest points of the land to be irrigated. From these it descends by gravitation through another system of pipes laid along the ridges of the hills, finding an outlet through stand-cocks placed at intervals, from which it is distributed through moveable iron pipes fitting into each other, and laid along the surface in whatever direction the supply is required. The land thus irrigated consists of three farms lying at some distance apart, the farthest point to which the liquid is conveyed being about two miles, and the highest elevation 80 feet above the site of the tank and engine. The principal use to which the irrigation has been applied has been to preserve the fertility of the pastures, the general appearance of which was at first rather disappointing, but this was explained by the fact that they are fully stocked, and that the cows rush with avidity to those parts that have been last irrigated, and eat them down

Manures.

quite bare. As is the case in other instances, however, by far the most profitable application has been found to be Italian rye-grass, of which 15 (Scotch) acres were under cultivation, some with seed supplied by Mr Dickinson, whose successful cultivation of it by similar means near London has long been known. The first cutting of this had yielded about ten tons the acre, the second nine, and the third, which was ready for cutting, was estimated at eight or nine more. Some crops of turnips and cabbages were pointed out to us in a state of vigorous growth, and with more than common promise of abundance; these were raised by a dressing of ashes and refuse (of little fertilising value, having been purchased at 2s. 6d. a ton), conjoined with four doses of liquid, one after the preceding crop of oats had been carried, one prior to sowing, and two more at different stages of growth. The enterprising gentleman who has carried out these works at his own expense, and in spite of the discouragement arising from partial failure in his earlier attempts, though speaking cautiously, as was natural in a tenant on a nineteen years' lease, of the pecuniary results of this undertaking, imparted some facts which leave little doubt that it must have been largely remunerative. Besides maintaining, if not increasing the fertility of the pastures, to which the solid manure from the byres was formerly devoted, at a heavy expense of cartage (the whole of which is now saved), he is enabled to sell all this manure of which we estimated the quantity at about 3000 tons a-year at 6s. a-load. For a good deal of the Italian rye-grass not required for his own consumption, he obtained upwards of 13s. a ton, the profit on which, taking into account the yield before stated, may easily be imagined. Thirteen carts, each containing six barrels of ten gallons each, are used to convey the milk to market, where it is sold at 5d. the Scotch pint, equal to six pints imperial measure. The income from milk would, therefore, be not less than L.43, 6s. 8d. per day, or L.15,816, 13s. 4d. per annum.

"The next place visited was the farm of Myre Mill, near Maybole, in Ayrshire, the property of Mr Kennedy, who adopted and improved on the method of distribution just described. On this farm, about 400 imperial acres of which are laid down with pipes, some of the solid as well as the liquid manure has been applied by these means, guano and superphosphate of lime having been thus transmitted in solution, whereby their value is considerably enhanced. This is especially the case with guano, the use of which is thus rendered in great measure independent of the uncertainties of climate, and it is made capable of being applied with equal advantage in dry as in wet weather. In some respects the farm labours under peculiar disadvantages, as water for the purpose of diluting the liquid has to be raised from a depth of 70 feet, and from a distance of more than 400 yards from the tanks where it is mixed with the drainage from the byres. These tanks are four in number, of the following dimensions respectively:—$48 \times 14 \times 12$; $48 \times 14 \times 15$; $72 \times 14 \times 12$; $72 \times 17 \times 12$. They have each a separate communication with the well from which their contents are pumped up; which are used in different degrees of 'ripeness,' a certain amount of fermentation induced by the addition of rape-dust being considered desirable. The liquid is diluted, according to circumstances, with three or four times its bulk of water, and delivered at the rate of about 4000 gallons an hour, that being the usual proportion to an acre. The quantity to be applied is determined by a float-gauge in the tank, which warns the engineer, whose business it is to watch it, when to cut off the supply, and this is a signal to the man distributing it in the field to add another length of hose, and to commence manuring a fresh portion of land. The pumps are worked by a 12-horse power steam-engine, which performs all the usual work on the farm, thrashing, cutting chaff and turnips, crushing oil-cake, grinding, &c., and pumping. The pipes are of iron; mains, submains, and service pipes, five, three, and two inches in diameter respectively, laid eighteen inches or two feet below the surface. At certain points are hydrants to which gutta-percha hose is attached in lengths of twenty yards, at the end of which is a sharp nozzle with an orifice ranging from one to one and a-half inch, according to the pressure laid on, from which the liquid makes its exit with a jet of from twelve to fifteen yards. All the labour required is that of a man and a boy to adjust the hose and direct the distribution of the manure, and eight or ten acres may thus be watered in a day. There are now 70 acres of Italian rye-grass, and 130 of root crops on the farm. The quantity they would deliver by a jet from a pump worked by a 12-horse steam engine, would be 40,000 gallons, or 178 tons per diem, and the expense per ton about 2d., but a double set of men would reduce the cost. The extreme length of pipe is three-quarters of a mile, and with the hose the total extent of delivery is about 1,900,000 yards, or 400 acres. To deliver the same quantity per diem, by water-carts to the same extreme distance, would be impracticable. One field of rye-grass sown in April, had been cut once, fed off twice with sheep, and was ready (August 20th) to be fed off again. In another, after yielding four cuttings within the year, each estimated at 9 or 10 tons per acre, the value of the aftermath for the keep of sheep was stated at 25s. an acre. Of the turnips, one lot of Swedes dressed with 10 tons of solid farm manure, and about 2000 gallons of the liquid, having six bushels of dissolved bones along with it, was ready for hoeing 10 or 12 days earlier than another lot dressed with double the amount of solid manure without the liquid application, and were fully equal to those in a neighbour's field which had received 30 loads of farm-yard dung, together with 3 cwt. guano and 16 bushels bones per acre; the yield was estimated at 40 tons the Scotch acre, and their great luxuriance seemed to me to justify the expectation. From one field of white globe turnips sown later, and *manured solely with liquid*, from 40 to 50 tons to the Scotch acre was expected. A field of carrots treated in the same manner as the Swedes, to which a second application of liquid was given just before thinning, promise from 20 to 25 tons the acre. Similarly favourable results have been obtained with cabbages; and that the limit of fertility by these means has not yet been reached, was clearly shown in one part of the Italian rye-grass which had accidentally received more than its allowance of liquid, and which showed a marked increase of luxuriance over that around it. The exact increase of produce has not been accurately determined, but the number of cattle on the farm has increased very largely, and by means of the Italian rye-grass at least *four* times as many beasts as before can be kept now on the same extent of land, *the fertility of the land being at the same time increased*. This plant, of all others, appears to receive its nourishment in this form with most gratitude, and to make the most ample returns for it; and great as are the results hitherto obtained, I believe that the maximum of productiveness is not yet reached, and that the present experiment must be carried yet further before we know the full capabilities of this manure. Of one important fact connected with this crop, I am assured, that notwithstanding the rank luxuriance of its growth, animals fed upon it, not only are not scoured, but thrive more than on any other kind of grass in cultivation.

Manures.

"Taking into the irrigation account the whole cost of the engine, and the whole of the fuel and wages—although half of these might have been deducted—the following appears to be the capital account and working expenses for fertilising Myre Mill farm:—

| | | | |
|---|---|---|---|
| Tanks complete | £300 | 0 | 0 |
| Steam-Engine | 150 | 0 | 0 |
| Pumps | 80 | 0 | 0 |
| Iron Pipes, laying, and hydrants | 1000 | 0 | 0 |
| Gutta-Percha, distributing pipes, &c. | 56 | 0 | 0 |
| | £1586 | 0 | 0 |
| Annual interest on £1586, and wear and tear, at $7\frac{1}{2}$ per cent. | £118 | 19 | 0 |
| Annual Wages | 104 | 0 | 0 |
| Fuel | 58 | 0 | 0 |
| | £281 | 19 | 0 |

This amount divided by the number of acres, is equal to the annual sum of 14s. per acre.

"I now come to the practical results of so cheap a mode of fertilising land.

"Mr Young informed me that in one of the fields he had

Manures.

himself measured the growth of Italian rye-grass, and had found it to be two inches in twenty-four hours; and that within seven months, Mr Kennedy had cut from a field we were passing at the time 70 tons of grass per acre. Where the whole is cut, four or five heavy crops are thus taken; but upon some of the land during the last two years 20 sheep to the acre have been penned in hurdles, and moved about the same field from time to time; after each remove the fluid has been applied, and immediately followed by an abundant growth of food. There is not the slightest appearance of exhaustion in the land,—its fertility appears to increase. I was informed that, before the liquid manure was used, the land would not keep more than a bullock or five sheep to the acre; now it will maintain, if the crops are cut and carried in, five bullocks or twenty sheep to the acre. Some beans, bran, and oil-cake are bought for the stock; but, on the other hand, one-third or more of the farm is kept in grain, notwithstanding the great number of live stock.

"*Canning Park.*—Mr Telfer's farm, near Ayr. This is a small dairy farm of 40 acres, near the level of the sea, and about a mile and a-half west of the town of Ayr. The subsoil is beach gravel with a slight admixture of clay. Water is too abundant. It lies dead within about 20 inches of the surface, and in winter nearer than that.

"No bedding or litter is used here. The cows lie on cocoa-nut mats. The ventilation is perfect; and the air sweeter than in the majority of the dwelling-houses of human beings.

"The following appears to be the cost of carrying out the system at Mr Telfer's farm:—

| | | | |
|---|---|---|---|
| "Tank | £30 | 0 | 0 |
| Engine | 60 | 0 | 0 |
| Iron pipes and hydrants | 100 | 0 | 0 |
| Distributing hose-pipe, &c | 20 | 0 | 0 |
| | £210 | 0 | 0 |

| | | | |
|---|---|---|---|
| "Annual interest on £210, and wear and tear at 7½ per cent | £15 | 15 | 0 |
| Wages and fuel | 11 | 0 | 0 |
| | £26 | 15 | 0 |

"In summer the cows have a quantity of oil-cake, as well as grass; and in winter they have turnips or mangel-wurzel, bean, or barley meal, and cut hay or grass; the whole mess being steamed together. Miss Bell, the cousin of Mr Telfer, manages the dairy, and said that last year the hay bought would amount to from £30 to £40, and she should think the grain to not less than £200. In general terms, the other food is produced upon the farm. As to the produce of grass, which is the chief article, the first cutting during the present year was in the latter end of March about 18 inches thick. The second was from 18 inches to 2 feet thick. The third was from 3 feet to 4 feet 6 inches thick. The fourth nearly the same. The fifth was 2 feet thick; and the sixth, in process of cutting at the time I was there, we measured at 18 inches thick. Taking the mean, where two dimensions are given for the same crop, I find the aggregate depth of grass, grown and cut off this farm within seven months, to be not less than 14 feet 3 inches. All this is, however, eaten upon the premises, and the whole marketable produce of the farm is represented by the milk and butter.

"As to the quantity and value of these, Miss Bell stated, that the previous week the butter was 114 lb. and 120 lb.,—together 234 lb. sold at 1s. per pound. This, she stated, was about the average quantity and price. The amount for butter would therefore be £11, 14s. per week, or per annum L.608, 8s. She informed me farther, that during about eight months in the year, the cold milk realises about the same amount as the butter. In the summer months, during hot weather, the market value of the milk is only about half that of the butter. From these data, the amount for milk sold per annum is £507.

"The total receipts for the two articles of milk and butter amount to £1115, 8s. per annum.

"I only need to add that, previously to the adoption of the present system of farming, these 40 acres of land were barely sufficient to support eight or nine cows, and would have been well let at a rental of 30s. an acre."

Manures.

The attention now so generally directed to this subject, and the importance attached to it in many quarters, justify this lengthened quotation, and call for some remarks upon it. We have carefully examined two of the instances referred to in this report, viz., Port Dundas and Myre Mill; and some smaller experiments more cursorily. After doing so we are sorry to say that we have arrived at a very different estimate of this system of manuring from that expressed in the above quotations. We at once, and with pleasure, acknowledge that in so far as concerns the storing up and preparing of the liquid manure, its application to the land, and the production, by means of it, of crops of Italian rye-grass almost surpassing belief in their luxuriance and weight of produce, Mr Kennedy's experiments have been crowned with complete success. The excellence of this grass as food for live stock, and their relish for it is also indisputable. Neither do we dispute the statements of those, who tell us that manure when largely diluted with water, and properly applied in the liquid form, is more beneficial to plants, than in any other way in which it can be presented to them. Admitting all this, the question remains, has it yet been shown that this system can be economically applied to ordinary farms. Data are still wanting from which to answer this question conclusively, but we shall state some of the reasons which constrain us, as presently advised, to do so in the negative.

Supposing an adequate motive power already to exist, and to be partly employed for other purposes, the capital that must be invested in providing the tanks and other apparatus necessary for carrying out this system, amounts to about L.4 per acre over a farm of average extent. If the system be a sound one, the great amount of this outlay cannot fairly be urged as an objection to it. The addition of a permanent rent charge of 5s. per acre to an entire farm, for a benefit which in any one year can be available to but a limited portion of it, is however a serious matter. In each case referred to in the "Minutes of Information," the whole annual charge, whether arising from interest on capital, wear and tear of machinery, or working expenses, is divided by the whole acreage of the farm. In the first seven cases given in the tabular statement,[1] this mode of calculation is correct, as the whole areas do actually benefit each year by the irrigating process. But when we come to those irrigated by machinery, we find that a half or two-fifths only of the land receives the benefits of it in any one year. If the annual charge in this latter class of cases is divided by the acreage actually irrigated, it becomes evident that the expense is double that of the Pusey meadows, and equal to that of the old meadows near Edinburgh, instead of being less as it is made to appear. Again, in estimating the profits, an opposite course is followed. While the charges are made to appear less by spreading them over the whole area of the farm, the enormous produce of grass from the irrigated parts is put prominently forward, and little is said about its produce as a whole. In the dairy cases too, we are told of enormous gross profits, without being pointedly reminded that the larger portion of the keep of the cows, such as distillery offal, bean-meal, hay, and even straw and turnips, is actually purchased; that in this way a quantity of extraneous manure becomes available for the associated farm, sufficient (however applied) to maintain it in a state of fertility; and that there would be handsome profits from the dairy, irrespective of the farm altogether. In fact, town dairies usually

[1] See next Page.

Table No. II., *Shewing Cost, &c., of the Application of Sewerage Waters and Liquid Manures.*

| Name of Place. | No. of English acres. | Mode of Application. | Cost of Works and Apparatus. L. s. d. | Annual Interest, &c., at $7\frac{1}{2}$ per cent. L. s. d. | Annual Working Expenses. L. s. d. | Total Annual Charge per English acre. L. s. d. | OBSERVATIONS. |

| *Glamorganshire.* | | | | | | | |
| Porth Kerry farm. | 50 | Gravitation, underground iron mains, gutta-percha hose and jet pipe,.................. | 300 0 0 | 22 10 0 | 0 10 0 | 0 13 0 | Tanks constructed sufficient for 300 acres. Between 9 and 10 feet of grass cut. |

Manures. have no land attached to them. The cows are maintained solely by purchased food, and the sale of manure, liquid and solid, forms one of the stated items of income. In Mr Harvey's and similar cases, two separate businesses are in fact mixed up, and yet the whole is spoken of in such a way as if the profit was mainly due to the use of liquid manure. Indeed the whole of these "Minutes of Information," issued by the General Board of Health, have an air of special pleading about them, which to us seriously detracts from their value.

The entire annual cost of applying manure in this manner is stated to amount to from 10s. to 14s. per acre for the whole extent of the farm. Now this would suffice to provide annually from 1 to 1½ cwt. of Peruvian guano (even at its present high price) for every acre of the farm, or from 2 to 3 cwt. per acre, if applied, as the liquid is, to the portion under green crop only. The stated application of such a dressing of guano, in separate portions, and during showery weather, will be found to yield results little inferior to those obtained by the use of liquid manure. To do this requires no costly apparatus, or permanent sinking of capital, and its application can be desisted from at any time when found unremunerative. The adoption of this plan of applying the liquid manure of the farm necessarily demands that the whole system of management be accommodated to it. In order to furnish this liquid manure, the whole green crops must, summer and winter, be conveyed to the homestead, and there consumed in such a manner as that the urine and dung of the animals fed upon it may be scoured into the tanks. It is no such easy matter to replenish these tanks as some persons seem to think. When cattle are housed in boxes or properly protected yards, the whole of the urine is absorbed by the litter, and goes to the field in the dung-cart. This is certainly a more expensive way of conveying it to the fields than by pipes. But then, as in the new system, the urine, &c. is diluted with at least three times its volume of water, there are 4 tons of manure to convey on the one plan for one on the other. Even where pipes are used, all the litter, and a portion at least of the dung has still to be carted out, so that no claim of a saving of carriage can validly be put forward on behalf of this system; but its merits must be grounded solely on the superior efficacy of manure, when applied in a liquid instead of a solid form.

In the case of dry and loose soils, the consuming of the turnip crop, by folding sheep upon it, has hitherto been regarded as at once the cheapest way in which it can be converted into wool and mutton, and the land consolidated and enriched, so as to fit it for producing grain and other crops. On tenacious soils, and in a moist climate, which is quite the case at Myre Mill, it is certainly impracticable to pursue this system in winter. It is perhaps also the case that sheep are healthier, fatten more rapidly, and yield more wool, when fed under cover, than when folded on the open turnip field. Admitting all this, however, we are disposed to think that these benefits are better secured by Mr Randell of Chadbury's plan of littering the pens with burnt clay, which keeps the sheep clean, and their feet in good order, and, when mingled with their urine and dung, forms a most valuable manure for any kind of land. Were this carried out by means of moveable covered pens, which could be erected and easily shifted from place to place in the turnip field, the carriage of the turnips and manure would be greatly reduced, especially if accomplished by means of the portable railway.

In the case of dairies near towns, where the cows are largely fed on brewery or distillery offal, and other purchased food, the circumstances are totally different from those of ordinary farms, depending solely on their own resources. The liquid manure that would otherwise run to waste, when thus applied, is so much clear gain, in so far as the value of the increased produce exceeds the cost of application. It may form a wholesome caution to some persons, to mention here that, notwithstanding all that has been written about the success of the spirited operations at Port-Dundas, we were recently told by Mr Harvey, that so dubious is he still about it, that if the thing were to do again, he would rather keep his money in his pocket, and let the urine run into the canal, as formerly. If there is doubt even in such a case, how much more when the manure must virtually be purchased. And this leads us to remark that we have better hopes of the ultimate success of this plan of manuring, when it is restricted to the application of the surplus liquid manure of the homestead to some piece of meadow near at hand, supplementing this supply, when necessary, by dissolving guano in water, and sending it through the pipes. These remarks apply even more strongly to the sewage from towns. The liquid, in this case, is highly charged with fertilising ingredients of the most valuable kind, seeing that it consists largely of night-soil from a population consuming much animal food. With few exceptions, this valuable liquid, which flows in such quantities from all our towns, is not only utterly lost, but is a grievous nuisance, by polluting our streams, and generating disease. In applying it as manure, the expense lies entirely in providing and working the necessary apparatus. In such cases, then, with an unfailing supply of highly fertilising liquid, costing nothing to begin with, there is every inducement to put into operation any plan by which it can be economically applied to field crops. The enhanced value of green forage in the vicinity of towns is an additional motive for attempting this. It is gratifying to think that this important problem (the profitable disposal of town sewage) is in a fair way of being satisfactorily solved. Manures.

The ingenuity and enterprise displayed by Mr Kennedy and others, in their endeavours to cheapen by this means the cost of farm produce, and the frankness and untiring patience with which they have shown and explained their proceedings to the unceasing stream of visitors, which the novelty of the operations has attracted from all parts of the kingdom, and even from foreign countries, are altogether so admirable and praiseworthy, that it requires no slight effort to speak of them otherwise than approvingly. The confidence with which various influential parties are proclaiming the complete success of this scheme of irrigation, and recommending it for general adoption, seems, however, to require that those who have examined it, and arrived at an opposite conclusion, should publicly say so.

It is unreasonable to expect that private parties are to divulge their whole business affairs; and yet, without a full *Dr.* and *Cr.* account for some ordinary arable farm treated on this system, it is impossible to arrive at a sound judgment on its merits. Until this can be done, it would be better to abstain from publishing partial statements, which tend only to mislead the public mind. We offer these remarks in no spirit of hostility to this new system of farming. We shall rejoice unfeignedly to find that our opinion of it is erroneous, and that it really warrants the sanguine expectations which some parties entertain regarding it. We simply maintain that as yet the case is "not proven," and our counsel to those who are disposed to try it is, not to embark in it to an extent that would embarass them, if, as we fear, it should prove a failure.

*Guano.*—Next to farm-yard manure, which must ever be looked to as the chief means of maintaining the fertility of a farm, guano claims our notice. This substance is the dung of sea-fowl, and is found on rocky islets in parts of the world where rain seldom falls. The droppings of the myriads of birds by which such places are frequented, have in many cases been permitted to accumulate during untold ages, and are now found in enormous deposits. The principal supply,

Manures.

both for quantity and quality, has hitherto come from the Chincha Islands on the coast of Peru. The introduction of this powerful and exceedingly portable manure has given a prodigious impetus to agricultural improvement. It is but ten years since a few casks of this article were brought to Liverpool from Peru, where it has been known and prized as a valuable manure from the remotest periods. No sooner had its value been discovered by our British agriculturists than the demand for it became most eager, and so greatly has the consumption already increased, that the importation during 1851 reached to 150,000 tons. The price at which it was sold at first was L.20 per ton, from which, with increased supplies it fell to L.11, when the discovery in 1844 of a considerable deposit on the Island of Ichaboe on the coast of Africa at once reduced the price to L.9. To shew the rate and extent of the increase in its consumption, we here give a table of imports.

"A Parliamentary paper issued on the motion of Mr Scholefield shews that the imports of guano were 2881 tons in 1841; 20,398 in 1842; 3002 in 1843; 104,251 in 1844; 283,300 in 1845; 89,203 in 1846; 82,392 in 1847; 71,414 in 1848; 83,438 in 1849; 116,925 in 1850; and 243,016 in 1851."

The Chincha deposit being the property of the Peruvian Government, is sold for their behoof through the medium of one British mercantile firm, Messrs Gibbs, Bright, & Co., and is thus a close monopoly, the holders of which regulate the price and the supply to suit their own interests. The price charged for quantities of 30 tons and upwards has for several years been L.9, 5s. per ton. Were the price lowered to L.5 or L.6 there can be no doubt that the consumption would at once be doubled. Discoveries have recently been made of other deposits on the Peruvian and African coast, and in Australia. The quality of both of the latter is much inferior to that from Peru. It is in a more advanced state of decay, and contains more moisture and sand. The value of that from Peru depends chiefly on the large amount of ammonia (about 18 per cent. in average samples) which it contains. Even at L.9, 10s. per ton, the price at which it is usually retailed, it is the cheapest form in which ammonia can be purchased. Guano is largely used as a manure for most of our field crops, but chiefly for turnips. The quantity applied per acre ranges from two to four cwt. It is most economically used in combination with other manures, as we shall have occasion to show when treating of turnip culture. The dung of birds, from its including both liquid and solid excrements, is superior as a manure to that of quadrupeds. Pigeon's dung has long been in high repute as an excellent fertiliser, and brought a high price in days when portable manures were scarcely to be had. It is now little heard of: Guano, the excrement of fowls which feed upon fish, being superior, weight for weight, and available to every one. The dung of domestic poultry is usually mixed with the general dung heap, but it could be turned to better account if kept by itself. It has been recommended to strew the floors of poultry houses daily with sawdust or sand, and to rake this with the droppings into a heap to be kept under cover and used like guano.

*Bones.*—It is now about forty years since ground bones began to be used by farmers in the east side of England as a manure for turnips. At first they were roughly smashed by hammers and applied in great quantities. By and bye mills were constructed for grinding them to a coarse powder, in which state they continued to be used as a dressing for turnips, at the rate of sixteen to twenty bushels per acre, in all parts of the kingdom and to a very great extent, until the admirable discovery by Baron Liebig of the mode of preparing superphosphate of lime by dissolving bones in sulphuric acid. We shall not attempt to explain on chemical principles the wonderful superiority of this substance over simple bone-dust in promoting the growth of the turnip plant. What we should do indifferently, by borrowing from others, will be found well done by an accomplished chemist in the separate article on Agricultural Chemistry. We can, however, testify from experience, to the important fact that *one* bushel of bone-dust dissolved by a third of its weight of sulphuric acid is superior in manurial value to *four* bushels of simple bone-dust. It is not merely, or even chiefly, in the lessened cost at which an acre of turnips can be manured that this superiority lies, but especially in this, that from the extraordinary stimulus given by superphosphate of lime to newly germinated turnip plants, they usually arrive at the stage when they are fit for thinning in from ten to fifteen days earlier than when sown over farm-yard dung or simple bone-dust, or both combined. This shortening of the critical period during which the attacks of the insignificant but dreaded turnip beetle so often baulk the hopes of the husbandman, is an advantage not easily estimated, and one well fitted to inspire him with confidence in the science to which he owes the discovery, and with grateful respect for the eminent discoverer. This powerful effect in quickening the growth of the young turnip plants is possessed in quite as great a degree by Peruvian guano, when it is supplied with sufficient moisture. In climates and seasons which may be characterised as moist and cool, guano will show best results, whereas in those which are rather hot and dry superphosphate has the advantage. Accordingly we find guano the comparative favourite in Scotland; and its rival in the drier counties of England.

Guano is believed to encourage a great expanse of foliage, and to be more especially suited for early sowings—and superphosphate to influence development of bulb, and to deserve the preference for a later seed time. The obvious inference is that, for the turnip crop at least, these valuable fertilisers should be used in combination; and actual experiment has verified its soundness. The use of them is universal and ever on the increase. They constitute also the standard by which farmers estimate the cost and effects of other purchased manures. The extent to which they are used, their high price, and the facility with which they can be adulterated with comparatively worthless ingredients, have led to almost unparalleled frauds. The adulteration of guano has in fact become a regular trade. Had farmers only their bodily senses to aid them, the detection of this fraud would be difficult—perhaps impossible. Here, however, they can call the chemist to their aid, with the certainty of ascertaining the real character of the articles which they are invited to purchase. If purchasers of guano would but insist in every instance on getting from the seller an analysis by some competent chemist, and along with it a written warrandice that the stock is of the quality therein indicated, detection and punishment of fraud would be easy. In regard to superphosphate of lime, the prudent and economical plan is for the farmer to purchase bone-dust and sulphuric acid and prepare it himself. We have conducted this process for several years past in the following way. A trough was provided 7 feet $\times$ 3·4 $\times$ 2·10, made of $2\frac{1}{2}$ inch deal, strongly jointed and secured at the corners by wooden pegs, as iron nails would be corroded by the acid. This holds conveniently 48 bushels of bones. The heap of bone-dust is then gone over with a barley riddle, and the small dust which passes through this is laid aside to be used as a drying material for the other portion, after it is subjected to the acid. We find that a third part of the bone-dust passes through the riddle. Three bottles, or carboys as they are called, of concentrated acid, averaging 180 lb. each, are then emptied into the trough and mixed with cold water at the rate of $1\frac{1}{2}$ of water, by measure, to 1 of acid. In practice, the water is poured

Adulteration of manures.

Mode of preparing superphosphate of lime.

Manures.

in first and then the acid. Into this mixture 48 bushels of bones, previously measured and laid close to the trough, are rapidly shovelled by two labourers, who will do well to be attired in clothes and shoes past spoiling. So soon as the bones begin to be thrown in, violent ebullition commences. By the time that the whole of the bones are thrown in, there will be barely liquid enough to moisten the last of them. The labourers therefore dig down at one end of the trough till they reach the bottom, and then carefully turn back and mix the whole quantity until they reach the other end. The surface is then levelled and covered with a layer of the dry riddlings two inches thick. In this state it is allowed to remain for two days, when the trough is emptied, and the same process is repeated until the whole quantity is gone over. When shovelled out of the trough the bones are found to have become a dark coloured paste, still very warm and emitting a sweetish smell. While one person throws it out, another adds to it its proportion of dry riddlings and mixes them carefully. This mass is heaped up in the corner of a shed, and augmented at each emptying of the trough, until the requisite quantity is obtained. After this the mass is carefully turned over several times, at intervals of five or six days, and is then dry enough for sowing either by hand or machine. Some prefer moistening the bones with boiling water, and then adding pure acid as they are shovelled into the trough; but by first mixing the acid and water there is greater certainty of all the bones being equally acted upon. There is also great convenience in using the finest portion of the bone-dust for drying the other, as suitable material for this purpose is sometimes difficult to procure.

Superphosphate from fossil bones or coprolites.

We have referred to superphosphate of lime, prepared from bones. A new source of supply has, however, been discovered of late years, the extent and importance of which is becoming more apparent as investigation proceeds. We allude to those phosphoric deposits found in such abundance in the crag, and upper and lower green-sand formations in the south of England. The existence of these fossil animal remains was first pointed out by Drs Mantel and Buckland, though it is to Professor Henslow that we are indebted for having called attention to their eminent agricultural value, and described the localities whence they may be most readily obtained. These remains consist of the fractured and rolled bones of sharks, gigantic sea-lizards, and whales, which at one period of our earth's history must have existed in myriads in our oceans and seas. Mixed with these bones are found many fish-teeth and shells of different species, and likewise immense numbers of rolled, water-worn pebbles, which at one period were imagined to be the fossilised excrements of the animals themselves, and were on this account called *coprolites* by Professor Henslow and others. Although this has since been proved a mistake, the name has been adopted and will probably be continued. These fossil bones, and so-called coprolites of the crag are found in enormous quantities on the coasts of Suffolk, Norfolk, and Essex, whence Mr Lawes of Rothamstead obtains nearly the whole of the material which he employs in the preparation of his well known "coprolite manure," or "Lawes' superphosphate." Already, it is believed, several thousands of tons of these fossils in one form or other are annually sold for manure, with a rapidly increasing demand. Those found in the crag formation are exceedingly hard, and require to be ground by powerful machinery, and dissolved in sulphuric acid to render the phosphate of lime available as manure. Fossils, though less abundant in the green-sand, can be reduced to the requisite fineness by simple machinery, and are then fit for agricultural purposes without any chemical preparation. They are found plentifully in the parish of Farnham, so long celebrated for the excellence and abundance of its hops, which are now discovered to be due to the presence in the soil of these fossil remains. The discovery of these *mines* of manure in various parts of our country has been made most seasonably, and may yet prove of immense national importance. When Liebig predicted that, "in the remains of an extinct animal world, England is to find the means of increasing her wealth in agricultural produce, as she has already found the great support of her manufacturing industry in fossil fuel," he was regarded by many as merely indulging a fine philosophic fancy; but enough has already been realised to convince the most sceptical of the importance of the data on which he founded his opinion. We have gleaned this information from an article "on the Phosphoric strata of the Chalk Formation," by Messrs Paine and May, in vol. ix. p. 56 of the *Journal of the Royal Agricultural Society of England;* and another in vol. xii. p. 91, by T. J. Herapath, on the "Fossil Bones and Pseudo-Coprolites of the Crag."

Fermented bones.

On mixing a quantity of bone-dust with its own bulk of mould or sand, and wetting the whole with the liquid which oozes from the dung-heap, violent fermentation immediately ensues, dissolving the bones, and making them more readily available for the nourishment of the turnip-crop. Many farmers are so satisfied with this preparation, that they dispense with the acid. This is not judicious, as the superphosphate of lime is a more valuable manure than bones dissolved by simple fermentation.

Bones as a top-dung for pasture land.

Bones are sometimes applied as a top-dressing to grass land with singular success. "This Cheshire practice consists in applying an extraordinary dose of bones to pasture-land. 'For pasture-land, especially the poorer kind,' says Mr Palin, 'there is nothing equal to bone-manure, either as regards the permanency of its effects, or the production of a sweet luxurious herbage, of which all cattle are fond. Many thousand acres of the poor clay soils have been covered with this manure during the last eight or ten years.' The average quantity used is about a ton and a half to the acre; it is therefore a landlord's improvement, on which 7 or 8 per cent. is generally paid. Boiled bones act as long as unboiled bones, retaining the phosphorus, though not so quickly, having lost the animal matter. Boiled bones (1845) cost L.3, 10s. per ton; the outlay then was five guineas per acre, sometimes L.7 or L.8. 'I have known,' says a correspondent, 'many instances where the annual value of our poorest clay-lands has been increased by an outlay of from L.7 to L.8 an acre, at least 300 per cent.; or, in other words, that the land has been much cheaper after this outlay at 30s., than in its native state at 10s. per acre; with the satisfaction of seeing a miserable covering of pink-grass, rushes, hen-gorse, and other noxious weeds exchanged for a most luxuriant herbage of wild clover, trefoil, and other succulent grasses.' Though much of the clover and trefoil may disappear in five or ten years (sometimes they last fifteen years), an excellent herbage remains. Draining, the writer adds, '*may be carried too far* where bones are used, for boned lands suffer by a dry summer. The land should be kept cool.' I have found the same thing on water-meadows. The freer the grass is growing, the more it suffers from drought; and this is natural, for a larger supply of sap is required. This writer adds, 'I have known many a poor, honest, but half-broken man raised from poverty to comparative independence, and many a sinking family saved from inevitable ruin, by the help of this wonderful manure.' Indeed, I believe land, after boning, will keep three cows where two fed before. As to this practice, however, caution is necessary. It seems to belong to cold clays for grass in Cheshire, though on such soil it would hardly answer elsewhere, even for turnips. A Cheshire landlord told me that he had tried it vainly for grass in Suffolk. I know no

Manures.

case of its success out of Cheshire, unless in the bordering counties, and have heard some cases of its failure even in those. It will not do, therefore, at all to adopt it hastily. We only know it to have succeeded about Cheshire, which is on the red marls geologically, and on the rainy side of the country, and must remember that it is a costly proceeding, striking in its success, but as yet circumscribed in its practice, and therefore in the proof of its efficacy."[1]

*Rape-Cake* reduced to powder forms an excellent manure for wheat and other crops. It is usually applied at the rate of from four to eight cwt. per acre. The cakes resulting after oil has been expressed from camelina, hemp, and cotton seeds, and from pistachio and castor-oil nuts, from beech, and other mast, all possess considerable value as manure.

All parts of the carcases of animals form valuable manure, and are now carefully used in that way whenever they are unfit for more important uses. The blood and other refuse from shambles and from fish-curers' yards, when mixed with earth and decomposed, make a valuable manure, and are eagerly sought after by farmers to whom such supplies are accessible. In Australia and South America it has long been the practice to slaughter immense numbers of sheep and cattle for the sake of their hides and tallow only, there being no market for them as beef and mutton. To obtain the whole tallow, the carcases are subjected to a process of boiling by steam and afterwards to pressure, and are then thrown aside in great piles. This dried flesh has recently been brought to this country and sold as a manure. A notice and analysis of it, by Dr Anderson, appears in the *Transactions of the Highland and Agricultural Society* for October 1850, p. 367.

The refuse from glue-works; the blubber and dregs from fish-oil; blood that has been used in the process of sugar-refining; the shavings and filings of horn and bones from various manufactures, and woollen rags, are all made available for manure.

*Night-soil* is a powerful manure; but owing to its offensive odour it has never been systematically used in Britain. Various plans are tried for obviating this objection, that most in repute at present being its mixture with charred peat. From the universal use of waterclosets in private dwellings, the great mass of this valuable fertilising matter now passes into sewers, and is carried off by streams and rivers, and is for the most part totally lost as a manure. When sewage water is used for irrigation, as in the neighbourhood of Edinburgh, it is to the night-soil dissolved in it that its astonishing effects in promoting the growth of grass are chiefly due. We have already expressed our views in regard to the use of it in this diluted form of sewage water. That mode of applying it is necessarily restricted to lands in the vicinity of towns. It is therefore much to be desired that a really effective process for preparing it for market in a dry, inodorous state, at a moderate price, and with its virtues unimpaired, should speedily be brought into general operation. The enormous and ever-increasing expenditure on guano, shows how unbounded will be the demand for it when it shall be thus available. The important progress that has recently been made towards the attainment of so desirable a result is shown in a paper by Professor Herapath in No. xxix. of the *Journal of the Royal Agricultural Society*, where he describes the process as carried on at Cardiff Gaol. These operations are well explained in the following letters, addressed by the governor of the gaol and the patentee, in reply to inquiries for further information, to the editor of the *North British Agriculturist* newspaper of 29th September 1852, from which we now quote:—

"*Cardiff Gaol, 20th September* 1852.

Mode of treating night-soil in Cardiff Gaol.

"Sir,—In reply to your letter on the subject of sewage manure, I beg first of all to state that the magistrates' principal object was to do away with the great nuisance arising from the drains emptying into a ditch, from which all the filth of the gaol was conveyed into a thickly populated part of the town.

"The expense of carrying on the drain to the sea was supposed to cost about £2000. This serious outlay induced the magistrates to apply to Mr Higgs, of 69 Lillington Street, Vauxhall, Westminster, who was in possession of a patent for deodorizing sewage, for plans, and the expense of converting the sewage into manure. The building, two sets of pipes (one for diverting the sewage into a large tank, the other for the water which passes from the tanks), sewage tanks, lime tanks, with a large pump, &c. for pumping the sewage into the operating tank, cost £200. The plan fully answers the purposes for which it was intended. The water passes off without any unpleasant smell. The sewage precipitates, and when dry enough it is moulded into bricks, dried and sold at 60s. per ton.

"The whole of the work being done by prisoners makes it all profit, except the lime used for condensing the effluvium. Being unable to furnish you with further particulars, I beg to refer you to Mr Higgs, who will give you every information on the subject. I am not aware that this plan has been tried in any other quarter. John B. Woods."

"69 *Lillington Street, Westminster, 25th Sept.* 1852.

"Sir,—In answer to your letter of the 22d inst., I beg to say it affords me much pleasure in communicating information to you, respecting my invention for collecting the contents of sewers, &c. and producing therefrom a concentrated and inodorous manure. This plan, which was patented in 1846, received the sanction of Parliament in the following session, by the incorporation of a company to carry it into operation in a portion of the metropolis, but which, owing to the commercial depression of that period, was not put into action; however, trial works were erected at Northumberland Wharf, Charing Cross, and carried on for the space of four months, which realized the most sanguine expectations which had been formed. These works were visited by the officers of the commissioners of sewage, and the secretary of the General Board of Health, who reported most favourably thereon; shortly after, the visiting justices of the county of Glamorgan, finding that the drainage of Cardiff Gaol was complained of, as being inimical to the healthy condition of a hamlet called New Town, through which it passed, resolved to try its efficacy; they therefore erected at Cardiff Gaol the works to which your letter refers. These were finished, and began to work on 25th October 1849, and have continued in operation ever since. That they have given satisfaction, you will see in a testimonial given by Walter Coffin, Esq., now M.P. for Cardiff.

"'As one of the visiting justices of the County Gaol at Cardiff, I am happy to be able to testify that Mr Higgs' method of disinfecting the sewage of the prison has been eminently successful, by removing the great evils attendant on improper drainage. The sewage thus disinfected becomes a portable and very powerful manure, as attested by the farmers who have tried it. (Signed) Walter Coffin.'

'*Cardiff*, 14*th August* 1851.

"Mr Wood also writes:—'Having watched the progress of Mr Higgs' patent for disinfecting sewage, and turning the same to a profitable purpose, I beg to express my entire concurrence in Mr Coffin's statement. (Signed) John B. Woods,
'Gov. of the County Gaol at Cardiff.'

"Before I give you a brief detail of the method, I beg to say that it is not intended to disinfect or deodorize matter which has already passed into a state of decomposition, such as the contents of old privies or cesspools, but it is intended to precipitate and collect the contents of current sewers, and to prevent that decomposition, so detrimental to the healthy state of the atmosphere, wherever it may take place.

"You will by this perceive that it is intended to preserve

[1] Article by Mr Pusey. See *Journal of Royal Society of England*, vol. xi. p. 409.

Manures.

the manure in its integrity, till decomposition takes place in the soil, where its fertilising effects are very powerful.

"The *modus operandi* is as follows:—

"The sewage matter intended to be operated upon is received into one or more tanks, as the case may require; at the same time a stream of milk-of-lime is caused to flow in and mix with the sewage—this, at once, as soon as the tank is full, and the fluid at rest, causes the precipitation of all the organic matter with the phosphates, urates, sulphates, &c. contained in the fluid, with the expulsion of the ready formed ammonia, if there be any. This altogether, with any other effluvium that may be disengaged, escapes by a pipe (the tank being closely covered), and passes through a convoluted chamber, where it is fixed by chemical agents, so that not an atom is lost. After the matter in the tank has been suffered to rest for about an hour, the supernatant water may be let off, quite clear and inodorous, and the pulpy manure, in another hour, dried by an apparatus and rendered fit for market.

"This may be accomplished at something less than £1 per ton, and you see it fetches at Cardiff £3 per ton; and from its effects it is calculated to fetch much more, for its efficiency is quite equal to the best guano.

"The agent by which this is in most cases accomplished, lime, is well known to be a most excellent fertiliser, as has been so well shown by Professor Johnston in his work on that subject, so that in this method nothing is added to the manure of a worthless or mischievous character; but the fertilising principles of the sewage, including its nitrogenous matter, are so well fixed, that last year Captain Buller, an excellent agriculturist of Devonshire, systematically tried it against guano, at £9, 10s. per ton, and pronounced in its favour, notwithstanding that the sewage had been collected as long ago as 1847.

"W. Higgs."

If the premium of L.1000 and the Gold Medal of the Society, recently offered by the Council of the Royal Agricultural Society to the discoverer of a manure equal to Peruvian Guano, to be sold at L.5 per ton, and procurable in unlimited quantities, is won at all, it seems likely that the material will be obtained from the contents of our sewers.

*Sea-weed.*—Along our sea-board large supplies of valuable manure are obtained in the shape of drifted sea-weed. This is either applied as a top-dressing to grass and clover, ploughed in with a light furrow, for various crops, or mixed in dung-heaps. It requires to be used in large quantities per acre—from 40 to 60 loads—and is evanescent in its effects. Grain grown on land manured with sea-weed, is generally of fine quality and is in repute as seed corn.

*Crops of Buckwheat, Rape, Vetches,* and *Mustard,* are sometimes ploughed in, while in a green, succulent state, to enrich the land. It is however more usual to fold sheep on such crops, and so to get the benefit of them as forage, as well as manure to the land. The leaves of turnips are frequently ploughed in after removing the bulbs, and have a powerful fertilising effect.

*Lime.*—Besides manures of an animal and vegetable origin, various mineral substances are used for this purpose. The most important and extensively used of these is lime. In the drier parts of England it is not held in much esteem, whereas in the western and northern counties and in Scotland, its use is considered indispensable to good farming. Experienced farmers in Berwickshire consider it desirable to lime the land every 12 years, at the rate of from 120 to 200 bushels of the unslacked lime per acre. It is found especially beneficial in the reclaiming of moory and boggy lands, on which neither green nor grain crops thrive until it has been applied to them. Its use is found to improve the quality of grain, and to cause it in some cases to ripen earlier. It facilitates the cleaning of land; certain weeds disappearing altogether for a time after a dressing of lime. It is the only known specific for the disease in turnips called "fingers and toes," on which account alone it is frequently used in circumstances which would otherwise render such an outlay unwarrantable. The practice, still frequent, of tenants at the beginning of a 19 years' lease, liming their whole farm at a cost per acre of from L.3 to L.5, proves conclusively the high estimation in which this manure is held. The belief—in which we fully concur—is however gaining ground, that moderate and frequent applications are preferable to these heavy doses at lengthened periods.

Carbonate of lime.

Modes of application.

When bare fallowing was in use, it was commonly towards the close of that process that lime was applied. Having been carted home and laid down in large heaps, it was, when slaked, spread evenly upon the surface and covered in by a light furrow. It is now frequently spread upon the autumn furrow preparatory to root crops, and worked in by harrowing or grubbing, and sometimes by throwing the land into shallow ridglets. Another method much used, is to form it into compost with decayed quickens, parings from road-sides, and margins of fields, &c. which, after thorough intermixture by frequent turnings, is spread even evenly upon in grass. A cheap and effectual way of getting a dressing of such compost thoroughly comminuted and incorporated with the surface soil, is to fold sheep upon it, and feed them there with turnips for a few days. The value of such compost is much enhanced by mixing common salt with the lime and earth at the rate of *one part* of salt by measure to *two parts* of lime. A mixture of these two substances in these proportions prepared under cover, and applied in a powdery state, is much approved as a spring top-dressing for corn-crops on light soils. In whatever way lime is applied, it is important to remember that the carbonic acid, which has been expelled from it by subjecting it in the kiln to a red heat, is quickly regained from the atmosphere, to which therefore it should be as little exposed as possible before applying it to the land. A drenching from heavy rain after it is slaked is also fatal to its usefulness. Careful farmers therefore guard against these evils by laying on lime as soon as it is slaked; or when delay is unavoidable, by coating these heaps with earth, or thatching them with straw. In order to reap the full benefit of a dressing of lime it must be so applied as, while thoroughly incorporated with the soil, to be kept near the surface. This is more particularly to be attended to in laying down land to pasture. This fact is so well illustrated by an example quoted in the last edition of this work that we here repeat it.

"A few years after 1754," says Mr Dawson, "having a considerable extent of outfield land in fallow, which I wished to lime previous to its being laid down to pasture, and finding that I could not obtain a sufficient quantity of lime for the whole in proper time, I was induced, from observing the effects of fine loam upon the surface of similar soil, even when covered with bent, to try a small quantity of lime on the surface of this fallow, instead of a larger quantity ploughed down in the usual manner. Accordingly, in the autumn, about twenty acres of it were well harrowed in, and then about fifty-six Winchester bushels only, of unslaked lime, were, after being slaked, carefully spread upon each English acre, and immediately well harrowed in. As many pieces of the lime, which had not been fully slaked at first, were gradually reduced to powder by the dews and moisture of the earth,—to mix these with the soil, the land was again well harrowed in three or four days thereafter. This land was sown in the spring with oats, with white and red clover and rye-grass seeds, and well harrowed without being ploughed again. The crop of oats was good, the plants of grass sufficiently numerous and healthy; and they formed a very fine pasture, which continued good until ploughed some years after for corn.

"About twelve years afterwards I took a lease of the hilly farm of Grubbet, many parts of which, though of an earthy mould tolerably deep, were too steep and elevated to be kept in tillage. As these lands had been much exhausted by cropping, and were full of couch-grass, to destroy that and procure a cover of fine grass, I fallowed them, and laid on the same

Manures.

quantity of lime per acre, then harrowed and sowed oats and grass-seeds in the spring, exactly as in the last-mentioned experiment. The oats were a full crop, and the plants of grass abundant. Several of these fields have been now above thirty years in pasture, and are still producing white clover and other fine grasses: no bent or fog has yet appeared upon them. It deserves particular notice, that more than *treble* the quantity of lime was laid upon fields adjoining of a similar soil, but which being fitter for occasional tillage, upon them the lime was ploughed in. These fields were also sown with oats and grass-seeds. The latter throve well, and gave a fine pasture the first year; but afterwards the bent spread so fast, that in three years there was more of it than of the finer grasses."

The conclusions which Mr Dawson draws from his extensive practice in the use of lime and dung, deserve the attention of all cultivators of similar land.

Conclusions as to the effects of lime and dung.

"1. That animal dung dropped upon coarse benty pastures produces little or no improvement upon them; and that, even when sheep or cattle are confined to a small space, as in the case of folding, their dung ceases to produce any beneficial effect after a few years, whether the land is continued in pasture or brought under the plough.

"2. That even when land of this description is well fallowed and dunged, but not limed, though the dung augments the produce of the subsequent crop of grain, and of grass also for two or three years, that thereafter its effects are no longer discernible either upon the one or the other.

"3. That when this land is limed, if the lime is kept upon the surface of the soil, or well mixed with it, and then laid down to pasture, the finer grasses continue in possession of the soil, even in elevated and exposed situations, for a great many years, to the exclusion of bent and fog. In the case of Grubbet-hills, it was observed, that more than thirty years have now elapsed. Besides this, the dung of the animals pastured upon such land adds every year to the luxuriance, and improves the quality of the pasture, and augments the productive powers of the soil when afterwards ploughed for grain; thus producing, upon a benty outfield soil, effects similar to what are experienced when rich infield lands have been long in pasture, and which are thereby more and more enriched.

"4. That when a large quantity of lime is laid on such land, and ploughed down deep, the same effects will not be produced, whether in respect to the permanent fineness of the pasture, its gradual amelioration by the dung of the animals depastured on it, or its fertility when afterwards in tillage. On the contrary, unless the surface is fully mixed with lime, the coarse grasses will in a few years regain possession of the soil, and the dung thereafter deposited by cattle will not enrich the land for subsequent tillage.

"*Lastly*, It also appears from what has been stated, that the four-shift husbandry is only proper for very rich land, or in situations where there is a full command of dung; that by far the greatest part of the land of this country requires to be continued in grass two, three, four, or more years, according to its natural poverty; that the objection made to this, viz. that the coarse grasses in a few years usurp possession of the soil, must be owing to the surface soil not being sufficiently mixed with lime, the lime having been covered too deep by the plough." (*Farmer's Magazine*, vol. xiii. p. 69.)

Marl.

Our remarks hitherto have had reference to carbonate of lime in that form of it to which the term *lime* is exclusively applied by farmers. But there are other substances frequently applied to land which owe their value chiefly to the presence of this mineral. The most important of these is marl, which is a mixture of carbonate of lime with clay, or with clay and sand, and other compounds. When this substance is found in the proximity of, or lying under, sandy or peaty soils, its application in considerable doses is attended with the very best effects. The fen lands of England, the mosses of Lancashire, and sandy soils in Norfolk and elsewhere, have been immensely improved in this way. In Lancashire, marl is carried on the mosses by means of portable railways at the rate of 150 tons, and at a cost of about L.3 per acre. In the fens long trenches are dug, and the subjacent marl is thrown out and spread on either side at an expense of 54s. per acre. By this process, often repeated, of *claying* or *marling*, as it is variously called, the appearance and character of the fen lands have been totally changed; excellent wheat being now raised, where formerly only very inferior oats were produced. As the composition both of peat and of clay marl varies exceedingly, it is always prudent, either by limited experiment, or chemical analysis of both substances, to ascertain the effect of their admixture. Lime is always present in those cases which prove most successful; but an overdose does harm.

*Shell-Marl.*—Under some mosses and fresh water lakes extensive deposits of shell-marl are frequently found. It contains a larger per-centage of lime than clay-marl, and must be applied more sparingly.

*Chalk.*—Throughout the extensive chalk districts of England, the practice of spreading this substance over the surface of the land, has prevailed from the remotest times. In the case of the Lincolnshire Wolds, once as celebrated for desolate barrenness as they now are of high culture and smiling fertility, chalking was one important means of bringing about this wonderful improvement, as it still is in maintaining it. "The soil being but a few inches in depth, and often containing a large proportion of flints, naturally possesses very little fertility—often being a light sand, not strong enough naturally to grow turnips—so that the farmers were at first obliged to *make* a soil, and must now maintain its new-born productiveness. The three principal means by which this is done, are the processes of *chalking*, and *boning*, and *manuring with sheep*. A dressing of 80 or 100 cubic yards per acre of chalk is spread upon the land, and then a crop of barley is obtained, if possible, being sown with seeds for grazing. The seeds are grazed with sheep two years, the sheep being at the same time fed with oil-cake; and then the land will be capable of producing a fine crop of oats. Bones are also used frequently for the barley crop, and when they first came into use were thrown upon the land in a chopped state, neither broken nor crushed, and as much as 40 or even 50 bushels per acre. The boning and sheep-feeding are in constant operation, but chalking is required only at intervals of a few years. On the western side of the Wold district, wherever the chalk adjoins the white or blue marl, an extensive application of it is made to the surface. Thus immense quantities of earth and stone have been added by manual labour and horse-carriage to the thin covering of original soil; and, besides this, the soil is being continually deepened by deep ploughing, the chalk fragments thus brought to the surface crumbling into mould."[1]

In Dorsetshire "it is usual to chalk the land once in twenty years, the sour description of soil being that to which it is found most advantageous to apply it. The chalk is dug out of pits in the field to which it is applied, and it is laid on sometimes with barrows, but chiefly with the aid of donkeys. The first method costs 40s. an acre, the last 35s. when hired donkeys are used; 20s. to 25s. where the donkeys are the property of the farmer. The chalk is laid on in large lumps, which soon break down by the action of frost and exposure to the weather. Chalk is occasionally burnt and applied as lime, in which state it is preferred by many farmers, notwithstanding the additional cost of the burning."[2]

*Shell-Sand and Limestone Gravel.*—On the western shores

Manures.

of Great Britain and Ireland are found great quantities of sand mixed with sea-shells in minute fragments. This calcareous sand is carried inland considerable distances and applied to the land as lime is elsewhere. Limestone gravel is also found in various places and used in the same way.

*Sulphate of Lime or Gypsum* is considered an excellent top-dressing for clover and kindred plants. It is thought by some, that the failure of red clover is to be accounted for, by the repeated crops of that plant having exhausted the gypsum in the soil. Its application has been followed by favourable results in some cases, but has yet quite failed in others. It is applied in a powdered state at the rate of *two* or *three* cwt. per acre when the plants are moist with rain or dew.

*Burnt Clay.*—Thirty years ago, burnt clay was brought much into notice as a manure, and tried in various parts of the country, but again fell into disuse. It is now, however, more extensively and systematically practised than ever. Frequent reference to the practice is to be found in the volumes of the *Journal of the Royal Agricultural Society of England.* This burning of clay is accomplished in several ways. Sometimes it is burnt in large heaps or clamps containing from 80 to 100 cart-loads. A fire being kindled with some faggots or brushwood, which is covered up with the clay, taking care not to let the fire break out at any point, more fuel of the kind mentioned, or dross of coals, is added as required, and more clay heaped on. A fierce fire must be avoided, as that would make the clay into brickbats. A low, smothered combustion is what is required; and to maintain this a good deal of skill and close watching on the part of the workman is necessary. A rude kiln is sometimes used for the same purpose. Either of these plans is suitable where the ashes are wanted at a homestead for absorbing liquid manure, &c.; but for merely spreading over the land, that called clod-burning is preferable, and is thus described in volume viii. page 78, of the *Royal Agricultural Society's Journal*:—" Roll and harrow, in dry weather, till the majority of clods are about the size of a large walnut; nothing so good as the clod-crusher to forward this operation: when perfectly dry, collect them into rows about six yards apart, with iron-teethed rakes; take a quarter of a whin faggot, or less, according to size, previously cut into lengths by a man with an axe; place these pieces about four yards apart in the rows, cover them with clods, putting the finest mould upon the top of the heap, to prevent the fire too quickly escaping; observe the wind, and leave an opening accordingly; having set fire to a long branch of whin, run from opening to opening till two or three rows are lighted, secure these, and then put fire to others; keeping a man or two behind to attend to the fires and earthing up till the quantity desired may be burned, which will generally take four or five hours, say from 25 to 35 loads per acre of 30 bushels per load.

" This work is often put out to a gang of men at about 10s. per acre for labour, and the whins cost 4s. 6d. per acre, not including the carting.

" When the heaps are cold, spread and plough in. The great advantage of burning clods in these small heaps in preference to a large one, is the saving of expense in collecting and spreading; there is much less red brick earth, and more black and charred; no horses or carts moving on the land whilst burning, and a large field may be all burned in a day or two, therefore less liable to be delayed by wet weather. In the heavy land part of Suffolk, the farmers purchase whins from the light land occupiers, and often cart them a distance of fourteen or sixteen miles, when there is no work pressing on the farm. These are stacked up and secured by thatching with straw, that they may be dry and fit for use when required. Bean straw is the next best fuel to whins or furze, and it is astonishing to see how small a quantity will burn the clods, if they are of the proper size and dry. Observe, if the soil is at all inclined to sand, it will not burn so well. I will here mention, that I often sift and store up a few loads of the best blackened earth to drill with my turnips, instead of buying artificial manure, and find it answers remarkably well, and assists in maintaining the position that a heavy land farm in Suffolk can be farmed in the first rate style without foreign ingredients."

Manures.

Burnt clay.

Its value as an absorbent of liquid manure.

Burnt clay is an admirable vehicle for absorbing liquid manure. A layer of it in the bottom of cattle boxes does good service, at once in economising manure, and yielding to the cattle a drier bed than they would otherwise have until the litter has accumulated to some depth. Valuable results have also been obtained by using it for strewing over the floors of poultry-houses, and especially of pens in which sheep are fed under cover. In the latter case, it is mixed with the excrements of the sheep as they patter over it, and forms a substance not unlike guano, nor much inferior to it as a manure. As an application to sandy or chalky soils, it is invaluable. It is mainly by this use of burnt clay, in combination with fattening of sheep under cover, that Mr Randell of Chadbury has so astonishingly increased the productiveness of his naturally poor clay soil. A Berwickshire proprietor, himself a practical farmer, who visited Mr Randell's farm in the summer of 1852, thus writes:—" I have visited most of the best managed farms in England, at least those that have so much of late been brought under general notice; but without exception, I never saw land in the splendid condition his is in. The beauty of the system lies in the cheap method he has imparted to it this fertility, and in the manner in which he keeps it up. A large part of the farm consisted, fourteen years ago, of poor clay, and was valued to him at his entry at 7s. 6d. per acre. It is now bearing magnificent crops of all kinds, the wheat being estimated to yield from 6 to 7 quarters per acre.

" Mechi has enriched Tiptree-heath, it is true; but then it is effected at a cost that will make it impossible for him to be repaid. Mr Randell, on the other hand, has adopted a course that is nearly self-supporting, his only cost being the preparation of the clay. The great secret of his success lies in his mode of using it; and as I never heard of a similar process, I will briefly explain to you how it is done:—His heavy land not permitting him to consume the turnip and mangel crops in the ground, he carts them home, and feeds his sheep in large sheds. They do not stand on boards or straw, but on the burnt clay, which affords them a beautiful dry bed; and whenever it gets the least damp or dirty, a fresh coating is put under them. The mound rises in height; and in February, when the shearlings are sold (for the sheep are only then twelve months old), the mass is from 7 to 8 feet deep. He was shearing his lambs when I was there, as he considers they thrive much better in the sheds without their fleeces. They are half-bred Shropshire Downs; and at the age I mention, attain the great weight of 24 lb. per quarter.

" I walked through the sheds, but of course they were then empty. I saw the enormous quantity of what he called his ' home-made guano,' the smell from it strongly indicating the ammonia it contained. He had sown his turnips, and other green-crops with it, and what remained he used for the wheat in autumn. He assured me he had often tested it with other manures, and always found 10 tons of the compound quite outstrip 4 cwt. of guano, when they were applied to an acre of land separately. Burned clay I never saw used before in this manner, and I felt very much interested in the plan he pursued."

*Charred Peat* has been excessively extolled for its value as a manure, both when applied alone, and still more in com-

Manures.

bination with night-soil, sewage water, and similar matters, which it dries and deodorises. So great were the expectations of an enormous demand for it, and of the benefits to result to Ireland by thus disposing of her bogs, that a royal charter was granted to a company by whom its manufactures has been commenced on an imposing scale. This charcoal is doubtless a useful substance; but Dr Anderson has recently proved that peat, merely dried, is a better absorber and retainer of ammonia than after it is charred. There seems much risk, therefore, of this peat-charcoal sharing the fate of so many other schemes for benefiting Ireland.

*Soot* has long been in estimation as an excellent top-dressing for cereal crops in the early stage of their growth, and for grasses and forage plants. It is applied at the rate of 15 to 30 bushels per acre. On light soils the addition of 8 or 10 bushels of salt to the above quantity of soot is said to increase materially its good effect. This mixture trenched, or deeply ploughed in, is also recommended as one of the most powerful of all manures for carrots.

In *London Labour and the London Poor* we find the following statistics as to metropolitan soot:—

| | Bush. of Soot per annum. |
|---|---|
| "53,840 houses, at a yearly rental above £50, producing six bushels of soot each per annum, | 323,040 |
| 90,002 houses, at a yearly rental above £30 and below £50, producing five bushels of soot each per annum.................................... | 450,010 |
| 163,880 houses, at a yearly rental below £30, producing two bushels of soot each per annum, | 337,760 |
| Total number of bushels of soot annually produced throughout London, | 1,100,810 |

The price of soot per bushel is but 5d., and sometimes 4½d., but 5d. may be taken as an average. Now, 1,000,000 bushels of soot at 5d., will be found to yield £20,833, 6s. 8d. per annum."[1]

*Salt.*—Muriate of soda or common salt has often been commended as a valuable manure, but has never been used in this way with such uniform success as to induce a general recourse to it. We have already spoken of it as forming a useful compound with lime and earth. It can also be used beneficially for the destruction of slugs, for which purpose it must be sown over the surface, at the rate of *four* or *five* bushels per acre, early in the morning, or on mild, moist days, when they are seen to be abroad. It is used also to destroy grubs and wireworm, for which purpose it is sown in considerable quantity on grass land, some time before it is ploughed up. It can be used safely on light soils, but when clay predominates, it causes a hurtful wetness, and subsequent incrustation of the surface. Its application in its unmixed state as a manure, is at best of doubtful benefit; but in combination with lime, soot, nitrate of soda, and perhaps also superphosphate of lime, it appears to exert a beneficial influence.

*Cubic Saltpetre*, or *Nitrate of Soda*, has now become one of our staple manures. The fertilising power of common saltpetre or nitrate of potass has been known from the earliest times, but its high price has hitherto hindered its use as a manure, except in the form in which it is obtained as refuse from the gunpowder mills. The cubic nitre is brought from Peru, where there are inexhaustible supplies of it. The principal deposits of nitrate of soda are in the plain of Tamarugal, at a distance of 18 miles from the coast. The beds are sometimes 7 or 8 feet in thickness, and from these it is quarried with perfect ease. It is not found in a perfectly pure state, but contains a mixture of several substances, chiefly common salt. To fit it for certain uses in the arts it is subjected to a process of purification by boiling and evaporation. As no fuel is to be found in that arid country, English coals are used, which are conveyed from the coast to the works on the back of mules, and the purified nitrate brought back in the same manner. As nitrate of soda is now invariably mixed with twice its weight of common salt before being used as a top-dressing for grain-crops, the purifying process seems altogether a redundancy, so far as its agricultural use is concerned. Were it brought to us just as it is quarried, and were it conveyed to the coast in wheel-carriages by a good road or railway, instead of miserable back-loads by mules, there seems no reason why we should not have it in abundant supplies, and at a third of the price which we have hitherto paid, viz., at from L.6 to L.7, instead of from L.16 to L.20 per ton. As cubic nitre and guano contains very nearly the same per-centage of nitrogen (the element to which the fertilising power of all manures is mainly due), it may seem surprising that the former should ever be used in preference to the latter. In practice, however, it is found that when applied as a top-dressing in spring, the former frequently yields a better profit than the latter; and hence the importance to farmers of getting it at a more reasonable price. Nitrate of soda is used as a manure for grain and forage crops. It is now extensively used in Norfolk, and elsewhere, as a top-dressing for wheat. For this purpose it is applied at the rate of 84 lb. per acre, in combination with 2 cwt. of salt. The nitre and salt are thoroughly mixed, and carefully sown, by hand, in two or three equal portions, at intervals of several weeks, beginning early in March, and finishing by the third week in April. If nitre alone is used, it has a tendency to produce over-luxuriance, and to render the crop liable to lodging and mildew. But the salt is found to correct this over-luxuriance, and a profitable increase of grain is thus obtained. Mr Pusey[2] informs us that an application of 42 lb. of nitrate of soda, and 84 lb. of salt per acre, applied by him to ten acres of barley that had been injured by frost, had such an effect upon the crop, that he had *seven* bushels more grain per acre, and of better quality, than on part that was left undressed for comparison. These seven bushels per acre were attained by an outlay of 6s. 4d. only. This nitre is also applied with advantage to forage crops. Mr Hope, Fenton Barns, East Lothian, states that he finds the use of it as a top-dressing to clover, at the rate of one cwt. of nitrate and two of guano per acre, profitable. Its beneficial effects are most apparent when it is applied to light and sterile soils, or to such as have been exhausted by excessive cropping.

*Artificial Manures.*—Besides those substances, the most important of which we have now enumerated, which are available as manure in their natural state, there are a variety of chemical products, such as salts of ammonia, potash, and soda, copperas, sulphuric and muriatic acid, &c. which, in combination with lime, guano, night-soil, and other substances, are employed in the preparation of manures, with a special view to the requirements of particular crops. In some cases these preparations have been eminently successful, in others but doubtfully so. Many failures are probably due to the spuriousness of the article made use of; as it is known that enormous quantities of worthless rubbish have, of late years, been sold to farmers, under high-sounding names, and at high prices, as special manures. We would recommend to those who desire information regarding the preparation and use of such compounds, to study the article on Agricultural Chemistry, by Mr Lawes of Rothamstead, in the *Journal of the Royal Agricultural Society of England*; the accounts of

[1] *Farmer's Magazine* for March 1852, p. 254.

[2] *Journal of Royal Agricultural Society*, vol. xiii. p. 349.

Grain Crops.

experiments, with special manures in the *Transactions of the Highland and Agricultural Society of Scotland;* articles on these topics in *Morton's Cyclopedia;* and that by Dr Anderson in the present work. Those who wish to apply such artificial compounds to their crops, will do well to purchase the ingredients where they are likely to get them genuine, and to mix and prepare them for themselves.

In applying these concentrated manures, those only of a slowly operating character should be used in autumn or winter, and at that season should invariably be mixed with the soil. Those in which ammonia abounds should, in spring, also be mixed with the soil when sowing the crops to which they are applied. When used for top-dressing growing crops, they should not be applied until spring-growth has commenced, and only in wet weather.

## CHAPTER VI.

### GRAIN CROPS.

Pursuing the plan announced at the outset, we have now to speak of field crops, and shall begin with the cereal grasses, or white-corn crops, as they are usually called by farmers.

*Wheat.*—It is unnecessary to dwell upon the value of this grain to the farmer and to the community. It constitutes emphatically our bread-corn—our staff of life. While its increased consumption is on the one hand an indication of an improved style of living among the general population, its extended culture points, on the other, to an improving agriculture, as it is only on soils naturally fertile, or that have been made so by good farming, that it can be grown with success. Wheat is sown both in autumn and spring, from which circumstance attempts have been made to classify its varieties, by ranging them under these two general heads. This distinction can only serve to mislead; for while it is true that there are varieties respectively best adapted for autumn and spring sowing, it is also true that a majority of the kinds most esteemed in Britain admit of being sown at either season, and in practice are actually so treated. It is not our intention to present a list of the varieties of wheat cultivated in this country. These are very numerous already, and are constantly being augmented by the accidental discovery of new varieties, or by cross-impregnation, artificially brought about for this purpose. The kinds at present in greatest repute in Scotland are the hardier, white wheats; among which Hunter's white still retains the first place. There are many kinds which, in favourable seasons, produce a finer sample: but its hardiness, productiveness, and excellent milling qualities, render it a general favourite both with farmers and millers. Its most marked characteristic is, that in rubbing out a single ear, part of the grains are found to be opaque and white, and others flinty, and reddish coloured, as if two kinds of wheat had been mixed together. Selections from Hunter's wheat have been made from time to time, and have obtained a measure of celebrity under various local names. The most esteemed of these is the Hopeton wheat. On very rich soils, both of these varieties have the fault of producing too much straw, and of being thereby liable to lodge. Hence, several new kinds with stiffer straw, and consequent lessened liability to this disaster, are now in request in situations where this evil is apprehended.

Varieties of wheat.

*Fenton Wheat*, possessing this quality in an eminent degree, and being at the same time very productive, and of fair quality, is at present extensively cultivated. It has the peculiarity of producing stems of unequal height from the same root, which gives a crop of it an unpromising appearance, but has perhaps to do with its productiveness. The red-straw-white and Piper's thick-set, are in estimation for the same properties as the Fenton. Piper's is said to be shortest and stiffest strawed wheat in cultivation. It is a yellow-grained and rather coarse variety, but exceedingly productive. It has recently been introduced into Scotland under the name of Protection Wheat. The red-chaff white is productive, and yields grain of beautiful quality, but it requires good seasons, as it sheds its seeds easily and sprouts quickly in damp weather. The Chiddam, pearl, white Kent, and Talavera have each their admirers, and are all good sorts in favourable seasons; but in Scotland, at least, their culture is attended with greater risk than the kinds previously named; they require frequent change of seed from a sunnier climate, and are only adapted for dry and fertile soils with a good exposure. As red wheats usually sell at from 2s. to 4s. less per quarter than white wheats of similar quality, they are less grown than heretofore. But, being considered more hardy and less liable to mildew than the finer white wheats, they are still grown in soils more or less adapted for them. Some of these red wheats are, however, so productive that they are preferred in the best cultivated districts of England. Spalding's Prolific holds a first place among these; being truly prolific, and producing grain of good quality. In Scotland, it shews a tendency to produce a rough quality of grain. The Northumberland red and the golden creeping are there in estimation; the former being well adapted for spring sowing, and the latter for poor soils and exposed situations. A red bearded variety, usually called April wheat, from its prospering most when sown in that month, is sometimes grown with advantage after turnips, when the season is too advanced for other sorts; but it seems only doubtfully entitled to a preference over barley in such circumstances. The list now given could easily be extended; but it comprises the best varieties at present in use, and such as are suited to the most diversified soils, seasons, and situations, in which wheat can be grown in this country.

Red wheats.

In regard to all of them it is advantageous to have recourse to frequent change of seed, and in doing this to give the preference to that which comes from a soil and climate better and earlier than those of the locality in which it is to be sown. Every farmer will find it worth his while to be at pains to find out from whence he can obtain a change of seed that takes well with his own farm; and having done so to hold to that, and even to induce his correspondent to grow such sorts as he prefers, although he should have to pay him an extra price for doing so. An experienced farmer once remarked to the writer, that by changing his seed he got it for nothing; that is, his crop was more abundant by *at least* the quantity sown, from the single circumstance of a suitable change of seed. In fixing upon the kind of wheat which he is to sow, the farmer will do well to look rather to productiveness than to fine quality. For however it may gratify his ambition to shew the heaviest and prettiest sample in the market, and to obtain the highest price of the day, no excellence of quality can compensate for a deficiency of even a few bushels per acre in the yield. It is of importance too, to have seed-corn free from the seeds of weeds, and from other grains, and to be true of its kind. Farmers who are systematically careful in these respects, frequently obtain an extra price for their produce, by selling it for seed-corn to others; and even millers give a preference to such clean samples. But there are seeds which no amount of care or accuracy in dressing can remove from seed-corn—viz., those of certain parasitical fungi, which must be got rid of by a different process. The havoc caused to wheat crops by Bunt, Black-ball, or Pepper-brand (*Uredo caries* or *Tilletia caries*) before the discovery of the mode of preventing it by steeping the seed-corn in some acrid or caustic bath, was often ruinous. The plan at first most usually adopted

Advantage of a change of seed.

Steep or bath for seed-wheat

Grain Crops.

was to immerse the seed-wheat in stale chamber-lie, and afterwards to dry it by mixture with quick-lime. This pickle, as it is called, is usually efficacious; but the lime vexes the eyes, and excoriates the hands and face of the sower, or clogs the hopper of the sowing machine, and has therefore been superseded by other substances. Blue vitriol (sulphate of copper) is as good as anything for this purpose, and is used in the following manner. A solution is prepared by dissolving powdered sulphate of copper in water, at the rate of *two* ounces to a pint for each bushel of wheat. The grain is emptied upon a floor; a little of it is shovelled to one side by one person, while another sprinkles the solution over it, and this process is continued until the whole quantity is gone over. The heap is then turned repeatedly by two persons working with shovels opposite to each other. After lying for a few minutes, the grain absorbs the moisture, and is ready for sowing either by hand or machine. The season for wheat-sowing extends from September to April, but ordinarily that succeeds best which is committed to the ground during October and November. When summer-fallows exist, the first sowings are usually made on them. It is desirable that the land neither be wet nor very dry when this takes place, so that the precise time of sowing is determined by the weather; but it is well to proceed as soon after 1st October as the land is moist enough to insure a regular germination of the seed.

Time of sowing.

Sowing on clover lays.

Over a large portion of England, wheat is the crop usually sown after clover or one year's "seeds." In such cases the land is ploughed in the end of September, immediately harrowed, and wheat sown upon it by a drilling machine. On loose soils the land-presser is frequently used to consolidate the soil and to form a channel for the seed, which in such cases comes up in rows, although sown broad-cast. It is more usual, however, first to level the pressed furrows by harrowing, and then to use the drill; by means of which, various portable manures are frequently deposited along with the seed-corn. The sowing of wheat after clover, or "seeds," as now described, is rarely practised in Scotland, where it so invariably fails as to show that it is unsuited to our northern climate. It is here not unusual, however, to plough up such land in July or August, and to prepare it for wheat-sowing by what is called *rag-fallowing*. After the first ploughing, the land is harrowed lengthwise, so as to break and level the surface of the furrows and close the interstices without tearing up or exposing any green sward. It is then allowed to lie for ten or fourteen days to allow the herbage to die, which it soon does at this season when light is thus excluded from it. A cross-ploughing is next given, followed by repeated grubbings, harrowing, and rollings, after which it is treated in all respects as a summer fallow.

Rag-fallowing.

The fallow and clover leas being disposed of, the land from which potatoes, beans, peas, or vetches, have been cleared off will next demand attention. When these crops have been carefully horse and hand hoed, all that is required is to clear off the haulm, to plough and sow. If the land is not clean, recourse must be had to a short fallowing process, before sowing wheat. For this purpose the surface is loosened by the grubber, the weeds harrowed out and raked off, after which the land is ploughed and sown. On soils well adapted for the growth of beans and wheat, viz., those in which clay predominates, any lengthened process of autumn cultivation is necessarily attended with great hazard of being caught by rain, to the loss of seed-time altogether. Every pains should therefore be taken to have the land so cleaned before-hand, that these unseasonable efforts may be dispensed with; and to have the sowing and harrowing to follow so closely upon the ploughing, as to diminish to the utmost the risk of hindrance from wet weather. As the crops of turnips, mangel, or carrots arrive at maturity and are either removed to the store-heap or consumed by sheep where they grow, successive sowings of wheat can be made as the ploughing is accomplished, and as the weather permits. It is to be noted, however, that it is only on soils naturally dry, or made so by thorough draining, and which are also clean, and in a high state of fertility, that wheat-sowing can be continued with advantage during the months of December and January. If the whole of these conditions do not obtain, it is wiser to refrain until February or March. When these late winter sowings are made, it is of especial importance to sow close up to the ploughs daily, as a very slight fall of rain will, at this season, unfit the land for bearing the harrows. This sowing and harrowing, in detail, is the more easily managed, that in the circumstances cross-harrowing is neither necessary nor expedient. Under the most favourable conditions as to weather and drainage, soils with even a slight admixture of clay in their composition will at this season plough up somewhat clammy, so that cross-harrowing pulls the furrows too much about, and exposes the seed, instead of covering it more perfectly. Two double tines of the harrows *lengthwise*, is as much as should be attempted at this season.

Sowing after green crops.

Spring wheat.

The sowing of spring-wheat is only expedient on dry and fertile soils with a good exposure. Unless the whole conditions are favourable, there is much risk of spring-sown wheat being too late to get properly ripened, or well harvested. On the dry and fertile soils in the valley of the Tweed, where the entire fallow break is sown with turnips, and where consequently it is difficult to get a large breadth cleared in time for sowing wheat in autumn, it is the practice to sow it largely in February and March, and frequently with good success. Many judicious farmers are, however, of opinion that, taking the average of a twenty years' lease, barley is a more remunerative crop than spring-sown wheat, even under circumstances most favourable to the latter. When it is resolved to try it, a very full allowance of seed should be given—not less than *three* bushels per acre, and $3\frac{1}{2}$ will often be better. If the plants have room they will tiller; and thus the ripening of the crop is retarded, the risk of mildew increased, and the quality of the grain deteriorated. As much seed should therefore be sown as will yield plants enough to occupy the ground fully from the first, and thus remove the temptation to tillering. By such full seeding a fortnight is frequently gained in the ripening of the crop, and this as frequently makes all the difference betwixt a remunerative crop and a losing one.

Thick and thin seeding.

Much controversy has taken place of late years about the quantities of seed-wheat which should be used per acre. The advocates of thin-seeding have been so unguarded and extravagant in their encomiums of their favourite practice, some of them insisting that anything more than a few quarts per acre does but waste seed and lessen the produce—that many persons have been induced to depart from their usual practice to their serious cost. It is true that with land in a high state of fertility, and kept scrupulously clean by frequent hoeings, a full crop of wheat may be obtained from *half* a bushel of seed per acre, provided that it is sown in September, and deposited regularly over the surface. But what beyond a trifling saving of seed is gained by this practice? And at what cost and hazard is even this secured? It is a mere fallacy to tell us, as the advocates of excessively thin seeding so often do, that they obtain an increase of so many hundred-fold; whereas, thick seeders cannot exceed from twelve to twenty fold, when after all the gross produce of the latter may exceed that of the former by more than the quantity of seed saved, with less expense in culture, less risk from accidents and disease, an earlier harvest and a better quality of grain. Such a crowding of the ground with plants as prevents the proper development of the ear is of course to be avoided; but the most experienced growers of

Grain Crops.

wheat are convinced of the benefit of having the ground fully occupied at the time when active spring growth begins. This is secured by using two bushels per acre for the sowing, made early in October, and by increasing this quantity at the rate of half a peck per week until three bushels is reached, which may be held as the maximum. Less than this should not be used from the middle of November to the end of the season. These are the quantities to be used in broad-cast sowing; when drilling or dibbling is resorted to, two-fifths less seed will suffice. In Scotland, at least, often-repeated trials have shewn that larger crops are obtained by broad-casting than by drilling. The latter mode is however to be preferred wherever the land is infected by annual weeds, which can then be got rid of by hoeing. When clover and grass-seeds are sown with the grain crop it is believed also that they thrive better from the grain being sown in rows, probably because in this case light and air are less excluded from them. It is believed also that in highly-manured soils of a loose texture grain deposited somewhat deeply in rows is less liable to lodge than when sown broad-cast and shallower. When drilling and hoeing are resorted to, the latter is effected most cheaply and effectively by using Garret's horse-hoe. The mere stirring of the soil is considered by many farmers to be so beneficial to the wheat crop that they use the horse-hoe irrespective of the presence of weeds. Others are of opinion that, apart from the destruction of weeds, hoeing is injurious to grain crops, alleging that the cutting of their surface roots weakens the stems and increases their liability to fall over. Carefully conducted experiments are required to settle this point. We have no personal experience bearing upon it beyond this, that we have repeatedly seen a wheat crop much benefited by mere harrowing in spring. It is always useful to roll wheat, and indeed all cereal crops, in order to facilitate the reaping process although no other benefit should result from it. When the plants have been loosened by severe frosts, or are suffering from the attacks of wire-worms, the use of Crosskill's roller is usually of great benefit to the crop.

Broad-cast *versus* drilling.

Tull's system revived by Mr Smith of Lois Weedon.

A plan of growing wheat year after year on the same field without the use of manure has been practised for several years past by the Rev. Mr Smith of Lois Weedon, Northamptonshire, and detailed by him in the pages of the *Royal Agricultural Society's Journal*, and in a pamphlet which has now had a very extensive circulation. His plan is to a certain extent a revival of that of Jethro Tull; but with this important difference, that whereas Tull occupied his ground with alternate double rows of wheat a foot apart, and vacant spaces five feet wide, which were carefully cultivated by ploughings and horse-hoeings repeated at intervals, from the springing of the wheat until midsummer, Mr Smith introduces two important elements in addition, viz., thorough draining and trenching the vacant spaces in autumn so as to bring portions of subsoil to the surface. A field treated on this system consists of alternate strips of wheat and bare fallow, which are made to exchange places year by year, so that each successive crop occupies a different site from its immediate predecessor. It has also the benefit of the fresh soil brought up by the previous autumn's double-digging, which is subsequently mellowed and pulverised by lengthened exposure to the atmosphere, and by frequent stirrings. The produce obtained by Mr Smith from his acre thus treated has been very nearly 34 bushels each year for five successive years. At first he restricted himself to the employment of manual labour, but he has since invented a set of implements for sowing, covering in, rolling, and hoeing his crops by horse labour. We give in his own words his directions for carrying out this system, what he believes to be the advantages of it, and the cost of thus cultivating an acre.

"I suppose, at the outset, the land intended for wheat, to be wheat land; having besides a fair depth of staple, and a subsoil, as will generally, though not universally, be the case, of the same chemical composition with the surface. I suppose it dry; or drained three feet deep *at least;* well cleaned of weeds; the lands cast; and the whole tolerably level.

"1. First of all, then, plough the whole land, when dry, one inch deeper than the used staple. If it turn up cloddy, bring the clods down with the roller or the crusher. Let this be done, if possible, in August. Harrow deep; so as to get five or six inches of loose mould to admit the presser. Before sowing wait for rain. After the rain wait for a fine day or two to dry the surface. With this early commencement a week or two is of no material importance compared with that of ploughing dry and sowing wet.

"As early as possible, however, in September, get in your seed with the presser-drill; or with some implement which forms a firm-bedded channel in which to deposit the seed, grain by grain, a few inches apart. Cover over with the crusher or rough roller.

"2. When the lines of wheat appear above ground, guard against the rook, the lark, and the slug; a trite suggestion, but ever needful, especially here. And now, and at spring, and all through summer, watch for the weeds, and wage constant warfare against them. The battle may last for a year or two, or in some foul cases even more; but, in the end, the mastery, and its fruits, without fail, will be yours.

"3. The plant being now distinctly visible, dig the intervals two spits deep; increasing the depth, year after year, till they come to twenty or twenty-four inches. Bring up at first only four, or five, or six inches, according to the nature of the subsoil, whether tenacious, or loamy, or light. To bring up more at the outset would be *a wasteful and injurious expense.*

"The digging is done thus: Before proceeding with the work, a few cuts are made within three inches of the wheat, the back of the spade being towards the rows. A few double spits, first of all, at the required depth, are then thrown out on the headland, and there left for the present. After this, as the digging proceeds, the staple is cast to the bottom, and the subsoil thrown gently on the top. This process is carried on throughout the whole interval; at the end of which interval, just so much space is left vacant as was occupied by the soil thrown out at the beginning of it. In commencing the second interval at that finished end, the earth is thrown out as at first, not on the headland, however, but into the vacant space of the first interval. And so on all over the acre.

"4. Late in winter, and early in spring watch your opportunity, in dry weather, before the roots of the plant are laid bare, to press them with the crusher.

"5. In the spring, and early summer, stir the spaces between the rows as often as the surface becomes crusted over; and move the settled intervals four or five inches deep, with the common scarifier, set first of all about 28 inches wide; reducing the width till it come by degrees to 24 and 18 inches. Continue the process, if possible, at the last-named width, up to the time of flowering in June.

"These operations are indispensable to full success; and happily can be carried on at little cost. For, while the intervals of each acre can be scarified in 50 minutes, the horse-hoe implement, covering two lands at once, can stir between the rows in 25.

"6. Immediately the crop is carried, clean the intervals, and move them with the scarifier in order to *sow*, without delay, the shed grains. When these vegetate and come up into plant, move the intervals again, five or six inches deep, and so destroy them. After that, level with the harrow implement, and the land is ready for the drill.

"If anything occur to prevent the sowing early in September, and to drive you to the end f October, set the drill for a thicker crop. But, if possible, sow early. For this reason. Tillered wheat has a bad name. But that has reference only to wheat which has tillered late in the spring. And certainly, in that case, there is the fear of danger to the crop and danger to the sample. For, supposing no mildew to fall on it, even then the plant ripens unevenly; the early stems being ready for the sickle, while the late grown shoots have scarcely lost

Grain Crops.

their verdure. But if mildew come when the stem is soft and succulent and porous, instead of being, as it should be at that time, glazed and case-hardened against its attacks, the enemy enters in and checks the circulating sap; and the end is, blackened straw, light ears, and shrivelled grain. Therefore, sow early. Let the plant tiller before winter. Give every stem an equal start at spring; and then, with a strict adherence to rule, there need be no alarm as to the result, subject only to those visitations from which no wheat on any system, in the same description of soil, and under the same climate, is secure." (See pamphlet, *Word in Season*, p. 36.)

"The advantages of the system of corn-growing which I have described are principally these. First, while one crop of wheat is growing, the unsown intervals of the acre are being fallowed and prepared for another. This the farmer well knows to be of infinite moment, meeting, as it does, one of the greatest difficulties he has to contend with. Next, upon this half-portion of the acre, tilled as I describe, there is a yield equal to average crops on a whole acre. Then, for half the portion of an acre, there is, of course, only half the labour and half the expense of an entire acre required for cultivation. And lastly, the hand-labour required finds constant employment for the poor."—(*Ibid.*, p. 17.)

"After harrowing, and cleaning, and levelling the whole, I marked out the channels for the seed with my *presser implement*, which is drawn with one horse, and presses two lands at once. My scheme of implements, to be complete, embraced a drill, which was to act immediately behind the presser-wheels, and to drop seed by seed into the hard channels. The spindle of the presser was to turn the drill-wheels, and the boxes were to be made removeable. Being unable to accomplish this in time for this year's sowing, I had the seed, as heretofore, dropped by hands, and covered over by rollers.

"These rollers form the *roller implement* in the same frame, and are managed thus: the three-wheeled pressers are removed from their sockets, and in their place two rough rollers formed of several wheels on the self-cleaning principle, are introduced, and cover over two lands at once.

"The portion of the field thus seeded will lie in this firm but rough state till spring time. Then, when the rollers have been applied again to keep the roots of the plant well in their place, they too will be removed from the frame, and light wheels and hoes will be attached; forming the *horse-hoe implement*, for hoeing and stirring between the wheat.

"There is yet one other use for the implement frame. The intervals of the wheat having been trenched in autumn, and well and frequently stirred by the common scarifier at spring, are shut out by the wide-spreading wheat-plant in June from all further processes till the crop is cut and carried. They are then to be moved and levelled by the common one-horse scarifier, for seed-time. After this will follow the harrow. The hoes will be removed from the frame, and two small harrows will be attached, to cover two lands at once; and with this implement the horse will walk on the stubble-land, between what before were the intervals; and the cycle of operations is now complete.

"In all these operations (excepting in that of scarifying), the sown lands, and lands about to be made ready for sowing, are untouched by the foot of man or horse.

"The time occupied in scarifying the land is about an hour the acre; in heavily pressing the channels for the seed, half-an-hour; in the other operations about 20 or 25 minutes."—(Pp. 25-26.)

"The presser-drill, spoken of in p. 25, is completed, and I now sow the four acres in 90 minutes, timed by watch; being at the rate of 18 or 20 acres a day in a day of 8 hours, with a horse of average power and speed.

"It has been thought advisable to keep the drill in its own frame,—devoting another frame to the roller-wheels or crusher, the hoes, the scarifiers, and harrows; all of which are made removeable, and which, with the exception of the spade, the hand-hoe, and the common scarifier for stirring the intervals, perform the whole cycle of operations for cultivating the land for wheat."—(Pp. 33-34.)

"I have only to shew now, by my fresh balance-sheet, how, with suitable implements, on wheat-land, the whole scheme I propose is economical, as well as easy and expeditious.

| | £ | s. | d. |
|---|---|---|---|
| "One double-digging in autumn, | £1 | 10 | 0 |
| Three stirrings with scarifier at spring (6d.), | 0 | 3 | 0 |
| One ditto with scarifier and harrow implement, before sowing, | 0 | 1 | 0 |
| Two pecks of seed (5s. the bushel), | 0 | 2 | 6 |
| Pressing and drilling, | 0 | 1 | 0 |
| Rough rolling, | 0 | 0 | 6 |
| Four hoeings between wheat with horse-shoe implement (6d.), | 0 | 2 | 0 |

"The produce, supposing it equal to that of former years, in round numbers, would be:—

| | £ | s. | d. |
|---|---|---|---|
| "Four quarters and two bushels of wheat (at 40s.), | £8 | 10 | 0 |
| One ton and 12 cwt. of straw (at £2 the ton), | 3 | 4 | 0 |
| | £11 | 14 | 0 |
| Deduct outlay, | 3 | 14 | 0 |
| Total amount of profit, | £8 | 0 | 0" |

—(*Ibid.*, p. 30.)

Public attention has more recently been directed to this system of wheat culture by a lecture on Tull's husbandry, delivered by Professor Way, at a council meeting of the Royal Agricultural Society of England, and by the animated discussion which followed; when several gentlemen who had visited Mr Smith's farm bore testimony to the continued excellence of his crops, and intimated that they and others had begun to test the system upon their own farms. If such a practice can indeed be pursued on the generality of clay-soils, then the puzzling problem of how to cultivate them with a profit is solved at once. It is impossible that practical farmers should regard otherwise than with incredulity a system which so flatly contradicts all existing theory and practice. The facts submitted to them by Mr Smith being beyond challenge, they will, in the meantime, hold to the belief that there is some peculiarity in the soil at Lois Weedon which enables it to sustain, as yet, such heavy and continued demands on its fertility; and that the issue, there and elsewhere, must ere long be utter sterility. For our own part, believing that we have exceeding much to learn in every department of agriculture, we cannot thus summarily dispose of these facts. We simply accept them as true, and leave the exposition of them to *experience*, whose verdict we await with much interest.

Mr Lawes' experiments.

But Mr Smith is not the only person who has furnished us with information regarding the continuous growth of wheat for a series of years on the same soil. Mr Lawes, at Rothamstead, in Herts, so well known by his interesting papers on agricultural chemistry in the *Royal Agricultural Society's Journal*, has furnished some facts in connection with the culture of wheat on clay soils, to which farmers were little prepared to give credence. Mr Caird, who visited Rothamstead early in 1851, thus refers to this subject in his valuable work:—

"On a soil of heavy loam, on which sheep cannot be fed on turnips, 4, 5, and 6 feet above the chalk, and therefore uninfluenced by it, except in so far as it is thereby naturally drained, *ten* crops of wheat have been taken in succession, one portion always without any manure whatever, and the rest with a variety of manures, the effects of which have been carefully observed. The seed is of the red cluster variety, drilled uniformly in rows at 8 inches apart, and two bushels to the acre, hand-hoed twice in spring, and kept perfectly free from weeds. When the crop is removed the land is scarified with Bentall's skimmer, all weeds are removed, it is ploughed once, and the

Grain Crops.

seed for the next crop is then drilled in. During the ten years, the land, in a natural state, without manure, has produced a uniform average of 16 bushels of wheat an acre, with 100 lb. of straw per bushel of wheat, the actual quantity varying with the change of seasons between 14 and 20 bushels. The repetition of the crop has made no diminution or change in the uniformity of the average, and the conclusion seems to be established, that if the land is kept clean, and worked at proper seasons, it is impossible to exhaust this soil below the power of producing 16 bushels of wheat every year.

" But this natural produce may be doubled by the application of certain manures. Of these, Mr Lawes' experiments led him to conclude that ammonia is the essential requisite. His conclusions are almost uniform, that no organic matter affects the produce of wheat, except in so far as it yields ammonia ; and that the whole of the organic matter of the corn crop is taken from the atmosphere by the medium of ammonia. There is a constant loss of ammonia going on by expiration, so that a larger quantity must be supplied than is contained in the crop. For practical purposes, 5 lb. of ammonia is found to produce a bushel of wheat, and the cheapest form of ammonia at present being Peruvian guano, 1 cwt. of that substance may be calculated to give 4 bushels of wheat. The natural produce of 16 bushels an acre may therefore be doubled by an application of 4 cwt. of Peruvian guano. To this, however, there is a limit,—climate. Ammonia gives growth, but it depends on climate whether that produce is straw or corn. In a wet cold summer, a heavy application of ammonia produces an undue development of the circulating condition of the plant, the crop is laid, and the farmer's hopes are disappointed. Seven of corn to ten of straw is usually the most productive crop ; five to ten seldom yields well. The prudent farmer will therefore regulate his application of ammonia with a reference to the average character of the climate in which his farm is situated.

" The practical conclusion at which we arrive is this, that in the cultivation of a clay-land farm, of similar quality of soil to that of Mr Lawes', there is no other restriction necessary than to keep the land clean. That while it is very possible to reduce the land by weeds, it is impossible to *exhaust* it (to a certain point it may be *reduced*), by cleanly cultivated corn crops. That it is an ascertained fact that wheat may be taken on soils of this description (provided they are manured) year after year with no other limit than the necessity for cleaning the land, and that may best be accomplished by an occasional green crop—turnip or mangold, as best suits—at great intervals, the straw being brought to the most rotten state, and applied in the greatest possible quantity to insure a good crop, which will clean the land well. If these conclusions are satisfactorily proved, the present mode of cultivating heavy clays may be greatly changed, and the owners and occupiers of such soils be better compensated in their cultivation than they have of late had reason to anticipate." (Caird's *English Agriculture*, in 1850 and 1851, pp. 460-462.)

It is certainly curious to observe, that the addition of 4 cwt. of guano brings up the produce of Mr Lawes' acre from its average annual rate of 16 bushels, under its reduced normal state, to very nearly the same as Rev. Mr Smith's acre under his system of alternate strips of corn and summer fallow.

Average yield of wheat.

From information carefully gathered, Mr Caird gives it as his opinion, that the average produce of wheat per acre in 26 of the 32 counties of England visited by him is $26\frac{2}{3}$ bushels, or 14 per cent. higher than it was estimated at in the same counties by Arthur Young 80 years before. Were the country generally anything like as well cultivated as particular farms that are to be met with in all parts of it, we should have the present average increased by at least 8 bushels per acre.

*Barley.*—In Great Britain, barley is the grain crop which ranks next in importance to wheat, both in an agricultural and social point of view. Its use as bread-corn is confined to portions of the lowlands of Scotland, where unleavened cakes, or " bannocks o' barley meal," still constitute the daily bread of the peasantry. It is more largely used in preparing the " barley broth" so much relished by all classes in Scotland. To fit the grain for this purpose, it is prepared by a peculiar kind of mill, originally introduced from Holland by Fletcher of Saltoun, in which a thick cylinder of gritty sandstone is made to revolve rapidly within a case of perforated sheet-iron. The barley is introduced betwixt the stone and its case, and there subjected to violent rubbing until first its husk, and then its outer coatings are removed. It is, however, in the production of malt liquor and ardent spirits, and in the fattening of live stock, that our barley crops are chiefly consumed. We have no doubt that it would be better for the whole community if this grain were more largely used in the form of butcher-meat, and greatly less in that of beer or whisky. It has been customary for farmers to look upon distillation as beneficial to them from the ready market which it affords for barley, and more especially for the lighter qualities of this and other grain crops. But this is a very short-sighted view of the matter ; for careful calculation shows that, when the labouring man spends a shilling in the dram-shop, not more than a penny of it goes for the agricultural produce (barley), from which the gin or whisky is made ; whereas, when he spends the same sum with the butcher or baker, nearly the whole amount goes for the raw material, and only a fraction for the tradesman's profits. And not only so, but the man who spends a part of his wages upon strong drink, diminishes, both directly and indirectly, his ability to buy wholesome food and good clothing ; so that, apart from the moral and social bearings of this question, it can abundantly be shown that whisky or beer is the very worst form for the farmer in which his grain can be consumed. Were the L.50,000,000 at present annually spent in Great Britain upon ardent spirits (not to speak of beer), employed in purchasing bread, meat, dairy produce, vegetables, woollen and linen clothing, farmers would, on the one hand, be relieved from oppressive rates, and, on the other, have such an increased demand for their staple products, as would far more than compensate for the closing of what is, at present, the chief outlet for their barley.

Wastefulness of brewing and distilling.

There are many varieties of barley in cultivation, and some of them are known by different names in different districts. Those most esteemed at present in Berwickshire and neighbouring counties, are the chevalier, the annat, and the common early long-eared. The chevalier produces the finest and heaviest grain, weighing usually from 54 lb. to 56 lb. per bushel, and is in high estimation with maltsters. It is also tall and stout in the straw, which is less liable to lodge than that of the common barley ; and when this accident does happen, it has the valuable property of not producing aftershoots or greens. It requires about fourteen days longer than the common-early to reach maturity, but as it admits of being sown earlier than the latter sort, this is in practice no drawback to it. The annat barley resembles the chevalier in its leading features, but is yellower in its complexion, and not quite so round in the grain. It ripens a few days earlier than the chevalier, and in our own experience is more productive. The common-early is more liable than those just noticed to suffer from over-luxuriance. It is generally used for the latest sowings, on those portions of land from which the turnip crop has been longest in being removed.

Varieties of barley.

In the elevated or northern parts of the kingdom, four-rowed barley, usually called *Bere* or *Bigg* is cultivated, as it is more hardy, and ripens earlier than the two-rowed varieties. A new variety called Victoria Bere is said to be so productive, and to yield such a heavy sample, as to be worthy of cultivation even in lowland districts.

Bere or Bigg.

Barley delights in a warm, friable soil, and thrives best when the seed is deposited rather deeply in a tilthy bed. Being the grain crop best adapted for succeeding turnips

Grain Crops.

that have been consumed by sheep-folding, advantage must be taken of favouring weather to plough up the land in successive portions, as the sheep-fold is shifted. So much of it as is ploughed before 1st February will usually get so mellowed by the weather as to be easily brought into suitable condition for receiving the seed. In Scotland, the usual practice is to sow broad-cast on this stale furrow, and to cover the seed by simple harrowing. A better way is first to level the surface by a stroke of the harrows, and then to form it into ribs *twelve* inches apart, by such an implement as has been described, when speaking of Tennant's grubber. Over this corrugated surface the seed is sown broad-cast, and covered by another turn of the harrows. The ribbing loosens the soil, gives the seed a uniform and sufficient covering, and deposits it in rows. The only advantage of such ribbing over drilling is, that the soil is better stirred, and the seed deposited more deeply, and less crowded than is done by the ordinary drills. It is certainly of great advantage to have the seed-corn deposited in narrow lines, so far as the working of the horse-hoe is concerned; but we are convinced that stiffer stems, larger ears, a more abundant yield, and a brighter sample are likely to be obtained when the seed is loosely scattered in a channel 3 or 4 inches wide than when crowded into a narrow line. This grain is now sown considerably earlier than heretofore. When the soil is enriched by plentiful manuring, its temperature raised by thorough draining, and the climate and exposure favourable, it should be sown as early in March as possible, and will often do remarkably well although sown in February. This early sowing counteracts that tendency to over-luxuriance, by which the crop is so often ruined in fertile soils. It is chiefly owing to this early sowing (although aided by the use of hummelling machinery) that the average weight of barley is so much greater now than it was twenty years ago. From 53 lb. to 54 lb. per bushel is now about the average weight in well-cultivated districts; while 57 lb. and 58 lb. is by no means rare. The produce per acre ranges from 36 to 60 bushels; 44 bushels being about the average. The quantity of seed used per acre, is from $2\frac{1}{2}$ to 3 bushels, for broad-cast sowing, and about a third less when drilled. As already remarked in regard to wheat, it is well, as the season advances, to avoid, by a fuller allowance of seed, the temptation to excessive tillering, and consequent unequal and later ripening.

*Oats.*—Over a large portion of England oats are grown only as provender for horses, for which purpose they are fully ascertained to be superior to all other grains. Except, therefore, on fen-lands, and recently-reclaimed muiry soils, the cultivation of oats in south Britain bears a small proportion to the other cereals. It is in Scotland, "the land o' cakes," that this grain is most esteemed, and most extensively cultivated. Considerably more than half of the annual grain crops of Scotland consists in fact of oats. The important item which oatmeal porridge forms in the diet of her peasantry, and of the children of her other classes, has something to do with this extensive culture of the oat; but it arises mainly from its peculiar adaptation to her humid climate. As with the other cereals, there are very numerous varieties of the oat in cultivation. In Messrs Lawson's *Synopsis of the Vegetable Products of Scotland*, it is said (Div. i. p. 80.) "Our collection comprises nearly sixty varieties, about thirty of which are grown in Scotland; but of these not more than twelve are in general cultivation. These twelve varieties enumerated in the order of their general cultivation, are, the Potato, Hopetoun, Sandy, Early-Angus, Late-Angus, Grey-Angus, Blainslie, Berlie, Dun, Friesland, Black Tartarian, and Barbachlaw." The first four kinds in this list are those

Varieties in cultivation.

chiefly cultivated on the best class of soils. It is to the produce of these that the highest market prices usually have reference. The weight per bushel of these sorts usually runs from 42 lb. to 46 lb. From 50 to 60 bushels per acre is a usual yield of oats. The two last-named kinds are chiefly esteemed for their large produce, and adaptation to inferior soils; but being of coarse quality, they are chiefly used for provender. A variety which stands the winter is now frequently grown in England, for the double purpose of first yielding a seasonable supply of green food to ewes and lambs in early spring, and afterwards producing a crop of grain. It has already been stated that, in Scotland, wheat does not prosper when sown after clover or pasture; but with the oat it is quite the reverse, as it never grows better than on land newly broken up from grass. It is, accordingly, almost invariably sown at this stage of the rotation. The land is ploughed in December or January, beginning with the strongest soil, or that which has lain longest in grass, that it may have the longest exposure to the mellowing influences of wintry weather. In March or April, the oats are sown broad-cast on this first ploughing, and covered in by repeated harrowings. These are given lengthwise until the furrows are well broken down, for if the harrows are worked across the ridges, before this is effected, they catch hold of the edges of the slices, and partially lifting them, permit the seed-corn to fall to the bottom, where it is lost altogether. As it is only when a free tilth is obtained that the crop can be expected to prosper, care must be taken to plough early and somewhat deeply, laying the furrows over with a rectangular shoulder; to sow when the land is in that state of dryness that admits of its crumbling readily when trode upon, and then to use the harrows until they move smoothly and freely in the loose soil, two or three inches deep. The Norwegian harrow is an important auxiliary to the common ones in obtaining this result. When wild mustard and other annual weeds abound, it is advisable to drill the crop and to use the horse-hoe. When the land is clean, the general belief in Scotland is that the largest crops are obtained by sowing broad-cast. When the latter plan of sowing is adopted, from 4 to 6 bushels per acre is the quantity of seed used. The latter quantity is required in the case of the Hopetoun and other large-grained varieties. The condition of the soil as to richness and friability must also be taken into account in determining the quantity of seed to be used. When it is in high heart and likely to harrow kindly, a less quantity will suffice than under opposite conditions. In breaking up a tough old sward, even six bushels per acre may be too little to sow. The following very interesting experiment bearing on this point was recently made in Fifeshire. "Mr Gulland, Wemyss, offered a sweepstakes in 1850, that 4 bushels of oats, sown per Scotch acre, in poor land, would yield a better produce than 8 bushels sown under similar conditions. The late Mr Hill, maintaining the contrary, accepted the sweepstakes, and a number of others took up the same. Experiments were made by Mr Dingwall, Ramornie, and Mr Buist, Hattonhill. . . . :—

"In Mr Buist's experiments,

"4 bush. sown yielded 28 bush. per acre, 34 lb. per bush.
8 bush. sown yielded 36 „ „ $34\frac{1}{4}$ lb. „

"In Mr Dingwall's experiments,

4 bush. sown yielded 45 bush. per acre, $38\frac{1}{2}$ lb. per bush.
8 bush. sown yielded 49 „ „ 39 lb. „ "[1]

The advocates for thin seeding will of course regard even the least of these quantities as foolishly redundant. It is quite true, that if the land is in good heart, the crop will ultimately stand close to the ground from a very small seeding; but it will take two or three weeks longer to do this than if the

[1] *Agricultural Gazette*, 20th November 1852.

Grain Crops.

land had been fully stocked with plants from the first, by giving it seed enough. In our precarious climate, where a late harvest and bad crops usually go together, it is of the utmost importance to secure early, uniform, and perfect ripening; and as liberal seeding tends directly to promote such a result, practical farmers will do well to take care how they omit such a simple means of attaining so important an end. We believe that it is on the principle now indicated that the superior result, both as respects quantity and quality of produce, in the double-seeded lots in the experiments now cited, is to be explained.

Change of seed.

As with wheat, the vigour and productiveness of the oat is much enhanced by frequent change of seed. Our agricultural authorities usually assert that the change should, if possible, always be from an earlier climate and better soil. This is undoubtedly true as regards high-lying districts; but with a good soil and climate, we have always seen the best results with seed from a later district.

Manures for oat crop.

On poor hard soils it is usually remunerative to apply a cwt. of guano per acre to the oat crop; sowing it broadcast, and harrowing it in, along with the seed. As much additional produce is thus ordinarily obtained as more than pays for the manure, and the land is, in all respects, left in better condition for the succeeding green crop. In the case both of very light and strong clay soils, we have obtained excellent results by applying a liberal dressing of farm-yard dung, in autumn, to grass-land about to be broken up for oats. By using, in this way, the dung produced during the summer months, we have obtained abundant crops of oats from portions of land which, but for this, would have yielded poorly; and, at the same time, by applying the bulky manure at this stage of the rotation, instead of directly for the succeeding green crop, an important saving of time and labour has been effected, as we shall have occasion to notice when treating of turnip-culture.

Diseases.

When the young oat plants have pushed their second leaf, it is always beneficial to use the roller, as it helps to protect the crop from the evil effects of drought, and facilitates the reaping of it. The oat frequently suffers much from a disease called "segging" or "tulip root," which appears to be caused by the presence of a maggot in the pith of the stems close to the ground. On land which is subject to this disease, it is advisable not to sow early. A dressing of lime is also believed to be serviceable as a preventative. On muiry soils, this crop is also not unfrequently lost by what is called "*slaying.*" This seems to result from the occurrence of frosty nights late in spring when the crop is in its young stage, and which, when grown on such soils, it cannot withstand. The best remedy is to improve the texture of the soil by a good coating of clay.

*Rye.*—The extensive cultivation of this grain in any country being alike indicative of a low state of agriculture, and of a poor style of living among its peasantry, it must be regarded as a happy circumstance, that it has become nearly obsolete in Great Britain. It is still occasionally met with in some of our poorest sandy soils, and patches are occasionally grown elsewhere for the sake of the straw, which is in estimation for thatching—for making bee-hives, and for stuffing horse-collars. Its cultivation as a catch crop, to furnish early food for sheep in spring, is on the increase.

### LEGUMINOUS CROPS.

The only members of this family statedly cultivated for their grain are beans and pease. Before the introduction of clover and turnips these legumes occupied a more important place in the estimation of the husbandman than they have done since. Indeed, in many districts naturally well adapted for the culture of turnips, that of beans and pease was for a time all but abandoned. Recently, however, increasing precariousness in the growth of clover, and even of turnips, where they have been sown on the same ground every fourth year for a lengthened period, has compelled farmers to return to the culture of beans and pease for the mere purpose of prolonging the intervals in the periodic recurrence of the former crops. But it is found, in regard to the bean itself, in districts where it has long occupied a stated place in rotations of six or seven years, that its average produce gradually diminishes. We have thus an additional illustration of the importance of introducing as great a variety of crops as possible into our field culture. It is on this principle that beans and pease are now again extensively cultivated on dry friable soils. Winter beans, or pease of some early variety, are generally preferred in such cases. The grain of these legumes, though partially used for human food, is chiefly consumed by horses and by fattening cattle and sheep. Being highly nutritious, they are well adapted for this purpose. By growing beans on a limited portion of the land assigned to cattle crops, a larger weight of beef and mutton can be produced from a given number of acres, than by occupying them wholly with roots, forage, and pasturage. Several varieties of field beans are cultivated in Great Britain; such as the common horse bean, the tick, the Heligoland, and the winter bean. The latter was introduced into England about the year 1825, and there rises steadily in estimation. It has been tried in many parts of Scotland and proves quite hardy, but is objected to from the exceeding shortness of its straw. But for this, it is a valuable acquisition, as it ripens so much earlier than the spring-sown varieties. Beans are either sown broad-cast, dibbled in narrow rows, or drilled at intervals varying from a foot to 27 inches. The last is undoubtedly the best method; regard being had both to the amount and quality of produce, and to the effects of bean culture on the after crops. Beans should never be sown on land that is foul. By diligent horse and hand hoeing, land that is clean to begin with, can be kept so under beans, and left in fine condition for carrying a white corn crop; but in opposite circumstances it is sure to get into utter confusion. It is found advisable therefore to take beans after the white crop that has succeeded roots or a bare fallow. In Berwickshire, where a five years' course, consisting of turnips, wheat or barley, two years seeds, and oats has long prevailed, beans are now not unfrequently introduced by substituting them for the second year's grass. A four years' course with beans instead of a portion of the seeds is certainly preferable. In cultivating this crop, the land is ploughed with a deep furrow in autumn, a dressing of dung being first spread over the surface and turned in by the plough. As soon in March as the state of the land admits, it is stirred by the cultivator, harrowed, and formed, by a single turn of the common plough, into shallow drills twenty-seven inches apart. Ten or twelve such drills being formed to begin with, the seed is scattered broad-cast, at the rate of 3 bushels per acre, by a sower who takes in six of these drills at a time, and gives them a double cast. The beans either roll into the hollows as they fall, or are turned in by the ploughs, which now proceed to open, each a fresh drill, in going down the one side of the working interval, and to cover in a seeded one in returning on the other side. If tares are cultivated on the farm, it is usual to sow a small quantity (say a peck per acre) amongst the beans, on which they are borne up and so ripen their seeds better, and yield more abundantly, than when trailing on the ground. When the crop comes to be thrashed, the tares are easily separated from the beans by sifting. Ten days or so after sowing, the drills are harrowed down; and, if the land is cloddy, it is smoothed by a light roller. If showers occur when the bean plants are appearing above ground, or shortly after, the harrows are used again with the best effect in pulverising the

Grain Crops.

Winter bean.

Time and manner of sowing.

Mixture with vetches.

Culture.

Grain Crops.

soil and destroying newly-sprung weeds. A horse and hand hoeing is then given, and is repeated if weeds again appear. When the plants have got about 6 inches high, it is beneficial to stir the soil deeply betwixt the rows by using Tennant's grubber, drawn by a pair of horses. For this purpose the tines are set so close together as to clear the rows of beans, and the horses are yoked to it by a main tree, long enough to allow the horses to work abreast in the rows, on either side of the one operated upon. The soil is thus worked thoroughly to the depth of 6 or 8 inches, without reversing the surface and exposing it to drought, or risk of throwing it upon the plants. Just before the blooms appear, some farmers pass a bulking-plough betwixt the rows, working it very shallow, and so as merely to move the surface-soil towards the plants. This may do good; but a deep earthing up is hurtful. When the blooms open, all operations should cease, as otherwise, much mischief may be done. Such an amount of culture may be thought needlessly costly and laborious; but unless a bean crop is kept clean, it had better not be sown. And it is to be remembered that the benefit of this careful tillage is not confined to it, but will be equally shared in by the wheat crop that follows. The culture of winter beans differs only in this; that they require to be sown as early in autumn as the removal of the preceding grain crop admits of.

*Pease* are sown in circumstances similiar to those just detailed; but they are better adapted than beans to light soils. They too are best cultivated in rows of such a width as to admit of horse-hoeing. The early stage at which they fall over, and forbid further culture, renders it even more needful than in the case of beans to sow them only on land already clean. If annual weeds can be kept in check until the pease once get a close cover, they then occupy the ground so completely, that nothing else can live under them; and the ground, after their removal, is found in the choicest condition. A thin crop of pease should never be allowed to stand, as the land is sure to get perfectly wild. The difficulty of getting this crop well harvested renders it peculiarly advisable to sow only the early varieties.

Bean straw as fodder.

In Scotland the haulm of beans is esteemed an excellent fodder for horses and other live stock; whereas in England it is thought unfit for such a use. The reason of this appears to be, that in the southern counties beans are allowed to stand until the leaf is gone, and the stems blackened before reaping; whereas in Scotland they are reaped so soon as the eye of the grain gets black. When well got, the juices of the plant are thus, to some extent, retained in the haulm, which, in consequence, is much relished by live stock, and yields a wholesome and nutritious fodder.

The cereals and legumes now enumerated, constitute the staple grain-crops of Great Britain. Others are grown occasionally, but more for curiosity than profit. Zealous attempts were made by the late William Cobbett to introduce *maize* or *Indian corn* as one of our regular crops. It has been conclusively proved that none of its varieties, yet tried, can be ripened in the ordinary seasons of this country. It has indeed been suggested that it might form a useful addition to our garden vegetables—using it, as it is done in America, by cooking the unripe cobs; and also that we might grow it beneficially as a forage crop. *Lentiles* have recently been grown in different parts of the country; but both of these grains can be imported of better quality, and at less cost, than they can be grown at home.

Maize.

Lentiles.

There is great inducement to agriculturists to endeavour more earnestly to obtain improved varieties of grain by cross-impregnation of existing ones. Something has already been accomplished in this direction; but only enough to show what encouragement there is to persevere. Whenever the same skill and perseverance are directed to the improvement of field crops, that our gardeners are constantly exerting, with such astonishing results, on fruits, flowers, and vegetables, we may anticipate a great increase of produce, not only from the discovery of more fruitful varieties, but of such as possess a special adaption to every diversity in the soil and climate of our territory.

### HARVESTING OF GRAIN CROPS, AND THEIR PREPARATION FOR MARKET.

Reaping with the sickle.

Several distinct modes of reaping grain are in use. The most ancient, and still the most common is by the sickle or reaping-hook, which is used either with a smooth or serrated edge. The latter was at one time preferred, as by it the work was performed most accurately. The smooth-edged instrument is, however, now the favourite, as it requires less exertion to use it, and the reaper can, in consequence, get through more work in a day; and also, because in using it the grain is less compressed, and consequently dries faster when made into sheaves. In some parts of England the crops are reaped in a method called *fagging* or *bagging*. The cutting instrument used is heavier, straighter, and broader in the blade than the common reaping-hook. The workman uses it with a slashing stroke, and gathers the cut corn as he proceeds by means of a hooked stick held in his left hand. It is a similar process to the mode of reaping with the Hainault scythe,—an instrument which has been tried in this country, but never adopted to any extent. The common scythe, especially with that form of handle known as the Aberdeen handle or *sned*, is very extensively used for reaping grain in all parts of the kingdom. Indeed the practice of mowing grain has been increasing of late years, and would extend more rapidly, but for the greater difficulty of finding good mowers than good reapers. A greater amount of dexterity is required to cut grain well by the scythe than by the sickle. The difficulty lies not in making smooth and clean stubble, but in so laying the swathe as to admit of the corn being sheaved accurately. When the mower lays his swathe at right angles to his line of progress, and the gatherer is skilful and careful, corn may be handled as neatly in reaping by the scythe as by the sickle. When the crops are not much laid or twisted, mowing is somewhat the cheapest of these modes of reaping. Its chief recommendation, however, is that mown sheaves dry most quickly, and suffer least from a drenching rain. This arises from the stems being less handled, and so forming an open sheaf, through which the wind penetrates freely. Tightly-bound sheaves are always difficult to dry. If it be true that we have at last got a really effective reaping-machine, it is probable that corn cut down by it will also possess this property of rapid drying.

Fagging.

Mowing.

In Berwickshire and adjoining counties, the reaping of the crops has hitherto been accomplished by employing, at days' wages, such a number of reapers as suffices to cut down the crops on each farm in from twelve to twenty days. The rate of wages paid to reapers for a number of years has ranged from 2s. to 2s. 6d. each *per diem*, with victuals in addition, costing about *eightpence* for each person. In marshalling the band, two reapers are placed on each ridge of 15 feet in breadth, with a binder to each *four* reapers, and a steward, or the farmer in person, to superintend the whole. When the crop is of average bulk, and lies favourable for reaping, each *bandwin*, or set of *four* reapers and a binder, clear *two* acres in a day of *ten* hours; but $1\frac{1}{4}$ to $1\frac{1}{2}$ acres only, if it is bulky and lodged. The cost of reaping by this method is therefore from 7s. 6d. to 12s. per acre. With such a reaping-machine as Bell's, cutting, say eight acres *per diem*, and requiring in all ten persons (five men and five women or stout lads), to attend to and clear up after it, at an average wage, including victuals, of 2s. 6d. each; and allowing

Grain Crops.

Reaping by machinery.

3s. *per diem* to cover tear and wear, and interest on its prime cost, there seems a reasonable prospect of a goodly portion of our future crops being reaped for about 3s. 6d. per acre. The labour of the horses employed in working the reaper is not included in this estimate, as at this season they would otherwise be idle, and yet eating nearly as much food as when at work. There would thus be a saving in actual outlay of 4s. per acre. But this is the least important view of the matter. On a Berwickshire farm producing 200 acres of crop, there are usually at least six pairs of horses kept, with a resident population, sufficient to yield about thirty persons (including women and youths), available for harvest labour. The stated forces of such a farm will therefore suffice to man *two* reaping-machines, and leave ten persons still available for opening up fields, clearing corners, and reaping such portions as the machines cannot deal with. In unfavourable seasons, one machine only might be able to work with twenty persons using the scythe or sickle. In either way the crop could be cut down in from ten to fifteen days with little or no extraneous aid; whereas, to accomplish it in the same time by hand labour only, from fifty to sixty persons are required. The rapidity and accuracy with which the sowing of grain is now accomplished, frequently issues in the whole crops of a wide district being simultaneously ready for the sickle. The consequence is, that the supply of labourers proves insufficient—there is a scramble to get them—the rate of wages becomes exorbitant, employers are fain to submit to much sauciness and turbulence; and all the while the crops are suffering from over-ripening and are exposed to shaking winds. Great then will be the boon to farmers, if, by means of this invention, they can bring their own heavy cavalry into the field—dispense with the services of mercenaries,—reduce their actual outlay, and yet shorten the period and lessen the risk of the harvesting process. The call for reaping-machines is now, therefore, more urgent than ever. Perhaps we might add, it is only now that our agriculture has made sufficient progress in other respects to be ready to gear on to such machinery when presented to us.

When grain is fit for reaping.

It is now agreed on all hands that grain should be reaped before it becomes what is called *dead* ripe. In the case of wheat and oats, when the grains have ceased to yield a milky fluid on being pressed under the thumb-nail, and when the ears and a few inches of the stem immediately under them have become yellow, the sooner they are reaped the better. Barley requires to be somewhat more matured. Unless the pink stripes on the husk have disappeared, and the grain has acquired a firm substance, it will shrink in drying, and be deficient both in weight and colour. When allowed to stand till it gets curved in the neck, the straw of barley becomes so brittle that many ears break short off in the reaping; and it suffers even more than other grain-crops under a shaking wind.

Different modes of stooking sheaves.

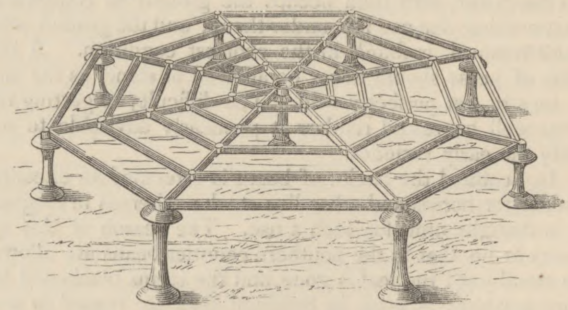
It is of great consequence to see that corn is dry when it is tied up in sheaves; that these are not too tightly bound, and that every sheaf is kept constantly on foot. From the increased demand for harvest labourers, and the rapidity with which operations must be carried forward, stooking is not now performed with the same accuracy that it was wont to be. There is therefore the greater need for employing a person to review the stooks daily, and keep every sheaf erect. It was formerly the practice in Scotland to set up oats and barley in full stooks of twelve sheaves each, viz., five pairs and two hood-sheaves. These hood-sheaves are an excellent defence when wet weather sets in, but they retard the drying of the corn in fine weather, and there are now few binders who can set them up so as to stand securely. It is better, therefore, to aim at rapid drying, and, for this purpose, to have the sheaves small individually, and to set but *four* or *six* of them together. Large sheaves are worse to dry than small ones, not only from their greater bulk, but from their being almost invariably tighter bound. The utmost vigilance is required on the part of farmers to avoid this fault.

Reaping of beans or pease.

Beans and pease are reaped by the sickle. The former are usually not bound into sheaves at once, but left prostrate in handfuls for a few days until they have withered a little. They are then sheaved, and bound with ties of twisted straw, which must be provided beforehand. In stacking beans, the tops of the sheaves are kept outwards, as by this means fewer pods are exposed to the weather, or to the depredations of fowls, &c., than when the butts are to the outside. Pease are rolled into wisps as they are reaped. and afterwards turned daily until they are fit to carry. When stacked, they must instantly be thatched, as they take in wet like a sponge.

Carrying in stacking grain crops.

It requires no little discrimination to know when sheaves are dry enough to keep in a stack. The farmer finds it for his profit to consult his most intelligent and experienced labourers on this point. On thrusting the hand into a sheaf sufficiently dried, there is a lightness and kindliness to the touch not easily mistaken when once understood. Whenever this is ascertained, the crop is carried with the utmost possible despatch. This is best accomplished by using one-horse carts, and by building the sheaves into round stacks of *ten* or *twelve* loads each. Very large stacks are for ostentation, not for profit. The labour of pitching up the sheaves to them is needlessly great; corn is much sooner in a state to keep in small stacks than in large ones, and sooner gets into condition for market; the crop is more accessible for thrashing in *ten*-load quantities than in huge ricks, and the crop of different fields and kinds of grain more easily kept separate.



YOUNG'S STACK-STOOL.

Stack stools.

It is always desirable to have the stacks built upon frames or stools elevated 18 or 20 inches from the ground. Besides the security from vermin thus attained, there is a free admission of air to every part, particularly when aided by a triangle of rough timber in the centre, which speedily insures thorough dryness in the whole stack. When stacks are built upon the ground, with a mere bedding of straw under them, the grain from the basement tiers of sheaves is often lighter by several pounds per bushel, than that from the rest of it. A farmer who has his rick-yard fully furnished with these frames, can often carry his crop without risk,—when, if built on the ground, it would inevitably heat,—and have the grain in condition for market earlier by months than in the latter case. We have elsewhere noticed a recent, but, perhaps, too costly improvement upon these stack-frames, viz., to have them mounted on wheels and set on rails, so that such stacks can be moved entire to the barn-door, when about to be thrashed.

Thatching stacks.

As the stacks are built, they are thatched without delay. For this purpose, careful farmers provide beforehand ample stores of thatch and straw ropes. The thatch is not elaborately drawn, but merely straightened a little as it falls from the thrashing-mill, tied into large bundles, and built up into stacks, where

Root Crops.

it gets compressed, and so lies more evenly than if used direct from the mill. A good coating of such thatch secured by straw ropes, interlacing each other in chequers, forms a secure and cheap covering, easily put on by ordinary farm-labourers; and possessing, with all its roughness, an air of unpretending rustic neatness, which harmonises well with surrounding objects, and which we greatly prefer to the elaborate ricks of the southern counties with their shaved sides, combed thatch, and weather-cock-a-peak. Apart from its cost, the shaving of stacks is objectionable, as they then suffer more from a beating rain or snow-drift, than when the natural roughness is left upon them, on the same principle that a coarse, shaggy topcoat shoots off wet, better than a smooth broadcloth.

With proper machinery propelled by steam or water, the thrashing and dressing of grain is a simple and inexpensive process. As grain is now universally sold with a reference to its weight per bushel, its relative value depends much upon its dryness and thorough freedom from chaff, dust, light grain, and seeds of weeds. Farmers who are systematically careful in the cultivation, harvesting, thrashing, and dressing of their crops, can always command the best prices of the day. In preparing a parcel of grain for market, it is a good plan to measure a few sacks very carefully, ascertain the average weight of these, and then fill every remaining sack to that weight exactly.

## CHAPTER VII.

### ROOT CROPS.

*Potato.*—The events of the past seven years render it necessary to regard this root somewhat differently than was warranted by its previous history. Its value, as an article of food, relished alike by prince and peasant, its easy culture, its adaptation to a very wide diversity of soil and climate, and the largeness of its produce, justly entitled it to the high esteem in which it was universally held. Like many other good gifts, it was, however, grossly abused, and diverted from its legitimate use. From an agreeable, wholesome addition to the daily food of the community, advantage was taken of its amazing productive powers, to put it in place of "the staff of life." In Ireland, and the Highlands of Scotland, the people already in a painfully degraded condition, and contented to exist with potatoes as their sole food from year's end to year's end, took occasion, from its very productiveness, under the rudest culture, to subdivide their lands, and marry prematurely, with reckless improvidence, and amid an ever-deepening degradation. We know now, from the utter prostration and helplessness into which this wretched population was at once thrown by the memorable potato disease, the terrible penalty which this abuse of "a good gift" has brought directly on the miserable sufferers, and indirectly on the whole community. It will be well if the stern lesson, enforced by famine and pestilence, have the effect of leading to a better social condition. Viewed in this light, the potato disease may yet prove a blessing to the nation. Its continued prevalence, although in a mitigated form, cannot well be regarded otherwise, when we remember the frantic eagerness with which the Irish peasantry replanted their favourite root on the first indication of its returning vigour, and the desperate energy with which they cling to it under repeated disappointments. Apart from this specialty, the precarious health of this important esculent is much to be regretted. It seems contrary to analogy to suppose that it is likely either to be entirely lost, or to manifest a permanent liability to this disease. It seems more natural to suppose that, by and by, this disease will disappear, or that some efficient remedy for it will be discovered. Railways now afford great facilities for transporting this bulky commodity at little expense to great distances, and thus render the market for it available to a wider district, and would, but for the disease, insure its more extended cultivation.

Effects of the "potato disease."

The varieties of the potato, whether for garden or field culture, are exceedingly numerous, and admit of endless increase by propagating from seeds. It would serve no useful purpose to enumerate here even a selection from the sorts in use in different parts of the country. In Messrs Lawson's *Synopsis of the Vegetable Products of Scotland*, a description of 175 kinds is given, to which the reader is referred for particulars. When the crop is grown for cattle food, bulk of produce will be the primary consideration; but for sale or family use, flavour, keeping quality, and handsome appearance, as well as good yield, will be particularly attended to. Exemption from disease is now a momentous consideration, whatever the use for which it is grown. There is this difficulty, however, connected with selections on the score of healthiness, that while in each season since the disease broke out, certain varieties have escaped, it is observed, from year to year, that the exempted list varies; certain kinds that had been previously healthy becoming as obnoxious to disease as any, and others in a great measure escaping that had suffered much before. Indeed, certain parties, from observing that diseased tubers left in the ground have produced healthy plants in the following season, have been induced purposely to plant diseased potatoes, and with good results. This, however, is probably due to the mere fact of their being kept in the earth.

Varieties exceedingly numerous.

In field culture, the potato is frequently grown on a portion of the fallow break; but its appropriate place in the rotation is that usually assigned to beans, with which, in an agricultural point of view, it has many features in common, and in lieu of which it may with advantage be cultivated. As the potato requires to be planted as early in spring as the weather will admit of, thus leaving little opportunity for cleaning the land, and as its mode of growth forbids any effective removal of root-weeds by after culture, it is peculiarly necessary to have the land devoted to this crop cleaned in autumn. Winter dunging facilitates the planting, and is otherwise beneficial to the crop by producing that loose and mellow condition of the soil in which the potato delights. The quality of the crop is also believed to be better when the dung is thoroughly incorporated with the soil, than when it is applied in the drill at the time of planting. A liberal application of manure is necessary if a full crop is expected. The rank growth thus induced renders it, however, more obnoxious to the murrain, and hence at present it is more prudent to aim rather at a sound crop than an abundant one, and for this purpose to stint the manure. When it is applied at the time of planting, the mode of procedure is the same as that which will presently be described in the section on turnip culture. The potato sets are prepared a few days before they are expected to be needed. Tubers about the size of an egg do well to be planted whole; and it is a good plan to select these when harvesting the crop, and to pit them by themselves, that they may be ready for use without further labour. The larger tubers are cut into pieces having at least one sound eye in each, although two are better. It is of great consequence to have seed-potatoes stored in a cool and dry pit, so that if possible they may be prepared for planting before they have begun to shoot. If there has been any heating in the pit, the potatoes are found to be covered by a rank crop of shoots, which are necessarily rubbed off, and thus the most vigorous eyes are lost, and much of the substance which should have nourished the young plant utterly wasted. A sufficient number of dormant eyes are no doubt left, but from the comparatively ex-

Preparation of the soil.

Preparation of the sets.

Root Crops.

hausted state of the tubers, these produce stems of a weaker and more watery character, and more liable to disease than those first protruded. To avoid these evils, gardeners are at pains to invigorate their seed potatoes and husband their whole powers for early and vigorous growth by *greening* them in autumn, storing them in a cool place with a current of air passing through it, and then in early spring exposing them to light on a floor, whence they are carefully removed and planted with their short, thick, *green* shoots unbroken.[1] Neither the *greening* nor the sprouting under cover and in the light, can ordinarily be practised on the scale on which the field culture of the potato is conducted. But the important feature in it, viz., so treating potatoes intended for seed that the crop shall be produced from the first and most vigorous shoots, and that these shall obtain the full benefit of the natural pabulum stored up for their use in the parent tuber, should be carefully considered and imitated if possible in field culture.

The report of the meeting of the Edinburgh Botanical Society, on 8th January 1852, bears that "Professor Simpson communicated the results of some experiments made by himself and Mr Stewart relative to the growth of alpine plants after having been kept artificially covered with snow in an ice-house for many months. Seeds and plants when kept in this way during winter, and then brought into the warm air of summer, germinate and grow with great rapidity. Mr Stewart had also made experiments with animals, and he found that the chrysalis so treated produced a moth in eleven days after being brought into the atmosphere, while other chrysalis of the same moth did not do so for three or four months after. In arctic regions the rapid growth of plants during the short summer was well known. Professor Simpson alluded to the importance of similar experiments being made on the different kinds of grain. He referred to the rapidity of harvest in Canada and other countries where the cold lasted for many months, and he was disposed to think that if grain was kept in ice-houses during the winter, and sown in spring, there might be an acceleration of the harvest."[2]

This suggestion for the treatment of seed corn is certainly deserving of trial. But the known difficulty of hindering the premature germination of potato sets in the ordinary method of storing them, seems to point to them as the peculiarly appropriate subjects of such an experiment.

Potato drills should not be less than 30 inches wide, nor the sets less than 10 or 12 inches apart in the rows. The usual practice is to take the sets to the field in sacks, which are set down at convenient distances for replenishing the baskets or aprons of the planters. When a large breadth is to be planted, a better way is to have the sets in carts, one of which is moved slowly along in front of the planters. A person is seated in the cart, who has by him several spare baskets which he keeps ready filled, and which are handed to the planters in exchange for empty ones as often as required. This greatly economises the time of the planters, and admits of a greater amount of work being accomplished by them in a day. Single-bout drills are quite sufficient so far as the success of the crop is concerned. Where neatness is much studied, a double-bout certainly makes a nicer finish, but as the drills should be partially levelled by a turn of the drill-harrows about ten or fourteen days after planting, as weather admits, very short time is allowed for admiring the trigness of the work; and the extra labour thus expended can certainly be more profitably employed at this busy season. So soon as the young potato plants are fairly above ground, the drill-grubber should be set to work and followed up without delay by hand-hoeing. Mr Wallace, North-Berwick-Mains, a most successful cultivator of potatoes, has for many years taken off all the shoots, save one, from the potato sets as they appear above ground, and the prunings are used in filling up blanks; the result has been, that the produce of the solitary stem is both larger and of more equal size and quality than when the shoots are all left. A turn of the horse-hoe and another hand-hoeing after a short interval are usually required, after which the common practice is to earth up the rows by the double mould-board ploughs. There is reason to believe that this latter practice usually does harm, rather than good. It no doubt prevents the uppermost tubers from getting greened by exposure to the light, but it is believed that the injury inflicted on the roots which spread into the intervals betwixt the rows far more than counterbalances any benefits that result or have been supposed to result from this earthing up. After the plants are a foot high, a slight stirring of the surface to keep down weeds is all the culture that is admissible consistently with the well-doing of the crop. When the crop is matured, which is known by the decay of the tops, and the firmness of the epidermis when the tubers are forcibly rubbed by the thumb, advantage is taken of every dry day in harvesting the crop. For small plots, the fork is certainly the most efficient implement for raising the tubers; but on the large scale when expedition is of such consequence, they are always unearthed by the double mould-board plough. Alternate rows are split open in the first instance, and then the intervening ones, as the produce of the first is gathered. When a convenient breadth has thus been cleared, a turn of the harrows is given to uncover such tubers as have been hid from the gleaners at the first going over. In Kincardineshire, this work is now accomplished by attaching to the common plough a crescent-shaped share about 18 inches broad, with four stout prongs, each a foot in height, welded to its upper surface, and set at an angle of 45° to the sole of the plough. This being worked directly under the row of potato plants, unearths the tubers, and spreads them on the surface by one operation. The potatoes are gathered into baskets from which they are emptied into carts and conveyed at once to some dry piece of ground, in which they are piled up in long narrow heaps and immediately thatched with straw. The base of the heaps should not exceed a yard in width, and should be raised above the surface level rather than sunk below it as is very usually done. As the dangers to be guarded against are *heating* in the first instance and frost ultimately, measures must be taken with an eye to both. The crop being put together in as dry and clean a state as possible, and covered with as much straw as will shoot off rain and protect from any early frost, is allowed to lie for three or four weeks. By this time the mass will have become considerably drier, and as weather admits, the whole is now turned over and shook in a riddle wide enough to pass dirt and small tubers: diseased roots are then carefully removed, and the sound ones formed into a heap as before, with a row of drain tiles laid along the centre of the base. A good covering of straw is then put on and coated over two or three inches thick with earth, care being taken to leave a chimney every two yards along the ridge. By thus keeping the heaps dry and cool, and secure from frost, it is usually possible, even yet, to preserve potatoes in good condition till spring. Such diseased ones as have been picked out, either at the first gathering or at the turning of the heaps, can be used for feeding cattle or pigs. The fact that pigs fatten, apparently, as well on diseased potatoes when cooked by steaming or boiling, as

[1] See a Pamphlet *On the Cultivation of the Potato* by Mr James Cuthill, Market-Gardener, Camberwell, London, which should be studied by every grower of potatoes.

[2] *Gardener's Chronicle*, 31st January 1852.

Root Crops.

on sound ones, is certainly a very important mitigation of this dreaded calamity. There are several varieties of the potato, such as "lumpers," "cups," "mangel-wurzel potato," &c., which, although unfit for human food, are much relished by cattle, and which from their abundant produce, healthiness and great fattening quality are well deserving of being more generally cultivated for the purpose of being used in combination with turnips and other substances in the fattening of cattle. The turnip crop of 1851 was nearly as much diseased as the potato crop, and as one remedy against "fingers and toes" in the former, is to let longer intervals of time intervene before their recurrence in the same field; and as it has been ascertained that an acre each of beans, potatoes, and turnips, will produce more beef than three acres of turnips alone, it is worthy the consideration of those concerned whether it would not be prudent to substitute a crop of these coarser potatoes for a portion of their turnip crop on fields or parts of fields that have borne diseased turnips in previous rotations.

*Turnips.*—The introduction of turnips as a field crop constitutes one of the most marked epochs in British agriculture. To the present day no better criterion exists by which to estimate its state in any district, or the skill of individual farmers, than the measure of success with which this or other root crops is cultivated. We have already, in our section upon fallowing, described in detail the process of preparing the soil for drilled green crops. Referring the reader to what is there said, we now proceed with our description of turnip culture.

Manure for turnip.

Previous to the introduction of bone-dust and guano, farm-yard dung formed, in the majority of cases, the only available manure for the turnip crop. It was almost invariably formed into heaps in the field to which it was to be applied, and repeatedly turned, as great stress was laid on having it well rotted. The introduction of these invaluable portable manures has, however, not only immensely extended the culture of the turnip; but has materially modified the course of procedure. On the first introduction of bone-dust, the practice was to use the fold-yard dung, as far as it would go, and to apply bone-dust alone, in quantities of from sixteen to twenty bushels per acre, to the remainder of the crop. Guano, too, for a time, was used to some extent on the same principle; but now it is most satisfactorily proved, that whereas very good crops of turnips can be obtained by manuring either with dung alone, at the rate of from fifteen to twenty tons per acre, or bones alone, at the rate of sixteen to twenty bushels, or guano alone, at the rate of three to four cwt., much *better* crops can be obtained by applying to each acre its proportion of each of these kinds and quantities of manures. A portion of the bones is now usually applied in the form of superphosphate of lime; and as this substance, and also guano, have a remarkable power of stimulating the growth of the turnip in its earliest stage, forcing it to the state fit for thinning from ten to fourteen days earlier than heretofore, there is now no occasion for the dung being in the advanced state of decomposition that was formerly found necessary. When farm-yard dung alone was used, it behoved to be in a soluble state, ready to furnish nourishment to the plant from the beginning. But in bringing it to that state, a considerable loss is sustained by fermentation, and its bulk is so much reduced, that it becomes difficult to distribute evenly the allowance which would be available for each acre, in order to give the whole crop a share of it. This, however, it is most desirable to do, as good farm-yard manure contains in itself the whole elements required by the crop. And hence an additional reason for the plans of applying farm-yard dung, which have already been noticed. If that made during the previous summer has been applied in autumn to the lea before ploughing for oats, as far as it will go, and another portion of the contemplated turnip break dunged before the winter furrow, with all that has been made up to that time, and the future accumulations up to April formed into heaps, to be applied in the drills for the latest sowings, the manure produced on the farm may be made to go over nearly the whole breadth under root crops.

Root Crops.

In proceeding to sow those portions that were dunged before the oat crop, and on the stubble, all that is required, is to form the drills, and apply the guano or bones, or mixture of both, by hand. In doing this, ten or twelve drills are set out the evening before, that all may be ready for a good start. The light manure is taken to the field in carts, which are unyoked at convenient distances for replenishing the aprons of the young persons (one for each plough) who distribute it along the drills. The sowers of the manure being started on the outside drills, the ploughmen proceed to open fresh ones inside in going, and to cover in the manure by reversing the first formed ridglets as they return. The seed-machine, sowing two rows at a time, follows close up to the ploughs, and thus the work goes rapidly on, each plough getting over from $2\frac{1}{2}$ to 3 acres a-day. When farm-yard dung is applied at the time of sowing, the process is the same, except that the drills must be opened somewhat deeper, and that the dung-carts, followed by an adequate number of spreaders, precede the sowers of the light manures. In filling the dung-carts, one able-bodied labourer is required for each plough employed in drilling; and where these amount to three, six spreaders are required to distribute it evenly along the drills. In some districts the double-breasted plough is used in forming the drills and covering in the dung. In the hands of a skilful ploughman, that implement does certainly make neater work to look at; but so far as the success of the crop is concerned, the common swing-plough is preferable, for in covering in with it, the earth is made to run over the top of the ridglet, by which means the clods fall into the hollow, and the finest of the mould is left on the top, where the seed is to be deposited. With the double mould-board this cannot so well be done, and the consequence is, that a groove is formed on the top of the ridglet, in which the small dry clods, carried up by the tail of the mould-board, are left, forming the worst possible bed for the seed. In parching weather, it is usual to pass a light roller over the drills, immediately after sowing, to retain the moisture, and insure germination. The seed is deposited near the surface, half an inch of mould being a sufficient covering. The quantity sown is 2 lb. per acre of globe or yellow turnip seeds, and 3 to 4 lb. of Swedes. Care must be taken that the seed is fresh, so as to have a vigorous and thick plant. Thick sowing increases the difficulty of thinning out the plants, but it hastens their growth, and diminishes the risk of failure from the depredations of the turnip beetle. The time of sowing in the south of Scotland extends from the middle to the end of May for Swedes, and thence to the middle of June for yellows and globes. A partial sowing of yellow or globe is however made by careful stockmasters before sowing the Swedes, to be ready for use by the end of August or beginning of September, when pasturage fails. Sowings of early varieties such as the stubble turnip and certain yellow kinds, are also made after winter tares or other catch crops, until the middle of July; but later than this they cannot be sown in Scotland with advantage, unless for the production of a crop of seed. The average weight per acre of Swedes may be stated at 18 tons, and of turnips at 22 tons, although double these rates have occasionally been obtained. Recent experiments go to show that with liberal manuring and early sowing, the weight of the crop is considerably increased by thinning out the plants at wider intervals than has hitherto been customary. The usual practice in Scotland has been to sow in

Root Crops.

ridglets 27 inches apart, with 9 or 10 inches betwixt the plants. Recent experiments establish the fact that with 15 inches from plant to plant, much larger bulbs and a greater acreable produce are obtained. As it is ascertained that in the case of Swedes the largest bulbs are also the best in quality, it is of the greater consequence to allow them ample room.

Thinning turnips.

The thinning is commenced as soon as the rough leaf is fairly developed. Previous to this operation the horse-hoe is worked betwixt the rows for the double purpose of destroying weeds and facilitating the operation of thinning. When the plants have rallied after the thinning, and begun to grow rapidly, the usual practice has been to turn a furrow from either side of them into the middle of the interval by a one-horse plough, and then to level this down by a turn of the horse-hoe. A great improvement on this practice is to use Tennant's grubber instead, adjusted for drill work in the manner already described. By thus using a strong implement drawn by two horses, the soil in the intervals betwixt the rows can be stirred a foot deep if required, without any risk of hurting the young plants, and this too is accomplished by a single operation. A second hand-hoeing is then given, which usually completes the after culture. It was formerly the invariable practice to finish off by passing a double mould-board plough betwixt the rows, which was called *setting up*. On dry soils this is not only useless, but positively hurtful to the crop; and those so wet as to require it are unfit for the profitable cultivation of turnips at all.

The nature of the soil will usually determine the mode of consuming the crop. On all loose, dry soils, feeding off by sheep is the most profitable plan; whereas on deep, strong loams it is advisable to withdraw the whole and eat them by cattle, as, unless in very favourable weather, when even a fourth is fed off by sheep, the extra manuring does not compensate to the after crops for the injury which they usually sustain from the treading and poaching. On the poorest class of light soils, the whole crop should if possible be consumed where it grows by sheep; but on those of a better description, a third, a half, or two-thirds may be withdrawn for the feeding of cattle according to circumstances. Whatever the proportion left on the ground, care is taken to regulate the intervals so as to distribute the treading and droppings of the sheep as equally as possible over the field.

The management of the turnip crop, so as that it may be supplied to the live stock in the best possible condition during the entire season is a point of the greatest importance. The portion that is to be used as cattle food is removed from the ground as soon as the crop has sufficiently matured, and before the time when drenching rains and severe frosts may ordinarily be looked for. The best way of preserving them is by storing in long narrow heaps on a dry and sheltered situation open to the sun, and covering them with a good coating of straw, secured by straw-ropes. The thatch of the corn-stacks that are thrashed in autumn is usually reserved for covering turnip heaps. After 1st November it is well to make diligent use of every favourable hour in thus securing the turnip crop. In corroboration and further illustration of this important point, we here engross an interesting communication recently received from Mr Archibald Hepburn, Whittingham Mains, East Lothian:—

"Mr Buist (Lord Haddington's factor) is compelled by reason of the game on the home-farm to store all his turnips except a few required for sheep. He sows very early in May, chiefly Swedes; stores in October; leaves the roots on; makes the heaps oblong, about 5½ feet by 4; thatches with ten inches of straw; turns the heaps, and rasps off the shoots in March. I have myself kept Skirving's purple-top yellow good in this way from November till the middle of May.

"Mr Cuthbertson, Greendykes, East Lothian, farms a clay-soil, which, although furrow-drained, and in very high condition, is, according to old preconceived ideas, ill adapted for the turnip husbandry; but by good management, few farmers succeed better in obtaining heavy crops of turnips. Of late years he has sown *nothing* but Skirving's purple-top yellow at the rate of *five pounds* per Scotch acre; commencing the sowing late in April, and finishing his whole *break* about the middle of May, weather permitting. Early in September he commences drawing and storing a proportion of each field, leaving the remainder to be consumed on the ground by sheep, which are folded on without delay; and the whole breadth left for that purpose is consumed, and wheat sown throughout November.

"The leaves of the turnip are chopped off about one inch from the bulb, and the tap-root is merely cleared of earth, particular care being taken to store the turnip when *quite dry* and free from frost. If it is necessary in clearing a field to cart off the bulbs when wet with rain, they are stored in a separate heap for early eating. Those carried in the above mentioned good condition are stored in long heaps, 20 feet broad at the base, and about 5½ or 6 feet high, and that in a roof-like fashion. The heaps are thatched with straw to the depth of about 10 inches, and secured with straw-ropes. The contents are never disturbed until they are required for daily consumption. The turnips are found to be excellent food for cattle, so late as the beginning of June. This most excellent practice and its happy results cannot be too widely known. Mr Cuthbertson used to store his yellow turnips according to Mr Buist's plan, but prefers these enormous heaps."

The difference both to the cattle and to the land betwixt the plan of having turnips stored in dry weather without poaching the fields and securing clean and fresh food in all weathers, and the other of bringing in only a few days' supply at a time, and so being often compelled to go upon the land when soaked with rain or bound with frost, and feeding the cattle with miry or frozen turnips, can scarcely be computed. The careful farmer will never feel at ease until his winter's provision is safe in the store-heap. The portion to be fed off by sheep must necessarily be treated in a different manner. What is to be used after Christmas can be very readily defended against frost, by earthing up in the drills with the common plough. But as what is to be consumed by the young sheep must be pulled and trimmed at any rate, in order to be sliced, the best way is to throw the turnips into heaps at regular distances, and cover them first with the greens, and then with a thin coating of earth. By this means the turnips are kept from running to stems, and the sheep get them clean and fresh whatever the state of the weather.[1] The same end is secured by opening a trench by a bout of the common plough, into which the turnips from two drills on either side are laid in regular order with their tops uppermost, and the earth turned over upon them by reversing the course of the plough. When wanted for use, they are again unearthed by means of the plough. The feeding qualities of turnips are so seriously impaired by exposure to frost, even when they escape actual destruction, that the expense of securing them by one or other of these methods, is always amply repaid. In very mild winters again, storing is equally effective in preventing the virtues both of the turnips and the soil from being wasted by the pushing of the seed stems. Such precautions are so usually omitted,

Preserving turnip for sheep feeding.

[1] During the unusually wet winter of 1852–3, we stored a large quantity of turnips and Swedes, intended for cattle food in this way. The trimming and storing was carried on every dry day, and the carting postponed until the occurrence of frost or drought admitted of its being done without injury to the land.

Root Crops.

and the loss thereby sustained is so serious, that it would be well for all who question the utility of the practice to satisfy themselves regarding it in some such way as this. Let two portions of a turnip field, as equal in all respects as possible, be selected, and let the crop from one of them be in December put into small store heaps or buried in the earth, and let the other remain on the ground untouched till the middle of March. Let a lot of sheep which have received the same previous treatment be then equally divided and fed respectively on these several portions for three or four weeks, and their weights ascertained before and after the trial. Let both portions be afterwards sown with barley under like circumstances, and the produce accurately ascertained. Assuming that an average amount of frost occurs, and that the unstored turnips have begun to push their seed stems when the sheep are put upon them, our personal experience warrants us in anticipating a difference of at least *six* bushels of barley per acre, and *two* lb. of mutton per sheep in favour of the portion on which the turnips are stored.

Diseases.

The turnip is liable in the early stages of its growth to the attacks of various insects. The most formidable of these enemies is the *turnip beetle*, which frequently settles upon the plant so soon as they appear above ground, in such numbers as totally to destroy the whole of them. The best way of guarding against these nimble adversaries, is to endeavour, by careful preparation of the soil, liberal manuring and thick seeding to secure a thick plant and rapid growth, for whenever the rough leaf is expanded, the risk from this quarter is over. From time to time the young turnip plants are assailed by the larvæ of certain butterflies and moths, which sometimes appear in such numbers as to cause serious alarm, but ordinarily their attacks occasion but a slight check to the growth of the crop.

"Fingers and toes."

A far more formidable evil is the disease called "fingers and toes," which, although long known, seems to be steadily extending, and has been wider spread and more virulent in the turnip crop of 1851 than in any previous year. This truly formidable disease sometimes shews itself by the time that the plants are ready for thinning, but more usually it is about the stage when the second hoeing is given that unmistakable indications of its presence are observed. The crop appears in high health, and is making rapid growth, when, suddenly under hot sunshine, numbers of the plants are seen to droop with flaccid leaves; and examination being made, it is found that the disease has already made serious progress. In some cases it is chiefly confined to the taproot, which is distorted with knobby excrescences. In others, the roots present a thickened, palmated appearance, giving rise to the popular name for the disease, "fingers and toes," while in others the lateral roots expand into glandular-looking tubers, which frequently appear partially above ground at distances of several inches from the central stem. For a time all these forms of the excrescences present a smooth healthy looking skin, yielding no trace of the presence of insects of any kind, either externally or internally. By and by the skin cracks over the excrescences, which speedily assume a gangrenous appearance. Indeed, the whole symptoms present a striking analogy to cancer in the animal system. By the time that the healthy plants are approaching near to maturity, the most diseased ones have usually lost all resemblance to turnips, and there remains on the land a substance like rotten fungus. In very bad cases, whole acres together are found in this state, with here and there a sickly distorted turnip still shewing a few green leaves. At other times a few only of the plants are wholly destroyed; the field, to a casual observer, looking not much amiss, though a closser inspection proves that the general crop is of stunted growth, with few plants entirely free from the disease. Such partially diseased roots are not absolutely rejected by sheep, but they are evidently unpalatable and innutritious, while the crop as a whole is more speedily consumed than its general appearance would lead one to expect. When this disease appears on farms that have previously been exempt from it, it is usually confined for a year or two to small patches, which, however, in the absence of remedial measures, steadily and rapidly extend, not only on the recurrence of a turnip crop on the same fields, but over the other parts of the farm. Indeed, there are not wanting indications of its being propagated by contagion; as, for instance, when tainted roots are carted into pastures, and the disease shews itself most in those places where they have been consumed, when, in course of rotation, the field comes afterwards to bear a turnip crop. When they are consumed by cattle in fold-yards, the dung may be the medium of contamination, on the supposition that this conjecture is well-founded. Ploughing land in a wet state evidently aggravates the disease. We know of one instance where a strip down the middle of a field was ploughed in autumn while soaked by rain, on which wet ploughed portion the turnips were evidently more diseased than over the rest of the field. In another instance which came under our personal observation, a ditch running along part of the top of a field, of upwards of 50 acres, was scoured in spring, and the mud spread back over the headland. The whole field was, in the same season, sown with turnips, which proved an excellent crop, entirely free from "fingers and toes," with the exception of that portion of headland on which the mud was spread, where every plant was diseased. Although wholly in the dark as to the nature and propagation of this disease, it is well to know that the judicious application of lime is a certain remedy. In order, however, to its efficacy, it must be applied in a *powdery state* after the autumn ploughing, and immediately incorporated with the soil by harrowing; or else as a compost with earth, spread on the lea, before breaking up for oats. We know from experience, that a very moderate dose (say four tons of unslaked shells), applied in this way will suffice as a prevention from this disease. It is on light soils that its ravages are most frequently experienced, and to these heavy doses of lime are unsuitable. Indeed, whether for promoting the general fertility of soils, or for warding off the attacks of this disease, moderate applications of lime every *twelve* years or so, seem preferable to heavier dressings at longer intervals. Beneficial effects are said to have been observed from the use of salt when scattered on the surface early in spring, and when applied in the drill in mixture with guano at the time of sowing the turnips. Substituting potatoes or some other crops for one round, so as to prolong the interval betwixt the recurrence of turnips to *eight* years instead of *four*, is said to be a certain remedy.

Beneficial effects of lime.

*Mangel-Wurzel.*—This root has been steadily rising in estimation of late years. It is peculiarly adapted for those southern parts of England where the climate is too hot and dry for the successful cultivation of the turnip. A competent authority declares that it is there easier to obtain thirty tons of mangel than twenty tons of Swedes, and that it is not at all unusual to find individual roots upwards of twenty lb. in weight. In Scotland it is just the reverse, it being comparatively easy to grow a good crop of Swedes, but very difficult to obtain twenty tons of mangel. This plant is very susceptible of injury from frost, and hence in the short summer of Scotland it cannot be sown so early nor be left in the ground so late as would be requisite for its mature growth. These difficulties may possibly be got over, either by the selection of hardier varieties or by more skilful cultivation. Its feeding quality is said to be superior to that of the Swede, it is much relished by live stock—pigs especially doing remarkably well upon it—and it has the very important property of keeping in good condition till midsummer if required. Indeed, it is only after it has been some months in the store heap that it becomes a palatable and safe food for cattle. It is moreover exempt from the attacks of the turnip beetle. On all these accounts, therefore, it is peculiarly valuable in those parts of Great Britain where peculiarity of climate renders it strong precisely where the turnip is defective.

Up to the act of depositing the seed, the processes of preparation for mangel are identical with those described for the turnip; winter dunging being even more appropriate for the former than for the latter. The ridglets being formed 28 inches apart, and charged with a liberal allowance of dung and guano, the seeds are deposited along the top, at the rate of about 4 lb. per acre. The common drilling machines are easily fitted for sowing its large rough seeds. The after culture is also identical with that of the turnip. The plants are thinned out at distances of not less than 15 inches apart. Transplanting can be used for the filling up of gaps with more certainty of success than in the case of Swedes. Several varieties of the plant are cultivated, such as, the yellow, the long-red, and the orange-globe. The crop requires to be secured in store heaps as early in autumn as possible, as it is easily injured by frost. The following graphic description of this process by Mr Morton of Whitfield, appeared in the *Agricultural Gazette* of 8th November 1851:—

"The mode of harvesting our root crop which we have adopted for several years is this; we let the lifting—cutting off the leaves and the roots, and putting the roots into the cart—at so much per acre, according to the weight of the crop, to one man, who gets other men to join with him in the work and share in the profits; and the arrangement I require to be adopted is, that the one-horse carts, which I employ to haul the roots, shall be constantly employed, and I require from 16 to 20 loads, or tons of roots, to be filled hourly. The number of carts required is according to the distance of the field from the store; thus the distance from the middle of the field to the store being 15 chains, four carts are required; 22 chains require five carts; and 30 chains require seven carts.

"*The mode of lifting the roots.*—Five men are employed to pull up the roots; each man pulls up two rows; standing between the rows, he takes with his left hand a root from the row on his left side, and with his right hand a root from the row on his right side, and pulling both up at the same time, places them side by side, across the row where he pulled up the roots with his right hand, so as to have the tops lying in the space between the two rows he has pulled up; the next man takes the two rows at the right hand of the last two rows we have just described, and he, with each of his hands, pulls up a row, and places them on the line of the row which he has pulled up with his left hand, with the root end lying towards the root end of the first row, so that we have now four rows of roots lying close together in two rows, side by side, with their leaves on the outside of each of these rows, and the roots of each row nearly touching each other; and every four rows, when growing, are thus, when pulled, laid in two rows, root to root, occupying not more than 27 inches. Now, as the next four rows are lifted in the same way, and placed in like manner, we have a space unoccupied of three times 27 inches, or 6 feet 9 inches between each double row of roots, for the cart to go between them (viz. this double row of bulbs after they have had the leaves and roots cut off), to carry off the bulbs to the store. After the five men who are pulling the roots, there follow ten women or boys with knives, made of pieces of old scythes, who, with repeated blows, cut off the leaves and roots, without ever moving one of them with their hands; this is constant, but not hard work, and it requires ten active women or boys to keep up with the five men pulling.

Immediately on the heels of the cutters follow the carts between the two double rows of bulbs as they lie, having their leaves and roots cut off; and a man, one of the principals of the gang, and nine young active boys and girls throw up the bulbs as fast as they can into the cart, the man speaking to the horse to move forward, or stop, as they clear the ground; when one cart is full, an empty one has been brought by one of the boys who drive the carts, and placed immediately behind the full one; so that, as he moves off with the full cart, the man calls the horse with the empty cart to move forward, and they proceed to throw the roots into the cart as fast as they did into the one that has just gone off the field.

"The pulling of the roots and the filling of the carts being the principal work, one of the leaders is in each of these departments of the work; so that, by his example, he shows those with him how he wishes them to work, and thus the work proceeds with the utmost regularity and despatch; 20 cart-loads are hourly filled in the fields and delivered in the store; 180 to 182 loads of 22 cwt. and 23 cwt. each in a day of nine hours; thus a cart-load is filled every three minutes by 10 pairs of hands, which are pulled by five pairs of hands, and the leaves and roots cut off by 10 pairs of hands—in all 25 pairs of hands, men, women, and boys; this has been repeatedly done in a day.

"The stores are made of posts and rails, enclosing a space 9 feet apart and 4½ feet high, and of any length, if the space will admit, and as near to where they are to be consumed as possible. The posts are 5 feet apart, let into the ground 18 inches, and 4½ feet above, with five rails above, 4 or 5 inches wide, nailed to the inside of the posts; and each of these stores is 3 feet apart. I have 14 of them about 70 feet long each, which is sufficient to store from 1000 to 1200 tons of bulbs."

The heaps are carefully thatched, and the spaces betwixt them filled with straw to keep out frost. The expense, exclusive of the carting, Mr Morton shows to be 3s. 6d. per acre.

It is believed that in many cases crops of turnip and mangel could be more cheaply stored by means of the portable railway than by carts, and with less injury to the land. This is especially the case with clay soils, and in such seasons as the autumn of 1852 has proved. In using it, eight drills of roots are trimmed and laid in two rows, as Mr Morton describes; the rails are shifted betwixt each of these pairs of rows; the roots pitched into light trucks, which a man pushes before him to the headland, where the contents are discharged by tipping. Being there heaped up and thatched, the roots are carted to the homestead as required.

*Carrots.*—This root, though so deservedly esteemed and universally grown in gardens, has not hitherto attained to general cultivation as a field crop. This is owing chiefly to certain practical difficulties attending its culture on a larger scale. Its light feathery seeds cannot easily be sown, so as to secure their regular germination; the tardy growth of the young plants, and the difficulty of discriminating betwixt them and weeds makes the thinning a troublesome affair; the harvesting of the crop is comparatively expensive; and it is only on sandy and light loamy soils, or those of a peaty character that it can be grown successfully. The increasing precariousness in the growth of potatoes, turnips, and clover, and the consequent necessity for a greater variety of green crops entitle the carrot to increased attention as a field crop. Its intrinsic qualities are, however, very valuable, especially since the introduction of the white Belgian variety. On light soils it is alleged that larger crops of carrots than of turnips can be obtained, and with less exhaustion of their fertility, which is explained as arising from the greater depth to which the carrots descend for their nourishment. This root is eaten with avidity by all kinds of farm stock. Horses, in particular, are very fond of it, and can be kept in working condition with a considerably smaller ration of oats when 20 lb. of carrots are given to them daily. They can also be readily kept to an advanced period of spring when stored with ordinary care.

The mode of culture is very similar to that already described for mangel-wurzel. A usual practise is to prepare

Root Crops.

the seed for sowing, by mixing it with moist sand, and turning the mass repeatedly for several days until germination begins, when it is sown by hand at the rate of 6 lb. per acre of the dry seeds, in a seam opened by the coulters of the corn or turnip drill, according as it is wished to have it on the flat or on ridglets. Some prefer merely to rub the mixture of seeds and sand or mould betwixt the palms, until the seeds are thoroughly separated from each other, and so divested of their hairs, as when mixed with sand to run from a drilling-machine. It is of the utmost importance to secure seeds of the previous year's growth, as if older their germination cannot be depended upon. Much care is also needed in saving the seed only from selected roots, as carrots have a decided tendency to degenerate. The white Belgian variety is certainly the best for farm use, not only from the weight of crop, but from its growing more rapidly in its earliest stage than other approved sorts, and showing a broader and deeper coloured leaf which can more easily be discriminated from weeds, and thus admits of the earlier use of the hoe. When the sowing and first hoeing and thinning of the crop are got over successfully, the after culture of the crop is very simple; all that is needed being the occasional use of the horse and hand-hoe to keep down weeds. The fork must be used in lifting the crop. The greens are then cut off and given to young stock or cows, and the roots stored in long narrow heaps, exactly as mangel. Fifteen tons per acre is an average crop, although on suitable soils, with liberal manuring and skilful cultivation, double the weight is sometimes obtained. Those who intend to cultivate this crop statedly, will do well to raise their own seeds from carefully selected roots. Unless genuine and fresh seed is sown, failure and disappointments can scarcely be avoided.

*Parsnip.*—This plant bears so close a resemblance to the carrot, and its culture and uses are so similar, that they need not be repeated. It can, however, be cultivated successfully over a much wider range of soils than the carrot, and, unlike it, rather affects those in which clay predominates. It is grown extensively, and with great success, in the Channel Islands. The cows there, fed on parsnips and hay, yield butter little inferior, either in colour or flavour, to that produced from pasture. About 10 lb. of seed are required per acre. It requires, like that of the carrot, to be steeped before sowing, to hasten germination, and the same care is needed to have it fresh and genuine. It should be sown in April. The roots, when matured, are stored like carrots.

*Jerusalem Artichoke.*—This root, although decidedly inferior to the potato in flavour, is yet deserving of cultivation. It grows freely in inferior soils, is easily propagated from the tubers, and requires little attention in its cultivation. When once established in the soil, it will produce abundant crops for successive years on the same spot. It is sometimes planted in woods to yield shelter for game, for which purpose it is admirably fitted, as it grows freely under the shade of trees, and yields both food and covert. In properly fenced woods it might yield abundant and suitable food for hogs, which might there root it at their pleasure, without damage to anything. Where they had mast along with these juicy tubers, they would undoubtedly thrive apace. After they had grubbed up what they could get, enough would be left to reproduce a crop for successive seasons. Such a use of this esculent seems well deserving of careful trial.

There are several crops which, under a strict classification, should be noticed among forage crops rather than here, but which, in an agricultural point of view, are so closely analogous to drilled root-crops, that we regard this as the suitable place in which to notice them.

*Cabbage.*—On strong rich soils, large crops of very nutritious food for sheep or cattle, and of a kind very acceptable to them, are obtained from the field culture of the Drumhead cabbage. A seed-bed is prepared in a garden, orchard, or other sheltered situation, in August, either by sowing in rows, 12 inches apart, and thinning the plants about 3 inches, in the rows, or, what is better, sowing in a bed, and transplanting them into narrow rows so soon as the plants will admit of it. In April, the land to be occupied with this crop is prepared as for turnips, in drills 27 to 30 inches wide, along the flattened top of which the cabbage-plants are dibbled two feet apart, and afterwards kept clean by horse and hand-hoeing. Another plan is to plough in the dung in autumn, and in April, when the soil is dry enough, to plough it and to dibble in the plants 30 to 36 inches apart each way in rectangular lines. A long line with feathers inserted in it at the requisite spaces for the guidance of the planters, is stretched along and set at the proper width; and, by employing a sufficient force of planters, the work proceeds simultaneously with the poughing,—a row of cabbages being inserted at every three or four furrows, according to the distance betwixt plants that is fixed upon. The advantage of this mode of planting is, that when accurately performed, the horse-hoe can be used in all directions, lengthwise, across, and diagonally, thus simplifying the summer culture. We have seen a crop of cabbages treated in this way, and planted but one to each square yard, completely closed in autumn. Cabbages are much in repute with breeders of rams and prize sheep, which fatten rapidly on this food. Cabbages are usually drawn off, and given to sheep on their pastures, or to cattle in byres and yards; but they are also fed off, where they grow, by sheep, in the same way as turnips. It is an exhausting crop when wholly drawn off, and is sometimes grown with advantage on this account on spots greatly enriched by irrigation with sewage or otherwise, and where the succeeding grain crop is expected to suffer from over-luxuriance, the cabbages being grown, as the phrase goes, to "take the shine out of it." In favourable circumstances, from 30 to 40 tons per acre of this nutritious crop may be obtained. From what has been said, it is evidently not adapted for extensive field culture; but on most farms a few acres might be grown annually with great advantage. It is a peculiarly suitable food for either sheep or cattle during the autumnal transition from grass to turnips.

*Rape.*—This plant is peculiarly adapted for peaty soils, and is accordingly a favourite crop in the fen-lands of England, and on recently reclaimed mosses and moors elsewhere. Its growth is greatly stimulated by the ashes resulting from the practice of paring and burning. In these cases it is sown broad-cast; but when such soils are brought into a regular course of tillage, it is drilled, and otherwise treated in the same manner as turnips. As we have described its culture under the head of "Oil-producing plants," we shall only say further here, that its highly nutritious leaves and stems are usually consumed by folding sheep upon it where it grows, and that there is no green food upon which they fatten faster. Occasionally it is carried to the homestead, and used with other forage in carrying out the system of soiling cattle.

*Kohl-Rabi.*—This plant has been frequently recommended to the notice of farmers of late years. Like mangel, it is better adapted for strong soils, and dry and warm climates, than the turnip. It may either be sown on drills in the same manner as the turnip, or in a seed-bed, and afterwards transplanted. The latter plan is expensive, if it is desired to cultivate the crops to any extent; but is commendable for providing a supply of plants to make good deficiencies in the rows of other crops, or when a small

Herbage and Forage.

quantity only is wanted. By sowing a plot of ground in March in some sheltered corner, and transplanting the crop early in May, it is more likely to prosper than in any other way. Cattle and sheep are fond of it, and it is said not to impart any unpleasant flavour to milk. We have seen a few trials of it in Scotland as a field crop; but, from whatever cause, the weight of food produced per acre was greatly less than from the mangel and Swedes growing alongside of it. For further information about this plant, the reader is referred to the *Book of the Farm*, vol. ii. p. 87; Hewit Davis' *Farming Essays*, p. 90; Lawson's *Synopsis of the Vegetable Products of Scotland*, Div. ii. p. 109. Mr Stephens calls it "turnip rooted cabbage," which is a distinct and inferior plant. Lawson says that the pulp or flesh of kohl has the same taste as the leaves of the cabbage, and hence its adaptation as food for milch cows.

## CHAPTER VIII.

### HERBAGE AND FORAGE CROPS.

Under this general heading, we propose to include what we have to say concerning the grasses, whether natural or cultivated, and those other crops which are grown expressly for the sake of the cattle food yielded by their leaves and stems. This kind of farm-produce is either consumed where it grows, by depasturing with live stock, or mown and given to them in a green state under cover, or dried and stored for after use. It thus embraces the cultivation of these crops, and their disposal, whether by grazing, soiling, or haymaking. Following this method, we shall first of all briefly describe the cultivation of those pasture and forage crops which are of best repute in British husbandry.

Tillage lands are now everywhere cropped according to some settled rotation, in which the well recognised principles of the alternate husbandry are carried out according to the actual circumstances of each locality. With rare exceptions, such lands at stated intervals bear a crop of the clovers or cultivated grasses. As these are usually sown in mixture, especially when intended for pasturage, the resulting crop is technically called "seeds." As it is of importance to have the land clean, and in good heart, when such crops are sown, they usually follow the grain crop which immediately succeeds the fallowing process. Being for the most part of a lower habit of growth than white corn crops, they can be sown and grow together without mutual injury. When the latter are harvested, the former being already established in the soil, at once occupy it, and grow apace. By this arrangement, there is therefore secured an important saving both of time and tillage. Barley being the crop amongst which the seeds of the clover and grasses are most frequently sown, and amongst which, upon the whole, they thrive best, it is customary to sow these small seeds at the same time as the barley, and to cover them in with a single stroke of the common harrows. This is erroneous practice, both as regards the time and manner of sowing these small seeds. We have already mentioned, in the proper place, that barley should be sown as early in March as possible. Now, if the clovers, &c., are sown as early as this, they are almost certain to get so forward as both to rob the barley of its due share of nourishment, and, when it is reaped, to bulk so largely in the sheaves, as to retard their drying, and aggravate the risk of their being ill harvested. It is found, moreover, that if there be but plants enough, the clovers stand the winter better, and ultimately yield a better crop, when but puny looking, than when very strong, at the reaping of the grain crop. It is better, therefore, to delay the sowing of the small seeds until April. As to the manner of covering them in, we have to remark that the smallness of these seeds, and their manner of germinating, alike requires that they receive only the very slightest covering of soil. This important fact is so well illustrated in the following table, which exhibits the results of some carefully conducted experiments, reported to the Highland Society by Mr Stirling of Glenbervie, that we shall here quote it:—

Sowing of clover and grass seeds.

"Column I. contains the scientific names.
Column II. contains the average weight of the seeds per bushel in pounds.
Column III. contains the average number of seeds in one ounce.
Column IV. shows, in inches, the depth of cover at which the greatest number of seeds brairded.
Column V. shows, in inches, the depth of cover at which only about half the number of seeds brairded.
Column VI. shows, in inches, the least depth of cover at which none of the seeds brairded.

"The results in the three last columns of the preceding table were obtained by sowing the seed in finely sifted dark loam, which was kept moist throughout the process of germination, to which is attributable the circumstance of so many of the sorts vegetating best—as shown in Column IV.—without covering, and under full exposure to the light. The combination of such favourable circumstances of soil and moisture, can, however, seldom be calculated upon in field sowing, therefore a covering of mould for the seeds, however slight, is always advisable. But it will be seen, by the results in Column VI., that a great number of seeds must be inevitably lost from over-depth of covering, unless the ground be in all cases carefully prepared and pulverised before sowing either the *natural* or *artificial* grasses."[1]

From this it is evident that to scatter these tiny seeds over a cloddy surface, and then to harrow it, may more aptly be called burying than sowing them. The following is a more rational mode of proceeding. When these seeds are to be sown among winter wheat, it is expedient to begin by using the horse-hoe (supposing the wheat to have been drilled), as well to loosen the surface and produce a kindly bed for the seeds, as to destroy weeds. In the case of broad-casted wheat, a turn of the harrows secures the same end. In the case of the more recently-sown barley, all that is needed is to smooth the surface with the one-horse roller. Over the ground thus prepared, the small seeds are distributed by a broad-cast sowing machine, which covers at once a ridge of 15 or 18 feet in width. The covering in is then effected by simply rolling with the smooth roller, or by dragging over the surface Smith of Deanston's chain-web, which may either be attached to the sowing machine, or to a separate frame; or by using Crosskill's roller with a hurdle interlaced with bushes tethered to it. On clay soils the chain-web is to be preferred; but on loose soils Crosskill's roller imparts a beneficial firmness, and with its tail-piece of bushes to fill up the indentations, gives an accuracy of finish, which rivals the neatness of a newly-raked garden plot. We have long regarded this covering in of grass seeds as the most important use to which Crosskill's valuable implement is put. The only drawback to it is, that it makes a heavy demand on the horse-power of the farm at a pressing season. As it can only be worked in dry weather, it is advisable, when the land is in trim, to work it double tides by means of a relay of horses. This mode of procedure is alike applicable to the sowing of mixed clovers and grasses, and to that of the clovers alone; and is the course usually pursued in sowing for one or two years' "seeds." When it is intended to lay down arable land to grass for several years, or to restore it to permanent pasture or meadow, it is always advisable to sow the seeds without a corn crop. This doubtless involves an additional cost at the outset, but it is usually more than repaid by the enhanced value of the pasture thus obtained. To grow the grasses well, the soil should be pulverised to the depth of 3 or 4 inches only, and be full of manure near the surface. There is no better way of securing these conditions, than by first consuming a crop of turnips on the ground by sheep folding, and then to pulverise the surface by means of the grubber, harrow, and roller, *without ploughing it.* Much diversity of practice exists in regard to the kinds and quantities of seeds used in sowing down with a grain crop. In Scotland from 2 to 4 pecks of ryegrass seeds, with from 10 to 14 lb. of those of red, white, and yellow clovers, in about equal proportions, is a common allowance for an acre. A pound or two of field-parsley is occasionally added, or rather substituted, for an equal weight of clover seeds. The natural grasses are seldom sown, and only when the land is to be laid to permanent pasture. In England ryegrass is in much less repute than in Scotland, the clovers being there very generally sown unmixed, and always in larger quantities than we have just named—20 lb. per acre being a common allowance. There can be little doubt that both of these plans are faulty. When a good natural pasture is carefully examined, it is found to consist of an amazing number of dif-

Great variety of plants in natural pastures.

[1] Morton's *Cyclopædia of Agriculture*—article "Grasses," p. 999.

Herbage and Forage.

ferent grasses and other plants. We once plucked *seventeen* distinct species in an old pasture, taking only those that could be reached without stirring a foot; and as it was only those that were in flower at the time, or which had escaped the browsing of the cattle that could be discriminated, we have no doubt that the list was far from complete. Not only does a natural pasture contain a great variety of herbage at any one time, but it has its plants which replace each other at different seasons; and some also which are prominent only in wet years and others in dry ones. The provision thus made for affording, at all times, such a variety of food as is at once grateful and wholesome to the animals which browse it, and for keeping the ground fully occupied under every diversity of seasons and weather, is truly admirable, and the study of it well-fitted to interest and instruct the husbandman. The importance of this subject is beginning to be appreciated by agriculturists; as one proof of which we now see our leading seedsmen regularly advertising for sale a numerous list of grasses, and other pasture plants. Most of them also, for the guidance of their customers, point out the kinds and quantities per acre, which are appropriate for diversity of soils and other circumstances. We refer, as an example of this, to the manual of Messrs Lawson of Edinburgh, who have devoted much attention to this subject.

The following tables are from another source.

" For sheep pastures, it will often be found advantageous to add from two to four lb. per acre of *parsley* seed to the above mixtures; and for pastures in certain upland districts, established practice will justify the introduction of an additional lb. or two of yellow clover (*Medicago lupulina*), together with from two to three lb. of ribgrass (*Plantago lanceolata*). And for very heavy, as well as for peaty soils, one to one-and-a-half lb. of *Phleum pratense* may be added advantageously, both for hay and pasture.

" In certain cases, the following additions to Table II. may be made, namely one to two lb. each of *Festuca rubra* and *Poa pratensis* on dry sandy soils; one lb. of *Achillea Millefolium*, and one to two lb. of *Petrosalinum sativum* in sheep pastures; two lb. chicory (*Cichorium Intybus*) in cattle pastures, six or ten lb. of *Onobrychis sativa* and four to six lb. of *Poterium Sanguisorba* (burnet) in dry calcareous soils. When a crop of hay is taken the first year, both the rye-grasses (*Lolium*) may be increased by a third; and two lb. of *Trifolium pratense* added. Also one-half to one lb. per acre of *Anthoxanthum odoratum* when occasional crops of hay are to be taken."[1]

Having described the means to be used for obtaining good pastures, let us now consider how to use them profitably. To the uninitiated the management of grass land may seem much easier than that of arable land, although the reverse is the case. After a lengthened practice, we, at least, find it so in our own experience. Nothing, indeed, can be more simple than to turn a quantity of live stock into a pasture in spring, and leave them there to shift for themselves until autumn; but such a procedure is *simple* in more than one acceptation.

The art of grazing.

The art of grazing embraces the practical solution of two important problems, viz., 1*st*, how to obtain the greatest amount and best quality of herbage from any given pasture; and, 2*d*, how to consume this herbage by live stock so as to make the most of it. The grazier has ever to keep in view what is best for his land, and what is best for his stock; and must take his measures throughout the entire season with an eye to both these objects. As regards the first of them, experience yields the following maxims for his guidance:—

Never to stock his pastures in spring until genial weather is fairly established, and the pasturage is abundant.

Never to allow the grasses to run to seed, nor parts of a field to be eaten bare, and others to get rank and coarse.

Duly to spread about the droppings of the cattle; to remove stagnant water, and to extirpate tall weeds.

Sometime in early autumn to make a point of having the pasture eaten so close that no dead herbage or "foggage" shall be left on any part of it.

In what more immediately concerns the welfare of the live stock he is in like manner taught in stocking his pastures,—

To adapt the stock as regards breed, size, condition, and numbers, to the actual capabilities of the pasturage.

To secure to the stock at all times a full bite of clean, fresh grown, succulent herbage.

In moving stock from field to field to take care that it be a change to better fare—not to worse.

Pasturage consists either of natural herbage or of "seeds." In the lowlands of Scotland there is little good old grass: all the really fertile soils being employed in arable husbandry, with the exception of small portions around the mansions of landowners. The pasturage consists, therefore, for the most part, of the cultivated clovers and grasses. Comparatively few cattle are there fattened on grass; the object of graziers being rather to stock their pastures with young and growing animals, and to get them into forward condition for being afterwards fattened upon turnips. The grazing season is there also much shorter than in England: old grass seldom affording a full bite for a well-conditioned bullock before the middle of May, or later than the middle of September. It is quite otherwise in England, various parts of which abound with old grass lands of the very richest description, on which oxen of the largest class can be fattened rapidly. These in many cases admit of being stocked towards the end of April, and under judicious

Rich old pastures of England.

[1] Morton's *Cyclopædia of Agriculture*—article "Grasses," p. 1000.

Herbage and Forage.

management, continue to yield excellent pasturage for half the year. When stocked with cattle in fresh condition, two sets or "runs" are not unfrequently fattened, in such pastures, in the same season. These grass-fed cattle begin to come to market early in July, and for four or five months thereafter constitute the chief supplies of beef in our markets.

Cattle grazing.

Cattle, already well-fleshed, are alone suitable for turning into these rich old pastures. When this is attended to, and care taken not to stock the pastures until they yield a full bite, the progress of the oxen will usually be very rapid. It is now customary to hasten this progress by giving about four lb. of oil-cake to each beast daily. The dust and crumbs being sifted out, the bits of cake are strewn upon the clean sward, from whence they are quickly and carefully gleaned by the cattle. This is usually a profitable practice. It brings the beasts forward rapidly, improves their appearance and handling, and, besides enriching the land, admits of about *twelve* per cent. more numbers being fed upon a given acreage. These choice old pastures are usually occupied in combination with others of inferior quality. The most forward lot of cattle having been fattened and sold off from the former, they are ready to receive a fresh stock. If it is contemplated to get them also fattened before the expiry of the season, they are not put on the best land instantly on the first lot being sold; but a crowd of sheep or store-beasts being turned upon it for a few days, the existing herbage is cleared off, and the pasture (*Anglice*) "laid in" or (*Scottice*) "hained," until a fresh, clean growth fits it for receiving a suitable number of the best cattle from the other pastures. It is inexpedient to graze sheep promiscuously with cattle on these best lands, as they pick out the sweetest of the herbage, and so retard the fattening of the oxen. Neither do we approve of having horses among such cattle; not so much from their interfering with their pasturage, as from the disturbance which they usually cause by galloping about. This does not apply to the draught-horses of a farm, which are usually too tired and hungry when turned out from the yoke to mind anything but food and rest; but it is better thrift to soil them; and frolicsome, mischievous colts are unsuitable companions for sedate, portly oxen. In favourable seasons, the grass often grows more rapidly than an ordinary stocking of cattle can consume it, in which case they select the best places and allow the herbage on some parts to get rank and coarse. If these rank places are neglected until the herbage gets dry and withered, the finer plants die out, the coarser-growing grasses usurp the ground, and the pasturage is injured for future years. To check this evil in time, these neglected places should be mown, and the grass either brought to the homestead for soiling, or left to dry where it grew; in which state the cattle will eat up most of it, and be the better for it, especially if their bowels are unduly relaxed by the succulence of the growing herbage. The remarks now made apply equally to all old pastures employed for the fattening of cattle, although not of the first quality. All that is required is, to observe a due proportion betwixt the capabilities of the pasturage and the breed and size of the cattle. A pasture that will fatten a fifty-stone ox may be quite inadequate for one of seventy, and the hardy Galloway or West Highlander will thrive apace where the heavier and daintier short-horn could barely subsist.

Sheep grazing.

With the exception of the best class of rich old pastures, grass is usually consumed to greater profit by a mixed stock of sheep and store cattle, than by one kind of animals only. This holds true both as regards the natural herbage of pastures, and water meadows, and cultivated grasses, clovers, and sainfoin. When old pastures and mixed "seeds" are grazed chiefly by sheep, the same rules apply that have already been noticed in connection with cattle. The herbage should if possible be fully established in a growing state, and so far advanced as to afford a full bite, before the pasture is stocked in spring. If the sheep are turned into it prematurely, their close nibbling hinders the plants from ever getting into a state of rapid growth and productiveness, and the necessity imposed upon the stock of roaming over the whole field, and keeping long afoot before they can glean enough to appease their appetite, is prejudicial alike to them and to their pasture. The prudent grazier endeavours to avoid these evils by having his stores of Swedes or mangels to last until the full time at which he may reckon on having good pasturage. In distributing the flocks to different fields, the best pasturage is allotted to those that are in most forward condition. It is advantageous to have the pastures so subdivided that one portion may be double stocked while another is rested. By frequently removing the stock from the one portion to the other the herbage of each by turns gets time to grow and freshen, and is more relished by the sheep, than when the whole is tainted by their uninterrupted occupation of it. In the case of clover, trefoil, sainfoin, and water-meadows, this principle is yet more fully carried out by folding the flock and giving them a fresh piece daily. The crop is thus eaten close off at once in daily portions and the plants being immediately thereafter left undisturbed, and receiving over the whole area their due share of the excrements of the flock, grow again more rapidly than when subjected to constant browsing under a system of promiscuous grazing. This plan of folding sheep upon such crops has the same advantages to recommend it as soiling, only that it is cheaper to shift the fold daily than to mow and cart home the forage and carry back the manure. In the case of water-meadows it is the practice to irrigate them afresh as each crop of grass is fed off. This is attended with considerable risk of the sheep getting tainted with rot, which must be guarded against as much as possible. In the first place it is well to give them a daily allowance of bran, beans, or cake, and salt; and besides this to put on this land only such sheep as are nearly ready for the butcher. They will thus fatten very rapidly, and be slaughtered before there is time for harm to ensue.

The modes of grazing which we have now described are appropriate for sheep in forward condition. The poorer pastures are usually stocked with nursing ewes and lean sheep bought in from higher grazings. Lambs, both before and after weaning, require clean pastures, and of course frequent changes. If kept on tainted pastures they are certain to become subject to diarrhœa, to be stinted in their growth, and to have their constitution so weakened that many of them will die when afterwards put upon turnips. To avoid these evils they must be frequently moved from field to field. A sufficient number of store cattle must be grazed along with them to eat up the tall herbage and rank places avoided by the sheep. After the lambs are weaned, the ewes require to fare rather poorly for a time, and can thus be made use of to eat up the worst pasturage, and the leavings of the young and fattening sheep. When the latter, with the approach of autumn, are put upon aftermath, clover-stubbles, rape, cabbages, or turnips, their previous pastures should in succession be thickly stocked by the ewes and other store stock so as to be eaten bare and then get leave to freshen and get ready for the ewes by rutting time, when they require better food. In depasturing sheep on poor soils it is usually highly advantageous to give them a daily allowance of grain or cake in troughs which must be shifted daily so as to distribute the manure regularly over the land. By means of this auxiliary food, sheep can be fattened on land, the herbage of which would not alone suffice to do this. It admits also of a larger number of sheep being kept per acre,

Herbage and Forage.

and of the pasturage being fed off more closely than could otherwise be done. The produce of poor siliceous soils, both in grass and after crops, is much increased by the additional manuring and treading which the consumption of such extraneous food upon them occasions.

It is always advantageous to have pastures provided with a shed under which the stock can find shelture from sudden storms, or from the attacks of insects, and the scorching rays of the summer's sun. When such sheds are regularly strewed with dried peat or burnt clay, much valuable compost for top-dressing the pasture can be obtained. The dung of the cattle thus secured and applied benefits the pastures more than that which is dropped upon it by the animals. Such clots require to be spread about from time to time.

To carry out successfully the various details now referred to, which constitute the art of grazing, there is required much foresight, accurate observation, sound judgment, and constant superintendence. Without all this it is impossible to make the most of any given amount of live stock and pasturage, and hence the extraordinary disparity in the results obtained by different graziers from similar materials.

Soiling *versus* grazing.

The temperate climate of Britain is so peculiarly favourable to the growth of the grasses and other pasture plants, and to the keeping of live stock with safety in the open fields for a large part of the year, that the practice of consuming these crops by depasturing, as already described, has hitherto been decidedly preferred to soiling. One consequence of this is, that forage crops have been comparatively neglected. There is now, however, a growing conviction among agriculturalists that it is more convenient to keep neat-cattle and horses, during summer, in yards or loose boxes, and to feed them with succulent forage, mown and brought to them daily as it is needed, than to turn them adrift to browse in the fields. The pasturing plan is preferred by many because it involves the least labour, and is alleged to be more healthful to the animals. In behalf of the soiling plan, it is urged that a given space of ground under green crop keeps nearly twice as much stock, when its produce is mown and consumed elsewhere, than when it is constantly nibbled and trodden upon; that housed cattle being exempted from the vicissitudes of the weather, the attacks of insects, mutual disturbance, and the labour of gathering their food, eat less and yet fatten more rapidly than they do at pasture; that more good is gotten of their excrements when mixed with litter, and trodden down under cover, than when dropped about in the open fields; and that land from which a green crop has been mown, when ploughed up, is freer of weeds and (other things being equal) bears a better corn crop than that which has been pastured. It is a further recommendation to the soiling plan that it admits of oil-cake or meal being administered along with green food with a precision and economy that is unattainable in the pasture fields. There being so many, and such cogent reasons in favour of the practice of soiling, we may warrantably anticipate that it will in future be much more generally adopted. It is proper, however, to notice that the success of this system is absolutely dependent on the following conditions. The green food must be mown and brought home at least *twice* a-day, owing to the rapidity with which it ferments when put together; it must be given to the stock not less than *four* times daily, and only in such quantity at each feed as they can eat clean up in the interval betwixt meals; they must have constant and ample supplies of pure water and of fresh litter; and, in particular, matters must be so arranged that there shall be an unfailing supply of green forage of the best quality, through the entire season. This is accomplished either by successive cuttings of one kind of crop from the same ground—as of irrigated meadow, or Italian ryegrass—or by a combination of such crops as naturally come to maturity in succession, or are made to do so by a sequence of sowings. From what has been said, it is obvious that soiling can only be carried out successfully with a moderately good soil and climate, a liberal use of manure, and skill and foresight on the part of the farmer. With these, however, its results will usually be highly satisfactory. It is peculiarly adapted for clay soils, on which the culture of root crops is attended with much difficulty, and where there is, therefore, abundance of litter for use in summer, and much need for the soiling system to get it converted into good manure.

In proceeding to notice the crops most usually cultivated in Britain for green forage, we shall begin with Natural Meadow Grass. In the south-western parts of England abundant crops of grass are obtained by irrigation with simple water. Our remarks shall here, however, be restricted to those situations where sewage from towns or villages is available. Wherever a few scores of human families are congregated together, and have their dwellings properly drained and supplied with water, there is an opportunity for manuring a considerable extent of meadow with the sewage-water accruing from them throughout the year. The celebrated meadows in the environs of Edinburgh are interesting illustrations of the value of such water for irrigating purposes, and of the astonishing bulk of rich herbage which can be obtained in the course of a year from an acre of land thus treated. From the thickness of the crop in these meadows, and the rank luxuriance of its growth, the grass must be cut before it exceeds *ten* inches in height, as otherwise the bottom gets blanched, and the grass rots out. The mowing begins usually in April, and continues till November, so that by fitly proportioning the head of stock to the extent of meadow, and having the latter arranged in plots to be mown in regular succession, soiling can be practised throughout the season by means of the produce of the meadow alone. This practice is necessarily limited to situations where sewage water is available. The following excerpt from the *Minutes of Information to the General Board of Health, collected in the practical application of Sewer Water and Town Manures to Agricultural Production*, p. 65, will explain the system here referred to, and exhibit its results:—

"Craigentinney Meadows, situate about one mile and a half south-east of Edinburgh, have been put under irrigation at various times, the most recent addition being nearly 50 acres laid out in the course of last year (1850) and the year previous, which lying above the level of the rest are irrigated by means of a steam-engine. The meadows first laid out are watered by contour channels following the inequalities of the ground, after the fashion commonly adopted in Devonshire; but in the more recent parts the ground is disposed in 'panes' of half an acre, served by their respective feeders, a plan which, though somewhat more expensive at the outset, is found preferable in practice. The whole 260 acres take about fourteeen days to irrigate; the men charged with the duty of shifting the water from one pane to another, give to each plot about two hours' irrigation at a time; and the engine serves its 50 acres in ten days, working day and night, and employing one man at the engine and another to shift the water. The produce of the meadows is sold by auction on the ground, 'rouped,' as it is termed, to the cowfeeders of Edinburgh, the purchaser cutting and carrying off all he can during the course of the letting, which extends from about the middle of April to October, when the meadows are shut up, but the irrigation is continued through the winter. The lettings average somewhat over L.20 the acre; the highest last year having brought L.31, and the lowest L.9; these last were of very limited extent, on land recently denuded in laying out the ground, and consequently much below its natural level of productiveness. There are four cuttings in the year, and the collective weight of grass cut in parts was stated at the extraordinary amount of eighty tons the imperial acre.

The only cost of maintaining these meadows, except those to which the water is pumped by the engine, consists in the employment of two hands to turn in and off the water, and in the expense of clearing out the channels, which was contracted for last year at L.29, and the value of the refuse obtained was considered fully equal to that sum, being applied in manuring parts of the land for a crop of turnips, which, with only this dressing in addition to irrigation with the sewage-water, presented the most luxuriant appearance. The crop from present indications, was estimated at from thirty to forty tons the acre, and was expected to realise 15s. the ton, sold on the land. From calculations made on the spot, we estimated the produce of the meadows during the eight months of cutting, at the keep of ten cows per acre, exclusive of the distillery refuse they consume in addition, at a cost of 1s. to 1s. 6d. per head per week. The sea-meadows present a particularly striking example of the effects of the irrigation; these, comprising between 20 and 30 acres skirting the shore between Leith and Musselburgh, were laid down in 1826 at a cost of about L.700; the land consisted formerly of a bare sandy tract, yielding almost absolutely nothing; it is now covered with luxuriant vegetation, extending close down to high-water mark, and lets at an average of L.20 per acre at least. From the above statement it will be seen how enormously profitable has been the application in this case of town refuse in the liquid form; and I have no hesitation in stating, that, great as its advantages have been, they might be extended four or five fold by greater dilution of the fluid."

*Italian Ryegrass* can, however, be cultivated over as wide a range of soils and climate as any forage crop which we possess, and its value for soiling is every day getting to be more generally appreciated. When first introduced, and indeed until very recently, it was chiefly sown in mixture with other grasses and clovers for pasturage, a purpose to which it is well adapted from its early and rapid growth in spring. Its true function, however, is to produce green food for soiling, for which purpose it is probably unrivalled. It is in connection with the system of irrigation with liquid manure, as practised at Myremill and elsewhere, that its astonishing powers have been most fully developed. When grown for this purpose it is sown in April, on land that has borne a grain crop after turnips or summer fallow. If sown *with* a grain crop and as thickly as is requisite, it gets nearly as tall as the grain, and both are injured. A liberal dressing of farm-yard dung is spread upon the stubble in Autumn, and immediately ploughed in. In the end of March or beginning of April the land is prepared for the seed by being stirred with the grubber and then well harrowed. The seed, at the rate of four bushels per acre, is then sown in the way already described for clover and grass seeds. When the liquid manure system is practised, the crop is watered as soon as the young plants are about an inch high, and so rapid is its growth in favourable circumstances that a cutting of ten tons per acre has in some cases been obtained six weeks after sowing. When there is no provision for supplying liquid manure, a top-dressing of guano, nitrate of soda, soot, or the first two articles mixed, is applied by hand-sowing, taking care to give this dressing when rain seems at hand, or has just fallen. A similar top-dressing is repeated after each cutting, by which means three cuttings are ordinarily obtained from the same space in one season. A very great quantity of stock can thus be supported from a very limited extent of ground. This grass is also found to be very grateful to the palates of horses, cattle, and sheep, which all thrive upon it. Though so very succulent, it does not produce purging in the animals fed upon it. It is peculiarly suitable feeding for milch cows, as appears from the published account at Canning park. Such results as those obtained by Mr Kennedy and others, are not to be expected unless under similar conditions; but on good loams, clean and in good heart, and under such treatment as is described at the beginning of this section, as large crops of this grass with at least equal feeding powers to red clover may be reckoned on, and with a degree of certainty which the farmer cannot now entertain in regard to the latter crop. If regularly mown when the ear begins to shew, taking care never to allow the seed to form, it is fully ascertained that this grass will grow abundantly for a second year, with the advantage of being ready for use very much earlier than in its first season. It is sometimes sown in Autumn, but those who have had the fullest experience in its cultivation give a decided preference to spring sowing, either after a grain crop which has followed a green crop or fallow, or at once after turnips. It is of great importance to get fresh and genuine seed. That directly imported from Italy yields the best crop when otherwise good. As a proof of the fondness of sheep for this grass, it has been observed that when it had been sown in mixture with red clover and cut for hay, sheep, on being turned into the aftermath, eat down the Italian ryegrass in preference to the clover.

*Crimson Clover*, though not hardy enough to withstand the climate of Scotland in ordinary winters, is a most valuable forage crop in England. It is sown as quickly as possible after the removal of a grain crop at the rate of 18 lb. to 20 lb. per acre. It is found to succeed better when only the surface of the soil is stirred by the scarifier and harrow, than when a ploughing is given. It grows rapidly in spring, and yields an abundant crop of green food, peculiarly palatable to live stock. It is also suitable for making into hay. It may be sown in mixture with Italian ryegrass with great propriety.

*Red Clover.*—This plant, either sown alone or in mixture with ryegrass, has for a long time formed the staple crop for soiling, and so long as it grew freely, its power of shooting up again after repeated mowings, the bulk of crop thus obtained, its palatableness to stock, and feeding qualities, the great range of soils and climate in which it grows, and its fitness either for pasturage or soiling, well entitled it to this preference. Except on certain rich calcareous clay soils, it has now, however, become an exceedingly precarious crop. The seed, when genuine, which unfortunately is very often not the case, germinates as freely as ever; and no greater difficulty than heretofore is experienced in having a full plant during autumn and the greater part of winter; but over most part of the country, the farmer, after having his hopes raised by seeing a thick cover of vigorous-looking clover plants over his field, by March or April finds, to his dismay, that they have either entirely disappeared, or are found only in capricious patches here and there over the field. No satisfactory explanation of this clover failure has yet been given, nor any certain remedy, of a kind to be applied to the soil, discovered. One important fact is, however, now well established, viz., that, when the cropping of the land is so managed as that clover does not recur at shorter intervals than eight years, it grows with much of its pristine vigour. The knowledge of this fact now determines many farmers in varying their rotation so as to secure this important end. At one time there was a somewhat prevalent belief that the introduction of beans into the rotation had a specific influence of a beneficial kind on the clover when it came next to be sown; but the true explanation seems to be, that the beans operate favourably only by the incidental circumstance of almost necessarily lengthening the interval betwixt the recurrences of clover. When the four-course rotation is followed, no better plan of managing this process has been yet suggested than to sow beans, pease, potatoes, or tares, instead of clover, for one round, making the rotation one of eight years instead of four. The mechanical condition of the soil seems to have something to do with the success or failure of the clover crop. We have often noticed that head lands,

Herbage and Forage.

or the converging line of wheel tracks near a gateway at which the preceding root crop had been carted from a field, have had a good take of clover when on the field generally it had failed. In the same way a field that has been much poached by sheep while consuming turnips upon it, and which has afterwards been ploughed up in an unkindly state, will have the clover prosper upon it, when it fails in other cases where the soil appears in far better condition. If red clover can be again made a safe crop, it will be a boon indeed to agriculture. Its seeds are usually sown along with a grain crop any time from 1st February to May, at the rate of 12 lb. to 20 lb. per acre when not combined with other clovers or grasses.

Italian ryegrass and red clover are now frequently sown in mixture for soiling, and succeed admirably. It is, however, a wiser course to sow them separately, as by substituting the Italian ryegrass for clover, for a single rotation, the farmer not only gets a crop of forage as valuable in all respects, but is enabled, if he choose, to prolong the intervals betwixt the sowings of clover to twelve years, by sowing, as already recommended, pulse the first round, Italian ryegrass the second, and clover the third.

These two crops, then, are those on which the arable-land farmer mainly relies for green forage. To have them good, he must be prepared to make a liberal application of manure. Good farm-yard dung may be applied with advantage either in autumn or spring, taking care to cart it upon the land only when it is dry enough to admit of this being done without injury. It must also be spread very evenly so soon as emptied from the carts. But it is usually more expedient to use either guano, nitrate of soda, or soot for this purpose, at the rates respectively of 2 cwt., 1 cwt., and 20 bushels. If two or more of these substances are used, the quantities of each will be altered in proportion. They are best also to be applied in two or three portions, at intervals of fourteen to twenty days, beginning towards the end of March, and only when rain seems imminent or has just fallen.

When manure is broad-cast over a young clover field, and presently after washed in by rain, the effect is identical with that of first dissolving it in water, and then distributing the dilution over the surface, with this difference, namely, that the first plan costs only the price of the guano, &c., and is available at any time and to every one, whereas the latter implies the construction of tanks and costly machinery.

*Vetches* are another very valuable forage crop. Being indigenous to Britain, and not fastidious in regard to soil, they can be cultivated successfully under a great diversity of circumstances, and are well adapted for poor soils. By combining the winter and spring varieties, and making several sowings of each in their season, at intervals of two or three weeks, it is practicable to have them fit for use from May till October, and thus to carry out a system of soiling by means of vetches alone. But it is usually more expedient to use them in combination with grass and clover, beginning with the first cutting of the latter in May, taking the winter vetches in June, recurring to the Italian ryegrass or clover, as the second cutting is ready, and afterwards bringing the spring vetches into play. Each crop can thus be used when in its best state for cattle food, and so as gratefully to vary their dietary.

*Winter Vetches.*—There is no botanical difference betwixt winter and spring vetches, and the seeds being identical in appearance, caution is required in purchasing seed to get it of the right sort. Seed grown in England is found the most suitable for sowing in Scotland, as it vegetates more quickly, and produces a more vigorous plant than that which is home-grown. As the great inducement to cultivate this crop, is the obtaining of a supply of nutritious green food, which shall be ready for use about the 1st May, and so as to fill up the gap which is apt to occur betwixt the root crops of the previous autumn, and the ordinary summer food, whether for grazing or soiling, it is of the utmost importance to treat it in such a way, that it may be ready for use by the time mentioned. To secure this, winter tares should be sown in August if possible, but always as soon as the land can be cleared of the preceding crop. They may yield a good crop though sown in October, but, in this case, will probably be very little in advance of early sown spring vetches, and possess little, if any, advantage over them in any respect. The land on which they are sown should be dry and well sheltered, clean, and in good heart, and be farther enriched by ploughing into it from 12 to 15 loads of farm-yard manure. Not less than 3½ bushels of seed per acre should be sown, to which some think it beneficial to add half a bushel of wheat. Rye is frequently used for this purpose, but it gets reedy in the stems, and is rejected by the stock. Winter beans would probably succeed better than either. The land having been ploughed rather deeply and well harrowed, it is found advantageous to deposit the seed in rows, either by a drilling-machine, or by ribbing. The latter is the best practice, and the ribs should be at least a foot apart and rather deep, that the roots may be well developed before top-growth takes place. As soon in spring as the state of the land and weather admits of it, the crop should be hoed betwixt the drills, a top-dressing at the rate of 40 bushels of soot, or 2 cwt. of guano per acre applied by sowing broad-cast; and the roller then used for the double purpose of smoothing the surface, so as to admit of the free use of the scythe, and of pressing down the plants which may have been loosened by frost. It is thus by early sowing, thick seeding, and liberal manuring, that this crop is to be forced to an early and abundant maturity. May and June are the months in which winter vetches are used to advantage. A second growth will be produced from the roots if the crop is allowed to stand; but it is much better practice to plough up the land, as the crop is cleared, and to sow turnips upon it. After a full crop of vetches, land is usually in a good state for a succeeding crop. When the whole process has been well managed, the gross amount of cattle food yielded by a crop of winter vetches, and the turnip crop by which it is followed in the same summer will be found considerably to exceed what could be obtained from the fullest crop of turnips alone, grown on similar soil, and with the same quantity of manure.

*Spring Vetches*, if sown about the first of March, will be ready for use by 1st July, when the winter vetches are just cleared off. To obtain the full benefit of this crop, the land on which it is sown must be clean, and to keep it so, a much fuller allowance of seed is required than is usually given in Scotland. When the crop is as thick set as it should be, the tendrils intertwine, and the ground is covered by a solid mass of herbage, under which no weed can live. To secure this, not less than four bushels of seed per acre should be used, if sown broad-cast, or three bushels if in drills. The latter plan, if followed by hoeing, is certainly the best; for if the weeds are kept in check until the crop is fairly established, they have no chance of getting up afterwards. With a thin crop of vetches, on the other hand, the land is so certain to get foul, that they should at once be ploughed down, and something else put in their place. As vetches are in the best state for use when the seeds begin to form in the pods, repeated sowings are made at intervals of three weeks, beginning by the end of February, or as early in March as the season admits, and continuing till May. With *two* sowings in autumn, and *four* in spring, a supply of this valuable food can be had in good condition from May till October, so that by means of vetches alone, if well managed, the interval betwixt the old and new crops of roots can be filled

Herbage and Forage.

up. There are, as we have seen, other forage crops, well worthy the attention of the farmer, but the vetch is less fastidious in regard to soil and climate than any of them, and can be grown successfully on very poor soils. The usual practice in Scotland has been to sow vetches on part of the oat break, once ploughed from lea. Sometimes this does very well, but a far better plan is to omit sowing clover and grass seeds on part of the land occupied by wheat or barley after turnips, and having ploughed that portion in autumn to occupy it with vetches, putting them *instead of* "*seeds*" for one revolution of the course.

Folding sheep upon vetches.

When vetches are grown on poor soils, the most profitable way of using them is by folding sheep upon them. A different course, must, however, be adopted than when turnips are disposed of in this way. When sheep are turned in upon a piece of tares, a large portion of the food is trodden down and wasted. Cutting the vetches and putting them into racks does not much mend the matter, as much is still pulled out and wasted, and the manure unequally distributed over the land. To avoid those evils, hurdles with vertical spars, betwixt which the sheep can reach with head and neck, are now used. These are set close up to the growing crop along a considerable stretch, and shifted forward as the sheep eat up what is within their reach. This requires the constant attention of the shepherd, but the labour is repaid by the saving of the food, which, being always fresh and clean, does the sheep more good. A modification of this plan is to use the same kind of hurdles, but, instead of shifting them as just described, to mow a swathe parallel to them, and fork this forward within reach of the sheep as required, repeating this as often during the day as is found necessary, and at night moving them close up to the growing crop, so that the sheep may lie for the next twenty-four hours on the space which has yielded food for the past day. During the night they have such pickings as have been left on the recently-mown space, and so much of the growing crop as they can get at through the spars. There is less labour by this last mode than the other, and in practice it has been found to do well.

As spring-sown vetches are in perfection at the season when pastures usually get dry and scanty, a common practice is to cart them on to grass land and spread them out in wisps, to be eaten by the sheep or cattle. It is, however, much better either to have them eaten by sheep where they grow, or to cart them to the homestead.

By means of the crops now enumerated, the practice of soiling can be carried out in all cases where it is practicable.

There are other valuable crops of this kind, several of which we shall now describe; but their culture is either limited by their requirements in regard to soil and climate, or attended with too great expense to admit of their competing with those already described.

*Sainfoin.*—This very important forage plant would be well entitled to a more prominent place in our list, but for the circumstance that it is only on dry calcareous soils that its excellences are fully developed; and to these accordingly its culture may be said to be confined. In all the chalk districts of England, sainfoin occupies an important place in the rotation of crops. Referring to the chalky downs round Ilsley in Berks, Mr Caird says:—"About a tenth part of the land is kept under sainfoin, in which it remains for four years, being each year cut for hay, of which it gives an excellent crop. A farmer having forty acres of sainfoin, sows out ten acres and breaks up ten acres annually. This goes regularly over the whole farm, the sainfoin not returning on the same field for considerable intervals, and when its turn comes round the field receives a rest of four years from the routine of cultivation. It is then ploughed up in spring, and sown with oats on one furrow, the crop of which is generally excellent, as much as eighty bushels an acre not being uncommon." The seed, at the rate of four bushels per acre, is drilled in immediately after barley or oats has been sown, working the drill at right angles to its course when it deposited the grain. It is frequently pastured for one or more years before being mown either for green forage or for hay. It is sometimes allowed to stand for eight or ten years, but the plan described in the above quotation is the more approved one. A variety called giant-sainfoin has been introduced by Mr Hart of Ashwell, Herts. As compared with the common sort it is more rapid in its growth in spring, and still more so after the first and second cuttings. Three cuttings for hay, and one of these ripening the seed, have been yielded by it in one year, and a good eddish after all. The yield from it in the first year, after sowing, is large in comparison with the common sainfoin, from its attaining maturity much sooner; but for the same reason it is thought judicious to break it up after three years, while still in vigour.

*Lucerne* is much cultivated as a forage crop in France and other parts of the continent of Europe, but has never come into general use in Britain. It is, however, frequently met with in small patches in districts where the soil is very light, with *a dry subsoil.* Its thick tap-roots penetrate very deeply into the soil; and if a good cover is once obtained, the plants will continue to yield abundant cuttings of herbage for eight or ten years, provided they are statedly top-dressed, and kept free from perennial weeds. In cultivating lucerne, the ground must first be thoroughly cleaned, and put into good heart by consuming a turnip crop upon it with sheep. In March or April, the surface-soil having first been brought to a fine tilth, the seed, at the rate of 10 lb. per acre, is sown in rows at 15 to 18 inches apart. So soon as the plants appear, they must be freed from weeds by careful hoeing and hand-weeding, repeated as occasion requires. Little produce is obtained from them the first season, and not a very heavy cutting the second; but by the third year it will yield two or more abundant crops of herbage, peculiarly suitable for horse-feed. It is the slow growth of the plants at first, and the difficulty of keeping them free from weeds on those dry soils which alone are adapted for growing lucerne, that have deterred farmers from growing it more extensively than has hitherto been done. We have grown it successfully in Berwickshire on a muiry soil, resting on sandstone rock, in an exposed situation, at an elevation of 400 feet. The time to cut it is, as with clover and sainfoin, when it is in full flower.

*Chicory*, *Burnet*, *Cow-Parsnip*, and *Prickly Comfrey*, all known to be palatable to cattle, and yielding a large bulk of produce, have probably been less carefully experimented with than their merits deserve. Although they have long figured in such notices as the present, or in occasional paragraphs in agricultural periodicals, they have never yet, that we are aware of, been subjected to such a trial as either conclusively to establish their claim to more extended culture, or to justify the neglect which they have hitherto experienced.

*Gorse* or *Whin.*—Notwithstanding its formidable spines, the young shoots of this hardy evergreen yield a palatable and nutritious winter forage for horses and cattle. To fit it for this purpose, it must be chopped and bruised to destroy the spines. This is sometimes done in a primitive and laborious way by laying the gorse upon a block of wood, and beating it with a mallet, flat at one end, and armed with crossed knife-edges at the other, by the alternate use of which it is bruised and chopped. There are now a variety of machines by which this is done rapidly and efficiently. and which are in use where this kind of forage is used to any extent. The agricultural value of this plant has often been over-rated by theoretical writers. In the case of very poor, dry soils, it does however yield much valuable food at a season when green forage is not otherwise to be had. It is, on this account, of importance to dairymen; and to them it has this further recommendation, that cows fed upon it give much rich milk, which is free from any unpleasant flavour. To turn it to good account, it must be sown in drills, kept clean by hoeing, and treated as a regular green crop. If sown in March, on land fitly prepared, and afterwards duly cared for, it is ready for use in the autumn of the following year. Only alternate rows should then be cut, and the others left for another year's growth. In this way a succession of cuttings of proper age are obtained for several years from the same field. It is cut by a short stout scythe, and must be brought from the field daily; for when put in a heap, after being chopped and bruised, it heats rapidly. It is given to horses and cows, in combination with chopped hay or straw. An acre will produce about 2000 faggots of green two-year-old gorse, weighing 20 lb. each.

This plant is invaluable in mountain sheep walks. The rounded form of the furze bushes that are met with in such situations, shows how diligently the annual growth, as far as it is accessible, is nibbled by the sheep. The food and shelter afforded to them in snow-storms by clusters of such bushes is of such importance, that the wonder is our sheep farmers do not bestow more pains to have it in adequate quantity. Young plants of whin are so kept down by the sheep, that they can seldom attain to a profitable size unless protected by a fence for a few years.

*Tussac Grass.*—The tussac grass of the Falkland Islands has, of late years, attracted considerable attention as a forage plant. From its gigantic growth, even in those ungenial regions, and the extraordinary relish manifested for it by horses and cattle, sanguine hopes were entertained that it was to prove a truly valuable addition to our present list of forage plants. The attempts hitherto made to introduce it in Britain have not been of a very encouraging kind. The only successful cases have been in the Orkneys and in Lewis. Messrs Lawson of Edinburgh, who have given much attention to it, say, "Our own experience leads to the conclusion, that localities within influence of the sea spray, the soil being of a peaty nature, are, without doubt, the best adapted for the growth of the tussac; and in such places it is likely to be of great service, as few other nutritive grasses will exist there. In our own experimental grounds it does not thrive well; which may, perhaps, be accounted for by the nature of the soil, which is light and dry. Regarding its value as a forage plant, we have before us an analysis made, at our request, by Professor Johnston, the results of which show that 'the tussac grass ought to be very nutritive.' Propagation, in the absence of seed, is easily effected, under favourable circumstances, by subdivision of the roots."

We have thus noticed all the more important of our forage crops of ascertained value. Additions will probably be made to them from time to time, especially from the increased attention now bestowed on green crops of all kinds. It has lately been suggested that maize, although unfit for our climate as a grain crop, might with advantage be tried as a forage plant.

*Haymaking.*—Having spoken of the cultivation and use in a green state of herbage and forage crops, it remains to describe the process by which they are preserved for use in a dry state, or *made into hay*. On every farm a supply of good hay, adequate to the wants of its own live stock is, or at least ought to be, statedly provided. This is, no doubt, an expensive kind of food, but on the other hand it is highly nutritious, and conduces much to the healthfulness of the animals fed upon it. Many a valuable farm horse is annually sacrificed to a false economy in feeding him solely on innutritious straw or ill-gotten hay. The owners of such stock would do well to consider that the price of an annual dead horse, and the impaired health and condition of the whole stud, more than counterbalance any saving that can be effected by using bad fodder instead of good. But the great consumpt of hay is by the numerous horses constantly required in this country for other purposes than farm labour. In the vicinity of towns hay is therefore a staple agricultural product, and haymaking an important branch of rural economy. It is one in the practice of which English farmers generally excel their brethren north of the Tweed. In the counties near the metropolis, in particular, this process is conducted with admirable skill.

In converting the grasses and forage plants into hay the object is to get quit of the water which they contain, amounting to nearly *two-thirds* of their weight, with the least possible loss of their nutritive qualities. In order to this the crops must be mown at that stage of their growth when the greatest weight of produce with the maximum of nutritive value can be obtained; and then so to conduct the drying process that the inspissated juices shall not be washed out and lost by external wetting. A simple and sufficiently accurate rule for determining the first point, is to mow when the plants are in full flower. If this stage is exceeded both the quality of the hay and amount of the foggage or aftermath are seriously impaired. It follows from this, that mowing should be commenced somewhat earlier than the stage indicated, otherwise before the whole can be cut, the last portion will have exceeded the proper degree of ripeness. By cutting a part too soon a slight loss of weight is incurred, which, however, is compensated for by a better aftermath, whereas if part is allowed to mature the seeds, there is a loss both of weight, quality, and aftermath. Haymaking, to be done well, must be done quickly, and, in order to this a full supply of labourers is indispensable. As a good mower can cut, on the average, an acre in a day, as many must be engaged as can overtake the extent of crop while it is in the best state for cutting. It is of great importance, too, to have the grass cut close by the ground. A loss of from five to ten per cent. on the gross produce is frequently incurred by unskilful or careless mowers leaving the sward too high. To admit of accurate and expeditious mowing, care must be taken, at the proper season, to remove all stones and other obstructions, and to make the surface smooth by rolling. Confining our attention, in the first place, to natural meadow grass, let us glance at the process as conducted by those who are most proficient in it. The mowers having commenced their work at sunrise, the haymakers, in the proportion of two men and three women to each mower, so soon as the dew is off, shake out the swaths evenly over the whole ground, until they have overtaken as much as they can get into cocks the same day. This quantity they now turn and toss about as frequently as possible, getting it, before evening, either into a compact windrow, or forming it into very small cocks. Next day these cocks are again opened out, and as much more of the grass in swath as can be overtaken, all of which is anew subjected to the same repeated turnings, and again, as evening approaches, secured from dew and rain by windrowing and cocking; that which is driest being put into larger cocks than on the previous day. If the weather is hot and parching, that which was first cut is by the fourth day ready for the stack, and is immediately carried. A large rick-cloth is drawn over the incipient stack until more hay is in condition to be added to it, and then, if weather favour, the whole process, from mowing to stacking, for a time goes on simultaneously, and is speedily completed. As the building of the stack proceeds, its sides are, by pulling, freed from loose hay and straightened; and, when completed, it is thatched with the least possible delay. If the weather proves showery, the grass is left untouched in the swath until it be-

Herbage and Forage.

gins to get yellow on the under side, in which case it is usually turned over without opening out until weather again favour. To produce fine hay, care must be taken to secure it from dew or rain by cocking, before nightfall, all that has been spread out during the day,—never to touch it until dew or wet is off,—to shake all out so thoroughly as that the whole may be dried alike,—and never to suffer it, after being tedded out, to lie so long as to get scorched on one side. When these operations are conducted successfully, the hay is of a fine, light-green colour, delightfully fragrant, and retains its nutritious matter unimpaired. To accomplish this in our variable climate, much skill and energy, and an ample command of labour, are necessary. The cost and labour of this process are now, indeed, much reduced by the use of machinery, consisting of haymakers and horse-rakes, by means of which a lad and horse can, in a day, break out from the swath, turn, and draw together into rows, as much grass as could be overtaken in the same time by fifteen people. The hay-tedder, moreover, shakes out the grass more thoroughly than it can be done by hand. After the hay is gathered into rows, horse labour is also sometimes employed to thrust it into heaps by means of a sweep, that is, a piece of plank with a rope attached to each end of it, by which a horse draws it along *on edge*, while two lads hold it down, and the hay is thus pushed forward in successive portions, which are then, by hand labour, made into orderly cocks. The yield of meadow hay ranges from one to two tons per acre, and the cost of making it about 10s. per ton. In London, hay is brought to market in trusses, each weighing 56 lb. and 36 of which are called a load. In cutting up a stack these trusses are removed from it in compact squares, which are then neatly secured by bands of twisted hay.

Haymaking machinery.

In converting the cultivated forage crops, such as clover (either pure or mixed with ryegrass), sainfoin, lucerne, or vetches, into hay, the procedure varies considerably from that pursued with the natural grasses. A considerable part of these plants consists of broad, tender leaves, which, when scorched by the sun, become so dry and brittle that, on the least rough handling, they fly into dust, and are totally lost. These crops, therefore, do not admit of being shaken asunder, and tossed about like the natural grasses, a circumstance which unfortunately forbids the use of machinery and horse labour in getting them. The swaths are accordingly left untouched until they have got slightly withered on the upper side, after which they are turned several times, with as little breaking up as possible; made up first into small cocks—opened out again—gently turned, and made into larger cocks, which, as speedily as possible, are carried and stacked. These crops can be stacked with safety in a very green state by mixing with them frequent layers of clean dry straw, by which the redundant juices are absorbed, and injurious heating prevented. The straw thus impregnated acquires a flavour which renders it palatable to cattle; but it is advisable, when this practice is adopted, to cut the whole into chaff before using it as fodder.

The following system of making clover and ryegrass into hay is practised in several districts:—

"So soon as the surface is dry, a portion, about a yard in length, of the swath is taken, and the surface folded inwards, and the whole rolled into a kind of cone. A piece of ryegrass is pulled out of the top, and tied round the head of the 'ruckle,' as it is called, and set in rows to admit of being easily carted. Thus, while the sun and air thoroughly dry the whole mass, the rain, should it come, descends over the inclined surface of the cone, and as the large mass of leaves the clover possesses renders it peculiarly liable to injury from the wet, this process is most valuable, and in few places is it secured in better condition. In a dry time it is carted directly from the 'ruckles' to the stack; in a damp one, they are sometimes to pull down before they are carted off, and made into 'pikes,' or small heaps, of from two to three cart-loads each; here the clover is allowed to ferment, and in a week or two, put into the stack."[1]

Saving the seeds of ryegrass.

When it is desired to save the seeds of Italian or common ryegrass, the crop after being sown is allowed to lie for a day or two in swath, and is then neatly gathered into sheaves, bound and stooked precisely like a crop of oats. When sufficiently dried, the seed is either thrashed out in the field, the straw stacked like other hay, and the seed spread thinly over a granary floor, and turned several times daily until it is dry enough to keep in a bin or in sacks; or the sheaves are built into small round stacks, which stand until the seed is wanted, when it is thrashed out by machinery like grain.

Defects in Scottish haymaking.

Much has been said and written about the wastefulness of the system of haymaking annually practised in Scotland. To a considerable extent these animadversions are merited, although those who make them usually overlook the causes which account for, and to some extent palliate, the faults complained of. The facts of the case are simply these. In many parts of England, hay is both an important marketable commodity and the principal winter food of the live stock of the farm. In Scotland it is neither, its place being there more than supplied by the turnip crop, to which accordingly the farmer devotes his chief attention. Not only so, but from the nature of the climate, these two crops demand instant attention at precisely the same time; the hay needing to be made just when the turnips are urgently in want of thinning. The more important crop of course gets the preference, and the other is comparatively neglected. Add to this that it is but seldom that the Scottish farmer can command extraneous labour to help him in this dilemma, and it will be seen that it is not from mere ignorance or slovenliness that his hay crop is usually so sadly mismanaged. This lack both of leisure and labour might be somewhat remedied by the use of haymaking machinery; but as it is almost exclusively "seeds" that are mown in Scotland, this resource is scarcely available. Still it might be cheaper to lose some weight of hay by the rough handling of the machinery than, as at present, by over-ripeness and exposure to the weather. Perhaps, also, some aid may by and by arise by the application of horse labour to the preliminary thinning of turnips, and thus enable the hands to be spared for the haymaking. While we think it due to truth to make these statements, we are far from thinking that they justify the present state of matters. It would be better to have no hay at all, than to ruin both crop and land, as is often done, by delaying to mow until the crop is little else than ripened seeds and woody fibre, and then to bleach it, and leave it afield in pikes, for weeks or even months before stacking. Such barbarity as this is of frequent occurrence, and is utterly inexcusable. We are but too well aware of the difficulty of doing anything like justice to a hay crop with a turnip one competing with it for attention; but yet, with favouring weather, their rival claims can be so far adjusted, as we find it practicable in our own case, to have good green hay in about *four* years out of *five*.

## CHAPTER IX.

### CROPS OF LIMITED CULTIVATION.

Crops of limited cultivation.

Under this head we shall notice a variety of crops which, however valuable in themselves, and important to the far-

[1] *Royal Agricultural Society's Journal*, vol. ix. p. 507.

Crops of limited cultivation.

mers of particular localities, are, from one cause or other, not adapted for general cultivation.

Flax.

*Flax* is probably the most important of them. Indeed, from the rapid growth of our linen trade, the growing demand for linseed and its products, and the fitness of the soil and climate for the successful growth of flax, it is not without cause that its more extended cultivation has been so strenuously urged upon our farmers, and that influential societies have been organised for the express purpose of promoting this object. Viewed merely as an agricultural crop, the cultivation of flax is exceedingly simple, and could be practised as readily and extensively as that of the cereal crops. The difficulty is, that before it can be disposed of to any advantage, it must undergo a process of partial manufacture; thus there is required not only an abundant supply of cheap labour, but such an amount of skill and personal superintendence on the part of the farmer, as is incompatible with due attention to corn and cattle husbandry. If a ready and remunerative market were available for the fibre in its simple form of flax straw, this, in combination with the value of the seed for cattle feeding, would at once hold out sufficient motive to our farmers to grow it statedly, and to any required extent. Until this is the case its culture cannot extend in the corn-growing districts of Great Britain. In Ireland, and parts of the Highlands of Scotland, where there is a redundant population much in want of such employment as the flax crop furnishes, and where the climate is suited for its growth, it is highly desirable that its culture should extend, and probable that it will do so.

Hindrances to its general cultivation.

Soils adapted for its growth.

Flax prospers most when grown upon land of firm texture resting upon a moist subsoil. It does well to succeed oats or potatoes, as it requires the soil to be in fresh condition without being too rich. Lands newly broken up from pasture suit it well, as these are generally freer from weeds than those that have been long under tillage. It is usually inexpedient to apply manure directly to the flax crop, as the tendency of this is to produce over-luxuriance, and thereby to mar the quality of the fibre, on which its value chiefly depends. For the same reason it must be thickly seeded, the effect of this being to produce tall slender stems, free from branches. The land having been ploughed in autumn, is prepared for sowing, by working it with the grubber, harrow, and roller, until a fine tilth is obtained.

Sowing of flax.

On the smooth surface the seed is sown broad-cast by hand or machine, at the rate of three bushels per acre, and covered in the same manner as clover seeds. It is advisable immediately to hand-rake it with common hay-rakes, and thus to remove all stones and clods, and to secure a uniform close cover of plants. When these are about three inches long the crop must be carefully hand-weeded. This is a tedious and expensive process, and hence the importance of sowing the crop on land as free as possible from weeds of all kinds. To obtain flax of the very finest quality the crop must be pulled so soon as the flowers fall, but in the improved modes of steeping, whether by Schenck's or Watt's patent, the value of the fibre is not diminished by allowing the seeds to mature. It must not, however, be allowed to become dead ripe, but should be pulled whenever the seeds appear, on opening the capsule, to be slightly brown coloured.

Pulling of flax.

The pulling requires to be managed with much care. It is performed by men or women, who seize a small quantity with both hands, and pull it by a slight jerking effort. The important point to be attended to, is to keep the butts even, as successive quantities are seized and twitched from the ground. When a convenient handful has been pulled it is laid on the ground, and the next parallel to it at a foot or so apart. The next handfuls are laid across these, and so on until a small pile is made, after which another is begun. After lying in this position for a few days, the seed-vessels or bolls are separated from the flax by lifting each handful separately and pulling the top through a ripple or iron comb, fixed upon a piece of plank. As many of these handfuls as will make a small sheaf are then laid very evenly together, and bound near both ends with bands formed of a few stems of flax. These sheaves are set up in stooks, and when dry enough to keep without heating, are stacked and thatched until an opportunity occurs of disposing of the flax straw. Sometimes the flax is bound into sheaves and stooked as it is pulled, and treated exactly like a grain crop. In this case the seed is separated from the straw by passing the head of each sheaf betwixt iron rollers. The only objection to this plan is that the bolls of separate sheaves get so entangled in each other, as to render it exceedingly difficult to handle them in carrying the crop, building, and taking down the stacks, without disarranging the sheaves and wasting much straw and seed.

Retting.

It would be tedious to enter here into a minute detail of the ordinary method of separating the flax fibre from the woody part of the stem. Suffice it to say that in the ordinary practice the sheaves or beets of flax straw are immersed in a pit or pool filled with clear soft water. The sheaves are kept under water by laying boards upon them loaded with stones to keep them down. Here the flax undergoes a process of fermentation by which the parts are separated. About nine or ten days are usually required for this purpose, but this is much influenced by the temperature. A good deal of skill and close watching is required to know exactly when it has been watered enough. The flax is now taken from the pit and evenly spread upon a smooth, clean, recently-mown meadow, where it lies for about ten days more, receiving several turnings the while. When the *retting*, as it is called, is perfected, the flax is carefully gathered up when perfectly dry, and again tied into sheaves, in which state it is stored under cover until the breaking and scutching can be overtaken.

Schenck's retting process.

All this necessarily requires much skilful watching and nice manipulation,—more, as we have already said, than is compatible with the other avocations of an extensive farmer. There are, however, improved modes of accomplishing this preliminary manufacture of flax, which, wherever established, pave the way for the growth of flax as an ordinary field crop. The first of these is known as Schenck's process, which is thus described in a report by "The Royal Society for the Promotion and Improvement of the growth of Flax in Ireland:"—

"The tenements containing the vats and drying-shelves, are simple wooden sheds, of cheap construction. In one end of the building are four vats, set parallel to each other, the length of the house. They are made of inch deal, in the form of a parallelogram, fifty feet long, six broad, and four deep. There are false bottoms, perforated with holes. Underneath these are introduced the steam-pipes, crossing the vats, and having stop-cocks at their entrance, by which the steam can be let on from the main pipe, as required. The steam is generated in a small boiler, which also serves to turn two hydro-extractors, —a patent apparatus used to drive off a portion of the water with which the flax is saturated, on being taken from the vats. The flax is packed into the empty vats, on the butt ends, in a half sloping position, precisely as in the case of a steep-pool, only one layer being the depth. The water is then let in, and a frame fastened over the top of the flax, answering the end of stones and straw, or sods, in the steep-pools—the prevention of the rising of the flax in the course of fermentation.

"The steam is then let into the pipes by turning the stop-cocks, and the water is some eighteen or twenty hours in becoming heated to the required point—85° to 90°. The fermentation then commences, and no further steam is required, the action going on until the flax is thoroughly retted, which is in forty hours afterwards, being sixty from the time of the admission of the water. It is worthy of remark, that, if the

Crops of limited cultivation.

water be heated before the flax is put into the vats, or if the heat be raised above 90°; the process is not in the least hastened, but, on the contrary, the fermentation is rather retarded. The footsteps of nature must be followed, and the heat gradually communicated to the water; otherwise the uniformity of watering, and the preservation of quality and colour, cannot be fully realised. At the end of the sixty hours, the flax is taken out, the water allowed to run off, and the vat permitted to cool. The same process is then repeated, with fresh water and fresh flax. When taken from the water, the flax is packed into the hydro-extractor, which is a round vessel of iron, made to revolve by steam-power with great velocity, the water being driven out of the flax on the principle of centrifugal force. Thirty beets or small handfuls are placed on this machine at a time, and about twenty pounds of water are extracted in three to five minutes. A few hours suffice for the contents of a vat, each vat containing two tons of flax straw. The hydro-extractor only separates a portion of the water; the flax now remains to be thoroughly dried. In summer, or, indeed, for six months in the year, this can be accomplished, as usual, by spreading on grass land in the open air. During winter, however, it is necessary to find other means of drying. A shed has therefore been erected communicating by doors with the vat house, filled with ranges of shelves, composed simply of railings of lathwood, in five or six tiers. The flax is spread lightly along these shelves by women, and the house is heated by steam-pipes. This house is capable of drying the full of one vat *per diem*. The flax, when dried, is made up in small beets or handfuls, of a size suited for feeding into the breaking-rollers of the mill.

"About ten vats per week can be steeped in this establishment—say twenty tons weight of straw, and producing, say two-and-a-half to three tons of fibre. Thus, in one year, such an establishment would be capable of turning out 120 to 150 tons of flax for market, being the produce of 400 to 500 statute acres. The fuel used for the boilers is principally 'shoves,' with a small quantity of turf. Mr Bernard estimates the cost of steeping, drying, heating, aud scutching the flax, at L.10 to L.11 per ton, which is L.3 per statute acre. Subtracting say 10d. per stone, or 6s. per cwt. for scutching, the cost of steeping and drying would thus appear to be about 24s. per acre—a sum certainly less than the usual estimates of these operations, as commonly performed by farm labour."[1]

Watt's process of retting.

More recently what is believed to be an improvement on this plan has been introduced by Mr Watt. It is thus described in the Annual Report of the Royal Society for the Promotion and Improvement of the growth of Flax in Ireland :—

"The flax straw is delivered at the works by the grower, in a dry state, with the seed on. The seed is separated by metal rollers, and afterwards cleaned by fanners. The straw is then placed in close chambers, with the exception of two doors, which serve the purpose of putting in and discharging the straw; the top, which is of cast-iron, serves the double purpose of a top and condenser. The straw is then laid on a perforated false bottom of iron, and the doors being closed and made tight by means of screws, steam is driven in by a pipe round the chamber and between the bottoms, and, penetrating the mass, at first removes certain volatile oils contained in the plant, and then is condensed on the bottom of the iron tank, descending in a continuous shower of condensed water, saturating the straw, and forming, in fact, a decoction of the extractive matters which attach the fibrous and non-fibrous portions of the plant. This liquid is drawn off from time to time, and the more concentrated portions are used for feeding; the process is shortened by using a pump, or such arrangements as will repeatedly wash the mass with the water allowed to accumulate. In about eight to twelve hours, varying with the nature of the straw, it is removed from the chambers, and having been robbed of its extractive matter without decomposition, it is then passed through the rollers for the purpose of removing the epidermis or outer skin of the plant, of discharging the greater part of the water contained in the saturated straw, and while in the wet and swollen state, splitting it up longitudinally. The straw being free of all products of decomposition, is then easily dried, and is in a few hours ready for scutching."[2]

The growth of flax has greatly increased in Ireland of late years. In the Irish Agricultural Return for 1852, it is stated that the extent of the flax crop in 1850 was 91,040 acres, which in 1851 had increased to 140,536 acres.

*Hemp*, although at one time very generally cultivated in Great Britain, is now so rarely met with, that it is unnecessary to enter into details of its management.

*Hops.*—The hop is, however, an important crop in several of the southern counties of England. We glean from Morton's *Cyclopædia*, and from the *Journal of the Royal Agricultural Society*, the following information regarding it. Although an indigenous plant, it was originally brought into England for cultivation from Flanders in 1525. It is cultivated to a considerable extent in Belgium, Bavaria, in the United States of America, and more recently in Australia. The duty now paid on home-grown hops is 17s. 7½d. per cwt.; that on those imported, is L.2, 5s. per cwt. Before the alteration of the tariff in 1846 it was L.4, 5s., and some years previous to that L.8, 8s., which in practice was a prohibitory duty. Hops, as is well known, are chiefly used for preserving and imparting a peculiar flavour to beer. Probably the only parts of the hop flower which enter into the composition of the beer, are the seeds, and the yellow glutinous matter which surrounds the outer integuments of the seed, and lies at the bottom of the petals. This yellow matter (technically termed the *condition* of the hop) has an intensely bitter taste, and emits a peculiar and very agreeable aroma, which, however, is extremely volatile; and hence the necessity for close packing as soon as possible after the hops are dried. When kept over a year, much of this aroma flies off, and hence *new* hops are indispensable in brewing the first kinds of beer. Several varieties of the hop are cultivated in England. Of these the Farnham and Canterbury whitebines, and goldings are esteemed the finest. These are tall varieties, requiring poles of from fourteen to twenty feet. The grapes, so called from growing in clusters, and of which there are several varieties of various quality, requires poles from ten to fourteen feet long. Jones's, adapted for lighter and inferior land, requires these but eight to ten feet. The colegates are a hardy and late ripening variety which grow best on stiff soils,—and the Flemish redbine only cultivated from its less liability than the other to be attacked by the aphis or black blight.

The hop is a very exhausting crop for the land, requiring to be planted only on the most fertile soils, and to have them sustained by frequent and large dressings of manure rich in nitrogen. Hops are principally cultivated in the counties of Kent, Sussex, Surrey, Hants, Worcester, and Hereford, and to a more limited extent in Essex, Suffolk and Nottingham. The best quality of hops are grown at Farnham in Kent, upon the outcrop of the upper greensand formation, from whence the phosphoric nodules or coprolites, now so well known in the manure market, are obtained. The greatest extent of land under this crop in any one year during the present century was in 1837, when it amounted to 56,323 acres. Owing to lower prices, and consequent less profitable returns, the extent in 1849 was reduced to 42,798 acres.

In forming a new plantation, the ground soon after Michaelmas is trenched to the depth of eighteen inches, if it has previously been in meadow or old pasture, taking care

[1] Morton's *Cyclopædia of Agriculture*, article "Flax."

[2] *North British Agriculturist*, 10th November 1852.

Crops of limited cultivation.

not to bury the surface-soil above half that depth. Subsoil-ploughing will suffice with land that is in tillage. If the land is wet, drains are made from four to five feet deep, laid with pipes, and a foot of broken stones over them, to prevent the roots of the hops from obstructing the pipes. The frequency of the drain is determined by the necessities of each case. Perfect draining is essential to the success of the crop; and the hops are planted in squares or triangles at equal distances, varying from six to seven feet, according to the fertility of the soil, and the greater or less luxuriant habit of growth of the variety selected. The plants are raised by cutting off the layers or shoots of the preceding year, which are bedded out during the month of March, in ground previously prepared, and in the succeeding autumn become what are called nursery plants or bedded sets. Early in November these are planted; one, two, or three being used for a hill, according to the strength of the plants. Care must be taken to introduce a sufficient number of *male* plants, six hills to the acre being deemed sufficient. The presence of these is found to induce earlier maturity, and to improve both the quality and weight of the crops. The ground must at all times be kept free from weeds, and have a good depth of pulverised soil. From the first, a stick six feet high or so, is placed to each hill, to which *all* the young bines, as they shoot out during summer, must be tied. A liberal dressing of superphosphate of lime and guano is in June hoed in around each hill, which is repeated in July, under which treatment, two or three cwt. of hops is obtained the first year, besides growing a crop of mangel, turnips, or potatoes, in the intervals betwixt the hills. On newly broken up ground, lime is applied the following spring. When a plantation has been established, the annual routine of culture begins in autumn, as soon as the crop has been gathered, when the haulm is stripped from the poles, and stored away as a substitute for straw. The poles are stacked or piled in quantities of 400 or 500, at regular distances on the ground. During winter they are sorted, and repointed when required, and new ones substituted for those that are broken or decayed; this work and the carrying on of manure being accomplished in frosty weather. The ground is dug over by the fork at this season. In March the earth is removed from the plants by a beck or pronged hoe till the crown is exposed, that the plant may be pruned. Immediately after this the poles are set, the length and number of these for each hill depending upon the kind of hops and amount of growth anticipated. They are fixed into holes made for them by a hop-bar. As the season advances, the ground is hoed and again dug or stirred by a nidget or scarifier drawn by a horse. Early in May, the bines or young shoots, as soon as long enough, are, by women, tied to the poles with rushes or bast. This tying is repeated several times as the bines get higher, and has even to be done by step-ladders. In June, the hops are earthed up or *hilled*, at which time weak plants get a dressing of guano. Throughout the summer weeds are destroyed as they appear, and the soil kept loose by the nidget or the hand-hoe. If poles are blown over by high winds, they are constantly replaced.

The picking of the hops usually begins about the second week in September, and furnishes ample employment for several weeks to the entire population of the districts, and to a large influx of strangers, men, women, and children, all engaging in it. In favourable years, a labourer with his wife and several children can earn from L.6 to L.8 during the hop-picking season. The hop-pickers are arranged into companies, and are supplied with baskets or bins, holding seven or eight bushels each, and which are gauged with black lines inside to save the trouble of measuring. Each company is under the superintendence of a hop bailiff, who keeps an account of the earnings, &c. Under him are several men called pole-pullers, whose duty it is to supply the pickers with poles of hops, and to assist in carrying the picked hops to the carts. They use an iron lever called a hop-dog, in pulling up the poles. The hops are picked, one by one, into the bins, care being taken that no bunches nor leaves, nor mouldy hops are included. The price paid for picking ranges from 1½d. to 3d. per bushel, although in blighted seasons it may be as high as 6d. The hops are dried in kilns or oast-houses, on floors of haircloth. Great improvements have been made of late years in the construction of these oasts. Much nice discrimination is required in managing the drying, so as to produce the best quality of hops. As soon as they are removed from the kiln they are packed into pockets, which, during the process, are suspended from a hole in the floor, and the hops trodden into them by a man. This is now done more accurately by machines, in which a piston presses the hops into the pockets. Hop-growing is a hazardous speculative business, the return at times being very great, and at other times not covering expenses. This arises from the liability of the hop to the attacks of insects, but more especially to blight and mould. The blight is caused by innumerable hordes of the *aphis humuli*, which sometimes destroy the plants altogether. The mould is a parasitical fungus. It is believed that a means has at last been discovered of checking the ravages of these assailants, by enveloping each plant separately in a light covering, and subjecting it to the fumes of tobacco in the case of blight, and to a cloud of powdered brimstone in the case of mildew. The charges attendant upon the cultivation of an acre of hop-ground are estimated, including rent, tithes, interest on capital and duty, at from L.50 to L.60; and as 10 cwt. is considered an average crop, and L.5 per cwt. a frequent price, it is evident that the business is a very precarious one. In blight years it usually happens, that some grounds altogether escape, in which case the returns from them are enormous, owing to the enhanced price.

*Sugar-Beet.*—"During the wars of the French revolution, the high price which colonial sugar obtained on the continent induced the manufacture of sugar in large quantities from beet-root. This has become so large in France that since the restoration of peace the French government have felt compelled to protect the beet-root sugar makers by the imposition of prohibitory duties on colonial sugars.

"Some years since, the manufacture of sugar from beet-root began to be attempted, and not without success, in England. The absence of any excise duties, and an existing considerable import duty on colonial sugars seemed to offer a kind of premium to the English makers. The government naturally took the alarm; a revenue on imported sugars, which in 1850 yielded about L.4,130,000, could not be allowed to be endangered. Parliament therefore interfered; and by the 1st Vict. c. 57 (1837), a duty of 24s. per cwt. was imposed on all sugar made from beet-roots in the United Kingdom. The manufacture was placed under the management of the Commissioners of Excise, and the entire process must now be carried on under the regular survey of their officers. Four hours' notice must be given before any maker can begin to rasp, or grind, or mash any beet-root, for the purpose of sugar-making, and other restrictions are directed. In 1840, by the 3d and 4th Vict. c. 57, the same duty was imposed upon sugar made from potatoes, rice, and other materials, in the United Kingdom. In 1845, however, by the 8th Vict. c. 13, the amount of this duty was reduced to 14s."[1]

[1] *Farmer's Magazine*, vol. i. p. 481.—(June 1852).

Crops of limited cultivation.

The matter has again been taken up in good earnest, and a company formed, by whom the process of manufacturing beet-sugar is in actual operation at Mount Meillick, in Queen's County, Ireland. By this operation the fact has already been established, that the climate and soil of Ireland are exceedingly favourable to the sugar-beet, and that the quality of the roots is equal, if not superior, to those of France or Belgium. By recent improvements in the manner of conducting the manufacture, it is said that the sugar obtained from beet amounts to 8 per cent. of the gross weight of the roots, instead of 5 per cent., as at first. "That this is a question of national importance is beyond all doubt; and to shut our eyes to the undisputed advantages which home-made sugar promises, is to reject a benefit which our continental neighbours have long turned to good account. At the earliest period of this manufacture in France, great mechanical and chemical difficulties had to be overcome. The English manufacturer goes to his task with all the experience at his command which the continent has acquired. In France, for these reasons, the progress was slow at the commencement, but once having taken root was never given up.

"We subjoin an historical sketch of the gradual progress of this branch of industry in France from 1820 to 1840:—

| Year. | Production of Inland Sugar. | Foreign Sugar entered for Consumption. | Total Consumption of Sugar. |
|---|---|---|---|
| | Kilogrammes. | Kilogrammes. | Kilogrammes. |
| 1820 | 50,000 | 44,416,795 | 44,416,795 |
| 1821 | 100,000 | 41,502,749 | 41,502,649 |
| 1822 | 300,000 | 49,328,057 | 49,328,057 |
| 1823 | 500,000 | 37,590,270 | 38,590,270 |
| 1824 | 800,000 | 56,048,430 | 56,048,439 |
| 1825 | 1,000,000 | 48,546,683 | 49,546,683 |
| 1826 | 1,600,000 | 64,407,342 | 65,407,342 |
| 1827 | 2,000,000 | 50,797,139 | 52,797,139 |
| 1828 | 2,700,000 | 61,987,771 | 64,987,771 |
| 1829 | 4,400,000 | 62,160,175 | 66,160,175 |
| 1830 | 5,500,000 | 54,647,941 | 60,647,941 |
| 1831 | 7,000,000 | 67,750,207 | 74,750,207 |
| 1832 | 9,000,000 | 62,642,643 | 71,642,643 |
| 1833 | 12,000,000 | 57,874,877 | 69,874,876 |
| 1834 | 20,000,000 | 65,643,511 | 85,643,511 |
| 1835 | 30,000,000 | 64,095,647 | 94,095,647 |
| 1836 | 40,000,000 | 56,276,475 | 96,276,475 |
| 1837 | 45,000,000 | 64,167,840 | 109,167,840 |
| 1838 | 50,000,000 | 63,251,965 | 113,251,965 |
| 1839 | 55,000,000 | 62,731,995 | 117,731,095 |

Within the last ten years the augmentation has been less rapid. In 1851, the production was 60,000 tons, or 60,000,000 of kilogrammes, notwithstanding the repeated prophecies that the beet-sugar would not compete with the cheap sugar of Brazil, Java, and Manilla.

In Germany, the manufacture of sugar is of more recent date than in France. Its progress of late has been,—

| Beet-root Sugar made in the Zollverein. | | Foreign Sugar imported. | |
|---|---|---|---|
| 1848 | 26,000 tons. | 1848 | 60,500 tons. |
| 1849 | 34,000 „ | 1849 | 54,000 „ |
| 1850 | 40,000 „ | 1850 | 48,000 „ |
| 1851 | 43,000 „ | 1851 | 45,000 „ |

In the Austrian empire 8000 tons were made in 1848, and in 1851, 15,000 tons. Russia is said to have contributed 25,000 tons in the year 1851.

It does not at all follow that sugar made in England is to drive our colonial sugar out of the market. There is more foreign sugar imported than we could hope to see replaced in many years. In 1851, it exceeded 45,000 tons, of which but a small portion was re-exported. To this figure we may therefore push our efforts; and most gratifying it is to be able to reflect, that while slave-labour must inevitably grow dearer, every mechanical and scientific improvement can but enhance the powers of the European producers, and ensure their ultimate victory over the slave-owner. Samples have been shewn in the city of beet-sugar from the Rhine, quite equal to "white Havanna, and refined sugar made from the same that could not be distinguished from West Indian."[1]

It has also been ascertained that excellent beer can be made from the juice of the beet. The refuse from the sugar manufacture is said to be available for feeding cattle and pigs, and as a manure.

The cultivation of the Silesian white-beet, which is the variety of this plant most in repute for yielding sugar, differs in no respect from that of mangel-wurzel, which we have already described.

*Chicory for its roots.*—The very extensive and constantly increasing consumption of the roots of chicory, as a substitute for coffee, renders it now an agricultural crop of some importance. The soils best adapted for its growth are deep friable loams. The process of cultivation is very similar to that required for the carrot, excepting only that it is not sown earlier than the first week of May, lest the plants should run to seed. When this happens, such plants must be thrown aside when the crop is dug, else the quality of the whole will be injured. About four pounds of seed is the quantity to sow per acre, either broad-cast or in rows. The latter is undoubtedly the best mode, as it admits of the land being kept clean, and yields roots of greater weight. The crop is ready for lifting in November. A long stout fork is the best implement for this purpose. In using it, care must be taken to get out the roots entire, not only for the sake of the roots, but to lessen an inconvenience attendant on the culture of this plant, namely, that the fragments left in the soil grow amongst the after crops, and are as troublesome as weeds. The roots, when dry, are carefully washed, cut into thin slices, and kiln-dried, when they are fit for the coffee-grinder. From 1 to $1\frac{1}{4}$ tons per acre of the dried root is an average produce. A few years ago, from L.20 to L.30 per ton was a current price for good samples, but like other crops of limited consumption, it has been grown too extensively—the market has been glutted, and the price reduced to L.6.

*Oil-yielding Plants.*—Various plants are occasionally cultivated in Britain for the sake of the oil which is expressed from their ripened seeds. We have already noticed the value of flax-seed for this purpose, although the fibre is the product which is chiefly had in view in cultivating it. The plants most commonly sown expressly as oil-yielding crops are, rape (*Brassica napus*), colsa (*Brassica campestris*), gold of pleasure (*Camelina sativa*), and the poppy (*Papaver somniferum*). Rape is the plant most frequently and extensively grown for the production of oil. The colsa or *B. campestris* is said to yield better crops of seed than the other species. This plant is much cultivated in Flanders for this purpose. In Great Britain it seems rather on the decline. It is chiefly on rich alluvial soils that this crop is grown. For a seed crop rape is sown in June or July pre-

[1] *Farmer's Magazine*, pp. 558, 559.

Crops of limited cultivation.

cisely in the manner already described for turnips. The young plants are thinned out to a width of six or eight inches apart, and afterwards kept clean by hoeing. The foliage may be eaten down by sheep early in autumn, without injuring it for the production of a crop of seed. In spring the horse and hand hoe must be used, and the previous application of one or two cwt. of guano will add to the productiveness of the crop. It suits well to lay down land to clover or grass after a crop of rape or turnip seed, and for this purpose the seeds are sown at the time of giving this spring culture. The crop must be reaped as soon as the seeds are observed to acquire a light-brown colour. The reaping is managed precisely as we have described in the case of beans. As the crop after being reaped and deposited in separate handfuls on the ground very soon gets dry enough for thrashing, and as the seed is very easily shed after this is the case, this process must be performed as rapidly as possible. Sometimes it is conveyed to the thrashing-mill on harvest-carts, on which a cloth is stretched to save the seeds knocked out in the loading and unloading, but more usually the flail is used on temporary thrashing-floors, provided in the field by spreading down large cloths. The crop is gently lifted from the ground and placed heads innermost, on a blanket which two persons grasp by the corners, and carry to the thrashing-floors. A great number of people are required to push this process through rapidly, for unless the crop is quickly handled, a great loss of seed ensues. The seed is immediately spread thinly upon a granary floor, and frequently turned until dry enough to keep in sacks, when it is cleaned and disposed of. On good soil, and in favourable seasons the yield sometimes reaches to forty bushels per acre. The haulm and husks are either used for litter, or burned. and the ashes spread upon the land. It makes good fuel for clay burning.

*Seeds of Agricultural Crops.*—In the case of seed-corn it is customary for farmers either to select from the best of their own growth, to exchange with or purchase from neighbours, or, if they wish a change from a different county, to employ a commission-agent to buy for them. In all districts there are careful farmers, who, by occupying land that produces grain of good appearance, and being at pains to have good and pure sorts, are stated sellers of seed-corn, and manage in this way to get a few shillings more per quarter for a part of their produce. It is therefore only in the case of new and rare varieties that professional seedsmen ordinarily deal in seed-corn. There are, however, other field crops, such as clovers, grasses, turnip, mangel, carrots, winter vetches, &c., the seeds of which, to a large extent, pass through the hands of seedsmen, and the growing of which is restricted to particular districts, and is in the hands of a limited number of farmers. In general, a good soil and climate, and a considerable amount of skill and minute personal attention on the part of the farmer are indispensable, in order to produce these seeds of good quality. These seed crops are sometimes very remunerative to the grower; but are hazardous ones for farmers to attempt at their own risk. The only safe course is to grow them at a stipulated price, to the order of some thoroughly respectable seedsman, and to hold to the production of the particular kind or kinds which he requires. This applies, in a less degree, to the clovers, and to the more commonly cultivated grasses than to the other seeds just referred to. Such an arrangement is beneficial to all concerned. The grower having a fixed price, and certain market, knows exactly what he is doing, the seedsman purchasing only from selected growers, to whom he usually supplies a choice stock of the article to be raised by them, can vouch for the genuineness and freshness of his seeds; and his customers knowing the guarantee against disappointment and loss which this mode of conducting his business affords to them, give him a full price, and find it true economy to do so.

Crops of limited cultivation.

We have already described the mode of saving the seeds of Italian or common ryegrass; and as other grasses are managed in the same way. it is unnecessary to say more regarding them.

Clover seed.

It is only in the southern parts of England that clover is grown for the sake of its seeds. When it is meant to take a crop of seed, the clover is fed off with sheep, or mown early in the season, and then allowed to produce its flowers, and ripen its seeds. This preliminary eating or cutting over causes the plants to throw up a greater number of seed-stems, and to yield a fuller and more equally ripening crop. The crop is mown when the seeds are seen to be matured. In the case of white clover the cutting takes place while the dew is upon the crop, as working amongst it when dry would cause a loss of seed. After mowing and turning the crop, the ground is raked with close-toothed iron rakes, to catch up loose heads. The thrashing is a twofold process; first the separation of the heads or cobs from the stem, called "cobbing," and then of the seeds from the husks, called "drawing." This was formerly accomplished by a laborious and tedious process of thrashing with flails, but it is now done by machinery. In favourable seasons. the yield is about five or six bushels (of 70 lb. each) per acre.

Turnip seed.

*Turnip Seed* is the next most important crop of this kind. From the strong tendency in the best varieties of turnips and Swedes to degenerate, and the readiness with which they hybridise with each other, or with any member of the family *Brassica*, no small skill and pains are needed to raise seed that can be depended upon to yield roots of the best quality. Turnip seed is saved either from selected and transplanted roots, or from such as have been sown for the express purpose, and allowed to stand as they grow. The first plan, if the selection is made by a competent judge, is undoubtedly that by which seed of the purest quality is obtained. But it is an expensive way, not only from the labour required in carrying it out, but from the yield of seed being generally much less than from plants that have not been disturbed. Professional seed-growers usually resort to a compromise, by which the benefit of both plans is secured, viz. by selecting with great care, and transplanting a limited number of bulbs, and saving the seed obtained from them to raise the plants which are to stand for their main seed crop. The latter are carefully examined when they come into bloom, and all plants destroyed the colour of whose flowers varies from the proper shade. Turnips that are to bear seed are purposely sown much later in the season than when intended to produce cattle food, as it is found that bulbs about 1 lb. weight are less liable to be injured by frost, or to rot before the seed is matured, than those of larger size. The management of a turnip-seed crop, both as regards culture and harvesting, is identical with that of rape for its seeds, which has already been described.

*Mustard.*—Both the white and brown mustard is cultivated to some extent in various parts of England. The former is to be found in every garden as a salad plant; but it has of late been coming into increasing favour as a forage crop for sheep, and as a green manure, for which purpose it is ploughed down when about to come into flower. The brown mustard is grown solely for its seeds, which yield the well-known condiment. When white mustard is cultivated for its herbage, it is sown usually in July or August, after some early crop has been removed. The land being brought into a fine tilth, the seed, at the rate of 12 lb. per acre, is sown broad-cast, and covered in in the way recommended for clover seeds. In about six weeks it is ready, either for feeding off by sheep, or for ploughing down, as a preparative for wheat or barley. White mustard is not fastidious

Crops of limited cultivation.

in regard to soil. When grown for a seed crop, it is treated in the way about to be described for the other variety. For this purpose either kind requires a fertile soil, as it is an exhausting crop. The seed is sown in April, is once hoed in May, and requires no further culture. As soon as the pods have assumed a brown colour the crop is reaped and laid down in handfuls, which lie until dry enough for thrashing or stacking. In removing it from the ground, it must be handled with great care and carried to the thrashing-floor or stack on cloths, to avoid the loss of seed. The price depends much on its being saved in dry weather, as the quality suffers much from wet. The yield varies from twenty to thirty bushels per acre, and the price from 10s. to 20s. per bushel. It is chiefly grown on rich alluvial soils in the south-eastern counties of England. This great evil attends its growth, that the seeds which are unavoidably shed in harvesting the crop remain in the soil, and stock it permanently with what proves a pestilent weed amongst future crops.

*Canary Seed* (*Phalaris canariensis*) is cultivated to some extent in Essex and adjoining counties, for the sake of its grain, which is used exclusively for feeding cage-birds. In an agricultural point of view, it is exceedingly similar to our staple corn crops, and in practice is sown instead of wheat or barley. It is drilled in February, at the rate of two gallons per acre, on land that has been ploughed the previous autumn, and stirred by the grubber immediately before sowing. It requires hoeing, to protect it from weeds during the first stages of its growth. It is late in ripening, and requires to be thoroughly dried before being stacked. It is recommended to stack it on frames, to guard it from the attacks of mice, which manifest a peculiar fondness for it. Its yield and weight per bushel are similar to those of wheat. Its price fluctuates exceedingly, but averages from 50s. to 60s. per quarter.

*Coriander and Caraway* are noticed together, not only because they are used for similar purposes, but because they are frequently grown in mixture. Both are cultivated for the sake of their seeds, which are used by confectioners, and for medicinal and other purposes. The coriander being an annual and the caraway a biennial, the former yields a crop the first year, and then leaves the latter in possession of the ground. At one time a third crop, viz. the teazel, was also sown with them, but owing to improvements on the machinery for dressing cloth it has become obsolete. The coriander being also less grown than formerly, the caraway is frequently drilled amongst wheat. After the latter is harvested, the stubble and weeds are cleared away by horse and hand hoeing. Beans or dwarf pease are also sometimes grown betwixt the rows of caraway during the first and unfruitful year of its growth. The mode of harvesting both of these crops is the same. They are reaped and deposited in handfuls until dry enough for thrashing, and are then carried with great care on cloth-covered sledges to a temporary thrashing-floor where the seeds are beaten out by flails. About ten cwt. of coriander and five of caraway per acre, is an average yield. The price of the former ranges from 10s. to 20s. per cwt., that of the latter from 35s. to 45s. per cwt. The cultivation of these crops for sale is nearly confined to the county of Essex; but plots of caraway are to be met with in farm and cottage gardens in all parts of Great Britain.

Garden seeds.

In Essex and Kent no inconsiderable extent of land is annually occupied in growing the seeds of the staple crops of our kitchen and flower gardens. Wholesale seedsmen contract with farmers to grow these seeds for them at a stipulated price.

Fruits and vegetables.

The growth of fruits and of culinary vegetables is in various parts of Great Britain an important department of farming—for the scale on which it is conducted allies it quite as much to agriculture as to horticulture. We learn from Mr Cuthill,[1] that in the counties contiguous to London above 12,000 acres are occupied in growing vegetables, and about 5000 more in producing fruit. About 35,000 people find employment in these market gardens. The system of cultivation pursued in them is admirable. The soil is trenched two spits deep for nearly every crop; it is heavily manured and kept scrupulously clean by incessant hoeing. Whenever a crop is removed, some other suited to the season is instantly put in its place, and not an inch of ground is suffered to be unproductive. A young farmer bent on knowing his business thoroughly, could not well occupy a few months to better purpose than by placing himself under one of these clever market gardeners.

Kent has long been peculiarly celebrated for its orchards. The best of them are on the borders of the greensand formation, or ragstone as it is provincially called. Apples, pears, plums, cherries, and nuts are produced in immense quantities. The filbert plantations alone are said to occupy 5000 acres. An abundant and cheap supply of fruit and vegetables for the inhabitants of our towns is undoubtedly an important object, and is likely to occupy increased attention wherever a suitable soil and exposure with facility of carriage by railway are combined.

## CHAPTER X.

### LIVE STOCK.

The breeding and rearing of domesticated animals has ever been a favourite pursuit in Great Britain, and has been carried to greater perfection than any other department of rural affairs. In no other country of similar extent can so many distinct breeds of each class of these animals be found; most of them excellent of their kind, and admirably adapted to the particular use for which they are designed. Observing the usual order, we notice first—

Saddle horses.

*Horses.*—In doing so we shall confine our attention to those breeds which are cultivated expressly for the labours of the farm; for although the breeding of saddle-horses is chiefly carried on by farmers, and forms in some districts an important part of their business, it does not seem advisable to treat of it here. It is a department of husbandry requiring such a combination of fitness in the soil, climate, and enclosures of the farm, of access to first-class stallions, and of taste and judgment on the part of the farmer, that few indeed of the many who try it are really successful. The *morale* too of the society into which the breeding of this class of horses almost necessarily brings a man, is so unwholesome, that none can mingle in it freely without experiencing to their cost that "evil communications corrupt good manners." We have noted it as a fact of peculiar significance, in this connection, that of the few men who really make money by this business, scarcely one desires to see it prosecuted by his sons.

London dray horses.

*Breeds.*—The immense size and portly presence of the English black horse, entitle him to priority of notice. This breed is widely diffused throughout England, though found chiefly in the Midland Counties. It is in the fens and rich pastures of these counties, that the celebrated London dray horses are bred and reared. "These ponderous animals are frequently seventeen hands high, and their sleek and glossy appearance as they move majestically through the streets of the metropolis, presents one of the most striking sights to the eye of the foreigner." These horses are too slow and heavy

[1] See *Market Gardening round London*, by James Cuthill, Camberwell, 1851.

Live Stock.

for ordinary farm-work, and would not be bred but for the high prices obtained for them from the great London brewers, who pride themselves on the great size, majestic bearing, and fine condition of their team horses. It is alleged indeed, that it is only such massive animals that can cope with the heavy loads of coals, timber, and merchandise of all kinds, requiring to be conveyed over jolting pavements from wharves and similar places. But in reality these heavy horses are destroyed by their own weight, few of them being free from ring-bone and other diseases of the feet and pasterns. Smaller but more muscular and energetic horses,—especially if yoked singly in carts, instead of by teams in great waggons,—would perform more work at less expense, and with less fatigue to themselves. The breeders of these horses employ brood mares and young colts exclusively for their farm-work. The colts are highly fed, and worked very gently until four years old, when they are sold to the London brewers, often at very great prices. The same breed is largely used in England for ordinary farm labour, although not found of such gigantic proportions as in those districts where they are bred for the special destination just referred to. Although very docile, their short step, sluggish gait, large consumption of food, and liability to foot lameness, render them less profitable for ordinary farm-work than the breeds about to be mentioned.

*The Suffolk Punch* is a well-marked breed which has long been cultivated in the county from which it takes its name. These horses are, for the most part, of a sorrel, bay, or chestnut colour, and are probably of Scandinavian origin. They are compact, as their name imports, hardy, very active, and exceedingly honest pullers. These horses at one time were very coarse in their form, and rather slow; but they have now been so much improved in form and action, that we find them the chief prize-takers at the recent exhibitions of the Royal Agricultural Society.

*The Cleveland Bays* are properly carriage-horses; but still, in their native district, they are largely employed for field work. Mr Milburn says, " The Cleveland, as a pure breed, is losing something of its distinctiveness. It is running into a proverb, that ' a Cleveland horse is too stiff for a hunter, and too light for a coacher;' but there are still remnants of the breed, though less carefully kept distinctive than may be wished by advocates of purity. Still the contour of the farm-horses of Cleveland has the lightness, and hardiness, and steadiness of the breed in outline; and it is singular that while the lighter soils have horses more calculated for drays, the strong-land farmer has the compact and smaller, but comparatively more powerful animal."

In the north-eastern counties of England, and the adjacent Scottish borders, compact, clean-legged, active horses, of medium size, with a remote dash of blood in them, are generally preferred to those of a heavier and slower kind. One needs only to see how such horses get along at turnip-sowing, or with a heavy load in a one-horse cart, to be convinced of their fitness for the general work of a farm.

*The Clydesdale Horses* are not excelled by any cart breed in the kingdom for general usefulness. They belong to the larger class of cart-horses, 16 hands being an average height. Brown and bay are now the prevailing colours. In the district whose name they bear, the breeding of them for sale is extensively prosecuted, and is conducted with much care and success. Liberal premiums are offered by the local agricultural societies for good stallions. Many admirable specimens of this breed of horses were brought forward at the Highland Society meeting at Glasgow in 1850; not the least interesting of which were those which competed for the premiums offered for the best cart-horses statedly employed on the streets of that city, attended by their usual drivers and mounted with their usual harness. Horses of this breed are peculiarly distinguished for the free step with which they move along, when exerting their strength in cart or plough. Their merits are now so generally appreciated, that they are getting rapidly diffused over the country. Many small farmers in Clydesdale make a business of raising entire colts, which they either sell for stallions, or send into distant counties to serve for hire in that capacity.

Live Stock.

Highland and Welsh ponies.

In the Highlands of Scotland, a breed of hardy and very serviceable ponies, or "Garrons," as the natives call them, are found in great numbers. In their native glens they are employed in tillage, and although unable for stated farm-work in the low country, are even there often used in light carts for work requiring despatch, rather than great power. Similar ponies abound in Wales.

*Breeding.*—In breeding cart-horses, regard must be had to the purpose for which they are designed. If the farmer contemplates the raising of colts for sale, he must aim at larger frame than if he simply wishes to keep up his own stock of working cattle. These considerations will so far guide him as to the size of the mares and stallions which he selects to breed from; but vigorous constitutions, perfect freedom from organic disease, symmetrical form, and good temper, are qualities always indispensable. Nothing is more common than to see mares used for breeding, merely because, from lameness or age, they have ceased to be valuable for labour. Lameness from external injury is, of course, no disqualification; but it is mere folly to expect valuable progeny from unsound, misshapen, ill-tempered, or delicate dams, or even from really good ones, when their vigour has declined from age. A farmer may grudge to lose the labour of a first-rate mare for two or three months at his busiest season; but if he cannot make arrangements for doing this, he had better let breeding alone altogether; for it is only by producing horses of the best quality that it can be worth his while to breed them at all. In the case of horses it is always desirable that both sire and dam should have arrived at maturity before being put to breed.

The head of the cart-horse should not be large, at least not heavy in the bones of the face and jaws, nor loaded with flesh. Full development of brain is, indeed, of great importance, and hence a horse somewhat wide betwixt the ears is to be preferred. Prick ears and narrow forehead have by some been reckoned excellences, but we have so invariably noticed such horses to be easily startled, given to shying, and wanting in courage and intelligence, that we regard such a form of head as a defect to be avoided. The eye should be bright, full, and somewhat prominent, the neck inclining to thickness, of medium length, and slightly arched, and the shoulders oblique. Upright shoulders have been commended as an advantage in a horse for draught, it being alleged that such a form enables him to throw his weight better into his collar. It should be remembered, however, that the horses which display the greatest power in drawing heavy loads, are characterised by muscular vigour and nervous energy, rather than mere weight of carcase; and these qualities are more usually found in connection with the oblique shoulder than the upright one—not to mention that this form is indispensable to that free and full step so necessary in a really useful farm-horse.

" The back should be straight and broad, the ribs well arched, and the false ribs of due length, so as to give the abdomen capacity and roundness. The tail should be well set out, not too drooping, and the quarters should be full and muscular. The horse should girth well, and have his height in his body rather than in his legs, so as to look less than measurement proves him to be. The forelegs should be strong, and flat below the knee, and by no means round and gummy either before or behind, neither should they have white hair about them, nor much hair of any colour. The hocks should be broad in front,

Live Stock.

and neither too straight nor too crooked, nor yet cat-hammed. All diseases of this joint, whether curbs, spavins, or thoroughpins, are sufficient grounds for rejecting a horse. The feet are a matter of very much importance. The tendency of many heavy horses is to have thin horn and flat feet. A stallion possessing such feet is exceedingly objectionable. Plenty of horn is a recommendation, and the feet had better be too large than too small. The brood mare should possess as many of the points now enumerated as possible. If the mare is small, but symmetrical, we may very properly select a large stallion, provided he has good action. If, on the other hand, the mare is large, and has a tendency to coarseness, we should select a middle-sized horse of symmetrical appearance."[1]

Sixteen hands is a good height for a farm-horse. Except for very heavy land, we have always had more satisfaction from horses slightly below this standard than above it.

We have repeatedly put a well-bred saddle mare to a cart-horse, and have invariably found the produce to prove excellent farm-horses. The opposite cross, betwixt a cart-mare and blood stallion, is nearly as certain to prove ungainly, vicious, and worthless. These horses are generally much stronger than their appearance indicates, have great powers of endurance, and can be kept in prime working condition at much less cost than bulkier animals. We have often noticed that village carters, who perform cartage for hire, invariably purchase small horses, and yet carry loads with them which farmers would consider too much for their best cattle. It is on muscular power, and nervous energy, that the strength of animals depends, and this, therefore, should be sought after in the farm-horse, rather than mere bulk.

Time when mares should foal.

Cart-mares should not foal earlier than May. So that they are not unduly pushed nor put to draw heavy loads, they may be kept at work almost up to their time of foaling, and are thus available for the pressing labours of spring. It is of importance, too, that the pasture should be fresh, and the weather mild, ere their nursing duties begin. Mares seldom require assistance in bringing forth their young, and although it is well to keep an eye upon them, when this event is expected, they should be kept as quiet as possible, as they are impatient of intrusion, and easily disturbed in such circumstances. The new-born foal not unfrequently has some difficulty in getting suck, and also in voiding the first fæces.

Treatment of foals.

Both these matters must be attended to, and assistance given if necessary. If it is observed to strain without voiding the tough excrement which is in its bowels at birth, greasing the passage, by pushing in a tallow candle, will usually afford it instant relief. A sheltered paddock with good grass, and where there are no other horses, is the most suitable quarters for a newly foaled mare. There must be no ditch or pond in it, as young foals have a peculiar fatality for getting drowned in such places. A mare, in ordinary condition, receives the stallion on the ninth or tenth day after foaling, and with a greater certainty of conceiving than when it is delayed until she is again in heat. If the mare's labour can at all be dispensed with, it is desirable to have her with her foal for two months at least. She may then be put to easy work with perfect safety, so that she is not kept away from the foal longer than two or three hours at a time. When the foal has got strong enough, it may even be allowed to follow its dam at her work, and to get suck as often as it desires it. Towards the end of September, foals are usually weaned, and are then put under cover at night, and receive a little corn, along with succulent food. If the dam has been put to work before weaning, she will have been allowed a feed of oats, in which case the foal will already have got a liking for this food by tasting a little along with her. This is a great advantage, as when put on its own resources, it takes at once to the generous fare which it ought always to be allowed at this stage. Good hay, bran, carrots, or Swedes, and a few oats, must be given regularly during the first winter, with a warm shed to lie in, and an open court for exercise. At weaning it is highly expedient to put a cavasin on colts, and lead them about for a few times. A few lessons at this early age, when they are easily controlled, saves a world of trouble afterwards. Before being turned to grass in spring, they should, on the same principle, be tied up in stalls for a week or so. It is customary to castrate colts at a year old. Some, indeed, advise its being done a few weeks after birth, when, of course, the pain to the animal, and risk of death, are less. It must, however, be borne in mind that this early emasculation will probably ensure a skranky neck, whereas a natural tendency to this defect can in good measure be remedied by deferring the operation. We have seen a puny colt much improved in figure by being left entire until he was two years old. By giving good pasture in summer, and a liberal allowance of hay, roots, and oats in winter, colts may, with safety, and even benefit, be put to moderate work in their third spring. Some time before this is done, they should be put through a short course of training, to use them to the bit, and make them quiet and handy. Many good cart-horses are ruined for want of a little timeous attention in this way. When they have got familiar with the harness, they should be yoked to a log of wood, and made to draw that up and down the furrows of a fallow field, until they become accustomed to the restraint and exertion, after which they may with safety be put to plough alongside a steady and good-tempered horse, and what is of equal conquence, under the charge of a steady good-tempered ploughman. As they should not have more than five hours' work a day for the first summer, it is always an advantage to have a pair of them to yoke at the same time, in which case they take half-day about, and do a full horse's work betwixt them. With such moderate work and generous feeding their growth will be promoted. By midsummer, the throng of field labour being over, it is advisable to turn the striplings adrift, and let them enjoy themselves in a good pasture until after harvest, when they can again be put to plough. Horses should not be required to draw heavy loaded carts until they are five years old. When put into the shafts earlier than this they frequently get strained and stiffened in their joints. On every farm requiring four or five pairs of horses, it is highly expedient to have a pair of young ones coming in annually. This enables the farmer to be provided against contingencies, and to have his stable occupied at all times with horses in their full vigour; which go through their work with spirit, and never falter for a little extra pushing in emergencies.

Importance of early training.

*Feeding and General Management.*—As there is true economy in employing only the best quality of horses, and these in their prime, so also is there in feeding them uniformly well, and looking to their comfort in all respects. The following quotation from the report of a discussion on the feeding of farm-horses, at a monthly meeting of the Highland and Agricultural Society of Scotland, published in the *Transactions* for October 1850, describes the practice of some of our most experienced farmers in this particular.

"The system of feeding I adopt is as follows:—From the middle of October till the end of May, my horses get one feed of steamed food, and two feeds of oats daily, with the best oat or wheat straw for fodder. I never give bean straw, unless it has been secured in fine condition, having often seen the bad

[1] Morton's *Cyclopædia of Agriculture*—article "Horse."

effects of it, partly owing, I think, to its long exposure to the weather. In our variable climate, and from the quantity of sand which adheres to it, I use it generally for litter. The steamed food used is well washed Swedish turnips and potatoes in equal proportions, mixed with sifted wheat-chaff. In those years when we had a total loss of potatoes, Swedish turnip alone was used, but not with the same good effects as when mixed with potatoes. This year having plenty of diseased potatoes in a firm state, I give a larger proportion of potatoes than turnip, and never upon any occasion give oat husks, commonly called meal-seeds, having often seen their injurious effects. At five o'clock in the morning each horse gets 6 lb. weight of bruised oats, at noon the same quantity of oats, and at half-past seven P.M., 47 lb. weight of steamed food. I find that it takes 62 lb. weight of unsteamed potatoes and turnip to produce 47 lb. steamed; to each feed of steamed food, 4 oz. of common salt are added, and mixed up with one-fourth part of a bushel of wheat-chaff, weighing about $1\frac{1}{2}$ lb., a greater quantity of wheat-chaff than this having generally too laxative an effect. Each horse eats from 14 lb. to 18 lb. of fodder during the twenty-four hours, besides what is required for litter. In spring I sometimes give a mixture of bruised beans and oats, instead of oats alone; from June to the middle of October, those horses that are required for the working of the green crop, driving manure, and harvest-work, are fed with cut grass and tares in the house; and about 7 lb. of oats each day, given at twice, increasing or decreasing the quantity according to the work they have to do; and I turn out to pasture only those horses that are not required until the busy season. I disapprove of horses that are regularly worked being turned out to grass, and exposed to all the changes of our variable climate, as I believe it to be the origin of many diseases. The expense of this mode of feeding, at present prices in this district, for each horse per annum, is as follows:—

| | L. | s. | d. |
|---|---|---|---|
| 12 lb. of oats per day, for 30 weeks, is $7\frac{1}{2}$ qrs. of 42 lb. per bushel. | | | |
| 7 lb. of do. do. 22 do. $3\frac{1}{8}$ do. do. | | | |
| $10\frac{5}{8}$ qrs. at 17s. | L.9 | 0 | 7 |
| 145 stones straw consumed, at 4d. per stone of 22 lb. | 2 | 8 | 4 |
| Each horse consumes 5 tons 16 cwt. of turnips and potatoes in 30 weeks. | | | |
| 58 cwt. potatoes, at 1s. 6d. .............................. | 4 | 7 | 0 |
| 58 cwt. turnips, at 9d. .............................. | 2 | 3 | 6 |
| 53 lb. salt, 1s. 8d., 52 bushels wheat-chaff, 4s. 4d. ... | 0 | 6 | 0 |
| 22 weeks on cut grass and tares, at 9d. per day ...... | 5 | 15 | 6 |
| | L.24 | 0 | 11 |

For the thirty weeks, the keep of each horse per day is 7d. for oats, $7\frac{1}{2}$d. for steamed food, and $2\frac{1}{2}$d. for fodder, or 1s. 5d. per day; for the twenty-two weeks, the keep is, grass 9d., oats 4d., or 1s. 1d. per day. The expense of preparing the steamed food, including coals, is 1s. 2d. per day for each horse. 260 stones of straw will be required for litter for each horse during the year; for this no charge is made, as it is left in manure. By this mode of feeding, the horses are always in fine sleek condition, and able for their work. I have acted upon this system for the last fifteen years; have always had from sixteen to twenty horses, and during that period I have only lost seven horses, three of them from accidental causes; and I attribute this, in a great measure, to the mode of feeding, and in particular, to the steamed food."

Berwickshire system of feeding.

The general treatment of horses in Berwickshire differs somewhat from that now detailed. They are usually turned to pasture so soon as the mildness of the weather and the forwardness of the pasture admit of it. While employed in carrying the crop, their fodder consists largely of tares, from whence until Martinmas they are fed on hay. From this date until 1st March, oat and bean straw are substituted, when, with the recurrence of harder labour, hay is again given until the return of the grazing season. During three-fourths of the year, they receive about 16 lb. of oats per diem, in three separate feeds. From the close of turnip-sowing until harvest, oats are either withheld or given only when a harder day's work occurs. The practice of bruising the whole of the oats given to horses, and also of chopping their hay, is now very prevalent. By giving a few pounds of chopped hay with each feed of bruised oats, and oat-straw in the racks, during the whole of the winter half-year, horses are kept in better condition, and at no more expense, than by giving them straw alone for half the period, and hay alone the other half. We are persuaded, also, that unless horses are stripped of their shoes and turned adrift altogether for a summer's run, that soiling in boxes, or sheds with an open yard, is preferable to grazing. The supper of cooked roots and chaff described in the Mid-Lothian practice, is probably preferable to the use of raw Swedes or potatoes, frequently given in other parts of Scotland. Hay and oats ought undoubtedly to constitute the staple fare of farm-horses. Without a liberal allowance of suitable and nourishing food, it is impossible that they can perform the full amount of work of which they are capable, or be sustained for any length of time in robust health. When *alleged* very cheap plans of feeding horses are inquired into, it is usually found that the amount and quality of the work performed by them is in fitting proportion. In this, as in so many other things, cheapness and economy are not convertible terms. The true way to economise the horse-labour of a farm is to have only good and well-fed cattle, and to get the greatest possible amount of work out of them.

### CATTLE.

As our limits do not admit of even a brief notice of all those breeds of cattle for which Great Britain is so famous, we shall restrict our remarks to some of the most important of them. Without entering upon curious speculations as to the origin of these breeds, we proceed to notice them in that order which is suggested by their relative importance in practical agriculture. The large lowland cattle thus claim our first attention, and amongst them we cannot hesitate in assigning the first place to the

Short-horn breed.

*Short-horns.*—It appears that from an early date the valley of the Tees possessed a breed of cattle which, in appearance and general qualities, were probably not unlike those *quasi* short-horns which abound in various parts of the country at the present day. By the time that the Messrs Colling came upon the field, it is evident that there were many herds around them in which considerable improvement had already been effected, and that they commenced their memorable efforts in cattle-breeding with exceedingly hopeful materials to work upon. But in their masterly hands these materials seemed at once to acquire an unwonted plasticity; for in an incredibly short time their cattle exhibited, in a degree that has not yet been excelled, that combination of rapid and large growth with aptness to fatten, of which their symmetry, good temper, mellow handling, and gay colours, are such pleasing indices and accompaniments, and for which they have now acquired a world-wide celebrity. It was by judicious selection in the first instance, and then by coupling animals of near affinity in blood, that they so developed and stereotyped these qualities in their cattle, as to entitle them at once to take rank as the progenitors of a new and well-marked breed. These *Durham*, *Teeswater*, or *Short-horn* cattle, as they were variously called, were soon eagerly sought after, and spread over the whole country with amazing rapidity. For a time their merits were disputed by the eager advocates of other and older breeds, some of which (such as the long-horns, once the most numerous breed in the kingdom) they have utterly supplanted, while others, such as the Herefords, Devons, and Scotch polled cattle, have each their zealous admirers, who still maintain their superiority to the younger race. But this controversy is meanwhile getting practically decided in favour of the short-horns, which constantly encroach upon

Live Stock.

their rivals even in their headquarters, and seldom lose ground which they once gain. Paradoxical as the statement appears, it is yet true that the very excellence of the short-horns has in many cases led to their discredit. For many persons desiring to possess these valuable cattle, and yet grudging the cost of pure-bred bulls, or being ignorant of the principles of breeding, have used worthless cross-bred males, and so have filled the country with an inferior race of cattle, bearing, indeed, a general resemblance in colour, and partaking in some measure of the good qualities of short-horns, but utterly wanting in their peculiar excellencies. By ignorant or prejudiced persons the genuine race is nevertheless held answerable for the defects of the mongrels which usurp their name, and for the damaging comparisons which are made betwixt them, and choice specimens of other breeds. That the short-horn breed should spread as it does, in spite of this hindrance, is no small proof of its inherent excellence, and warrants the inference that whenever justice is done to it, it will take its place as the one appropriate breed of the fertile and sheltered parts of Great Britain. This desirable consummation has hitherto been retarded by the scarcity and high price of pure-bred bulls. We are quite aware that bull-breeding, as hitherto conducted, is a hazardous and unremunerative business, notwithstanding the great prices sometimes obtained for first-class animals. We are of opinion, however, that it might be conducted in such a way as to be safer and more profitable to the breeder, and more beneficial to the country at large than it has hitherto been. There is at present a large and growing demand for good yearling short-horn bulls, at prices ranging from L.20 to L.30. With a better supply, both as to quality and numbers, this demand would steadily increase, for we have long observed that there is no want of customers for really good animals at such prices as we have named. When higher prices than these are demanded, farmers who breed only for the production of beef feel that they are beyond their reach, and are fain to content themselves with lower-priced and inferior animals. What we desire is, to see this business taken up by parties who, avoiding all needless expense, diminishing the risk of abortion and barrenness in their cows by never overfeeding them, and bestowing more pains to have their cows good milkers, would look for their profit from the sale of large numbers at moderate prices, rather than of few at exorbitant ones. The portraits of short-horn cattle appended to this treatise afford a good illustration of the prominent features of the breed.

Bull-breeding.

Herefords.

As already hinted, the *Hereford* is the breed which, in England, contests most closely with the short-horns for the palm of excellence. They are admirable grazier's cattle, and when of mature age and fully fattened, present exceedingly level, compact, and massive carcases of excellent beef. But the cows are poor milkers, and the oxen require to be at least two years old before being put up to fatten, defects which, in our view, are fatal to the claims which are put forward on their behalf. To the grazier who purchases them when their growth is somewhat matured they usually yield a good profit, and will generally excel short-horns of the same age. But the distinguishing characteristic of the latter is that, when properly treated, they get sufficiently fat, and attain to remunerative weights at, or even under, two years old. If they are kept lean until they have reached that age their peculiar excellence is lost. From the largeness of their frame they then cost more money, consume more food, and yet do not fatten more rapidly than bullocks of slower growing and more compactly formed breeds. It is thus that the grazier frequently gives his verdict in favour of Herefords as compared with short-horns. Even under this mode of management short-horns will usually yield at least as good a return as their rivals *to the breeder and grazier conjointly.* But if fully fed from their birth so as to bring into play their peculiar property of growing and fattening simultaneously, we feel warranted in saying that they will yield a quicker and better return for the food consumed by them than cattle of any other breed. Unless, therefore, similar qualities are developed in the Herefords, we may expect to see them more and more giving place to the short-horns. These remarks apply equally to another breed closely allied to the Herefords, viz. the

Devons.

*North Devons*, so much admired for their pleasing colour, elegant form, sprightly gait, and gentle temper, qualities which fit them beyond all other cattle for the labour of the field, in which they are still partially employed in various parts of England. If it could be proved that ox-power is really more economical than horse-power for any stated part of the work of the farm, then the Devons, which form such admirable draught oxen, would be deserving of general cultivation. We see, however, that duly as agriculture reaches a certain stage of progress, ox-labour has been found inadequate to the more rapid and varied operations that are called for, and has been superseded by that of horses. But supposing the ox-team to be everywhere laid aside, is this beautiful breed of cattle not worthy of being cherished for the purposes of the dairyman or the grazier? Now, although the milk of the Devon cows is very rich, it is too scanty, and they go too soon dry to admit of their being selected for strictly dairy purposes, or by the breeder who desires to rear several calves by the milk of each cow; and, although the oxen of this breed, *when their growth is matured*, can be fattened more quickly and on less food than short-horns of the same age, they do not yield so good a return as the latter for the whole food consumed by them respectively from birth to maturity. We consequently infer that they will, like other cherished breeds, either be superseded by the short-horns or amalgamated with them.

Ox-power *versus* horse-power.

Long-horns.

Until a comparatively recent period the *Long-horns* were the prevailing breed of our midland counties, as they still are of many parts of Ireland. Bakewell applied himself with his characteristic skill and success to the improvement of this breed; but at best they were so decidedly inferior to short-horns that they have now everywhere given place to them. Even in Lancashire, where they lingered longest, they have, within these few past years, nearly disappeared.

Scotch polled breeds.

Scotland possesses several indigenous breeds of heavy cattle, which, for the most part, are black and hornless, such as those of Aberdeen, Angus, and Galloway. These are all valuable breeds, being characterised by good milking and grazing qualities, and by a hardiness which peculiarly adapts them for a bleak climate. Cattle of these breeds, when they have attained to three years old, fatten very rapidly, attain to great size and weight of carcase, and yield beef which is not surpassed in quality by that of any cattle in the kingdom. The cows of these breeds, when coupled with a short-horn bull, produce an admirable cross-breed, which combines largely the good qualities of both parents. The great saving of time and food which is effected by the earlier maturity of the cross-breed has induced a very extensive adoption of this practice in all the north-eastern counties of Scotland. Such a system is necessarily inimical to the improvement of the pure native breeds: but when cows of the cross-breed are continuously coupled with pure short-horn bulls, the progeny in a few generations become assimilated to the male parent, and are characterised by a peculiar vigour of constitution, and excellent milking power in the cows. With such native breeds to work upon, and this aptitude to blend thoroughly with the short-horn breed, it is much more profitable to introduce the latter in this gradual way of continuous crossing than at once to substitute the one pure breed for the other. The cost of the former plan is much less, as there needs but

Cross-breeds.

Live Stock.

the purchase from time to time of a good bull; and the risk is incomparably less, as the stock is acclimated from the first, and there is no danger from a wrong selection. The greatest risk of miscarriage in this mode of changing the breed is from the temptation to which the breeder is exposed, on a false view of economy, of rearing a cross-bred bull himself, or purchasing a merely nominal short-horn bull from others.

From this hurried review of our heavy breeds of cattle it will be seen that we regard the short-horn as incomparably the best of them all, and that we anticipate its ultimate recognition as the breed which most fully meets the requirements of all those parts of the country where grain and green crops are successfully cultivated.

Dairy breeds.

The *dairy breeds* of cattle next claim our attention, for although cattle of all breeds are used for this purpose, there are several which are cultivated chiefly, if not exclusively, because of their fitness for it. Dairy husbandry is prosecuted under two very different and well-defined classes of circumstances. In or near towns, and in populous mining and manufacturing districts, it is carried on for the purpose of supplying families with new milk. In the western half of Great Britain, and in many upland districts, where the soil and climate are more favourable to the production of grass and other green crops than of corn, butter and cheese constitute the staple products of the husbandman. The town dairyman looks to quantity rather than quality of milk, and seeks for cows which are large milkers, which are long in going dry, and which can be readily fattened when their daily yield of milk falls below the remunerative measure. Large cows, such as short-horns and their crosses, are accordingly his favourites. In the rural dairy, again, the merits of a cow are estimated by the weight and quality of the cheese or butter which she yields, rather than by the mere quantity of her milk. The breeds that are cultivated expressly for this purpose are accordingly characterised by a less fleshy and robust build than is requisite in graziers' cattle. Of these we select for special notice the Ayrshire, the Jersey, and the Suffolk-dun breeds.

Ayrshire breed.

The Ayrshires, by common consent, now occupy the very first rank as profitable dairy cattle. From the pains which have been taken to develop their milk-yielding power it is now of the highest order. Persons who have been conversant only with grazing cattle cannot but be surprised at the strange contrast betwixt an Ayrshire cow in full milk, and the forms of cattle which they have been used to regard as most perfect. Her wide pelvis, deep flank, and enormous udder, with its small wide-set teats, seem out of all proportion to her fine bone and slender forequarters. As might be expected, the breed possesses little merit for grazing purposes. Very useful animals are however obtained by crossing these cows with a short-horn bull, and this practice is now rather extensively pursued in the west of Scotland by farmers who combine dairy-husbandry with the fattening of cattle. The function of the Ayrshire cattle is however the dairy. For this they are unsurpassed, either as respects the amount of produce yielded by them in proportion to the food which they consume, or the faculty which they possess of converting the herbage of poor exposed soils, such as abound in their native district, into butter and cheese of the best quality.

Suffolk Duns.

The county of Suffolk has for centuries been celebrated for its dairy produce, which is chiefly obtained from a polled breed of cattle, the prevailing colour of which is dun or pale red, from whence they are known as the *Suffolk Duns.* They have a strong general resemblance to the Scotch polled cattle, but nevertheless seem to be indigenous to Suffolk. They are ungainly in their form, and of little repute with the grazier, but possess an undoubted capacity of yielding a large quantity of milk in proportion to the food which they consume. They are now encroached upon, and will probably give place to the short-horns, by which they are decidedly excelled for the combined purposes of the dairy and the fattening stall.

Jersey breed.

The breeds already referred to are those to which professional dairymen give the preference, but the cattle of the Channel Islands, of which the *Jersey* may be regarded as the type, are so remarkable for the choice quality of the cream and butter obtained from their rather scanty yield of milk, that they are eagerly sought after for private dairies, in which quality of produce is more regarded than quantity. The rearing of heifers for the English market is of such importance to these islands, that very stringent regulations have been adopted for insuring the purity of their peculiar breed. These cattle in general are exceedingly ungainly in their form, and utterly worthless for the purposes of the grazier. The choicer specimens of the Jerseys have a certain deer-like form which gives them a pleasing aspect. The race, as a whole, bears a striking resemblance to the Ayrshires, which are alleged to owe their peculiar excellencies to an early admixture of Jersey blood.

Mountain breeds.

The mountainous parts of Great Britain are not less favoured than the lowlands in possessing breeds of cattle peculiarly adapted to the exigencies of the climate.

Kyloes.

The *Kyloes* or *West Highland cattle* are the most prominent of this group. They are widely diffused over the Highlands of Scotland, but are found in the greatest perfection in the larger Hebrides. Well-bred oxen of this breed, when of mature growth, and in good condition, exhibit a symmetry of form and noble bearing which is unequalled by any cattle in the kingdom. Although somewhat slow in arriving at maturity, they are contented with the coarsest fare, and ultimately get fat, where the daintier short-horns could barely exist. Their hardy constitution, thick mellow hide, and shaggy coat peculiarly adapt them for a cold humid climate and coarse pasturage. Fewer of these cattle are now reared in the Highlands than formerly, owing to the lessened number of cottars and small tenants, and the extension of sheep husbandry. Large herds of cows are however kept on such portions of farms as are unsuited for sheep walk. The milk of these cows is very rich, but as they yield it in small quantity, and go soon dry, they are unsuited for the dairy, and are kept almost solely for the purpose of suckling each her own calf. The calves are generally housed during their first winter, but after that they shift for themselves out of doors all the year round. Vast droves of these cattle are annually transferred to the lowlands, where they are in request for their serviceableness in consuming profitably the produce of coarse pastures and the leavings of daintier stock. Those of a dun or tawny colour are often selected for grazing in the parks of the aristocracy, where they look quite as picturesque as the deer with which they are associated. Indeed, they strikingly resemble the so-called wild cattle that are carefully preserved in the parks of several of our nobility, and like them are probably the descendants of the cattle of the ancient Britons. This view is confirmed by the strong family likeness borne to them by the

*Welsh cattle*, which is quite what might be expected from the many features, physical and historical, which the two provinces have in common. Although the cattle of Wales, as a whole, are obviously of common origin, they are yet ranged into several groups, which owe their distinctive features either to peculiarities of soil and climate, or to intermixture with other breeds. The *Pembrokes* may be taken as the type of the mountain groups. These are hardy cattle, which thrive on scanty pasturage and in a humid climate. They excel the west highlanders in this respect, that they make good dairy cattle, the cows being peculiarly adapted

Pembrokes

Live Stock.

for cottagers' purposes. When fattened they yield beef of excellent quality. Their prevailing and most esteemed colour is black, with deep orange on the naked parts. The *Anglesea* cattle are larger and coarser than the Pembrokes, and those of Merioneth and the higher districts are smaller and inferior to them in every respect. The county of Glamorgan possesses a peculiar breed, bearing its name, which has long been in estimation for combined grazing and dairy purposes. It has latterly been so much encroached upon by Herefords and short-horns that there seems some likelihood of its becoming extinct, which will be cause for regret unless pains are taken to occupy their place with cattle not inferior to them in dairy qualities. We conclude this rapid review of our native breeds by noticing the most singular of them all, viz.

The *Shetland cattle*, which are the most diminutive in the world. The carcase of a Shetland cow when fully fattened scarcely exceeds in weight that of a long-woolled wedder. These little creatures are however excellent milkers in proportion to their size, they are very hardy, are contented with the scantiest pasturage, they come early to maturity, are easily fattened, and their beef surpasses that of all other breeds for tenderness and delicacy of flavour. These miniature cows are not unfrequently coupled with short-horn bulls, and the progeny from such apparently preposterous unions not only possess admirable fattening qualities, but approximate in bulk to their gigantic sires. These curious and handsome little creatures, apparently of Scandinavian origin, are so peculiarly fitted to the circumstances of their bleak and stormy habitat, that the utmost pains ought to be taken to preserve the breed in purity, and to improve it by judicious treatment.

We cannot leave this part of our subject without reminding the reader of the singular richness of our country in cattle, not merely as regards numbers, but variety of breeds, endowed collectively with qualities which adapt one or other of them to every diversity in its soil and climate. So great is this diversity, and so complete that adaptation, that the requirements of each district are met, and the country as a whole enriched with every benefit that the domestic ox is capable of rendering to mankind.

Farm management of cattle.

We shall now endeavour to describe the farm management of this valuable animal, under the several heads of *breeding*, *rearing*, and *fattening*. What is peculiar to dairy management will be found treated of in a separate article. The breeding and rearing of cattle—subject to the exception just intimated—is prosecuted almost exclusively for the production of beef. The proceedings of those engaged in it are however largely determined by the character of the soil and climate of particular districts and farms. The occupiers of all comparatively fertile soils carry forward to maturity such animals as they breed, and dispose of them directly to the butcher. Those who are less fortunately circumstanced in this respect, advance their young cattle to such a stage as the capabilities of their farms admit of, and then transfer them to others by whom the fattening process is conducted. The ultimate object of both these parties being essentially the same, their practice, as far as it goes, ought undoubtedly to be also similar. In practice, this, we regret to say, is very far from being the case. The principles upon which this branch of husbandry should be conducted are indeed little affected by diversity of situation. This may and ought to determine the particular breed of cattle to be selected, but it is everywhere alike important to have a breeding stock of the best quality, to keep their produce uniformly in good condition, and to dispose of them whenever they cease to improve on such food as the farm affords. It cannot be too strongly impressed upon those who engage in this business that it never can be profitable to breed inferior cattle; or (however good their quality) to suffer their growth to be arrested by cold or hunger; or to sell them in a lean state.

Breeding of cattle.

In selecting a breeding stock of cattle, the qualities to be aimed at are, a sound constitution and a symmetrical form, aptitude to fatten, quiet temper, and large milk-yielding power in the cows. As all these qualities are hereditary, cattle are valuable for breeding purposes not merely in proportion as they are developed in the individuals, but according to the measure in which they are known to have been possessed by their progenitors. A really good pedigree adds therefore greatly to the value of breeding-stock. It is doubtless important to have both parents good; but in the case of ruminants, the predominating influence of the male in determining the qualities of the progeny is so well ascertained, that the selection of the bull is a matter of prime importance. We are able to state, from ample personal experience, that by using a bull that is at once good himself, and of good descent, a level and valuable lot of calves can be obtained from very indifferent cows. In Berwickshire it is the practice to employ chiefly married labourers who reside upon the farm, and one part of whose wages is the keep of a cow. These labourers usually give the preference to small cows, and—so that they are healthy, and yield milk plentifully—care little about their breed or other qualities. A good judge of grazier's cattle could not easily imagine a more unpromising breeding-stock than is furnished by these cottager's cows; and yet when they are coupled with a really good short-horn bull, it is truly surprising to see what admirable cattle are obtained from them. It is indeed miserable economy to grudge the price of a good bull.

Wastefulness of breeding inferior cattle.

Coarse, mis-shapen, unthrifty cattle cost just as much for rearing and fattening as those of the best quality, and yet may not be worth so much by L.3 or L.4 a-head, when they come ultimately to market. The loss which is annually sustained from breeding inferior cattle is far greater than those concerned seem to be aware of. It is impossible to estimate this loss accurately, but from careful observation and inquiry, we feel confident that it amounts to not less than 50s. a-head, on one half of the fat cattle annually slaughtered in Great Britain. If this be so, it follows that without expending a farthing more than is done at present on food, housing, and attendance, the profit which would accrue from using only the best class of bulls would be equivalent to an advance of 1s. per stone in the price of beef as regards half of the fat bullocks brought to market. This profit could moreover be secured by a very moderate outlay; for if properly gone about, the best class of bulls might be employed without adding more than 3s. or 4s. a-head to the price of each calf reared. We may surely anticipate that such a palpable source of profit will not continue to be neglected by the breeders of cattle. There are many instances in which landlords would find it much for their interest to aid their tenantry in at once procuring really good bulls. Cattle-shows and prizes are useful in their way as a means of improving the cattle of a district, but the introduction of an adequate number of bulls from herds already highly improved is the way to accomplish the desired end cheaply, certainly, and speedily. We must here protest against a practice by which short-horn bulls are very often prematurely unfitted for breeding. Their tendency to obesity is so remarkable that unless they are kept on short commons they become unwieldy and unserviceable by their third or fourth year. Instead, however, of counteracting this tendency, the best animals are usually "made up" as it is called, for exhibition at cattle-shows, or for ostentatious display to visitors at home, and the consequence is that they are ruined for breeding purposes. We rejoice to see that the directors of our national agricultural societies are resolutely setting their faces against this pernicious practice. It is needful certainly that all young ani-

Live Stock. mals, although intended for breeding stock, should be well fed, for without this they cannot attain to their full size and development of form. But when this is secured, care should be taken in the case of all *breeding* animals never to exceed that degree of flesh which is indispensable to perfect health and vigour. The frequent occurrence of abortion or barrenness in high-pedigreed herds seems chiefly attributable to overfeeding. The farmer who engages in cattle-breeding with the view of turning out a profitable lot of fat beasts annually, will take pains first of all to provide a useful lot of cows, such as will produce good calves, and if well fed while *giving milk* will yield enough of it to keep two or three calves a-piece. That he may be able to obtain a sufficient supply of good calves, he will keep a really good bull, and allow the cottagers residing on the farm or in its neighbourhood to send their cows to him free of charge, stipulating only that when they have a calf for sale he shall have the first offer of it. When cows are kept solely for the purpose of rearing calves, it becomes a matter of prime importance to have an adequate and seasonable supply of them from some source that can be relied upon both as regards their quality and numbers. We have long observed that calves produced in the early and late months of the year thrive better than those that are born about midsummer. Cottagers and others who keep cows in rural districts usually find it most suitable to have them to calve in spring, that they may be in full milk when pasturage is at its best. On the other hand, dairymen who provide milk for the supply of large towns, usually try to have a set of cows to calve in autumn, as it is in the winter months that their produce is most valuable. When a farmer has access to both these sources of supply, he can, by having his own cows to calve chiefly in spring, avail himself of both, and thus rear four or five calves annually, by the milk of each cow which he keeps, and, at the same time, allow her to go dry for two or three months before again calving. Cows are an expensive stock to keep, and it is therefore of importance to turn their milk to the best account. It is poor economy, however, to attempt to rear a greater number of calves than can be done justice to. Seeing that they are to be reared for the production of beef, the only profitable course is to feed them well from birth to maturity. During the first weeks of calf-hood the only suitable diet is unadulterated milk, warm from the cow, given three times a-day, and not less than two quarts of it at each meal. By three weeks old they may be taught to eat good hay, linseed cake, and sliced Swedes. As the latter items of diet are relished and freely eaten, the allowance of milk is gradually diminished until about the twelfth week, when it may be finally withdrawn. The linseed cake is then given more freely, and water put within their reach. For the first six weeks calves should be kept each in a separate crib; but after this they are the better of having room to frisk about. Their quarters, however, should be well sheltered, as a comfortable degree of warmth greatly promotes their growth. During their first summer, they do best to be soiled on vetches, clover, or Italian ryegrass, with from 1 lb. to 2 lb. of cake to each calf daily. When the green forage fails, white or yellow turnips are substituted for it. A full allowance of these, with abundance of oat straw, and not less than 2 lb. of cake daily, is the appropriate fare for them during their first winter. Swedes will be substituted for turnips during the months of spring, and these again will give place in due time to green forage, or the best pasturage. The daily ration of cake should never be withdrawn. It greatly promotes growth, fattening, and general good health, and in particular is a specific against the disease called blackleg, which often proves so fatal to young cattle. Young cattle that have been skilfully managed upon the system which we have now sketched, are at 18 months old already

Treatment of young calves.

of great size, with open horns, mellow hide, and all those other features which indicate to the experienced grazier that they will grow and fatten rapidly. This style of management is not only the best for those who fatten as well as rear; but is also the most profitable for those who rear only. We cannot better illustrate this statement, than by referring to a set of contemporaneous sales of young cattle which recently came under our personal observation. In June 1851 we happened to purchase in Kelso market at L.6, 18s. a head, a lot of fifty two-year-old short-horn steers from a dealer who had just brought them from Yorkshire. A fortnight before this a lot of *yearlings* (steers and heifers), bred and reared in the heart of the Lammermuirs, were sold in a neighbouring market at L.8, 8s. each. About the same time a friend of ours in Roxburghshire who annually rears a large lot of cattle, having noticed one of his calves affected with giddiness, forwarded him to Newcastle market, where he was sold to a butcher for L.8, being then not quite eight months old, and not a better animal than many of his lot. Now, these cases are the more valuable, because none of them were extreme ones; but just fair average examples of the fruits of the systems to which they respectively belong. They show conclusively that of a number of persons engaged contemporaneously in the business of cattle-rearing, and bringing their stock to the same markets, those who adopted the generous system of feeding, realised handsome profits, while those who, for thrift, starved their cattle must have done so at a loss to themselves. Nor are the evils of the starving system limited to the breeder. The grazier who purchases cattle that have been hunger-bitten in their youth, finds to his cost that he can only fatten them by an extra expenditure of time and food, and that after all they are worth less—weight for weight—than such as have never been lean.

Live Stock.

Bad effects of starving cattle.

We have already stated that, in Scotland, comparatively few cattle are fattened on pasturage. An increasing number of fat beasts are now prepared for market during the summer months by soiling on green forage; but it is by means of the turnip crop, and during the winter months, that this branch of husbandry is all but exclusively conducted in the northern half of Great Britain. But a few years ago, the fattening of cattle on Tweedside, and in the Lothians, was conducted almost exclusively in open courts, with sheds on one or more sides, in which from two to twenty animals were confined together, and fed on turnips and straw alone. Important changes have now been introduced, both as regards housing and feeding, by means of which a great saving of food has been effected. Under the former practice, the cattle received as many turnips as they could eat; which, for an average-sized two-year-old bullock, was not less than 220 lb. daily. The consequence of this enormous consumption of watery food was, that for the first month or two after being thus fed, the animals were kept in a state of habitual diarrhœa. Dry fodder was, indeed, always placed within their reach; but as long as they had the opportunity of taking their fill of turnips, the dry straw was all but neglected. By stinting them to about 100 lb. of turnips daily, they can be compelled to eat a large quantity of straw, and on this diet they thrive faster than on turnips at will. A better plan, however, is to render the fodder so palatable as to induce them to eat it of choice. For this purpose the straw is mixed with a third part of hay, and cut up into $\frac{3}{4}$-inch lengths, by a chaffing machine. A large wooden trough or bin with a lid to it being provided, the chaff, at the rate of three pecks for each beast, is put into it in layers, over each of which meal is sifted at the rate of 2 lb. to 4 lb. a head, and intermingled by stirring with a fork. Over the whole as much boiling water, with a little salt dissolved in it, is poured as will moisten the entire mass.

The fattening of cattle.

Live Stock.

The lid is then closed for a short time, and the mess thereafter served out to the cattle. The meal may be that of barley, oats, beans, or, in short, whatever is cheapest at the time, including all the inferior grain of the farm, with the addition of ½ lb. of ground linseed for each animal. An appropriate mode of administering the food is to give 50 lb. of sliced turnips early in the morning, the cooked mess about noon, and as much more turnips in the afternoon. A little oat straw is also given to them daily. For a few weeks before the completion of the fattening process, it is usually remunerative to give 4 or 5 lb. of linseed cake, and 6 lb. of good hay to each beast daily; the cake in combination with the cooked mess, and the hay in lieu of the oat-straw. From the peculiar structure of the digestive organs of the ox—which are adapted for disposing of bulky and but moderately nutritious food—this plan of inducing him to eat a considerable quantity of straw promotes his health and comfort, and economises the more costly food. The Rev. Mr Huxtable has pointed out a still cheaper way of accomplishing the same end. He shreds his turnips by a machine, analogous to a bark-mill, and then mixes them with cut straw, so that the cattle must eat both together. His opinion is, that he not only gains the element of bulk in this way, but that, from the straw and turnips being swallowed together, the hurtful chilling effect of the latter is avoided. He finds that 70 lb. of turnips thus administered is a sufficient daily ration for a fattening bullock.[1]

Best mode of housing cattle.

A better appreciation of the effects of temperature on the animal economy has of late years exerted a beneficial influence upon the treatment of fattening cattle. Observant farmers have long been aware that their cattle, when kept dry and moderately warm, eat less and thrive faster than under opposite conditions. They accounted for this in a vague way by attributing it to their greater comfort in such circumstances. Scientific men have now, however, shewed us that a considerable portion of the food consumed by warm-blooded animals is expended in maintaining the natural heat of their bodies, and that the portion of food thus disposed of is dissipated by a process so closely analogous to combustion, that it may fitly be regarded as so much fuel. The fat which, in favourable circumstances is accumulated in their bodies, may in like manner be regarded as a store of this fuel laid up for future emergencies. The knowledge of this fact enables us to understand how largely the profit, to be derived from the fattening of cattle, is dependent upon the manner in which they are housed, and necessarily forms an important element in determining the question whether *yards*, *stalls*, or *boxes*, are best adapted for this purpose. A really good system of housing must combine the following conditions:—

1*st*, Facilities for supplying food and litter, and for removing dung with the utmost economy of time and labour.

2*d*, Complete freedom from disturbance.

3*d*, A moderate and equal degree of warmth.

4*th*, A constant supply of pure air.

5*th*, Opportunity for the cattle having a slight degree of exercise; and

6*th*, The production of manure of the best quality.

We have no hesitation in expressing our opinion that the whole of these conditions are attained most fully by means of well-arranged boxes. Stalls are to be preferred where the saving of litter is an object; and yards for the rearing of young cattle, which require more exercise than is suitable for fattening stock.

But however excellent the system of housing and feeding which is adopted, a successful result will, in every instance, be much dependent upon the viligant superintendence of the owner, and his skill in so managing the commissariat, as to secure throughout the year a sufficiency of suitable food for the stock on hand. Unless this is attended to, he may find himself necessitated to sell his cattle before they are fat, and when markets are glutted. Whenever they have attained to what is technically called *ripe* fatness, and prices are at their average rate, it is generally more profitable forthwith to dispose of them, than to speculate upon a rise in the markets.

### SHEEP.

When Fitzherbert so long ago said, "Sheep is the most profitablest cattle that a man can have," he expressed an opinion in which agriculturists of the present day fully concur. But if this was true of the flocks of his time, how much more of the many admirable breeds which now adorn the rich pastures, the grassy downs, and heath-clad mountains of our native country. Their flesh is in high estimation with all classes of the community, and constitutes at least one-half of all the butcher meat consumed by them. Their fleeces supply the raw material for one of our most flourishing manufactures. They furnish to the farmer an important source of revenue, and the readiest means of maintaining the fertility of his fields. The distinct breeds, and subvarities of sheep found in Great Britain are very numerous. We have no intention of noticing them in detail, but shall rather confine our observations to those which, by common consent, are the most valuable for their respective and appropriate habitats. They may be fitly classed under these three heads, viz. the heavy breeds of the low country, those found on our downs and similar localities, and the mountain breeds.

Leicester breed.

Of the first class, the improved *Leicesters* are still the most important to the country. They are more widely diffused in the kingdom than any of their congeners. Although, from the altered taste of the community, their mutton is less esteemed than formerly, they still constitute the staple breed of the midland counties of England. Leicester rams are also more in demand than ever, for crossing with other breeds. It is now about a century since this breed was produced by the genius and perseverance of Bakewell, in whose hands they attained a degree of excellence that has probably not yet been exceeded by the many who have cultivated them since his day. The characteristics of this breed are extreme docility, extraordinary aptitude to fatten, and the early age at which they come to maturity. The most marked feature in their structure is the smallness of their heads, and of their bones generally, as contrasted with their weight of carcase. They are clean in the jaws, with a full eye, thin ears, and placid countenance. Their backs are straight, broad, and flat, the ribs arched, the belly carried very light, so that they present nearly as straight a line below as above, the chest is wide, the skin very mellow, and covered with a beautiful fleece of long, soft wool, which weighs on the average from 6 to 7 lb. On good soils, and under careful treatment these sheep are currently brought to weigh from 18 to 20 lb. per quarter at 14 months old, at which age they are now usually slaughtered. At this age their flesh is tender and juicy; but when carried on until they are older and heavier, fat accumulates so unduly in proportion to the lean meat, as to detract from its palatableness and market value.

Lincoln breed.

*Lincolns.*—These were at one time very large, ungainly animals, with an immense fleece of very long wool. By crossing them with the Leicesters the character of the breed has been entirely changed, and very greatly for the better. It is now, in fact, a subvariety of the Leicester, with larger frame and heavier fleece than the pure breed. Sheep of

[1] See "Present Prices" by Rev. A. Huxtable. Ridgway. London, 1850.

Live Stock. this kind are reared in immense numbers on the wolds and heaths of Lincolnshire, and are sold in the wool, and in very forward condition, when about a year old, to the graziers of the fens and marshes, who ultimately bring them to very great weights.

*Cotswolds.*—These also are large and long-woolled sheep, with good figure and portly gait, but somewhat coarse in in the bone, and in the quality of their flesh. They are found in the district whose name they bear. A variety of the Cotswold, obtained, we presume, by crossing with the Leicester, has acquired considerable reputation of late years, under the name of *New Oxfords*. These are large, heavy, rapid-growing sheep, very docile, with a fleece analogous to the Leicester, which breed, in fact, they resemble in their leading characteristics, save that they want their symmetry and fine flesh. They are bred in Oxfordshire and neighbouring districts. Both of these last-named breeds suit admirably for crossing with short-woolled sheep, and are likely to be in increasing demand for this purpose.

New Oxfords.

*Teeswaters.*—This breed, found formerly in the vale of the Tees, used to have the reputation of being one of the largest and heaviest of our native breeds. They had lighter fleeces than the old Lincolns, but greater aptitude to fatten. Like them, however, they have been so blended with Leicester blood, as to have lost their former characteristics. As now met with, they constitute simply a subvariety of the latter breed.

The *Kents*, or *Romney Marsh Sheep*, are another distinct long-woolled breed, which have much in common with the old Lincolns, although they never equalled them either in the weight or quality of their fleece. They, too, have been much modified by a large infusion of Leicester blood; but as their distinctive qualities fit them well for a bleak and humid habitat, there is now an aversion to risk these by further crossing. As they now exist they are a great improvement upon the old breed of the Kentish marshes; and this, in the first instance at least, was the result of crossing rather than selection.

The breeds peculiar to our chalky downs, and other pastures of medium elevation, next claim our notice.

*South Downs.*—Not long after Robert Bakewell had begun with admirable skill and perseverance to bring to perfection his celebrated Leicesters, which, as we have seen, have either superseded, or totally altered the character of, all the heavy breeds of the country; another breeder, Mr John Ellman of Glynde, in Sussex, equal to Bakewell in judgment, perseverance, and zeal, and wholly devoid of his illiberal prejudice and narrow selfishness, addressed himself to the task of improving the native sheep of the downs, and succeeded in bringing them to as great perfection, with respect to early maturity and fattening power, as they are perhaps susceptible of. Like Bakewell, he early began the practice of letting out rams for hire. These were soon eagerly sought after, and the qualities of this improved flock being rapidly communicated to others, the whole race of down sheep has more or less become assimilated to their standard. These improved south downs have, in fact, been to all the old *forest*, and other fine-woolled breeds, what the Leicesters have been to their congeners. Many of them have entirely disappeared, and others only survive in those modifications of the improved south-down type, which are to be found in particular localities. These down sheep possess certain well-marked features, which distinguish them from all other breeds. They have a close-set fleece of fine wool, weighing, when the animals are well-fed, about four pounds; their faces and legs are of a dusky brown colour, their neck slightly arched, their limbs short, their carcase broad and compact, their offal light, and their buttocks very thick and square behind. They are less impatient of folding, and suffer less from a pasture being thickly stocked with them than any other breed. It is in connection with this breed that the practice of folding as a means of manuring the soil is so largely carried out in the chalk districts of England. It is well ascertained that the injury done to a flock by this practice exceeds the benefit conferred on the crops. Now that portable manures are so abundant, it is to be hoped that this pernicious practice of using sheep as mere muck machines will be everywhere abandoned.

Improved by Mr Ellman.

Live Stock.

Evils of folding.

These sheep are now usually classed as Sussex downs and Hampshire downs, the former being the most refined type of the class, both as regards wool and carcase, and the latter, as compared with them, having a heavier fleece, stronger bone, and somewhat coarser and larger frame. These breeds are peculiarly adapted for all those parts of England where low grassy hills occur, interspersed with, or in proximity to, arable land. In such situations they are prolific, hardy, and easily fattened at an early age. It is to their peculiar adaptation for crossing with the long-woolled breeds, that they are indebted for their recent and rapid extension to other districts.

*Dorsets.*—This breed has, from time immemorial, been naturalised in the county of Dorset, and adjacent parts. They are a whitefaced, horned breed, with fine wool, weighing about four pounds per fleece. They are a hardy and docile race of sheep, of good size, and fair quality of mutton. But the property which distinguishes them from every other breed in Great Britain is the fecundity of the ewes, and their readiness to receive the male at an early season. They have even been known to yean twice in the same year. Being, in addition to this, excellent nurses, they have long been in use for rearing house-lamb for the London market. For this purpose the rams are put to them early in June, so that the lambs are brought forth in October, and are ready for market by Christmas. But for this peculiarity, they would ere now have shared the fate of so many other native breeds, which have given place either to the Leicesters or south downs, according to the nature of the pastures. So long, however, as the rearing of early house-lamb is found profitable, there is a sufficient inducement to preserve the Dorset breed in its purity, as they are unique in their property of early yeaning.

*Cheviots.*—As we approach and cross the Scottish border we find a range of hills covered with coarser herbage than the chalky downs of the south, and with a climate considerably more rigorous. Here the south-down sheep have been tried with but indifferent success. This, however, is not to be regretted, seeing that the native Cheviot breed rivals them in most of their good qualities, and possesses, in addition, a hardihood equal to the necessities of the climate. This breed, besides occupying the grassy hills of the border counties, is now found in great force in the north and west Highlands of Scotland. In the counties of Sutherland and Caithness, where they were introduced by the late Sir John Sinclair, they have thriven amazingly, and in the hands of some spirited breeders have attained to as great perfection as in their native district. During the last thirty years, this breed has undergone very great improvement in size, figure, weight of fleece, and aptitude to fatten. In proof of this, it is enough to mention that Cheviot wedder lambs are now in the border counties brought to market when weaned, and are transferred to the low country graziers, by whom they are sent fat to the butcher at sixteen months old, weighing then from 16 to 18 lb. per quarter. This is particularly the case in Cumberland, where Cheviot lambs are preferred by the low country farmers to all other breeds, and by whom they are managed with great skill and success. It is not at all unusual with them to realise an increase of from 20s. to 25s. per head on the purchase price of these lambs, after a twelvemonth's keep. This fact is peculiarly interesting from the proof which it affords of a hitherto unsuspected capacity in Cheviots, and probably in other upland breeds, to attain to a profitable degree of fatness and weight of carcase, at almost as early an age as the lowland breeds, when the same attention and liberal feeding is bestowed upon them. Such a system is moreover greatly more profitable both for breeder and grazier than the old one. It is every way better for the farmer to occupy his pastures with breeding stock only, and to get quit of his lambs as soon as they are fit for weaning. It is better for the grazier to get hold of them when full of their lamb flesh, as by transferring them at once to good keep, he can carry them forward without a check to the earliest stage, at which he can realise with a profit. Very great pains are now bestowed on the improvement of this breed; in proof of which it may be mentioned, that at the autumn fairs, such as Hawick, Moffat, &c., where great numbers of rams are presented for sale, L.10 a head is not unfrequently paid to the more noted breeders for their choicest animals. In August 1851 Mr Brydon of Moodlaw, whose flock of Cheviots has long enjoyed the reputation of being one of the very best in the country, sold 148 rams by public auction, at an average price of L.7, 9s. per head. The competition for these choice specimens of Cheviot sheep was so keen that one was sold for L.37, and several more from L.20 to L.30. There is no breed equally well adapted for elevated pastures, consisting of the coarser grasses, with a mixture of heath; but whenever, from the nature of the soil or greater elevation, the heaths unmistakeably predominate, a still hardier race is to be preferred, viz.

The *Blackfaced* or *Heath Breed.*—They are accordingly found on the mountainous parts of Yorkshire, Lancashire, Cumberland, and Westmoreland; over the whole of the Lammermuir range; the upper part of Lanarkshire; and generally over the Highlands of Scotland. Both male and female of this breed have horns, which, in the former, are very large and spirally twisted. The face and legs are black, with an occasional tendency to this colour on the fleece; but there is nothing of the brown or russet colour which distinguishes the older fine-woolled races. The choicest flocks of these sheep are found in Lanarkshire and in the Lammermuirs, where considerable pains are now bestowed on their improvement. Their chief defects are coarseness of fleece, and slowness of fattening until their growth is matured. In most flocks the wool, besides being open, and coarse in the staple, is mixed with *kemps* or hairs which detract from its value. Rams with this defect are now carefully avoided by the best breeders, who prefer those with black faces, a mealy mouth, a slight tuft of fine wool on the forehead, horns flat, not very large, and growing well out from the head; with a thickset fleece of long, wavy, white wool. Greater attention is now also being paid to their improvement in regard to fattening tendency; in which respect we do not despair of seeing them brought nearer to a par with other improved breeds. Whenever this is accomplished we shall possess in the breeds now enumerated, and their crosses, the means of converting the produce of our fertile plains, grassy downs, rough upland pastures, and heathclad mountains, into wool and mutton of the best quality, and with the utmost economy of which the circumstances admit.

A branch of this family of the heath breeds called Herdwicks, having its headquarters in Cumberland, although found also in Westmoreland and Lancashire, is frequently much extolled. We are of opinion, that in all their good qualities they are excelled by the best style of pure blackfaced sheep as met with in Tweeddale and the Lammermuirs.

*Cross-breeds.*—We have thus enumerated the most important of our pure breeds of sheep, but our list would be defective, were we to omit those cross-breeds which are acquiring increased importance every day. With the extended cultivation of turnips and other green crops there has arisen an increased demand for sheep to consume them. Flock-masters in upland districts, stimulated by this demand, happily bethought them of putting rams of the improved low-country breeds to their smaller ewes, when it was discovered that the lambs produced from this cross, if taken to the low-country as soon as weaned, could be fattened nearly as quickly, and brought to nearly as good weights, as the pure low-country breeds. The comparatively low prime cost of these cross-bred lambs is a farther recommendation to the grazier, who finds also that their mutton, partaking at once of the fatness of the one parent, and of the juiciness, high flavour, and larger proportion of lean flesh of the other, is more generally acceptable to consumers than any other kind, and can always be sold at the best price of the day. The wool, moreover, of these crosses being at once long and fine in the staple, is peculiarly adapted for the manufacture of a class of fabrics now much in demand, and brings in consequence the best price of any British-grown wool. The individual fleeces, from being close set in the pile, weigh nearly as much as those of the pure Leicesters. On all these accounts, therefore, these sheep of mixed blood are rapidly rising in public estimation, and are produced in ever increasing numbers. This is acccomplished in several ways. The occupiers of uplying grazings in some cases keep part of their ewe flock pure, and breed crosses from another part. They sell the whole of their cross-bred lambs, and get as many females from the other portion as keeps up the number of their breeding flock. This system of crossing cannot be pursued on the highest class of farms, as ewes bearing these heavier crossed lambs require better fare than when coupled with rams of their own race. The surplus ewe lambs from such highlying grazings are an available source of supply to those of a lower range, and are eagerly sought after for this purpose. Others, however, take a bolder course. Selecting a few of the choicest hill-country ewes which they can find, and puting these to a first-rate Leicester ram, they thus obtain a supply of rams of the first cross, and putting these to ewes, also of the first cross, manage in this way to have their entire flock *half-bred* and to go on continuously with their own stock without advancing beyond a first cross. They, however, never keep rams from such crossed parentage, but always select them from the issue of parents each genuine of their respective races. We know several large farms on which flocks of crosses betwixt the Cheviot ewe and Leicester ram have been maintained in this way for many years with entire successs; and one at least in which a similar cross with south down ewes has equally prospered. Many, however, prefer buying in females of this first cross, and coupling them again with pure Leicester rams. In one or other of these ways cross-bred flocks are increasing on every side. So much has the system spread in Berwickshire, that whereas, in our memory, pure Leicesters were the prevailing breed of the county, they are now all but confined to a few ram-breeding flocks.

### GENERAL MANAGEMENT.

As the management of sheep is influenced mainly by the nature of the lands upon which they are kept, we shall first describe the practice of Lowland flock-masters, and afterwards that pursued on Highland sheep-walks.

On arable farms, where turnips are grown, and a breeding stock of sheep regularly kept, it is usual to wean the lambs about the middle of July. When this has been done, the aged and faulty ewes are drafted out, and put upon good aftermath, or other succulent food, that they may be got ready for market as soon as possible. In many districts it is the practice to take but three crops of lambs from each

Live Stock.

ewe. A third part of the breeding flock, viz. the four-year old ewes, is thus drafted off every autumn, and their places supplied by the introduction of a corresponding number of the best of the ewe-lambs of the preceding year's crop. These cast or draft ewes are then sold to the occupiers of richer soils in populous districts, who keep them for another season to feed fat lambs. Such parties buy in a fresh stock of ewes every autumn, and, as they phrase it, "feed lamb and dam." In other cases the ewes are kept as long as their teeth continue sound, and after that they are fattened and sold to the butcher directly from the farm on which they have been reared. When the ewes that are retained for breeding-stock have been thus overhauled, they are put to the worst pasture on the farm, and run rather thickly upon it. Attention is necessary, for some days after weaning, to see that none of them suffer from gorging of the udder. When it appears very turgid in any of them, they are caught and partially milked by hand; but usually the change to poorer pasturage, aided by their restlessness and bleating for want of their lambs, at once arrests the flow of milk.

Rutting season.

The time of admitting the ram is regulated by the purpose for which the flock is kept, and by the date at which fresh green food can be reckoned upon in spring. When the produce is to be disposed of as fat lambs, it is of course an object to have them early; but for a holding stock, to be reared and fattened at fourteen to sixteen months old, from 20th Sept. to 20th Oct., according to the climate of the particular locality, is a usual time for admitting rams to ewes. A fortnight before this takes place the ewes are removed from bare pasture, and put on the freshest that the farm affords, or better still, on rape, failing which one good feed of white turnips per diem is carted and spread on their pastures, or the ewes are folded for part of the day on growing turnips. The rams are turned in amongst them, just when this better fare has begun to tell in their improving appearance, as it is found that in such circumstances they come in heat more rapidly, and with a greatly increased likelihood of conceiving twins. On level ground, and with moderate sized inclosures, one ram suffices for sixty ewes. Sometimes a large lot of ewes are kept in one flock, and several rams, at the above proportion, turned among them promiscuously. It is better, however, when they can be placed in separate lots. The breasts of the rams are rubbed with ruddle, that the shepherd may know what they are about. Those who themselves breed rams, or others who hire in what they use at high prices, have recourse to a different plan, for the purpose of getting more service from each male, and of knowing exactly when each ewe may be expected to lamb; and also of putting each ewe to the ram most suitable to her in point of size, figure, and quality of flesh and fleece. The rams in this case are kept in pens in a small inclosure. What is technically called a *teaser* is turned among the general flock of ewes, which, on being seen to be in heat, are brought up and put to the ram that is selected for them. They are then numbered, and a note kept of the date, or otherwise a common mark, varied for each successive week, is put on all as they come up. The more usual practice is to mark the breast of the ram with ruddle, as already described, for the first seventeen days that they are among the ewes—that being the time of the periodic recurrence of the heat—and then to use soot instead. When lambing-time draws near, the red-rumped ewes, or those that conceived from the first copulation, are brought into the fold, and the remainder after the lapse of the proper interval. If all goes on well, six weeks is long enough for the rams to remain with the flock. The ewes are then put to more moderate fare, taking care, however, not to pinch them, but to preserve the due medium betwixt fatness and poverty. Under the first-mentioned extreme, there is great risk of losing both ewe and lamb at the time of parturition; and under the second, of the ewe shedding her wool, and being unable to nourish her lamb properly either before its birth or after. When there is a considerable breadth of grass-land, the *grit* or inlamb ewes are run thinly upon it, so long as the weather continues moderate. As the pasturage fails, or winter weather sets in, they receive a daily feed of turnips or hay, or part of both. In districts where the four-course rotation is pursued, and wheat sown after seeds, there is a necessity for keeping the ewes wholly on turnips and chopped hay or straw. In this case they are made to follow the fattening sheep, and to eat up their scraps, an arrangement which is suitable for both lots.

Lambing season.

The period of gestation in the ewe is twenty-one weeks. No lambs that are born more than twelve days short of this period survive. Before any lambs are expected to arrive, a comfortable fold is provided, into which either the entire flock of ewes, or those that by their markings are known to lamb first, are brought every night. This fold, which may either be a permanent erection, or fitted up annually for the occasion, is provided all round with separate pens, or cribs, of size enough to accommodate a single ewe, with her lamb or pair. The pasture or turnip fold to which the flock is turned by day is also furnished with several temporary but well-sheltered cribs, for the reception of such ewes as lamb during the day. It is of especial consequence that ewes producing twins be at once consigned to a separate apartment, as, if left in the crowd, they frequently lose sight of one lamb, and may refuse to own it, when restored to them, even after a very short separation. Some ewes will make a favourite of one lamb, and wholly repudiate the other, even when due care has been taken to keep them together from the first. In this case the favourite must either be separated from her, or be muzzled with a piece of network, to prevent it from getting more than its share of the milk in the shepherd's absence. Indeed the maternal affection seems much dependent on the flow of milk, as ewes with a well-filled udder seldom trouble the shepherd by such capricious partialities. So soon as the lambs have got fairly afoot, their dams are turned with them into the most forward piece of seeds, or to rape, rye, winter-oats, or water-meadow, the great point being to have abundance of succulent green food for the ewes as soon as they lamb. Without this they cannot yield milk abundantly; and without plenty of milk it is impossible to have good lambs. It is sometimes necessary to aid a lamb that has a poor nurse with cow's milk. This is at best a poor alternative; but if it must be resorted to, it is only the milk of a farrow cow, or at least of one that has been calved six months, that is at all fit for this purpose. To give the milk of a recently calved cow to a young lamb is usually equivalent to knocking it on the head. Ewe milk is poor in butter, but very rich in curd, which is also known to be, in a measure, the character of that of cows that have been long calved, and are not again pregnant. We have found the Aberdeen yellow bullock turnip the best for pregnant and nursing ewes. Mangel-wurzel is much approved of by the flock-masters of the southern counties for the same purpose. It is of importance, at this season, to remove at once from the fold and pens all dead lambs, and filth of every kind, the presence of putrefying matter being most hurtful to the flock. Should a case of puerperal fever occur, the shepherd must scrupulously avoid touching the ewe so affected; or if he has done so, some one should take his accoucheur duties for a few days, as this deadly malady is highly contagious, and is often unconsciously communicated to numbers of the flock by the shepherd's hands. Unnecessary interference with ewes during parturition is much to be deprecated. When the presentation is all right, it is best to leave them as much as possible to their natural ef-

Live Stock. forts. When a false presentation does occur, the shepherd must endeavour to rectify it by gently introducing his hand after first lubricating it with fresh lard or olive-oil. The less dogging or disturbance of any kind that ewes receive during pregnancy, the less risk is there of unnatural presentations. As soon as lambs are brought forth, the shepherd must give them suck. When they have once got a bellyful, and are protected from wet or excessive cold for two or three days, there is no fear of their taking harm from ordinary weather, provided only that the ewes have plenty of suitable food. Lambs are castrated, docked, and ear-marked, with least risk when about ten days old. Ewes with lambs must have good and clean pasturage throughout the summer. For this purpose they must either be run thinly among cattle, or have two or more inclosures, one of which may always be getting clean and fresh for their reception, as the other gets bare and soiled. We have not found any advantage in allowing lambs yeaned in March to run with their dams beyond 20th July. A clover edish, or other perfectly clean pasture, is the most suitable for newly weaned lambs. Such as abound in *tath*, as it is called in Scotland, that is, rank herbage growing above the droppings of sheep, or other animals, are peculiarly noxious to them. Folding upon rape or vetches suits them admirably, so that fresh supplies are given regularly as required. All sheep are liable to be infested with certain vermin, especially by "fags," or "kaids," and by lice. To rid them of these parasites, various means are resorted to. Some farmers use mercurial ointment, which is applied by parting the wool, and then with the finger rubbing the ointment on the skin, in three or four longitudinal seams on each side, and a few shorter ones on the neck, belly, legs, &c. Those who use this salve dress their lambs with it immediately after shearing their ewes, and again just before putting them on turnips. More frequently the sheep are immersed, all but their heads, in a bath, in which arsenic and other ingredients are dissolved. On being lifted out of the bath, the animal is laid on spars, over a shallow vessel, so placed that the superfluous liquor, as it is wrung out of the fleece, flows back into the bath. If this is done when the ewes are newly shorn, the liquor goes farther than when the process is deferred until the lambs are larger and their wool longer. It is good practice to souse the newly shorn ewes, and indeed the whole flock at the same time, in a similar bath, so as to rid them all of vermin.

Salving or bathing.

The object being to bring these young animals to early and profitable maturity, every pains must be taken not only to preserve their health, but to insure their rapid and uninterrupted progress. For this end it is necessary to provide ample supplies of food suitable for the particular season. As turnips constitute their staple winter fare, it is necessary to have a portion of these sown in time to be fit for use in September. Young sheep always show a reluctance to take to this very succulent food, and should therefore be put upon it so early in autumn that they may get thoroughly reconciled to it while the weather is yet temperate. Rape or cabbages suit admirably as transitionary food from grass to turnips. When this transference from summer to winter fare is well managed, they usually make rapid progress during October and November. Some farmers recommend to give the *hoggets*, as they are now called, a daily run off from the turnip fold to a neighbouring pasture for the first few weeks after their being put to this diet. We have found it decidedly better to keep them steadily in the turnip fold from the very first. When they are once taught to look for this daily enlargement, they become impatient for it, and do not settle quietly to their food. If possible not more than 200 should be kept in one lot. The youngest and weakest sheep should also have a separate berth and more generous treatment. Turnips being a more watery food than sheep naturally feed upon, there is great advantage in giving them from the first, along with turnips, a liberal allowance of clover hay cut into half-inch chaff. When given in this form in suitable troughs, and in regular feeds, they will eat up the whole without waste, and be greatly the better for it. To economise the hay, equal parts of good oat straw may be cut up with it, and will be readily eaten by the flock. A liberal supply of this dry food corrects the injurious effects which are so often produced by feeding sheep on turnips alone, and at the same time lessens the consumption of the green food. We believe also that there is true economy in early beginning to give them a small daily allowance, say $\frac{1}{4}$ lb. each, of cake or corn. This is more especially desirable when sheep are folded on poor soil. This extraneous food both supplies the lack of nutrition in the turnips, and fertilises the soil for bearing succeeding crops. An immense improvement has been effected in the winter feeding of sheep by the introduction of machines for slicing turnips. Some careful farmers slice the whole of the turnips used by their fattening sheep, of whatever age; but usually the practice is restricted to hoggets, and only resorted to for them when their milk-teeth begin to fail. In the latter case the economy of the practice does not admit of debate. When Mr Pusey states the difference in value betwixt hoggets that have had their turnips sliced and others that have not, at 8s. per head in favour of the former from this cause alone, we do not think that he over-estimates the benefit. Those who slice turnips for older sheep, and for hoggets also as soon as ever they have taken to them, are, we suspect, acting upon a sound principle, and their example is therefore likely to be generally followed. There is no doubt of this, at least, that hoggets frequently lose part of the flesh which they had already gained from the slicing of the turnips being unduly delayed. By 1st December, their first teeth, although not actually gone, have become so inefficient, that they require longer time and greater exertion to fill themselves than before; and this, concurring with shorter days and colder weather, operates much to their prejudice. When the slicing is begun, it is well to leave a portion of growing turnips in each day's fold, as there are always some timid sheep in a lot that never come freely to the troughs; and they serve moreover to occupy the lot during moonlight nights, and at other times when the troughs cannot be instantly replenished. As the sheep have access to both sides of the troughs, each will accommodate nearly as many as they are feet in length. There should therefore be provided at least as many foot-lengths of trough as there are sheep in the fold. These troughs are usually placed on low cross feet, with a top-rail to keep the sheep from getting into them. It is better to raise them about 18 inches from the ground on feet standing well out, to prevent them from being overturned. This preserves their food from being dirtied and wasted, better than a top-rail. When corn or cake is given, it is best to use separate troughs for it of smaller dimensions, and to turn them over after each feed, to keep them clean and dry.

Putting hoggets to turnips.

Benefit of giving dry food along with turnips.

Slicing turnips for sheep.

Much discussion has taken place of late years, as to whether sheep can be fattened more economically in the open field or under cover. When the soil is at all dry, the preponderance of evidence is in favour of the former practice. There can be no doubt, however, of the propriety of providing some temporary shelter for fattening sheep against severe winter weather. This is done to some extent by forming the whole or part of the fold fence of wattled hurdles. A double row of common hurdles, set about a foot apart, and having the interstices daily stuffed with fresh straw, forms at once a screen from the weather, and a rack for dry fodder. In very inclement weather, a rude shed can

Sheepfeeding.

Live Stock. be constructed with stout double hurdles, stuffed between with litter, and having others laid across them, similarly covered with spadefuls of earth thrown on here and there to prevent the straw from being blown away. We have already, when treating of turnip culture, pointed out the advantage of having all that are to be consumed after Christmas secured in some way against bad weather and running to seed. To clear the ground in time for the succeeding grain crop, a portion of the turnip crop is usually stored on some piece of grass or fallow where the flock is folded until the pastures are ready to receive them. As the date of this varies exceedingly, it is well to lay in turnips for a late season, and rather to have some to spare than to be obliged to stock the pastures prematurely. If corn or cake has been given in the turnip field, it must be continued in the pasture. Hoggets that have been well managed will be ready for market as soon as they can be shorn, and may not require grass at all. They usually, however, grow very rapidly on the first flush of clovers and sown grasses, especially when aided by cake or corn. When the soil is of poor quality, it is expedient to continue the use of such extra food during summer. The best sheep are generally sent to market first, and the others as they attain to a proper degree of fatness. Store sheep or cattle are then purchased to occupy their places until the next crop of lambs is weaned.

*Management of Mountain Sheep.*—We have already taken notice of the extent to which Cheviot sheep have of late years been introduced in the Highlands of Scotland. Many of the immense grazings there are rented by farmers resident in the south of Scotland, who only visit their Highland farms from time to time, and entrust the management of their flocks and shepherds, which rival in numbers those of the ancient patriarchs, to an overseer, whose duty it is to be constantly on the grounds, to attend in all respects to the interests of his employer, see his orders carried into effect, and give him stated information of how it fares with his charge. We are happy at being enabled to submit to the reader the following account of Highland sheep-farming, with which we have been favoured by a gentleman who is extensively engaged in this business.

"The hills in the north of Scotland are mostly stocked with Cheviot sheep, except in the shires of Perth and Argyll, where the blackfaced breed are still considered the most suitable; and a considerable quantity of cattle also are reared. The farms in the high districts are often of great size, some of the largest extending even to 50,000 or 60,000 acres. The land, however, some few valleys excepted, is of a very barren description, much broken with rocks and large stones, or else, as in some parts of Sutherland, extending in vast ranges of moss, covered with the different heaths. It requires generally about three acres to keep a sheep through the season; they never get hay or any foreign feeding during winter, but some of the highest hirsels have sometimes to be driven off to lower ground in severe storms. As the sheep lie scattered over such a great extent of ground, their management entails much more fatigue on the shepherd than in more fertile districts. Many of these shepherds have been brought from the border counties; their wages are from L.16 to L.18, with house, two cows' grass, ground for potatoes, and 65 stones of oatmeal. The natives of the district get something less. In some cases the grazing of 60 or 70 sheep is given instead of money, but on account of the trouble they cause at sortings, wages in cash are now generally preferred. The number of sheep in a hirsel is about 500, but in some cases twice that number are under the charge of one man.

One of the most trying seasons for the shepherd is lambing-time, which begins about 20th or 25th April. The number of lambs reared on Mr Sellar's farm[1] is much above an average. Low-lying sheltered districts may commonly rear 15 or 16 lambs for every 20 ewes put to the tup; but on the high grounds, although the ewes there are much more careful of their lambs, yet from exposure to the weather and various casualties, there are seldom produced more than 13 or 14 lambs for every 20 ewes. On account of the difficulty of rearing lambs in these high districts, the farmers there find it more profitable to keep most of their land under wedders, and purchase what lambs they require from the low-lying farms near the coast, many of which are now under a ewe stock; there are not yet, however, enough of wedder lambs bred to supply this demand, as large lots are annually driven north from the border markets. The sale wedders (almost all of which are three years' old) are clipped as early as possible, say about the middle of June, the ewes, &c., in the beginning of July. Plenty of clippers are to be had from the villages at 1s. per day with victuals. The weight of the fleeces varies much; the average may be about 4 lb. of smeared wool. A great part of the wool and sheep of the northern counties is sold at the Inverness and Fort-William markets, or consigned to commission-agents in Liverpool. The highest prices for both are obtained by the Sutherland farmers. Everything is sold by character, no stock or samples of any kind are shewn; and it is said that no lawsuit has occurred from any disputed bargain. The principal lots of sheep are bought into Dumfries, Cumberland, and other western counties, and there has been an increasing demand of late years from Ireland. Those unsold are driven to Falkirk, travelling there from the most northern farms in about four weeks, at an expense of 1s. 6d. per head; some few lots have of late years been sent south by the west-coast steam-boats.

"Few Highland farms, like Mr Sellar's, contain any arable land; and one of the greatest difficulties the farmer has to contend with is getting the lambs wintered. The ewe-lambs are thought hardier than the wedders; it is also of consequence to have them thoroughly inured to the pasture and climate; so they are commonly kept at home, and either placed on the most suitable hirsels, or left following their mothers through the whole season; the loss during winter amounting to from 4 to 6 out of every 20. Great part of this loss is caused by braxy, which prevails over the whole Highlands, and is often worst in those places which, from their lowness and richness, are most suitable for wintering lambs. No preventive has yet been found.[2] Poverty and casualties make up the rest of the loss. About the beginning of November, all the wedder lambs are driven off to turnips grown on the east coasts (a few lots of them go to sheltered grazings). They are taken there from great distances, even from Lewis, and often suffer much from bad weather and fatigue during the journey. The expense of wintering them there is from 1¾d. to 2d. per week, but the loss seldom exceeds 2 out of every 20. They return to the hills again in March and April. The average loss of old sheep during a season may be about 2 out of every 20.

"There are some fine lots of tups bred in Sutherland, which have taken prizes in every district; large numbers also are taken every year from the border counties. In some wide-lying hirsels one tup is required for every 30 ewes; 45 being about the average number. All the sheep are smeared with tar and butter, at a cost of 4½d. or 5d. each; no substitute has yet been found for it, and attempts to keep them white have not been successful. The rents vary from 2s. to 2s. 9d. per sheep; on some low rich farms they are still higher. The capital required of late years has been 20s. or 25s. for each sheep kept."

The following remarks are from another extensive Highland sheep-farmer:—

"The management of flocks in the Highlands is much the

---

[1] See *Farm Reports, or Accounts of the Management of Select Farms.* Sutherland. By Patrick Sellar.

[2] We have been informed by a gentleman who has recently entered upon sheep farming in the west of Ireland on a large scale, that the small farmers in his neighbourhood regularly shear their lambs in August, and assign as their reason for this apparently barbarous practice, that hoggets so treated stand the winter better, and are more exempt from braxy and other diseases than those that are allowed to retain their lamb's wool. The limited experiments hitherto made by our informant and several graziers of his acquaintance, have so far confirmed the propriety of this strange treatment.

Live Stock. same as on high and exposed farms in the higher districts of Roxburghshire, Dumfriesshire, and Selkirkshire, as regards the ewe hirsels; the ewe lambs either not being weaned, or that only for eight or ten days, so that they may continue to follow their mothers. The wedder lambs are sent to the wedder-ground about the beginning of August, and herded on the part of it considered most adapted for their keep, till about the middle of October, when they are sent to turnips mostly in Ross-shire, where they remain till the middle of March or beginning of April. This is one of the heaviest items of expense in Highland farming, amounting to fully 4s. per head; and thus, upon a farm equally stocked with ewes and wedders, adds just about one-third to the rental of the farm. On the return of the wedder hogs, they are put to particular parts of the wedder ground, at large amongst the other ages of wedder stock, where they remain until drawn out when three years' old at the usual season to send to market; with this exception, that the year following (when they are dinmonts), the smallest of them, those that are not considered capable of wintering at home, say to the extent of two or three to the score, are again drawn out and sent with the hogs to turnips.

"Mr Sellar, in his Report of the County of Sutherland, gives a very minute and detailed account of the mode of management as practised on his farms. This, however, does not apply to extensive West Highland farms, which have no arable farms attached, no fields to bring in the diseased or falling-off part of the stock to, nor is it ever practicable to shift any part of the stock to different parts of the farm from that on which they have been reared."

The farms occupied by Cheviot sheep on the hills inclosing the valley of the Tweed and its tributaries, and many similar localities elsewhere, usually include a portion of arable land, which is chiefly valued for the opportunity which it affords of providing a supply of turnips on which the ewes and young sheep are partially fed for six weeks or so immediately preceding the lambing season. The practice is to admit the flock to the turnip fold for four or five hours daily, and then turn them off to some neighbouring piece of heather or rough ground. On such farms the pastures are more devoid of nourishing herbage of any kind during the months of February and March than even in midwinter. A daily feed of turnips at this season, when the sheep are in reduced condition from previous privation, is therefore invaluable. The sown grasses on such farms are usually made into hay, which supplies the flock with fodder during snow-storms. The aftermath is also of great service in aiding late lambs, and other weakly sheep. As the culture of grain crops on such elevated grounds is usually anything but remunerative, the farmer may actually be at more expense in growing turnips at home than if he were to board his flock for the same length of time in some low-country farm. He is compensated, however, by having his flock less disturbed, and better attended to than if they were sent from home.

It is not at all unusual for one farm to be stocked partly with Cheviots, and partly with blackfaced sheep. The lowest and grassiest grounds are assigned to the pure Cheviots, and if there are enclosed fields of tolerably good grass, a portion of the ewes—the oldest class—are taken to breed crosses from the Leicester ram. The medium grounds, consisting partly of rough herbage mixed with heather, and partly of higher portions producing heather alone, are stocked with blackfaced ewes which are crossed with Leicester rams, while, on the highest and bleakest parts, covered chiefly with heather, pure blackfaced sheep are bred.

We begin our description of the management of such flocks with autumn, and assume that the yearly cast of lambs and aged ewes has been disposed of, only so many of the ewe-lambs being retained as are required to keep up the breeding stock. A former practice was to keep these ewe-lambs or hoggets by themselves on the best portions of the respective walks, or *rakes* as they are called on the borders. Now, however, they are kept apart from their dams only so long (eight or ten days) as suffices to let the milk dry up; Live Stock. whereupon they are returned to the flock or *hirsel* to which they belong, and at once associate again, each with its own dam. The hoggets, under the guidance of the ewes, are thus led about over the ground, according to varying seasons, and under the promptings of an instinct which far surpasses the skill and care of the best shepherd. The latter, indeed, restricts his interference chiefly to keeping his flock upon their own beat, and allows them to distribute themselves over it according to their own choice. When thus left to themselves each little squad usually select their own ground, and may be found—the same individuals, about the same neighbourhood—day after day. This plan of grazing the hoggets and ewes together has been attended with the best results. There are far fewer deaths among the former than when kept separate, and being from the first used to the pasturage and acquainted with the ground, they get inured to its peculiarities, and grow up a healthy and shifty stock, more easily managed and better able to cope with trying seasons than if nursed elsewhere, and brought on to the ground at a more advanced age. Each hogget and its dam may be seen in couples all through the winter and spring, and with the return of summer it is a pretty sight to see these family groups grown into triplets by the addition to each of a little lamb. As the autumn advances, the flock-master makes his preparations for smearing or bathing. The smearing material is a salve composed of tar and butter, which is prepared in the following manner:—Six gallons of Archangel tar and 50 lb. of grease-butter are thoroughly incorporated, and as much milk added as makes the salve work freely. This quantity suffices for 100 sheep. This salve destroys vermin, and by matting the fleece is supposed to add to the comfort and healthiness of the sheep. It adds considerably to the weight of the fleece, but imparts to it an irremediable stain, which detracts seriously from its value per lb. A white salve introduced by Mr Ballantyne of Hollylee, is now in repute on the borders. It is prepared as follows:—30 lb. butter, 14 lb. rough turpentine, and 3 lb. soft soap are melted and mingled in a large pot; 2 lb. soda, and ½ lb. arsenic are then dissolved in a gallon of boiling water, and this along with 12 gallons more of cold water is intimately mixed with the other ingredients, and yields enough for dressing 100 sheep, at the rate of a quart to each. Some persons believing the arsenic an unsafe application, substitute for it the juice from 10 lb. of tobacco-paper. Instead of the rough turpentine, some also use half-a-gill of spirit of tar for each sheep; this ingredient being mixed in each quart-potful at the time of application.

In applying these salves, the sheep are brought to the homestead in daily detachments, according to the number of men employed, each man getting over about sixty in a day. A sheep being caught and laid upon a stool, the wool is parted in lines running from head to tail, and the tar salve spread upon the skin by taking a little upon the fingers and drawing them along. The white salve is kept in a semifluid state by occasionally placing the large kettle in which it is concocted upon a slow fire, or by adding as needed a small quantity of boiling water. Each shepherd has a boy assistant who pours the liquid salve from a tin pot with a spout, while he holds the wool apart. This white salve destroys vermin, and is believed to nourish the wool and to promote its growth. It does not, however, cause the fleece to adhere like the tar ointment; and hence, the better to defend the hoggets from wet and cold, some flock-masters after salving them put a piece of coarse woollen cloth over the back of each, and sew it to the fleece all round the edges with worsted thread. This "brat" as it is called prevents the wool from parting over the spine, and protects the animal from wet and cold far more effectually than smearing the fleece with tar-salve.

Live Stock.

Where the *bratting* plan has been adopted, the usual rate of mortality has been reduced, and the vigour of the flock increased. This salving and bratting must all be accomplished before the 20th November, about which time the rams are admitted to the flock. Before this is done another preliminary is required. As the ewe hoggets graze with the flock, it is necessary to guard them from receiving the male, for which purpose a piece of cloth is sewed firmly over their tails, and remains until the rams are withdrawn. This is called *breeking* them. On open hilly grounds about forty ewes are sufficient for each ram. To insure the vigour and good quality of the flock it is necessary to have a frequent change of blood. To secure this by purchasing the the whole rams required would be very costly, and therefore each flock-master endeavours to rear a home supply. For this purpose he purchases every autumn, often at a high price, one or two choice rams from some flock of known excellence, and to these he puts a lot of his best ewes carefully selected from his whole flock. These are kept in an enclosed field until the rutting season is over, and after receiving a distinctive mark are then returned to their respective hirsels. From the progeny of these selected ewes a sufficient number of the best male lambs are reserved to keep up the breeding stock of the farm. The rams are withdrawn from the flock about 1st January, and are then kept in an enclosed field where they receive a daily feed of turnips. Except in heavy falls of snow and intense frosts, the flocks subsist during the entire season on the natural produce of their pastures. It is necessary, however, to be provided for such emergencies both as regards food and shelter. For this purpose each shepherd has at suitable parts of his beat several *stells* or artificial shelters such as are described at p. 358, and beside each of them a stack of hay from which to fodder the flock when required. So long as the sheep can get at heather or rushes by scraping away the snow with their feet, they will not touch the hay, but when the whole surface gets buried and bound up, they are fain to take to it. The hay is laid out in handfuls over the snow, twice a-day, at the rate of 22 lb. to each score of sheep. Much vigilance, promptitude, and courage are required on the part of shepherds in these wild and stormy districts, in getting their flocks into places of safety on the breaking out of sudden snow-storms. Where turnips are grown they are reserved for spring use, and are given to the ewes as already mentioned, for a few weeks before the lambing season commences, so as to encourage a flow of milk. This indulgence is bestowed only upon the Cheviots; the hardier blackfaces not only not requiring this artificial aid, but in general doing better without it. If the supply of turnips is ample, the whole of the Cheviot ewes get a daily feed, but if this indulgence cannot be afforded to the whole flock, the shearling ewes and such older ones as are in poorer condition than the average of the flock are drawn out from the general hirsel, and receive the benefits of the succulent food for the full period named above; the older and stronger ewes being kept upon the hill until near the lambing time. This turnip fare not only benefits the flock while they receive it, but their usual pasture in the meantime gets clean, and freshens against their return to it, which takes place as soon as lambs begin to drop. The flock-master usually endeavours to store a portion of his turnip crop, and to retain it for daily distribution, in a convenient enclosure, to such of the flock as stand in need of such indulgence, after the flock at large have been replaced on their respective *rakes*. The lambing season is one of much anxiety to the master: and to his shepherds and their faithful sagacious dogs one of incessant toil. They must be a-foot from "dawn till dewy eve," visiting every part of their wide range several times a-day, to see that all is right, and to give assistance when required.

Lambing season.

The ewes of these hardy mountain breeds seldom require man's assistance in the act of parturition, but still cross-presentations and difficult cases occur even with them. Deaths occur also among the newly-dropt lambs, in which case the dam is brought home, and a twin lamb (of which there are usually enough to serve this purpose) put in the dead one's place. The dead lamb's skin is stript off, and wrapt about the living one, which is then shut up beside the dam in a small crib or *parik*, by which means she is usually induced in a few hours (and always the sooner the more milk she has) to adopt the supposititious lamb. As the lambing season draws to a close, each shepherd collects the unlambed ewes of his flock into an enclosure near his cottage, and examines them one by one to ascertain which are pregnant. To the barren ones he affixes a particular mark, and at once turns them again to the hill, but the others are retained close at hand until they lamb, by which means he can attend to them closely with comparatively little labour. The lambs are castrated and docked at from 10 to 20 days old. For this and for all sorting and drafting purposes an ample fold and suite of pens, formed of stout post and rail, is provided on some dry knoll convenient for each main division of the flock. To this the flock is gently gathered, and penned off in successive lots of 10 or 12, taking care that each lamb has its own dam with it before it is penned, and to do this with as little dogging and running as possible. The male lambs of the pure blackfaced breed when designed to be kept as wethers are not castrated until they are eight or ten weeks old, partly because when done sooner their horns have a tendency to get so crumpled as to grow into their eyes, and partly because a bold horn is thought to improve the appearance of an aged wether.

Shearing.

On these elevated sheep-walks, shearing does not take place until July. It cannot, in fact, be performed until the young wool has begun to grow or *rise*, and so admit of the shears working freely betwixt the skin and the old matted fleece. The sheep are previously washed by causing them to swim repeatedly across a pool with a gentle current flowing through it. They are made to plunge in from a bank raised either naturally or artificially, several feet above the surface of the water. This sousing and swimming in pure water cleanses the fleece far more effectually than could be supposed by persons accustomed only to the mode pursued in arable districts. Shearing takes place three or four days after washing, and in the interim much vigilance is required on the part of the shepherd to prevent the sheep from rubbing themselves under banks of moss or earth, and so undoing the washing. To diminish the labour to the shepherd, and disturbance to his flock, consequent on frequent gathering, each hirsel is if possible shorn in one day. For this end the shepherds from neighbouring farms assemble, and by turns assist each other. Abundance of good cheer is provided for them by the masters on such occasions, which are usually characterised by much hilarity and keen discussion of the merits of their respective flocks. Each man usually shears about sixty sheep a-day. It is neither practicable nor expedient to shear these mountain sheep so closely as the fat denizens of lowland pastures. At these great *clippings* each shearer is provided with a low-legged sparred stool, having a seat at one end, or with a bench built of green turf, which are arranged in a row close in front of a pen, in which the unshorn sheep are placed. The shearers being seated, each astride his stool or bench, with their backs to the pen, a man in it catches and hands over a sheep to each of them. The sheep is first laid on its back upon the stool, and the wool shorn from the under parts, after which its legs are bound together with a soft woollen cord, and the fleece removed first from the one side and then from the other, by a succession of cuts running from head to tail. The fleeces

Live Stock. are thrown upon a cloth and immediately carried to the wool-room, where, after being freed from clots, they are neatly wrapped up and stored away by young women. Before the shorn sheep are released, each receives a mark or *buist* by dipping the owner's cypher in melted pitch, and stamping it upon the skin of the animal. To discriminate different ages and hirsels, these marks vary in themselves, or are affixed to different parts of the sheep. Once or twice a year all stray sheep found upon the farms of a well-defined district are brought to a fixed rendezvous, where their marks are examined by the assembled shepherds, and each restored to its proper owner.

Weaning. Weaning takes place in August or early in September. A sufficient number of the best ewe lambs of the pure breeds are selected for maintaining the flock, and are treated in the way already noticed. With this exception, the whole of the lambs are sold either to low-country graziers, or as fat lambs to the butcher. The wedder lambs usually go to the former, and the ewe lambs of the cross betwixt blackfaced ewes and Leicester rams to the latter. These ewes, being excellent nurses, make their lambs very fat in favourable seasons, in which case they are worth more to kill as lambs than to rear.

Immediately after the weaning, the ewes which have attained mature age are disposed of generally to low-country graziers, who keep them for another year, and fatten lamb and dam. To facilitate the culling out of these full-aged ewes, each successive crop of ewe lambs receives a distinctive ear-mark, by which all of any one age in the flock can be at once recognised.

*Wool* is such an important part of the produce of our flocks, that it seems proper to offer a few remarks upon it before leaving this section. We here insert with much pleasure the following communication from John Barff, Esq. of Wakefield, with which we have been favoured:—

"I willingly give you a reply to your various inquiries regarding wool as far as I am able. As to the kinds grown in the various counties of the United Kingdom, this I cannot fully answer, as there are some counties' wools which have not come much under my inspection; but generally I may remark that wherever the turnip can be cultivated and has been introduced, the Leicester, Lincolnshire, Coteswold, and the half-breds from Down and Cheviot are to be found; and in the same counties, in several instances, you have several kinds, if we except Lincolnshire, and Leicestershire, which have entirely the long-wool sheep. The great bulk also of York, Warwick, Oxford, Cambridge, Gloucester, Northampton, and Nottingham shires, have this description of sheep, but they have also Downs and half-breds. Kent has its own sheep called Kents; the wool being much finer than the real longwool sheep, running in quality and weight of fleece between these latter and the Down, something like your half-breds from Cheviot ewes by Leicester rams. They have somewhat of a similar sheep in Devon, Cornwall, Hereford, and Shropshire, but the quality in the two former counties scarcely so fine as the two latter, or the Kent wools. Norfolk has the original Down and the half-bred; Surrey, Suffolk, Essex, Sussex, and Hampshire, are nearly all Down wools, though in these counties, upon some of their best lands, where they can cultivate the turnip, the half-bred are being introduced; and I need to you scarcely say, the Leicester sheep, as well as half-breds and Cheviots are to be found in Durham, Northumberland, Berwickshire, Roxburghshire, Lothians, and other parts of Scotland where the turnip is cultivated, and in those parts where it is not, and on the hills, the Cheviot and blackfaced prevail. The blackfaced are used for low padding cloths, carpets, and horse-rugs. The Down wools were formerly all used for cloths and flannels; but now from the improvement in worsted machinery, one-third is used for worsted yarns, and goods; and as the portion suitable for combing purposes is more valuable for this purpose than for cloths or flannels, the grower aims at getting it as deep-stapled as possible; and this has led to a great increase in the weight of the fleece, but at the same time a deterioration in the quality. The Leicester, Lincolnshire, half-bred, and Coteswold, as well as the Kents and Devons are entirely used for worsted yarns and goods; and a very small portion of the wools imported come in competition with them. The nearest approach is a little imported from Holland and Denmark; but they partake more of your cross from a blackfaced ewe by a Leicester ram. The Irish wools are either the longwoolled sheep, similar to the Leicester, the mountain sheep similar to your Cheviot, or the small Welsh sheep. The Irish wools are generally open haired, and have not the richness of the Leicester or our English; and are not so much esteemed or valuable as English wool of apparently the same quality by ½d. to 1d. per lb. Richness of handle is now very desirable, as there is a demand for what are called *glossy* yarns, which wools fed on pasture or good new seeds can only produce, and cannot be obtained from the wools grown on chalk or hard lands, such as our midland counties, viz., Oxford, Bedford, and Northampton generally produce.

"In every fleece of wool there are two or three qualities, not more than two or three in the blackfaced, four to five in the longwoolled sheep, five or six in the half-bred, and seven or eight in a Down fleece, and I may say every fleece undergoes this sorting or separation, before being put into any process of manufacture. Of course the more there is of the best quality in any fleece, the more desirable and valuable the fleece is; in blackfaced, to be free from dead hair or kemps; and we find in all the other wools, that the closer the staple and *purly* the wool, the more it yields of the finer qualities, whilst the open-haired makes more of the lower quality. The breeder should, therefore, in selecting his tups with a view to good wool, choose them with a close purly staple. A great deal of the excellence, however, of wool depends upon the nature of the soil on which the sheep are fed. Upon the chalk and sandy hard lands, we always find the worst qualities of wool of its kind, whilst the best comes from the rich good lands, where there is plenty of old grass or seeds. Thus the wools of Roxburghshire, as a general rule, are better than Berwickshire or Lothian; Leicester, Lincolnshire, Nottingham and Warwickshire, superior to Oxford, Cambridge, Bedford, or Northampton; and, in Downs Sussex and Surrey better than Essex and Norfolk, from their downs being more grassy and the land better. The principal quality required in wool is a rich soft handle, as such is always found to improve in every process it is put through in the various stages of its manufacture, whilst the wools grown on chalk or hard lands, and which have a hard bristly handle, get coarser as they progess in the manufacture.

"With regard to the salves or baths used for destroying vermin, we do not know what kinds are used in the different localities, but of those used with you we dislike the spirit of tar and tobacco. Wilson of Coldstream's dip appears to answer, and one called Ballantyne's used in Selkirkshire; but in all these a great deal depends upon their being properly attended to, and being put on at the proper season. If put on in the autumn, we don't perceive that they have been used, and whenever we have to make a complaint on this head, we find it arises from the baths having been used in spring."

To the above interesting information we add the following items from Mr Southey's valuable pamphlet:—

"The manufacture of wool, besides being our oldest branch of in-door industry, may justly be considered as characteristic of the British Isles, and it has now reached an amount, as well as acquired a degree of importance, by no means duly appreciated. It is also more generally diffused throughout the country, although it flourishes most in the West Riding of Yorkshire; but, at the same time, other English counties have a proportionate share, and in Scotland it equally forms a prominent feature in the industrial enterprise of the inhabitants. To meet the growing demand for a continuous supply, consequently requires a large, and indeed, as fashions go, a varied producing power, and this fortunately we possess within ourselves, without being dependent, as in reality we are for cotton, upon foreign sources.

"When the manufacture of woollens commenced among us, the chief reliance of the undertakers was upon home production, but being once fairly started, this supply was found to be beneath the actual requirements. Parties concerned were thus

Live Stock.

compelled to call in foreign aid, and among other expedients resorted to, we became a kind of tributary to Spain, whence in 1815 we imported 6,927,934 lb. of wool, besides 3,137,438 from Germany; but in 1849 our importations of the same article from Spain dwindled down to 127,559 lb., and in the interval we ourselves became extensive exporters of certain qualities to Germany; notwithstanding we thence still continue to receive some supplies of the most marketable kind. To illustrate this striking change in the sources of our external supply, I beg to subjoin the following comparative statement of wools, imported at a remote and recent period:—

| | 1815. lb. | 1849. lb. |
|---|---|---|
| "Spain | 6,927,934 | 127,559 |
| Germany | 3,137,438 | 12,750,011 |
| Other parts of Europe | 3,416,132 | 11,432,354 |
| South America | 45,838 | 6,014,525 |
| Cape of Good Hope | 23,363 | 5,377,495 |
| British India | ... | 4,182,853 |
| Australian Colonies | 73,171 | 35,879,171 |
| Other Parts | 10,291 | 1,004,679 |
| | 13,634,167 | 76,768,647 |

"In 1699 it was computed that there were twelve millions of sheep in England and Wales, valued besides the skin at 7s. 4d. each, and the wool yearly shorn, worth, at 3s. 4d. per fleece, L.2,000,000, at which amount our exportation of woollens was then rated. This subject was afterwards much neglected, nor had we any satisfactory elucidations upon it till Mr Luccock published his *Treatise on English Wools*, drawn up with great diligence and research, and at the time entitled to much respect, but owing to the want of materials, evidently defective in many of its parts.

"Mr Luccock estimated that the total produce of our flocks in 1800 was 384,000 packs of 240 lb. each, or 92,544,000 lb.; and Mr James Hubbard, an experienced and extensive woolstapler of Leeds, when the subject was before the memorable committee of the House of Lords, and a searching inquiry going on, satisfactorily demonstrated, that supposing Mr Luccock's estimate to have been tolerably correct at the time it was made in 1828, the period to which his own researches were immediately directed, our total production of wool could not be less than 463,169 packs, being only an increase of 20 per cent. and corresponding in the aggregate to 111,623,729 lb. Relying upon these data, and taking into account the high price which this commodity subsequently attained, as well as the greater weight of both fleece and carcase, thus yielding to the farmer more profit than at any former period, Mr M'Culloch, writing in 1846, came to the conclusion that the total production of wool, in the British Isles, was then not less than 540,000 packs, or 130,140,000 lb.

"Considering that these data, however respectable, did not afford any just conception, under our altered circumstances, either of the increased number of sheep among us, or the advantage gained through the additional weight of fleece, I addressed letters of inquiry upon these two points to some of our most eminent breeders in the kingdom, and at the same time caused others to be forwarded, and to the same effect, to every part of the country, by long-established staplers and practical men, who readily volunteered to join me in so useful and reasonable a research.

"From all the evidence before me, founded upon information gathered from authentic sources, two important facts result,—1*st*, That our flocks in England, Wales, and Scotland, have gradually increased within the last twenty years; and 2*d*, That the fleece throughout is materially improved in weight.

"As far as I can judge, we annually clip forty millions of sheep, while the fleeces of fifteen millions more, slaughtered, pass through the hands of fellmóngers to the consumer. Hence it would follow that we have the yearly fleeces of fifty-five millions of domestic sheep to work upon, averaging, it may be safely admitted, 5 lb. each. The basis of our manufactures, as far as regards home-grown wool, would thus be about 275,000,000 lb., which little more than confirms my Bradford correspondent's estimate, and to these are to be added seventy-seven millions of pounds more imported. From these two amounts are to be deducted,—1*st*, 4,000,000 lb. of British wool exported, and 2*d*, 12,500,000 lb. of Colonial re-exported, thus leaving the balance annually consumed in our looms and for domestic purposes at about 335,000,000 lb., or nearly one-half of the total amount of the cotton which we import,"[1]

Live Stock.

GOATS.

Goats never occupied an important place among the domesticated animals of the British Islands, and, with the exception of Ireland, their numbers have been constantly diminishing. By the statistical returns it appears that in 1849 there were 1,777,111 goats in Ireland, which in 1850 had increased to 1,876,096. This increase is said to be "entirely owing to the impoverished state of the country, which has obliged persons to sell their cows, and to replace them with goats, on whose milk they subsist instead of that of cows." The value of goat's milk, as a source of household economy, is much greater than is usually supposed. This is so well shown by Cuthbert W. Johnston, Esq., in the *Farmer's Magazine* for April 1852, that we shall quote from his article:

"The comfort derived by the inmates of a cottage from a regular supply of new milk, need hardly be dwelt upon. Every cottager's wife, over her tea, every poor parent of a family of children fed almost entirely on a vegetable diet, will agree with me, that it is above all things desirable to be able to have new milk as a variation to their daily food of bread and garden vegetables. The inhabitant of towns and of suburban districts, we all know, is at the mercy of the milk dealer; the milk he procures is rarely of the best quality, and under the most favourable circumstances he receives it with suspicion, and his family consume it with sundry misgivings as to its wholesomeness.

"Having personally experienced these difficulties, and having about three years since commenced the attempt to supply my family with goat's milk, and as our experience is cheering, I desire in this paper to advocate the claims of the milch goat to the attention of the cottager, and the other dwellers in the suburban and rural districts.

"Few persons are perhaps aware of the gentleness and playfulness of the female goat—how very cleanly are its habits, how readily it accommodates itself to any situation in which it is placed. Confined in an outhouse, turned on to a common or into a yard, tethered on a grass plat, it seems equally content. I have found it readily accommodate itself to the tethering system, fastened by a leathern collar, rope, and iron swivel, secured by a staple to a heavy log of wood. The log is the best (and this with a smooth even surface at the bottom), because it can be readily moved about from one part of the grass plat to another. The goat too uses the log as a resting place in damp weather. The goat should be furnished with a dry sleeping place, and this, in case of its inhabiting open yards, can bo readily furnished; any thing that will serve for a dry dog-kennel will be comfortable enough for a goat.

"The milk of the goat is only distinguishable from that of the cow by its superior richness, approaching, in fact, the thin cream of cow's milk in quality. The cream of goat's milk, it is true, separates from the milk with great tardiness, and never so completely as in the case of cow's milk. This, however, is of little consequence, since the superior richness of goat's milk renders the use of its cream almost needless. The comparative analysis of the milk of the cow and goat will show my readers how much richer the latter is than that of the former; 100 parts of each, according to M. Regnault, gave on an average,—

| | Cow. | Goat. |
|---|---|---|
| "Water | 84·7 | 82·6 |
| Butter | 4·0 | 4·5 |
| Sugar of milk and soluable salts | 5·0 | 4·5 |
| Caseine (cheese), albumen, and insoluble salts | 3·6 | 9·0 |

[1] *The Rise, Progress, and Present State of Colonial Sheep and Wools*, by Thomas Southey. London, 1850.

Live Stock.

"So that, while the milk of the cow yields 12·6 per cent. of solid matters, that of the goat produces 17·10 per cent, goat's milk yielding rather more butter, rather less sugar of milk, but considerably more caseine (cheese) than that of the cow.

"It must not be supposed that the *taste* of the milk of the goat differs in any degree from that of the cow; it is, if anything, sweeter, but it is quite devoid of any taste which might very reasonably be supposed to be derivable from the high-flavoured shrubs and herbs upon which the animal delights to browse.

"The amount of the milk yielded by the goat varies from two quarts to one quart per day; it is greatest soon after kidding time, and this gradually decreases to about a pint per day,—a quantity which will continue for twelve months. This is not a large supply, it is true; but still it is one which is available for many very useful purposes; and, be it remembered, that when mixed with more than its own bulk of lukewarm water, it is then, in every respect superior to the milk supplied by the London dairymen.

"In regard to the best variety of goat to be kept, I would recommend the smooth-haired kind, which are quite devoid of beards or long hair. In this opinion I am confirmed by an experienced correspondent, Mr W. H. Place of Hound House near Guildford, who remarked, in a recent obliging communication,—'I found that the short-haired goats with very little beards were the best milkers; but from these I seldom had more than four pints a-day at the best (I should say three pints were the average), and this quantity decreases as the time for kidding approaches (the goat carries her young 21 to 22 weeks). They should not be fed too well near the time of kidding, or you will lose the kids. In winter I gave them hay, together with mangel-wurzel, globe, and Swedish turnips, carrots, and sometimes a few oats, and these kept up their milk as well as anything, but of course it was most abundant when they could get fresh grass. The milk I always found excellent, but I never had a sufficient quantity to induce me to attempt making butter except once, as an experiment: my cook then made a little, which was easily done in a little box-churn; the butter proved very good. I found the flesh of the kids very tender and delicate.'

"I can add little to Mr Place's information as to their food; mine have generally fed out of the same rack as a Shetland pony, with whom they are on excellent terms. The pony throughout the summer is soiled with cut-grass, and I notice that the goats pick out the sorrel, sow thistle, and all those weeds which the pony rejects.

"In the garden (if they are, by any chance, allowed to browse), I notice that they select the rose-trees, common laurels, arbutus, laurestinas, and the laburnum. Of culinary vegetables they prefer cabbages and lettuces; they also bite pieces out of the tubers of the potato. They carefully pick up the leaves, whether green or autumnal, of timber trees; of these they prefer those of the oak and elm, and delight in acorns and oak-apples. We are accustomed to collect and store the acorns for them against winter; spreading the acorns thinly on a dry floor, to avoid the mouldiness which follows the sweating of acorns laid in a heap. As I have before remarked, none of these astringent substances affect the taste of their milk; and I may here observe, that with ordinary gentleness, there is no more difficulty, if so much, in milking a goat than a cow.

"The he-goat engenders at a year old. The she-goat can produce when seven months old. She generally yeans two kids. The manure of the goat is perhaps the most powerful of all our domestic animals.

"Such are the chief facts which I have deemed likely to be useful in inducing the extended keeping of the milch-goat. It is an animal that, I feel well assured, may be kept with equal advantage by the cottager and the dwellers in larger houses. It is useless to compare it with the cow, or to suppose that the goat can supplant it in situations where the cow can be readily kept; but in the absence of pastures, and in places where there is too little food for cows, I feel well convinced that, with ordinary care and attention, and a moderate firmness in overcoming the prejudices of those unaccustomed to the goat (and without these are found in the owner, live stock never are profitable), the value and the comfort of a milch-goat are much greater than is commonly known.

"The waste produce of a garden is exceedingly useful in the keep of a goat. By them almost every refuse weed, all the cuttings and clearings which are wheeled into the rubbish yard, are carefully picked over and consumed. To them the trimmings of laurels and other evergreens, pea-haulm, and cabbage stalks, &c. are all grateful variations of their food. In winter a little sainfoin, hay, or a few oats, keeps them in excellent condition. In summer, the mowings of a small grass-plot, watered with either common or sewage water, as described in the following little account, will, with the aid of the refuse garden produce, keep a goat from the end of April until October."

HOGS.

Although occupying a less prominent place in the estimation of the farmer than the ox and sheep, the hog is nevertheless an animal of great value. He is easily reared, comes rapidly to maturity, is not very nice as to food, consuming offal of all kinds, and yields a larger amount of flesh in proportion to his live weight, and to the food which he has consumed than any other of our domesticated animals whose flesh is used for food. To the peasantry he is invaluable, enabling the labouring man to turn the scraps even from his scanty kitchen, and from his garden or allotment to the best account. On such fare, aided by a little barley or pollard, he can fatten a good pig, and supply his family with wholesome animal food at the cheapest possible rate. The breeds of swine in Great Britain are numerous, and so exceedingly blended that it is often impossible to discriminate or classify them properly. The original breeds of the country seem to be two, viz. "The old English hog," tall, gaunt, very long in the body, with pendant ears and a thick covering of bristles. The representatives of this old breed are found chiefly in the western counties of England, especially in Lancashire, Yorkshire, and Cheshire, where hogs of immense size are still reared, but greatly improved as compared with their ancestry. Their bones are smaller, their hair finer and thinner set, their skin thinner and with a pink tint, the ears still pendulous but much thinner, the carcase much thicker, and their propensity to fatten greatly increased. This large breed is exceedingly prolific, and the sows are excellent nurses, it being quite common for them to farrow and rear from 12 to 18 pigs at each litter. They are somewhat tardy in arriving at maturity, and do not fatten readily until that is the case. After sixteen months old, they, however, lay on flesh very rapidly, grow to very great weights, and produce hams of excellent quality, with a large proportion of lean flesh in them. The Berkshire and Hampshire hogs seem originally to have been from the same stock, but by some early cross acquired the thicker carcase, prick-ears, shorter limbs, and earlier maturity of growth, by which they are characterised. The other native breed is found in the Highlands and Islands of Scotland. They are very small, of a dusky brown colour, with coarse bristles along the spine, and prick-ears. They are exceedingly hardy and subsist on the poorest fare, being often left to range about without shelter, and support themselves as they best can on the roots of plants, shell-fish, seaweed, and dead fish cast up by the tide.

The improved breeds now so abundant have been obtained by crossing these old races with foreign hogs, and chiefly with the Chinese and Neapolitan. Our modern white breeds, with prick-ears, short limbs, fine bone, delicate white flesh, and remarkable propensity to fatten at an early age, are indebted for these qualities to the Chinese stocks. The improved black breeds, of which the Essex may be selected as the type, and which possess the qualities just enumerated in even a greater degree, are a cross from the Neapolitan. They are characterised by their very small muzzle, fine bone, black colour, and soft skin nearly destitute of hair. They can be brought to profitable maturity at from eight to twelve months old, the white breeds at from twelve to sixteen months. Both kinds are peculiarly suitable for producing small pork to be used fresh, or for pickling. The flesh of these smaller

Live Stock.

breeds produces, however, excellent bacon when used in that manner, and at less cost than that of the larger breeds, for this reason, that it is only from the flesh of a hog that has reached maturity that bacon of the first quality can be produced; and as these have reached that point at an age when the others are but ready for beginning the fattening process, it follows that the carcase of the former, in a state fit for curing, is produced at less cost than that of the latter. Sows of the Neapolitan breed and its crosses are better mothers and nurses than the Chinese. Both kinds require peculiar care, to prevent the pregnant sow from becoming hurtfully fat. Unless kept on poor and scanty fare they inevitably become useless for the purpose of breeding. The Berkshire hog combines the good qualities of the larger and smaller breeds already referred to so happily, that he deservedly enjoys the reputation of being as profitable a sort for the farmer as can be found. With proper treatment he arrives at maturity about sixteen months old, yields a good weight of carcase for the food which he has consumed, and his flesh is well adapted for being used either as fresh meat, pickled pork or bacon, according to the age at which he is slaughtered. A very profitable hog is also obtained by coupling sows of the larger breeds with males of some of the smaller *races*.

It too frequently happens that less care is bestowed on the breeding of pigs than of the other domesticated animals. From the early age at which they begin to breed, there is need for constant change of the male, to prevent the intermingling of blood too near akin. These animals, too, are exceedingly sensitive to cold, and often suffer much from the want of comfortable quarters. Whether for fattening hogs, or sows with young pigs, there is no better plan than to lodge them in a roomy house with a somewhat lofty *thatched* roof, the floor being carefully paved with stone or brick, and the area partitioned off into separate pens, each furnished with a cast-iron feeding-trough at the side next the dividing alley, and with adequate drainage, so that the litter in them may be always dry. The period of gestation with the sow is sixteen weeks, and as her pigs may be weaned with safety at six weeks old, she usually farrows twice in the year. In this climate it is desirable that her accouchement should never occur in the winter months. It is a common arrangement to have a pig-shed so placed that the store pigs lodged in it can have access to the cattle-courts, where they grub amongst the litter, and pick up scattered grains that have escaped the thrashing-mill, and fragments of turnips and other food dropped by the cattle. On such pickings, and the wash and offal from the farm kitchen, aided by a few raw potatoes, Swedes, or mangel, and in summer by green vetches, a moderate number of store pigs can be got into forward condition, and afterwards fattened very quickly, by putting them into pens and improving their fare. There is no cheaper way of fattening hogs than by feeding them on boiled or steamed potatoes, mashed and mixed with a portion of barley or pease meal. When barley-meal alone is used, it should be mixed with cold water, and allowed to soak for twelve hours before being given to the hogs. A few morsels of coal should be frequently thrown into their troughs. These are eaten with evident relish, and conduce to the health of the animals.

An interesting account of the most approved methods of cutting up, curing, and disposing of carcases of pork, is given in the *Journal of the Royal Agricultural Society*, vol. xi. p. 585.

### RABBITS.

It has been usual, in agricultural works, to take some notice of rabbits. We have so often witnessed the destruction of crops, and consequent vexation and quarrels caused by these creatures, that we regard them only as noxious vermin. It may be true that there are, in various parts of the country, tracts of sand so barren that it is more profitable to stock them with rabbits than anything else. Those who choose, whether for pleasure or profit, to keep such stock, ought, however, to be compelled to restrain them within the hutch or warren; for certainly they are intolerable anywhere else. A more useful and manageable class of live-stock claims our attention, viz.

### POULTRY,

which we consider worthy of more attention than farmers generally bestow upon it. There are, indeed, few farm-yards untenanted by fowls of some sort, and few homesteads without a place called a poultry-house. It is rare, however, to meet with an instance where the breeding and management of poultry is conducted with the care and intelligence so frequently bestowed on other kinds of live stock. Now, if poultry is kept at all, whether for pleasure or profit, it is surely worth while to use rational means for securing the object in view. To have good fowls, it is necessary to provide a dry, warm, well-ventilated house, in which they may roost and deposit their eggs. This house must be kept clean, and its tenants regularly supplied with abundance of suitable food. Constant and careful attention is also absolutely indispensable. On farms of the lesser sort, this duty is usually undertaken by the farmer's wife or daughters. It will, however, in most cases, be better to entrust the entire charge of the poultry to some elderly female-servant, who shall give her undivided attention to it. As unremitting attention and trustworthiness are the qualities chiefly required in a henwife, and the actual work connected with the office is not very heavy, it affords a fitting opportunity for pensioning a faithful domestic, or the widow of some esteemed farm-labourer, who is getting too old for heavier labour.

The kinds of poultry most suitable for a farm-yard are the common fowl, geese, and ducks. Turkeys and guinea-fowl are difficult to rear, troublesome to manage, and less profitable than the other sorts. Of the common fowl there are now many excellent and distinct breeds. The *Cochin-China* or *Shanghae* is the largest breed we have. They are hardy and very docile; their flesh is of good quality; their eggs, of a buff colour, are comparatively small, but excellent in flavour, and are produced in great abundance. The hens resume laying very soon after hatching a brood; sometimes so soon as three weeks. They are the more valuable from the circumstance that their principal laying season is from October to March, when other fowls are usually unproductive. The *Dorkings*, of which there are several varieties, as the speckled, the silver, and the white, are not excelled by any breed for general usefulness. The hens are peculiarly noted for their fidelity in brooding, and their care of their young. The *Spanish fowls* are very handsome in their plumage and form, have very white and excellent flesh, and lay larger eggs than any other breed. The *Polish* and *Dutch every-day layers*, are peculiarly suitable where eggs rather than chickens are desired; as the hens of both these breeds continue to lay for a long time before showing any desire to brood.

A competent authority recommends that, except in situations where 2s. can be got for a good chicken, the return should be sought for chiefly in eggs. He gives the following statement of the cost and produce of a given number of fowls:—

"The following is the weekly consumption of food, and the average produce of eggs of four hens of the Dutch every-day laying variety:—

| | s. | d. |
|---|---|---|
| 1·4 gallons of barley, at 20s. per quarter ....... | 0 | 6 |
| 26 eggs, at 1s. per score............................ | 1 | 3½ |
| Profit | 0 | 9½ |

being upwards of 150 per cent. The consumption of food in this case is very great, being upwards of 1½d. each per week. We are at present trying experiments with the Spanish breed. We find that three hens and a cock consume in a week—

| | |
|---|---|
| ½ gallon of oats, at 14s. per quarter ............ | 1·3125 |
| ½ stone of barley-meal, at 8d. per stone ....... | 4· |
| | 5·3125 |

or rather more than 1¼d. each per week. If the fowls had a free range, we would calculate on keeping them on one-fourth of this amount."[1]

A suitable stock of fowls being selected, pains must be taken to preserve their health and other good qualities by breeding only from the best of both sexes, and these not too near akin. A very simple plan for securing this is to select a cock, and not more than six or eight hens, of the best that can be got, to entrust these to the care of some neighbouring cottager, whose dwelling is sufficiently apart to prevent intercourse with other fowls, and then to use only the eggs from these selected fowls for the general hatching. There are many advantages in such a course. The whole stock of fowls can thus be had of uniform character, and superior quality. If it suit the fancy or object of the owner, his fowls may be of several distinct breeds without any risk of their intermingling; the select breeding stocks can be kept up by merely changing the cock every second year, and not more than one cock to thirty hens need be kept for the general stock, as it is of no consequence whether their eggs are impregnated or no. Besides having the run of the barn-door, cattle courts, and stack-yard, fowls are greatly benefited by having free access to a pasture or roomy grass-plot. If the latter is interspersed with evergreen shrubs, so much the better, as fowls delight to bask under the sunny side of a bush, besides seeking shelter under it from sudden rain. Their court should also be at all times provided with clean water, and a heap of dry sand or coal-ashes, in which they wallow, and free themselves from vermin. To keep them in profitable condition, they require, besides scraps from the kitchen, and refuse of garden stuffs, &c., a daily feed of barley or oats at the rate of a fistful to every three or four fowls. In cold weather, they are the better of having some warm boiled potatoes thrown down to them, as also chopped liver or scraps of animal food of any kind. There is an advantage in having the poultry-house adjoining to that in which cattle-food is cooked in winter, as, by carrying the flue of the furnace up the partition-wall, the fowls get the benefit of the warmth thus imparted to their roosting-place. Saw-dust, dried peat, or burnt clay, are suitable materials for littering poultry-houses, and are preferable to straw. By strewing the floor with such substances two or three times a week, each time carefully removing the previous application, and storing it with the mingled droppings of the fowls *under cover*, a manure little inferior to the best guano can be secured. When 100 common fowls, a score of geese, and a dozen or two of ducks, are kept, the quantity and value of the manure produced by them, if kept by itself and secured from the weather, will surprise those who have not made trial of such a plan.

Within the past two or three years, the breeding of poultry has in various parts of the kingdom become quite a passion. Not only have many separate treatises been published entirely devoted to this subject, but every agricultural periodical now bears evidence to the popularity of this pursuit. Our national agricultural societies, and many of the provincial ones, now offer numerous and liberal prizes to poultry. It is in connection with these shows that the public have been made aware of the extraordinary enthusiasm with which a numerous portion of the community have engaged in poultry-breeding. At the Birmingham show, held in December 1852, no less than 1200 pens of poultry were exhibited. A pen of Spanish fowls, consisting of a cock and four hens, was claimed by a purchaser, although the reserve price put upon it by the owner was fifty guineas. For a single Cochin China cock L.25 was refused. But the importance of the show is best shown by the receipts in money, which were—

| | | | |
|---|---|---|---|
| For admission of visitors............ | L.1842 | 19 | 0 |
| Sale of catalogues...................... | 279 | 4 | 0 |
| Do. of poultry ........................ | 1636 | 15 | 6 |
| | L.3758 | 18 | 6 |

Similar results occurred in connection with the more recent metropolitan show, when 695 pens of poultry were brought forward. On the first day of exhibition, each visitor was charged 5s., and yet, at this rate, several hundreds sought admission. Next day, at 1s. each, there were upwards of 5000 visitors, a greater number the following day; and on the fourth and last day of the show, they reached nearly to 12,000. The prize Cochin China cock and hen were sold for forty-seven guineas; a hen and pullet of the same breed brought eighteen guineas each; another pair twenty-five guineas; a pen of Poland fowls twelve guineas; and several pens of Aylesbury ducks from L.10 to L.14. The whole sales on this occasion realised upwards of L.1000. It is known that even these extraordinary prices have since been exceeded; a prize Cochin China cock having actually been sold for L.100. Not a few farmers who were fortunate in early securing good specimens of the popular breeds of poultry, have found the breeding of them more remunerative than that of bullocks. This will, of course, last only until the present poultry-mania abates; but, in the mean time, greatly improved breeds of this interesting and useful kind of live stock have been diffused over the country; more judicious modes of treating them than were formerly practised have been made known, and our markets will henceforward be more fully supplied with eggs and fowls of superior quality.

*Treatment of Live Stock under Disease.*—Time was when every such treatise as the present was expected to contain a description of the diseases to which the domesticated animals are most subject, and instructions for their treatment under them. But now that farriery is discarded, and veterinary medicine is taught in colleges, the handling of such a subject is obviously beyond the province of a practical farmer. A few general observations is all therefore that we offer regarding it. The province of the stock-master obviously is to study how to prevent disease, rather than how to cure it. For this end let him exercise the utmost care, first, in selecting sound and vigorous animals of their respective kinds, and then in avoiding those errors in feeding and general treatment, which are the most frequent causes of disease. When cases of serious disease occur, let the best professional aid that is available be instantly resorted to; but in all those cases which farmers usually consider themselves competent to treat, we advise that they should trust rather to good nursing, and to the healing power of nature, than to that indiscriminate bleeding and purging which is so commonly resorted to, and which, in the majority of cases, does harm instead of good. Those farmers who have the most implicit faith in their phlemes and physic balls, must admit that their treatment often fails, and that even when their patients do recover, they appear to have suffered more from the depletion than from the disease. We have proved this system fully, and know but too well its pernicious effects.

[1] *Essay on the Rearing and Management of Poultry*, by William Trotter; in Royal Agricultural Society's Journal, vol. xii. p. 198.

Waste Lands.

We are glad, therefore, to be able to direct the attention of the owners of live stock to a safer and better one. Five years ago, at the urgent recommendation of a friend, we obtained a copy of Gunther's *Manual of Homœopathic Veterinary Medicine*, and a supply of the medicines there prescribed. Ever since doing so, we have relied upon this system alone, in treating such cases of disease as have occurred amongst our live stock. These have been both numerous and varied, including not a few of pleuro-pneumonia in cattle; and the success has exceeded our most sanguine expectations. We shall not attempt to discuss the merits of a system of medicine, which is at present so keenly controverted by members of the medical profession. We have simply to state, that we have had ample proof in our personal experience of the power of minute (but appreciable) doses of a variety of medicines, *when administered on the principle, that "like cures like,"* to arrest and cure disease in the lower animals; and we earnestly recommend to veterinary surgeons, and to the owners of live stock, to give this system a full and impartial trial.

## CHAPTER XIII.

### WASTE LANDS.

Notwithstanding the great progress which agriculture has made, and the immense amount of capital, energy, and skill, which for generations have been brought to bear upon the improvement of our soil, there are still large portions of the surface of our country lying in their natural state, and usually classed under the head of *Waste lands*, in contradistinction to those which are under tillage, or have at some time been subjected to the plough. Of this (so called) waste land, but a limited portion is absolutely unproductive. Much of it is capable of being converted into arable land, and doubtless will in course of time be so dealt with, but, in the mean time, this class of waste lands, and very much more that will never be tilled, is of great and steadily increasing value as sheep walks. Even for this purpose most of it is susceptible of great improvement, and would well repay for it. These lands are comprised under the following descriptions; 1*st*, Those hilly and mountainous parts of Great Britain which, from their steep and rugged surface and ungenial climate, are unfit for tillage; 2*d*, Those which lie uncultivated owing to natural poverty of soil, its wetness, or the degree to which it is encumbered with stones; 3*d*, Bogs and mosses; 4*th*, Lands so near the sea-level as to be more or less liable to be submerged; and 5*th*, Blowing sands.

High lying sheep pastures.

The lands referred to under the first of these heads are of very great extent, embracing the whole of the mountainous parts of Scotland and Wales, and much of the high grounds in the north of England and south of Scotland. These high grounds afford pasturage for innumerable flocks of sheep of our valuable mountain breeds. The business of sheep-farming has received a great stimulus of late years from the ever-growing demand for sheep to consume the green crops of arable districts. These upland sheep-walks are accordingly rising in value, and their improvement is becoming every day of increasing importance. The improvement of these hill grazings embraces these leading features, viz. drainage, shelter, and enclosure.

Drainage.

Until of late years our hill flocks were peculiarly liable to rot and other diseases arising from the presence of stagnant and flood water upon their pastures. Many grazings that had at one time an evil reputation on this account now yield sound and healthy sheep, solely from the care with which they have been drained. To guard against the pernicious effects of flooding, the courses of brooks and runnels which in heavy rains overflow their grassy margins, are straightened, deepened, and widened, to such an extent as is required to carry off all flood water without allowing it to overflow. Some grounds are naturally so dry, that this is all that is required to render them safe. But, in general, the slopes and hollows of hilly grounds abound with springs, and deposits of peat, and with flats on which water stagnates after rain. On well-managed grounds such places are covered with a network of open drains or shallow ditches, about 30 inches wide at top, and half as many deep, by which superfluous water is rapidly carried off. The cutting of these drains cost from 6s. to 8s. per 100 roods (of six yards each). In pastoral districts there are labourers who are skilled in this kind of work, and to whom the laying out of the lines is frequently entrusted, as well as the execution of the work. Where the ground slopes considerably, they are careful to avoid a run directly down the declivity, as a strong current of water in such circumstances gutters the bottom of the drain, and chokes those below with the debris thus produced. In cutting these drains, two men work together. After ripping the turf on either side at the proper width, one man, by means of a large triangular spade, nearly of the same width and depth as the drain, and having a cross handle to the shaft, which he grasps with both hands, cuts out, sod after sod, by first striking it down to the full depth, and then using it as a lever, while his assistant pulls out the pieces by striking a dung-drag into them, and deposits them in a regular row, green side uppermost, along one side of the drain. The bottom is afterwards cut even and shovelled out. When such drains have been properly made, it is necessary to have them statedly overhauled and kept in good order.

Shelter.

Next in importance to drainage is good and sufficient shelter. This, in the absence of natural coppices of birch or hazel, is provided by means of clumps and belts of fir plantation. These should always be of such extent that the trees may shelter each other as well as the sheep. Trees planted in a mass always shoot up faster than in narrow strips, and restrain the snow-drift which passes through the latter. A shepherd who knows the ground well should always be consulted about the sites of such plantations. The conditions requisite are, that the soil be such as trees will grow in; that it be so far removed from any brook, ravine, or bog, as to be accessible to the flock from all sides; that there be rough herbage, such as heather, gorse, or rushes near at hand, which the sheep may be able to get at in deep snow; that it be contiguous to the sheep-walk; and placed so as to afford defence against the most prevalent winds. A less costly shelter is formed by building what are called *stells*, which consist of a simple dry-stone wall, enclosing a circular space, twenty yards or so in diameter, with an opening on one side; or forming a cross, in one angle of which the sheep find shelter from whatever point the wind blows. A haystack is a necessary adjunct to such defences.

Enclosure by march fences.

It is a further point of importance to have such grazings surrounded with a ring fence, consisting either of dry-stone walls, turf walls with wire a-top, or a simple wire fence. This prevents trespass; and the sheep having freedom to range, without watching, up to the boundary, more of them can be kept on the ground than when they are ever and anon turned back by the shepherd. These needful and inexpensive improvements are now generally attended to over the wide pastoral districts of the Scottish border counties. In the remote Highlands they are still much neglected. There are few agricultural improvements which yield so quick and certain a return as these.

Reclaiming of muiry soil.

The improvement of the second class of these unreclaimed lands is now much facilitated by the readiness with which portable manures can be obtained for them. Draining and enclosing here necessarily demand the first attention. In some cases the land is so encumbered with stones,

Waste Lands.

that careful trenching of the whole surface is the only way of getting rid of them. In Aberdeenshire, many thousands of acres, formerly useless, have been converted into valuable arable land by this means.

In nearly all parts of the country, there are extensive tracts of this muiry soil producing only a scanty and coarse herbage, which are susceptible of remunerative improvement. We are happy at being able to submit to the reader the following detailed account of a recent and successful instance of this, which has been kindly furnished to us by George A. Grey, Esq. of Millfield Hill, Northumberland.

THE RESULT OF PARING AND BURNING MOORLANDS.

Paring and burning.

"It is said that 'necessity is the mother of invention.' I was told by some of my friends that I had given too high a price for this estate, and that it would be a dearer farm to me now than when I rented it from Lord Grey. To overcome this opinion or fact, I thought of several plans of making it more remunerative, and decided on that which I am now about to describe,—

"On the high part of the farm, at an elevation of from 400 to 500 feet above the sea, I had upwards of 100 acres of moorland of a poor description, which had never been under plough. This consisted of short heath, bilberry bushes, and dry white bent grass, and a soft dry deep moss, delightful as a Turkey carpet under foot, and excellent excursive ground for old hunters, with a small portion of spratty grass and rushes in the damp hollows. The soil is of a free turnip and barley loam on the rotten whinstone. By planting on the west side, and in some places suitable for shelter, I reduced the quantity to about 100 acres. This I divided into three fields of about 33 acres each.

"My great dread was the length of time which such a rough dry surface would require to decompose sufficiently to allow of cultivation, having seen heathery moors in many parts of Scotland lying for two, three, and four years before crops could be obtained, owing to the great cover of coarse vegetation preventing the furrow from lying over, and keeping the land so open and dry through summer that if a *braird* of corn or green crop was obtained, it would wither away in dry weather.

"I had heard of paring and burning, but knew nothing of the process. I, however, obtained the necessary information very much from Mr Langlands of Bewick, who had practised it to a considerable extent. With what I saw there I was so much pleased, that I determined to proceed at once.

"I also saw Mr Langlands' work done by a paring-plough, such as is used in the south of England, with a wide plate to cut a furrow of 10 or 12 inches in width. On the point of this is an upright piece of steel which cuts and divides the heath,—the mould-board turns the furrow over flat on its back, and from end to end of the landing the furrows lay side by side like planks from a saw-mill, and were about half an inch in thickness.

"I must, however, remark, as a caution to others against falling into the same error as I did, that this land had been in tillage at some former time, and was in ridges with a regular surface, so that when the plough was *set*, it cut the whole furrow at a uniform depth, and was drawn by two horses with ease, and at an expense of about eight shillings per acre.

"I got this plough and gave it a fair trial, but from my land never having been laid smooth, it cut one part as thin as was wished, and the next yard, perhaps, six or twelve inches thick, which caused a great extra expense in drying, lifting, and burning, and wasted more soil than was necessary or desirable. Also my land having a great deal of small whinstone below the turf, the steel plate frequently got injured and broken. It was therefore with great reluctance laid aside, and the ordinary method of paring by hand adopted, which is slower and much more expensive, but very perfect. It saves soil, and cheapens the burning operation, the paring being so thin when the heath, &c. was divided, that light could be seen through the sod, which was only held together by the roots and fibres.

Waste Lands.

"I began to No. 1 field in July 1849. I let the paring and burning to a company at 25s. per acre, but they made low wages, and after getting more than their work came to, gave up the job. I then got some experienced hands to pare, and paid them the usual wages at that time, 9s. per week, and gave them their food, say 13s. per week, the work being very hard. The total cost of this averaged me 24s. 9d. per acre. A portion of the top part of No. 1 was left undone owing to the lateness of the season. This was dry benty turf. It was ploughed in the common way and grew no oats in 1850. It was again ploughed and much harrowed and rolled, and sown with the remainder of the field in 1851 with rape, and has grown only a few plants at wide distances. It is still in such a dry undecomposed state, that although it is on the high part of the field where sheep draw to lie, I do not expect that it will grow a crop of corn next year; while a portion which was pared down the middle of it grew good corn and rape.

"A portion of No. 2 field was also ploughed in the ordinary way. This was moist land, growing shorter and sweeter grass than any other. It grew a very thin irregular crop of oats in 1850, not within four bolls per acre of the pared land, but is now (1851) bearing a good crop of oats, that field being a second time in oat crop. To return:

"I had a fair crop of rape in the autumn of 1849 on a considerable portion of No. 1, where it was sown in tolerable season during all August, after that it appeared to be too late. All was, however, ploughed up at once to secure the ashes, and was well harrowed and sown with oats in the spring of 1850. The pared land turned out to be much too thickly sown at four bushels per acre. Corn tillers so much on such land, that in some parts it prevented it from coming to maturity. I have since sown much thinner, say three bushels per acre, and even in some degree I find the same fault, there being from five to eight stems from one root. My crop of 1850 turned out to be 30 bushels per acre, but it was on the point of being cut when the high wind in August devastated this district, and that lying high and fully exposed to the wind, suffered most severely. I should say it was not below six quarters per acre, and the quality of the grain good.

"In June and July 1850, I pared No. 3 by the same hands who finished my work the previous year. I let the burning of it to an Irishman at 2s. 6d. per acre, binding him to burn it closely piled up in good-sized heaps like hay-cocks to prevent the escape of the ashes in the shape of smoke into the atmosphere.

"This, with the paring, cost me on 36 acres 19s. 6d. per acre. I got 20 acres of it ploughed and sown with white turnips, broadcast in July and August. I had a close nice crop, though the roots were small, which kept a large flock of sheep for several weeks. This had the good effect of treading down the land and making it plough up better for oats.

"Nos. 1 and 2 were limed at the rate of 7 loads per acre. In June 1851, No. 1 was sown broadcast with rape, by mixing 4 lb. of rape-seed with one bushel of oat shellings for an acre, and sowing them out of a grass-seed machine. The crop is very close and fine, and has kept twenty scores of sheep from an early day in August to this date (September 27th).

"No. 2 in 1851 was again sown with oats, which are a very fine crop, as is also No. 3. My men think them nine quarters per acre. They are very thick and tall, and have very long

Waste Lands.

large heads; and the grain is plump and good, the stalks being strong, the crop is not lodged so as to injure the yield. I estimate it at certainly 7½ quarters per acre, but shall calculate it at 6 quarters.

"I sow on that land the sandy oat, being early, not liable to lodge nor to shake in moderately high winds, although it was not proof against that of 1850.

"Previously to breaking up, I drained with pipes all the land which required drying, of which I shall give a statement, along with the expenses and profits of the whole.

"The result shows, that if I had some years ago, when prices of grain were good, done as *a tenant* what I have done now, I should have been amply repaid by the first or second crops, and have had my farm for the remainder of a twenty-one years' lease worth fully L.100 a-year more than when I began.

"The result of my experience is, that I neither agree with the generality of Scotchmen nor with many Southerns; the former of whom are of opinion that burning wastes the vegetable matter, which should be kept to decompose and enrich the soil, not considering that at once the land receives a rich dressing of ashes quite equal to two quarters of bones, or 4 or 5 cwt. of the best guano; and that, during the several years which such a slow process would require to take place, the land might be much more enriched by growing, and having eaten upon it fine crops of rape and turnip, and by producing heavy corn crops which would in a much shorter space be returned to it in the shape of manure, and also that, by the process of burning, the land is freed from the larvæ of insects, such as grubs, slugs, wireworms, &c. &c., which are engendered among the rough grass, and fostered for a length of time under the rough, dry, undecomposed turf. To say nothing of the length of time which the speculator is kept out of a large amount of capital and interest, instead of having the former returned with the latter after the first or at most the second year.

"And the latter of whom (the Englishmen) are too much in the habit of repeating the operation of burning, even after the land has lain in grass only for a few years, when it might as well be ploughed and cultivated without such expense, thereby unnecessarily reducing the soil, there not being the same difficulties to be overcome, nor the same advantage to be gained from it.

"I should certainly burn all land with a rough harsh surface, and should as certainly plough and sow all land with a sweet grassy face upon it.

"In my opinion there are few farms in this country which do not contain certain portions of land capable of remunerative improvement, and I have shown that such improvement is quite within the scope of a tenant with a lease, without which no man can farm well, at least in the Northumbrian system. Would it not be better, then, for landlords, tenants, and the country generally, were tenants to employ labourers on works so speedily remunerative to themselves, rather than run to their landlord whenever they feel the screw, and ask for abatement of rent, or to be allowed to plough out some piece of valuable old grass, or otherwise cross crop their land with a view of obtaining some temporary advantage, but in the end to the inevitable injury of all concerned?

"*P.S.*—I have not charged for spreading the lime, but charged all the carting as if it had been hired, whereas most of it was carted by my own carts, which carry much larger loads than hired carts, and the difference will more than outbalance the cost of laying on.

"I credit the land with the straw, as the dung will not be returned to that land, it being sufficiently rich with the ashes and lime, &c., to grow turnips and rape crops without manure, and those being eaten on, will make it almost too rich for corn crops.

"Any further information I shall be glad to give to the best of my power. (Signed) "G. A. Grey.

"*Millfield Hill, Dec.* 1. 1851."

Bogs.

The reclamation of extensive bogs, or deposits of peat, is a more arduous undertaking, requiring a considerable expenditure of capital and longer time before a return is obtained from it. The extent of land of this description in Great Britain and Ireland is very great. Very exaggerated statements of the profits to be derived from its improvement have often been published, and not a few persons have incurred serious loss by rashly undertaking this kind of work. On the other hand, when bogs are favourably situated with reference to a command of marl or other calcareous matter to assist in their decomposition and consolidation, and of manure to enrich them, their reclamation has proved a very profitable speculation. The well-known instance of Chat Moss in Lancashire affords so interesting an example of this that we shall here quote from a recent description of it.

Chat Moss.

"Chat Moss, well known as that black barren swamp between Liverpool and Manchester, contains 6000 acres, one-half of which is in the township of Barton, and the remainder in the townships of Bedford, Astley, and Worsley.

"The principal part of this moss which lies in Barton township, belongs to the Trafford family, and is entailed, but the ancestor of the present Sir Thomas de Trafford, appears to have obtained, at the latter end of the last century, an Act of Parliament to grant a ninety-nine years' lease of 2500 acres to a Mr Wakefield, who about the year 1805 disposed of his interest in it to the late William Roscoe of literary celebrity, who spent a large sum in a fruitless endeavour to improve it, failing in which, the lease was sold in 1821 to other parties. J. A. Brown, Esq. of Woolden Hall, brought 1300 acres; the late Edward Baines, M.P. for Leeds, purchased the remaining 1200 acres. The most extensive and successful efforts at improving this moss, have been made on a part of the 1200 acres bought by Mr Baines, who, besides occupying the part operated upon by Mr Roscoe, improved a considerable breadth himself, and let several portions to other parties, who have made considerable progress in improving small portions. The most extensive operations, however, upon the whole, have been carried out by a company to whom Mr Baines, in 1828, granted a lease of 550 acres for 68 years, the remainder of the original term, at a nominal rent for the first year, increasing gradually, till at the end of five years the rent attained its maximum of L.165 per annum, for the 550 acres. This company which was formed at the time the Liverpool and Manchester Railway was in progress of being made on the property, consisted, amongst others, of some practical farmers, and originated with William Reed, who for the three first years was the manager, and resided on this farm, which they called Barton Moss farm. During that period I had the pleasure of paying my friend Reed a visit, and of witnessing the skill and success attending his enterprise and various experiments.

"Travelling by the railway from Liverpool towards Manchester the Barton Moss farm is on the right hand, excepting a narrow strip of about six acres which is on the left, and abuts on the line for a quarter of a mile on each side of the Barton Moss station, which is seven miles from Manchester. The long narrow belts of fir and other trees and the quick-thorn hedges which run north and south, give it an appearance that would lead a casual observer to suppose that it was sound land, or at least that the moss was not so deep under it, as on the other

Waste Lands.

parts over which the railway passes; its depth, however, is the same, and an iron rod may be thrust down by the hand to the depth of eighteen feet in almost any part of it.

"The first operation, that of draining, had been effected by opening side drains at intervals of fifty yards, into which were laid covered ones six yards apart, at right angles with, and emptying into the open side drains.

"The moss being in a semifluid state, it was necessary to proceed slowly with draining, taking out only one graft or depth at a time, allowing it to remain a week or a month, according to the state of the weather, before taking out the second graft; this admitted of the sides becoming consolidated, and of the second graft being taken out without the moss closing in. It was again allowed to remain as before, till sufficiently dry to admit of the third being removed.

"The open drains were made 3 feet wide and 3 feet 6 inches deep, and the covered drains 16 inches wide and 3 feet deep; the last graft of the latter being only about 6 inches wide at the top, tapering to 4 inches at the bottom, and being taken out of the middle of the cut, left a shoulder on each side. The sod or graft first taken out had by this time become tough and dry, and was placed with the heath side downwards in the shoulder, thus leaving the narrow spit at the bottom open for a depth of about 14 inches; the other square sod being put on the top completed the drain.

"The cost of this mode of draining, including the side drains, was about 38s. per acre. The drains first put in required to be renewed in a few years, in consequence of the moss becoming so much consolidated and reduced in height that the plough, as well as the horses' feet, broke through the roof, although the horses were shod with "pattens" or boards of about 10 inches square, with the angles taken off. The second draining, however, was more permanent, and would probably not have required renewing for many years, but for the moles, which have been very troublesome in working down to the drains, and filling them up in various places; so that the operation of draining has required to be partially renewed in every field, and in many of them entirely so; and thus, these little animals have been the cause of a very considerable increase in the cost of labour. It has subsequently been found advisable to put the under drains in at 4 yards, instead of 6 yards asunder, and the advantage in one crop has been quite sufficient to pay the extra cost. A two-horse engine was erected, which drives the thrashing machine, straw cutter, and crushing mill; and the escape-steam from it steams the horses' food.

"The buildings were erected principally of timber, covered with asphalted felt.

"After draining, making roads, and burning off the heath plant, the land was scarified lengthwise of the fields, by an implement, with knives shaped like coulters, reversed, sharp on the convex side, fixed in two bars, and drawn by three horses yoked abreast.

"The tough surface was by this means cut at every four inches; the land was then ploughed across the scarifying; a roller, surrounded with knives, was next passed across the ploughing; after this the land was well harrowed till sufficiently reduced.

"The next operation was that of marling, for which purpose a railway was constructed, at the joint expense of Mr Baines and the company, from the river Irwell on the south, running through a bed of marl, and through Mr Baines' farm, as well as the Barton Moss farm, to the Liverpool and Manchester railway, with which it is connected at the Barton Moss station. The length of this railway is about a mile and three quarters; it affords the opportunity of getting manure from Manchester, either by the river or by the railway, as well as the supply of marl or gravel. Further, to facilitate their operations, the company constructed also a *moveable* railway, to be laid down along the cross roads and on the fields, upon which about a cubic yard of marl was taken on each waggon, directed to the very spot where it was wanted: thus the marling could be proceeded with in all weathers, and much more rapidly than perhaps such work ever was done before, or could now be done, except by similar means.

"The iron for the rails was rolled expressly for the purpose, and weighed 14 lb. per yard. It was fitted longitudinally on the apex of a triangular wooden sleeper.

Waste Lands.

"The permanent way cost L.520 per mile, and the moveable one L.280. The latter was in twelve feet lengths, and the pair of rails, with the sleepers and cross ties, weighed 1 cwt. 3 qrs. It was shifted from place to place on the land by two men at a cost of 2s. 6d. per acre.

"From 60 to 100 cubic yards of marl were put on an acre, and in the following summer the land was manured, also by means of the moveable railway, at the rate of fifty tons of black Manchester manure per acre, and planted with potatoes, which were followed by wheat, sown with red clover and rye-grass, for mowing for one or two years; then oats and potatoes, &c. as before. These were all flourishing crops, the wheat in particular looked bright and beautiful. The potatoes were sold for L.25 and L.30 per acre, which more than paid the whole cost of improvement. Mr John Bell, resident bailiff, has made many valuable experiments relative to the improvement of raw moss, one of which has resulted in a discovery likely to be of considerable importance, which is, that a mixture of lime and salt applied a while before seeding, with the addition of a good dressing of guano, in the proportion of four tons of lime and five cwt. of salt per acre, qualifies it to produce a crop of potatoes or oats equal to that after the application of 60 yards of marl per acre. It is essential that the mixture should be spread while it is hot. Mr Evans (one of the proprietors) is convinced that the peat on the surface ought never to be burned; he has always found that, when the heath sod is turned down to decay, much better crops have been obtained than when it has been burnt off, or than when the top has been taken away either for fuel or other purposes. What are termed moss-fallows, that is parts which have had the moss taken off for fuel, will never bear so good a crop as the upper surface, however deep the moss may be underneath."—(See *Notes on the Agriculture of Lancashire, with Suggestions for its Improvement*, by Jonathan Binns.)

Blair-Drummond moss.

Nearly a century ago the late Lord Kames, on becoming proprietor of the estate of Blair-Drummond, in the county of Perth, began the improvement of a large tract of worthless moss, by a totally different process from that now detailed. In this case the moss had accumulated upon a good alluvial clay soil. Instead, therefore, of attempting to improve the moss itself, it was floated off piecemeal into the neighbouring Frith of Forth. The supply of water required for this purpose was obtained from the river Teith, from which it was raised to the requisite height by a powerful water wheel. Being conveyed through the moss in channels, successive layers of peat were dug and thrown into these channels, which were shifted as occasion required, until the whole inert mass was removed. A thin stratum next the clay was burnt, and the ashes used as manure. An immense extent of moss has thus been got rid of on that estate, and on others in the neighbourhood, and "an extensive tract of country, where formerly only a few snipes and muirfowl could find subsistence, has been converted, as if by magic, into a rich and fertile carse of alluvial soil, worth from L.3 to L.5 per acre."

Fen lands.

We next notice the fen lands of England. "In popular language, the word *fen* designates all low wet lands, whether peat-bog, river alluvium, or salt marsh; but in the great Bedford level, which, extending itself in Cambridgeshire and five adjoining counties, is the largest tract of fen land in the kingdom, the farmer always distinguishes, and it is thought conveniently and correctly, between fen land and marsh land. By the former they mean land partly alluvial, and formed by river floods, and partly accumulated by the growth of peat. Such lands are almost invariably of a black colour, and contain a great per-centage of carbon. By marsh lands they mean low tracts gained from the sea, either by the gradual silting up of estuaries, or by artificial embankments." Low-lying peat occurs in small patches in nearly every maritime county of Britain, being usually separated from the sea or from estuaries by salt marsh or alluvium. There is a large extent of such land in Somersetshire, yet but partially drained, and a still larger breadth in Lancashire where its

Fen Lands. improvement makes steady progress. In Kent, on the seaboard of Norfolk, on both shores of the Humber, and stretching along the sides of its tributaries, there are immense tracts of this description of land. But these are all exceeded in importance by the "great level of the fens, which occupies the south-eastern quarter of Lincolnshire, the northern half of Cambridgeshire, and spreads also into the counties of Norfolk, Suffolk, Huntingdon, and Northampton. Its length is about 70 miles, its breadth from 3 or 4 to 30 or 40 miles, the whole area being upwards of 1060 square miles, or 680,000 acres. On the map the fens appear like an enlargement of the Wash, and in reality have the aspect of a sea of land, lying between that bay and the high lands in each of the above named counties, which seem to form an irregular coast line around it." This fen country has for centuries been the scene of drainage operations on a stupendous scale. The whole surface of the great basin of the fens is lower than the sea, the level varying from four to sixteen feet below high-water mark in the German Ocean. The difficulty of draining this flat tract is increased, from the circumstance that the ground is highest near the shore, and falls inland towards the foot of the slope. These inland and lowest grounds consist of spongy peat, which has a natural tendency to retain water. The rivers and streams which flow from the higher inlands, discharge upon these level grounds, and originally found their way into the broad and shallow estuary of the Wash, obstructed in all directions by bars and shifting sand-banks. These upland waters being now caught at their point of entrance upon the fens, are confined within strong artificial banks, and so guided straight seaward. These waters are thus restrained from flooding the low grounds, and by their concentration and momentum, assist in scouring out the silt from the narrow channel to which they are confined. The tidal waters are at the same time fenced out by sea-banks, which are provided at proper intervals with sluice doors, by which the waters escape at ebb-tide. To show the extent of these operations, it may be mentioned that the whole sea-coast of Lincolnshire, and part of Norfolk, a line of at least 130 miles, consist of marsh lands lower than the tides, and is protected by barrier banks, besides which there are hundreds of miles of river embankments. When this does not provide such a drainage as to admit of cultivation, the water is lifted mechanically by wind or steam mills into the main aqueducts. The number of windmills formerly at work on the whole of the fens between Lincoln and Cambridge, probably exceeded 700; at present there are about fifty mills in the Lincolnshire part of the level, and perhaps 170 in the Bedford level and adjacent fens, or a total of 220. The number of steam-engines may be estimated at sixty. They lift the water (almost universally by scoop-wheels, not pump) from six to sixteen or twenty feet, and the area of land thus drained may be computed at not less than 222,000 acres.

Great level of the fens.

Use of the steam-engine in draining the fens.

The first use of steam-engines for the purpose of draining was in Deeping fen, where, in 1824-5, two, of eighty and sixty horse-power respectively, were erected. By means of these two engines upwards of 20,000 acres have now a good drainage, whereas formerly, forty-four wind-mills, with an aggregate power of 400 horses, failed to keep them sufficiently dry. The scoop-wheel of the larger engine is twenty-eight feet in diameter, and the float-boards are five feet wide. It was intended to have a "dip" of five feet, but the land has subsided so much in consequence of the draining that it seldom has a dip of more than two feet nine inches. The water is lifted on an average seven feet high. When both engines are at work they raise 300 tons weight of water per minute.

The soil of the fens consists for the most part of dark coloured peat, from one to eight or ten feet in depth. The surface in general is not pure peat, but is mixed with silt or other soil. Under this there is in general a stratum of brown spongy peat, which sometimes rests upon gravel, but for the most part upon clay, which usually contains a portion of calcareous matter. The removal of the water has, of course, been the primary improvement; but subsidiary to this, the rapid amelioration and great fertility of the fen lands is largely due to this fortunate conjunction of clay and peat. The early practice of the fen farmers was to pare and burn the surface, grow repeated crops of rape, oats, wheat, &c., and burn again. The subsidence of the soil, subsequent to the draining and repeated paring and burning, brought the surface nearer to the subjacent clay, which the cultivators by and by, began to dig up and spread over the surface. This practice is now universal, and its continued use, together with careful cultivation and liberal manuring, has changed a not very productive peat into one of the most fertile soils in the kingdom. Nowhere in our country has the industry and skill of man effected greater changes than in the fens. What was once a dismal morass, presenting to the view in summer a wilderness of reeds, sedges, and pools of water, among which the cattle waded, and in winter almost an unbroken expanse of water, is now a fertile corn land. The fen men, who formerly lived upon the adjacent high lands, and occupied themselves with fishing, fowling, and attending to their cattle, have now erected homesteads upon the fen lands, divided them by thorn hedges, and brought them into the highest state of cultivation.

Marsh Lands.

Claying fen lands.

Marsh lands.

We referred at the outset to the distinction betwixt *fen* land and *marsh* land. In the district called Marsh land in Norfolk, extending between the Ouse and the Nen; in that called South Holland, in Lincolnshire, stretching between the Nen and the Welland; northward of Spalding, and also north-east of Boston, there is a considerable tract of marine clay soil. In Marsh land this is chiefly arable-land, producing large crops of wheat and beans; but in Lincolnshire it forms exceedingly fine grazing land. This tract lies within the old Roman embankment, by which the district was first defended from the ocean. Outside this barrier are the proper marsh lands, which have been reclaimed in portions at successive periods, and are still intersected in all directions by ranges of banks. The extraordinary feature of this tract is, that the surface outside the Roman bank is three or four feet higher than that in the inside, and the level of each new enclosure is more elevated than the previous one. The land rises step by step, as the coast is approached, so that the most recently reclaimed land is often twelve or even eighteen feet higher than the lowest fen land in the interior, the drainage from which must nevertheless be conveyed through these more elevated marshes to the sea.

Schemes for reclaiming more land from the sea.

The extent of this kind of land already rescued from the sea is very great, and is constantly augmenting. The whole Wash may, in fact, be regarded as a broad expanse of marsh in course of formation. A considerable portion of it is already so much raised as to be left bare at low water. The "Norfolk Estuary Scheme," now in progress, contemplates the enclosure of a large tract of these sands, and the "Victoria Level," if ever executed, will confine the waters to a channel four miles wide, running down the centre of the Wash, and add 150,000 acres to our territory. This would not be all, for if these works are accomplished, they will lower the water in all the fen rivers, and afford a natural drainage to the whole of the great level.

Warping.

Lands, such as some of those which we have just been describing, are often greatly improved, or rather may be said to be *made* by means of a peculiar mode of irrigation, called "warping." It is practicable only in the case of land lying below the level of high tide in muddy rivers. It is

Marsh Lands.

little more than a century since it was first practised in England, the first instance of it being near Howden, on the banks of the Humber. But although the practice is comparatively new in Britain, it has long been in use on the Continent of Europe, particularly in Italy, and is thus described by Mr Cadell:—"In the Val de Chiana, fields that are too low are raised and fertilised by the process called *colmata*, which is done in the following manner:—The field is surrounded by an embankment to confine the water. The dike of the rivulet is broken down so as to admit the muddy water of the high floods. The Chiana itself is too powerful a body of water to be used for this purpose; it is only the streams that flow into the Chiana that are thus used. This water is allowed to settle and deposit its mud upon the field. The water is then let off into the river at the lower end of the field, by a discharging course called *scolo*, and in French *canal d'ecoulement*. The water-course which conducts the water from a river, either to a field for irrigation or to a mill, is called *yora*. In this manner a field will be raised 5½ and sometimes 7½ feet in ten years. If the dike is broken down to the bottom, the field will be raised to the same height in seven years; but then in this case, gravel is also carried in along with the mud. In a field of 25 acres, which had been six years under the process of *colmata*, in which the dike was broken down to within 3 feet of the bottom, the process was seen to be so far advanced, that only another year was requisite for its completion. The floods, in this instance, had been much charged with soil. The water which comes off cultivated land completes the process sooner than that which comes off hill and woodland. Almost the whole of the Val di Chiana has been raised by the process of *colmata*."[1]

This process of warping is now systematically practised on lands adjoining the Humber and its tributaries, and by means of it vast tracts of sterile, sandy, and peaty soils are yearly converted into arable land of the very best quality. The warping of such lands has this farther advantage, that it raises their level, and thus admits of their more perfect drainage. The operation is conducted thus:—

"The first step in the process is to erect a sluice on the bank of the Trent, or other tidal channel, and cut a main drain to the fields which are to be flooded. The sluice-doors point outwards, so as to exclude the tides, except when held open by rods and staples provided for the purpose, and the drain ought to have an area equal to three times that of the sluice, in order to prevent any considerable resistance to the flow of water. The land is then surrounded by an embankment of variable altitude, according to the level of the surface, and from two to three feet wide at the top, the usual slope of the banks being from 15 to 18 inches on each side for every 12 inches perpendicular rise. The tide flows rapidly in, and meeting with no obstruction to detain its current, holds in suspension the particles of sediment with which it is loaded; but directly it leaves the narrow channel, and spreads itself over the broad surface, the rapidity of motion is lost, and the atoms of warp, no longer projected forward, sink quietly to the bottom. A deposit is thus formed greatest near the mouth of the drain, and in order to equalize the amount of warp over the whole ground, the water is conducted to different parts of the compartments by smaller drains called 'inlets.' When the deposit is raised sufficiently high next to the end of these channels, the current is carried forward by extending the banks of the inlets in different directions, and thus, by a skilful and careful guiding of the water, the whole of the land is warped to an equal height. The water is conducted by a temporary drain, first to the further side of the plot, and, when the deposit there is sufficiently high, is allowed to escape at intervals along the side of this drain until the whole area is equally raised. The tide having thrown down much of its mud, returns by the warping-drain into the river, scouring out the sediment which might have accumulated in the drain." . . . . "Generally speaking, the spring-tides only are used, as they have sufficient volume of back-water to keep the warping-drains clear and open. The land is raised from one to three feet in one or two years." . . . . . "The expense of warping is very variable: Where the cost of the large drains and other works is included, the calculation would probably be L.12 to L.20 per acre; but on lands contiguous to the public warping-drains the expense of flooding is only about L.2, 2s. Within the last thirty years all the peat-lands within three miles of the Trent (in the isle of Axholme) have been warped, the drainage greatly improved, and the soil, from being almost worthless, made worth from L.60 to L.100 per acre." Taking both sides of Trent, about 16,000 acres have, since the year 1800, been covered with the richest soil to an average depth of two feet, and the process is still extending. (See *Prize Report on the Farming of Lincolnshire*, by John Algernon Clarke, in vol. xii. of *Royal Agricultural Society's Journal*, from which, and from article on "Fen Lands," by the same gentleman, in *Morton's Cyclopædia of Agriculture*, the foregoing information has been gleaned or quoted).

Blowing sands.

On many parts of our sea-coasts, and especially in the Hebrides, there occur extensive tracts of blowing sands, which are naturally not only sterile themselves, but a source of danger to better lands adjoining them, which in some instances have been quite ruined by the sand deposited upon them by the winds. This mischief is effectually prevented, by a process beautifully simple and useful, namely, planting the sand-banks with sea bent-grass (*Arundo arenaria*), the matting fibres and stems of which not only bind the sand, but clothe it with a herbage which is relished by cattle, and which being able to resist the severest winter weather, furnishes a valuable winter forage in those bleak situations. This bent-grass can be propagated by seed, but in exposed situations it is found better to transplant it. This operation is performed betwixt October and March, as it succeeds best when the sand is moist, and evaporation slow.

Use of sea bent-grass in fixing sand.

## CHAPTER XIV.

### GENERAL OBSERVATIONS.

General Observations.

According to the method proposed at the outset, we now offer a few observations on several topics connected with our subject.

*Of the Tenure of Land.*—The extent of land in Great Britain occupied by its owners for agricultural purposes bears a very small proportion to the whole area. The yeoman class is still numerous in several parts of England, but must have diminished greatly from that continuous amalgamation of small estates into large ones which has formed a marked feature in our social history for the past 50 years. This change, although to be regretted on public grounds, has had a favourable influence on the cultivation of the soil, for it almost invariably happens, that a larger produce is obtained from land when it is occupied by a tenant than when it is cultivated by its proprietor. As a matter of fact, the land of the country is now, with trifling exceptions, let out to professional farmers in quantities varying from the rood-allotment of the village labourer to the square miles of the Highland grazier. Farms of all sizes are usually to be found

Size of farms.

[1] *Journey in Carniola, Italy, and France*, by W. A. Cadell, Esq., F.R.S.

General Observations.

in any district, and most important it is that this should be the case; but the extent of farms is chiefly determined by the amount of hired labour employed upon them, and the measure of personal superintendence on the part of the tenant which the kind of husbandry pursued upon them calls for. We accordingly find that in very fertile tracts, in the vicinity of towns, and in dairy districts, they seldom exceed 200 acres; where the ordinary alternate husbandry is practised, the average ranges from 300 to 400. In more elevated tracts, where a portion of natural sheep-walk is occupied along with arable land, it rises to 800 or 1000; while that of the sheep-grazings of our hills and mountains is limited only by the capital of the tenant. About a century ago there occurred, in various parts of Great Britain, a similar amalgamation of small holdings into farms of the sizes which we have now referred to, as is at present in progress in Ireland. This enlargement of farms, and the employment of increased capital in their cultivation, insures a more rapid reclamation of waste lands, and general progress of agriculture up to a certain point, than would otherwise take place. But as every step in advance beyond this point implies an increase of acreable outlay, and the need for closer superintendence, it seems likely that, in future, the size of arable farms will not further increase, but may rather be expected to approximate to that which at present obtains in suburban districts.

Farms are held either by yearly tenancy, or under leases for a specified number of years. The latter plan is that upon which nearly the whole lands of Scotland are let; and it obtains also to a considerable extent in the northern counties of England, in West Norfolk, and in Lancashire. But with these and other exceptions, amounting altogether to about a tenth part, the farms of England are held by yearly tenancy, which can be terminated by either of the contracting parties giving to the other a six-months' notice to that effect. This precarious tenure has been attended by far fewer changes than a stranger could suppose, owing to the highly honourable conduct for which English proprietors as a class have long been noted. On all the large estates it is quite common to find families occupying farms of which their ancestors for generations, or even centuries, have been tenants. The mutual esteem and confidence which usually subsists betwixt such landlords and tenants is undoubtedly much to the credit of both, but not the less has the system, as a whole, operated unfavourably for all concerned; for however numerous and striking the exceptions, it is yet the fact that under this system of tenancy-at-will, less capital has been invested in the improvement of farms, less labour has been employed, and less enterprise displayed in their ordinary cultivation, less produce has been obtained from them by the occupiers, and less rents have been received for them by the owners, than in the case of similar lands when let on leases for a term of years. These diverse results ensue, not because tenants with leases are abler men or better farmers than their neighbours who are without them, but solely because the one system recognises certain important principles which the other ignores. It is contrary to human nature to expect that any body of men will as freely invest their capital, whether in the shape of money, skill or labour, in a business yielding such slow returns as agriculture, with no better guarantee than the continued good-will of existing proprietors, or those who any day may succeed them, that they or their families shall reap the fruits of it, as they will do with the security which a lease for a term of years affords. It does, therefore, seem strange that a majority of the farmers of Great Britain should be tenants at will, and still more strange that they should be so of choice. It is nevertheless true, that a considerable portion of the tenantry of England are even less disposed to accept of leases than their landlords are to grant them. The latter cling to the system because of the greater control which they thereby retain over their estates, and the greater political influence with which it invests them; the former do so because low rents are one of its accompaniments. Since the removal of restrictions on the importation of foreign agricultural produce, there are indications that neither landlords nor tenants are so well satisfied with this system of tenancy-at-will as they once were. Not only is the granting of leases becoming more common than it has hitherto been, but there is a growing desire on the part of tenants to obtain the benefit of that guarantee for the realising of their capital which *tenant-right* affords to enterprising farmers who may have unexpectedly to quit their farms. In certain districts of England this claim, called *tenant-right*, has been recognised so long, that apart either from written stipulation or statutory enactment, it has, by mere usage, attained to something like a legal standing. In Lincolnshire, an away-going tenant can, by virtue of this usage, claim from his landlord or successor repayment, in certain definite proportions, of the cost of such ameliorations of a specified kind as he may have made during the last years of his occupancy, and the benefits of which his removal hinders him from realising in the natural way.

Tenancy-at-will.

Tenant-right.

Benefit of leases.

Tenant-right is certainly a valuable adjunct to tenancy-at-will, but still it does not meet the real exigencies of the case. There are feelings inherent in man's nature which cause him to recoil from exertions the fruits of which are as likely to be enjoyed by a stranger as by himself or his family. This repugnance, and its paralysing influence, is not to be removed by a mere "right" to pecuniary compensation. It is certainty of tenure—so far at least as human arrangements can be certain—which will really induce a farmer to throw his whole heart into his business. It is accordingly to this principle, that leases owe their excellence, and by it also that the only weak point in them is to be accounted for. The first years of a lease are usually characterised by an energetic performance of various improvements, whereas, towards its close, there is usually such a withdrawing even of ordinary outlay, as is unfavourable to the interests of either landlord or tenant. There is at present a very generally entertained opinion that this inconvenience would be obviated by engrafting the system of tenant-right upon that of leases. A proposal to this effect would probably be well entertained by the holders of existing leases; but we believe that it would be anything but popular with in-coming tenants. This view of the matter is confirmed by the experience which we have of the effects of having the straw and dung produced on farms *steel-bow*—that is the property of the landlord, and transferred by him free of charge to entering tenants on condition that they leave them so to their successors. This arrangement is generally admitted to be better for all parties, than when away-going tenants have a "right" to claim payment for these commodities from their successors, or to sell them off the farm if they prefer to do so. Scottish experience is therefore unfavourable to the system of tenant-right, in the only instance of it which obtains there. We know of no practicable remedy for the injurious lowering of the condition of farms at the close of leases, but in the parties renewing their contract in time to prevent it.

Duration of leases.

It seems to be generally admitted, that twenty one years is the proper duration for an agricultural lease. Such a term suffices to give confidence to the tenant in embarking his capital, and secures to the landlord his legitimate control over his property, and due participation in its varying value. It is generally felt by tenants that the lease, or document in which their agreement with their landlord is engrossed, might, with advantage, be much shortened, as well as simplified in its terms. When treating of the succession

General Observations.

of crops, we have already expressed our views regarding those restrictive clauses which usually occupy a prominent place in such writings. Such restrictions are, of course, introduced with the view of guarding the property of the landlord from deterioration. But when he is so unfortunate as to meet in with incompetent or dishonest tenants they entirely fail to secure this object, and yet are a hindrance and discouragement to enterprising and conscientious ones. It is probable that the existence of the law of distraint, or hypothec, which gives to landlords a lien over the effects of their tenantry in security for the payment of the current year's rent, has had its influence in adding to the number and stringency of these clauses, and has encouraged the practice of letting lands by tender to the highest offerer. For the law in question, by rendering landlords to a considerable extent independent of the personal character and pecuniary circumstances of the occupiers of their land, has a direct tendency to render them less cautious who they deal with, than they otherwise would be; and to induce them, when tempted by the promise of high rents, to trust more to this legal security than to the moral character, business habits, professional skill, and pecuniary competency, of candidates for their farms.

Capital required for working a farm.

The amount of capital that is required in order that the business of farming may be conducted advantageously, is largely determined by the nature of the soil, &c., of each farm, the system of management appropriate to it, the price of stock and of labour, and the terms at which its rents are payable. In the case of land of fair quality, on which the alternate husbandry is pursued, and when the rents are payable as the produce is realised, L.5 per acre may be regarded as an amount of capital which will enable a tenant to prosecute his business with advantage and comfort. In letting a farm, a landlord not only does a just and prudent thing for himself, but acts as a true friend to his proposed tenant, when he insists upon being shown that the latter is possessed of available funds to an amount adequate to its probable requirements.

The importance of the topics to which we have thus referred, is happily expressed by Mr Pusey, when, after enumerating various agricultural desiderata, he says, "In some degree none of us carry out all that is in our power; but want of capital, or want of confidence in the tenure of farms are, I suppose, the two principal causes of this omission."

Education of farmers.

But the mere possession of capital does not qualify a man for being a farmer, nor is there any virtue inherent in a lease to insure his success. To these must be added probity, knowledge of his business, and diligence in prosecuting it. These qualifications are the fruits of good *Education* (in the fullest sense of that term), and are no more to be looked for without it than good crops without good husbandry. Common-school instruction will, of course, form the groundwork of a farmer's education; but to this should be added, if possible, a classical curriculum. It has been the fashion to ask, "Of what use are Greek and Latin to a farmer?" Now, apart from the benefit which it is to him, in common with other men, to know the structure of language, and to read with intelligence the literature of his profession which more and more abounds in scientific technicalities, we believe that no better discipline for the youthful mind has yet been devised than the classical course which is in use in our best public schools. Of this discipline we desire that every future farmer should have the advantage. But the great difficulty at present lies in finding appropriate occupation for such youths betwixt their fifteenth and twentieth years. In many cases the sons of farmers are during that period put to farm labour. If they are kept statedly at it, and are made proficient in every kind of work performed on a farm, it is a good professional training as far as it goes. The more common one—at least as regards the sons of the larger class of farmers—which consists of loitering about without any stated occupation, attending fairs and markets, and probably the race-course and hunting-field, is about the most absurd and pernicious that can well be imagined. Such youths are truly to be pitied; for they are neither inured to bodily labour, nor afforded the benefits of a liberal education. It need not surprise any one that such hapless lads often prove incompetent for the struggles of life, and have to yield their places to more vigorous men who have enjoyed the benefit of "bearing the yoke in their youth." Unless young men are kept at labour, either of mind or of body, until continuous exertion during stated hours, confinement to one place, and prompt obedience to their superiors have ceased to be irksome, there is little hope of their either prospering in business, or distinguishing themselves in their profession. Owing to the altered habits of society, there is now less likelihood than heretofore of such young persons as we are referring to being subjected to that arduous training to bodily labour which was once the universal practice; and hence the necessity for an appropriate course of study to take its place. Many Scottish farmers endeavour to supply this want by placing their sons for several years in the chambers of an attorney, estate-agent, or land-surveyor; partly in order that they may acquire a knowledge of accounts, but especially for the sake of the wholesome discipline which is implied in continuous application and subjection to superiors. It is also common for such youths to be sent to Edinburgh for a winter or two to attend the class of our accomplished professor of Agriculture, and perhaps also that of Chemistry and the Veterinary College. This is well enough in its way; but yet there is wanting in it an adequate guarantee that there is real study—the actual performance of daily mental work. The agricultural college at Cirencester appears to come more fully up to our notion of what is needed for the professional training of farmers than any other institution which we yet possess. We shall rejoice to see such opportunities of instruction as it affords multiplied in Great Britain. After enjoying the benefits of such a course of training as we have now indicated, young men would be in circumstances to derive real advantage from a residence with some experienced practical farmer, or from a tour through the best-cultivated districts of the country. We are well aware that what we have now recommended will appear sufficiently absurd to the still numerous class of persons who believe that any one has wit enough to be a farmer. But those who are competent to judge in the case can well afford to smile at such ignorance. They know that agriculture is at once an art, a science, and a business; that the researches of naturalists, chemists, geologists, and mechanicians are daily contributing to the elucidation of its principles and the guidance of its practice; and that while its pursuits afford scope for the acutest minds, they are relished by the most cultivated ones. As a business it shares to the full in the effects of that vehement competition which is experienced in every other branch of industry, and has besides many risks peculiar to itself. The easy routine farming of the olden time is gone for ever; and without a good measure of tact, energy, and industry no man can now obtain a livelihood by it. It were well that all this were better known; for nothing has been more common than for parents who have sons that are too dull for scholars, or too indolent for trade, to put them to farming; or than for persons who have earned a competency in some other calling, to covet the (supposed) easy life of a farmer, and to find it to their sorrow a harassing and ill-requited one.

Farm labourers.

The agriculture of a country must ever be largely affected by the condition and character of the peasantry by whom its labours are performed. An acute observer has recently shown that in England a poor style of farming and low

General Observations.

wages—good farming and high wages usually go together; and that a low rate of wages is significantly associated with a high poor-rate. The worst paid and worst lodged labourers are also the most ignorant, the most prejudiced, the most reckless, and insubordinate. The eminence of Scottish agriculture is undoubtedly largely due to the moral worth and intelligence of her peasantry. For this she is indebted to the early establishment of her parochial schools, and to the sterling quality of the elementary education, based upon the Bible, which the children of her tenantry and peasantry have for generations received in them together. These schools are unfortunately now inadequate to the increased population; but still in the rural districts of the Scottish lowlands it is a rare thing to meet with a farm labourer who cannot both read and write. Apart from higher benefits the facilities which the services of such a class of labourers have afforded for the introduction and development of improved agricultural practices, the use of intricate machinery, and the keeping of accurate accounts cannot well be overrated. It is an interesting testimony to the value of a national system of Christian education that our Scottish peasantry should be in such request in other parts of the kingdom, as bailiffs, gardeners, and overseers. Let us hope that this inestimable blessing will speedily be enjoyed by our entire population.

Evil fruits of the law of settlement.

The pernicious influence of the present law of Settlement and Removal upon the English labourer, is now attracting that attention which it so urgently demands. The proprietors and tenants of particular parishes in various parts of England, at present combine to lessen their own share of the burden of the poor-rate, by pulling down cottages and compelling their labourers to reside out of their bounds. The folly and cruelty of such short-sighted policy cannot be too strongly reprobated. These poor people are thus driven into towns, where their families are crowded into wretched apartments, for which they must pay exorbitant rents, and where they are constantly exposed to moral and physical contamination of every sort. From these comfortless abodes the wearied and dispirited men must trudge in all weathers to the distant scene of their daily labours. One cannot conceive of a prosperous agriculture co-existing with such a system; nor feel any surprise that thieving, incendiarism, and burdensome rates should be its frequent accompaniments. It is pleasant to contrast with this close-parish policy the conduct of some of our English nobility, who are building comfortable cottages and providing good schools for the whole of the labourers upon their princely estates.

What the legislature should do for Agriculture.

The further progress of our national agriculture is undoubtedly to be looked for from the independent exertions of those immediately engaged in it; but important assistance might and ought to be afforded to them by the legislature, chiefly in the way of removing obstructions. What we desiderate in this respect is the repeal, or at least the important modification, of the law of distraint; the commutation of the burdens attaching to copyhold lands; the reformation of the law of settlement; the removal of the risk and costs which at present interfere with the transference of land; the establishment of a really *national* system of Christian education; the endowment of an adequate number of agricultural colleges, with suitable museums, apparatus, and illustrative farms; the authoritative collection and publication of agricultural statistics; and the compulsory adoption of a uniform standard of weights and measures. We desire also to see the *arterial* or *trunk-drainage* of the country undertaken by government. Until this is done, vast tracts of the most fertile land in the kingdom cannot be cultivated with safety and economy, nor attain to the productiveness of which they are capable. Our national interests surely require that its agriculture should be freed from such obstructions as these, and that it should receive the benefit of a fair share of such public provision as is made for training youths for the learned professions, and for the public service; and of such grants as are given in aid of scientific research, for the encouragement of the fine arts, and for the furtherance of manufactures and commerce.

On carefully comparing the present condition of British agriculture with what it was twenty years ago, the change for the better is found to be very great indeed. But on all hands indications are to be found, which warrant the anticipation, that the progress of discovery and improvement in future will be more steady, more rapid, and more general than it has hitherto been. There is not only a wider-spread and more earnest spirit of inquiry; but practical men instead of despising the aids of science, seek more and more to conduct their investigations under its guidance. Experiments are made on an ever-widening scale, and upon well-concerted plans; their results are so recorded and published, that they at once become available to all, and each fresh investigator, instead of wasting his energies in re-discovering what (unknown to him) has been discovered before, now makes his start from a well-ascertained and ever-advancing frontier. Hitherto the knowledge of the husbandman consisted very much of isolated facts, and his procedure often little better than a groping in the dark. As the rationále of his various processes is more clearly discovered, he will be enabled to conduct them with greater economy and precision than he can do at present. A clearer knowledge of what really constitutes the food of plants, and of the various influences which affect their growth, will necessarily lead to important improvements in all that relates to the collection, preparation, and use of manures. We appear to be at present on the very eve of a great revolution in agricultural mechanics. We noticed in its proper place the benefits which have already ensued from the use of improved implements and machines, but especially from the application of steam-power to much of the heavy work of the homestead. It is known, however, that zealous endeavours are being made by various parties, to render this power available for the tillage of the soil. Some persons are attempting to do this by applying it to the traction of the common plough, or rather of apparatus in which its principle is retained. Of these the Marquis of Tweeddale appears to be the most successful. Others, such as Mr Usher of Edinburgh, are attempting to solve this problem by attaching to a locomotive engine a rotating apparatus, by which the soil is at one operation so broken up and comminuted, as without more ado to be fit for a seed-bed. Mr Samuelson of Banbury has recently brought out what he calls a digging machine, adapted to work by means of horse-power, and of the efficacy of which the most encouraging reports have already appeared. If the improvements which Mr Usher announces that he has made upon his locomotive engine are verified on trial, these gentlemen have only to combine their respective inventions, and "cultivation by steam" is an accomplished fact.

The plough, the sickle, the flail, and the quern claim, we believe, an equal antiquity. We have seen the two last of these venerable compeers entirely superseded by steam-propelled mills. Who will say for how much longer the two first are to retain their time-honoured place as the insignia of agriculture? With such machines before him as Fowler's draining apparatus, Samuelson's digger, Usher's steam-cultivator, and Bell's reaper, a sober-minded man may warrantably expect that at no very distant day our fields will be drained, tilled, sown, and reaped by the same potent agency which already thrashes our crops, and prepares them for the use of man and beast. In speculating upon the future of our national agriculture, we do certainly cherish the anticipation

Report on East Lothian.

that, by the time another edition of the Encyclopædia Britannica is called for, the writer (for it) of the article "Agriculture" will be able to point to far greater achievements, and to a more prosperous state of matters than has fallen to the lot of any of his predecessors.

## Appendix A.

We have already directed attention to the most important features in the progress of British agriculture during the period which has elapsed since the publication of the last edition of this *Encyclopædia;* but with the view of presenting the results of this progress in a more definite and interesting form, we have much pleasure in submitting to the reader the following report on the farming of East Lothian, which has been kindly furnished to us for this purpose by Mr Patrick Sherriff, formerly of Mungoswells :—

### On the Agriculture of East Lothian.

"Haddingtonshire, or East Lothian, has long been celebrated as a grain-producing district, and this leading feature of its rural economy may perhaps have originated from the dry and early climate of the district. Here many practices which have distinguished Scotch husbandry were first introduced; and the farmers, profiting by the fortuitous circumstances under which they have been placed, are not slow in adopting discoveries which are likely to promote their interests. Accordingly, in this progressive age, the recent changes in the agricultural system have been very striking, and may be well illustrated by what has taken place in the parish of Dirleton since 1836, when the Rev. John Ainslie wrote an excellent description of the parish, and which forms a part of the new Statistical Account of Scotland.

"The parish of Dirleton is situated on the shores of the Firth of Forth, and in soil and climate may be considered a fair specimen of the parishes in the county which are bounded by the sea. The surface embraces soils of every texture from adhesive clay to drift sand; the latter, which exists to a considerable extent along the whole line of coast, is consigned to permanent pasture, and chiefly stocked with rabbits. The land under cultivation extends to between 5000 and 6000 acres. Since 1836, when the new Statistical Account of Scotland was published, no land has been reclaimed, in the common acceptation of the term, neither has any permanent pasture been subjected to the plough; and as the surface may be considered unchanged in extent as well as in aration, the increase of disposable produce which has since taken place must be regarded as the results of improved farming.

"From a statistical report of the parish of Dirleton for 1627, it appears that farms were then held by leases of considerable length, and at corn-rents. Afterwards rents payable in money seem to have been introduced; and in the early part of the present century, nearly all the land in the parish was so rented. During this period, when the lease of a farm expired, the increase of rent was great; generally keeping pace with, and often exceeding, the rise which had taken place in the price of agricultural produce during the war with France. The fall of prices which followed the return of peace and the passing of Peel's currency bill, joined to deficient crops for a succession of years, commencing with 1826, involved the occupiers of land in severe distress. Many individuals were unable to meet their liabilities, fell into arrears of rent, and ultimately became unable to cultivate the land in a proper manner for want of capital. This crisis brought about a return to corn-rents, payable in money at fiars prices; and at present there is only one farm in the parish differently rented. The change from money to corn rents took place subsequent to 1830, and the new arrangements having been made with liberality and kindness on the part of landowners, and carried out with energy by the tenantry, the results have proved beneficial to the contracting parties as well as to the public. Ferrygate, one of the best farms in the parish, was held in 1836 at a mitigated rent of 406½ quarters, was re-let in 1852 at 525 quarters of wheat, payable in money at fiars prices. The farm of Chapel having been leased in 1814, was rented in 1832 at L.1150, and re-let in the following year at 260 quarters of wheat, the landlord engaging to drain the farm; and in 1852 the farm was again re-let at a rent understood to be 180 quarters of wheat and L.495 of money, with the addition of 4 per cent. upon any outlay which may be required for draining. Assuming 40s. per quarter as the price of wheat, this would indicate an advance of 64 per cent. upon the previous letting. This farm had been unusually low rented in 1832, in consequence of a panic that then prevailed among farmers.

Report on East Lothian.

"In 1836 Mr Ainslie states, 'now there is hardly one open field in the parish.' The original fences chiefly consisted of thorn hedges, there being few stone walls, with a ditch to carry off water. The hedges had been so long neglected, that, with their wide-spreading branches, they often resembled a row of trees; and a considerable portion of ground remained uncultivated under the branches of the hedges, as well as on the margin of the ditch opposite to the hedge. Within these sixteen years past, the ditches have been transformed into covered drains, and the straggling hedge into a straight line, the roots being regularly dug and freed from weeds. The hedge and ditch of 1836, with the uncultivated land on their margins, often occupied a space 18 feet in width; the fences of the present time seldom exceed 2 feet wide. Taking the fields of the parish, which were bounded by hedge and ditch, to average 25 acres in size, more than two per cent. has been added to their arable surface of late years, and perhaps the fences of the present day do not occupy more than one-half per cent. of the surface.

"Mr Ainslie states, that 'the drainage of the parish is in the course of being made very complete. Springs have long since been laid dry, and tiles are now extensively employed to carry off the surface water. On the soft muirish land, a drain is made every second furrow or 36 feet asunder.' This drainage was soon found to be insufficient for drying the land, and in consequence drains were placed 16 or 18 feet distant; and on this scale the drainage of nearly all of the wet soils has been completed. About the time Mr Ainslie wrote, tiles were occasionally brought a considerable distance by sea for the purpose of draining, but soon afterwards two works for the manufacturing and sale of tiles were erected within the parish; and on the draining of the neighbourhood being completed, they have been removed, and the ground on which they stood restored to fertility. Such has been the progress of knowledge in respect to draining, that a farmer in the parish who asked and obtained from his landlord a grant of L.300 to complete the drainage of the lands which he occupied, and which had been previously drained on the system of deep cross cuts, actually expended this sum, and upwards of L.2000 of his own capital in furrow-draining the farm.

"Mr Ainslie mentions, that in 1835 a few bones and about 100 tons of rape cake were used within the parish. The manures brought into the parish and applied to crop 1851, consisted of about 1600 tons of street manure, 277 tons of guano, 33 tons of rape cake, 30 tons of charcoal, 5 tons of sulphate of ammonia, 5 tons of bones, 2 tons of superphosphate of lime, and 2 tons of nitrate of soda. There were also 150 tons of oil-cake, and 37 tons of grain used in fattening animals, and which, like extraneous manures, increase the productiveness of the farm.

"In 1836, the parish contained nine stationary steam-engines for thrashing grain; in 1852 the number had increased to fourteen.

"The statistical account of 1836 shows, that there were about 468 cattle and 2000 sheep fed within the parish, both kinds of stock being chiefly bred in other districts. The turnip and grass crops of 1850, aided by oil-cake and grain, fatted 779 cattle and 4070 sheep. When it is considered that permanent pasturage is unchanged in all respects, and that the home consumption of grass and turnip by milch cows and farm horses is nearly the same, the increase of animal food since 1836 resulting from improved farming may be taken to exceed 100 per cent.

"The buildings connected with farms have generally been enlarged and improved since 1836. In several instances they

Report on East Lothian.

have been entirely re-built, and in general they embrace substantial accommodation for the machinery and animals essential to high farming. In alluding to the peasantry, Mr Ainslie states, that 'their cottages have also been materially improved in comfort and cleanliness. The pigsty and dunghill form no longer the foreground decorations; and in many places, especially in the village of Dirleton, have been supplanted by roses and evergreens. In some of the late-built cottages there are two rooms, an example well worthy of imitation, as eminently conducive to the morality, no less than to the comfort and health of the people.' The dwellings of two apartments, so properly commended by Mr Ainslie, were soon followed by houses of three rooms; and more recently, cottages of one story have been built for farm-servants, containing a kitchen, three sleeping apartments, dairy and scullery, with a sink and rain-water pipe. Each cottage has a garden, pigsty, and other conveniences; and there is a pump-well and bleaching-green common to all. In Somerville's Survey of East Lothian, published in 1812, the dimensions of a labourer's cottage are stated to be 20 feet by 17, with walls 7 feet high, and the area undivided. The dimensions of a good cottage of the present time are 21 feet by 31, outside measure, with walls 8 feet high, and the area divided into four or more compartments. The improvement of the cottages has led to improved habits of personal cleanliness in the families of the labourers, as well as to improved floral taste. To 'the roses and evergreens' of Mr Ainslie's time, have been added fuchsias and the most choice creepers, while more tender plants growing in pots are displayed inside of the large-sized windows. In one instance the buildings connected with a farm of moderate size must have cost in erecting between L.4000 and L.5000, exclusive of the haulage of materials. Such accommodation cannot fail of being favourable to the health of the indwellers, rational and irrational, of making farmers and labourers discharge their respective duties more cheerfully, and of increasing the rentals of landholders.

"The alternate system of white and green crop continues to be followed; but of late years summer fallow has been diminished in extent, and the growth of turnips increased. Less land is devoted to clover and ryegrass, in consequence of pasturing being generally restricted to one year; while the bean and pea have, to a considerable extent, been supplanted by the potato.

"The assistance which nature has of late years received from drainage and extraneous manures, combined with improved implements, increased skill and industry amongst farmers and labourers, have produced important results on the productiveness of the parish. We have ascertained by enumeration, that the production of meat has been doubled in fifteen years; and although this mode of estimating quantity is not practicable with all the other products of the parish, there is no doubt of the increased productiveness being great. On some farms where nearly the whole of the surface is annually dressed with extraneous fertilizers supplementary to the ordinary manure of the farm, where the home consumption is taken from the home produce, and where the growing of potatoes has been extensively substituted for the bean and pea, the marketable produce has been increased fourfold. High farming has not, however, been universally practised, and therefore it cannot be said that the disposable produce of the whole parish has been more than doubled in the time specified.

"The inhabitants are either employed in the cultivation of the soil, or are chiefly dependent for employment on those connected with agriculture. By the census of 1841 the population of the parish was 1497, and in 1851 the inhabitants numbered 1646. At the present time there is an increasing demand for agricultural labour; but the addition to the number of inhabitants does not show forth all the increased employment arising from the improved state of agriculture since 1836. Many people residing beyond the parish must be employed in preparing and bringing forward the extraneous fertilizers and fattening auxiliaries now so extensively used, in the transport and manufacturing of the increased disposable produce of the land, as well as in the production and distribution of commodities required by the increased numbers and the improved condition of the resident population.

"The progress of agriculture in the land-bound parishes has been similar to what has been detailed in connection with Dirleton. Throughout the whole of the county the improvement of cottages, farm buildings, and fences can be traced. Furrow-draining has been extensively practised, the application of extraneous fertilizers and the use of fattening auxiliaries generally carried out. The application of lime to the soil has long been decreasing. With the exception of a few spots being reclaimed on the slopes of the Lammermuir hills, lime is now seldom used in agriculture.

"Within these last sixteen years little difference is observable in the breeds of sheep fatted within the county, with the exception of the introduction of a few South-downs; but a striking change has taken place with regard to cattle. For the fine and mature-aged animals from the northern counties of Scotland, which formerly graced the feeding courts during winter, have been substitued young and inferior descriptions of short-horns from Ireland and the north of England. This change has perhaps been owing to more of the northern cattle being now fatted where they are bred, and sent direct for the English shambles; but there is no reason for supposing that the farmers of East Lothian have sustained a loss by this change of breeds, as the young short-horn is considered to grow more in size while under the fatting process. In the modes of fattening animals changes have recently crept in. With cattle there has been introduced box feeding and an extended use of auxiliary foods. Sheep are fatted in July, August, and September by folding off winter and spring tares approaching ripeness, with addition of oil-cake; and also from the middle of August onwards by means of early sown turnips. The cultivation of winter tares upon a considerable scale has hitherto been confined to the neighbourhood of Ormeston where they were successfully grown by Mr Wight 130 years ago.

"The improvement in implements and machinery has hitherto been slow; but a spirit of inquiry has lately been directed towards this department of agriculture. The thrashing machine, which was first invented in this country in 1786, continues to be used with some of its defects uncorrected. Within fourteen years, as a substitute for the scutching drum, the American peg drum has been tried and laid aside; and very recently the English bolting drum has been introduced. The bolting drum and concave, from acting by a union of beating and rubbing, preserves the straw nearly unbroken, facilitates the shaking and winnowing processes, extracts the corns from the ears whatever may be the position of the sheaf on entering the machine, and is easily propelled. From combining so many good properties the bolting drum and concave is likely to supersede Meikle's scutching drum.

"The first properly authenticated attempt to construct a thrashing machine was made in this country in 1732, by Mr Michael Menzies; and the machine now in use was introduced by an inhabitant (Mr Andrew Meikle) in 1786. No individual has laid claim to the invention of the rubbing drum and concave now so generally found in the southern parts of England, and there is every reason to believe that they originated with Mr (afterwards Sir Francis) Kinloch of Gilmerton in this county. Evidence of this fact may be obtained in the *Survey of East Lothian*, by Mr Buchan Hepburn, in 1794, and in a letter from George Rennie, Esq., of Phantassie, published in the *Farmer's Magazine* for 1811.

"No change deserving of notice has lately taken place with regard to ploughs and harrows. Scoullar's and Tennant's grubbers, both recent inventions, are much esteemed. In some instances they have supplanted Finlayson's harrow, which has been the favourite grubber in the county since 1826.

"Several improvements in corn drills have lately been effected by Hunter of Samuelston, and Sheriff of Westbarns, in this county; but the drilling of corn crops is far from being general in East Lothian. The practice has not increased of late years, a belief existing amongst farmers that drilling affords no increase of produce unless the ground is hoed when infested with annual weeds. Garret's and Sheriff's horse-hoes for drilled corn crops are used by a few farmers.

"After reaping machines having engaged the attention of some of the inhabitants of this county for nearly half a century, the harvest of 1852 brought into the field six or seven of

Report on East Lothian.

Hussey's American reapers manufactured by Crosskill; all of which were laid aside after the first trial, with exception of one, the owner of which successfully persevered throughout the harvest. Bell's reaping machine was also exhibited at work within the county, and met with general approbation, after having been neglected for nearly a quarter of a century. The cutting of crops by machinery having been publicly demonstrated, there is reason to believe that reaping machines will be much used in time to come. Hitherto the extensive harvests of East Lothian have been chiefly cut down by people from other districts, enticed by the hope of high wages, and who return to their homes when the harvest is over. The recent increase of commercial and manufacturing employment, resulting from freedom of trade and consequent improved state of the lower classes, joined to an extensive and extending emigration of labourers, also the result of free trade, has so diminished the number of itinerating harvesters, that, in future, East Lothian farmers must either employ reaping machines or allure assisting hands by extravagant wages.

"Within these last sixteen years no striking advance has perhaps been made in improving the implements of the farm; but considerable changes are taking place in the uses to which they are applied. Of late years the plough and the roller are seldomer, and the grubbers are oftener, employed in preparing soils for green crops, and in extracting root-weeds from them, whether the cleaning process is performed in spring or in autumn. It frequently happens that clay soils, which were formerly ploughed four or five times, and received perhaps as many harrowings and rollings to fit them for a turnip-crop, are now prepared by one ploughing: natural agencies being more effectual than the implements of man in pulverizing such soils.

"Hunter's, Hopetoun, and Fenton wheats all originated in East Lothian; and at the present time are the standard wheats of the county. Many new varieties of the different grains are introduced from time to time, and generally find a short-lived reputation; but although no very marked improvement of agricultural plants has lately taken place, there are no signs of degeneracy in the oldest kinds of grain. At the shows of seed corn under the auspices of the East Lothian Agricultural Society, in the case of the mentioned wheats the prizes are occasionally carried off by parcels grown upon the farms where the variety was first propagated, and where it has been since cultivated without a change of seed from the time of discovery; proving beyond question that, when soil and climate are congenial to the wheat plant, change of seed is unnecessary. Vast and increasing quantities of seed corn are annually sent from East Lothian to other districts. With turnips, Skirving's purple-top yellow has supplanted, in many instances, the white globe and the Swede, having been found to answer well both for early and late consumption.

"In the rotations of cropping, or in the relative extent which one description of crop bears to another, the chief change has taken place with the turnip and the potato; the one having supplanted the bean, and the other naked fallow. The increased growth of these plants is chiefly owing to drainage, and the application of extraneous manures—the one having supplied nourishment, and the other a fitting condition of soil. Without a union of these improvements, the cultivation of such crops could not have been successfully extended.

"The potato disease which has been so prevalent of late years throughout Britain, and more especially on its western shores, has been comparatively little felt in East Lothian, and hence the extended growth of this root. Whatever may be the cause of the potato being less affected by disease in East Lothian than in the surrounding districts, the fact is unquestionable. So fine has been the quality of this root, that large quantities of potatoes have been annually sent to the markets of England, Ireland, and Wales.

"Amongst the recent changes affecting agriculture, railways ought not to be forgotten. The North British Railway and its branches intersect East Lothian, and afford a cheap and an expeditious conveyance for manures and farm produce, whether in a raw or manufactured state, and more especially for the potato, which is one of the most perishable and cumbrous commodities of the farm.

"However great the advances of East Lothian agriculture may have been of late years, its future progress is likely to be still more rapid. Without placing undue reliance on the discoveries which the intelligence and enterprise of the age are likely to effect, there is much to be expected from what is now at command. Unrestricted competition, which has been found so beneficial with other classes, will urge agriculturists to adopt, and energetically to employ, all agencies within their reach. Naked summer fallow, which at one time was considered so beneficial, that a monument was proposed to be erected to John Walker, who first practised it in East Lothian, must be entirely laid aside. The occupiers of clay soil, by substituting the grubber for the plough, and early for late green crops, will vie with the possessors of light land in the fattening of animals, without diminishing the corn crops which such soils are so pre-eminently calculated to yield. By an extended use of portable manures, combined with early sowing of early varieties, much of the uplands, now yielding scanty returns, will equal soils near the level of the sea in the production of butcher meat and grain, with an increase of sustenance for the breeding flocks, which constitute the staple commodity of such districts. In the genial climate of East Lothian, annual applications of fertilisers to the whole arable surface of the farm could not fail of proving advantageous. And with the adoption of the changes enumerated the disposable produce of the county would be vastly increased in a few years.

"It will be found that the state of the population connected with farming is often affected by the security of tenure granted to, and the amount of rent paid by, the occupiers of the soil. Leases have long been general in East Lothian, and in some cases the rents of farms have always been quantities of corn either delivered in bulk or payable in money at fiars prices. The money-rents contracted previous to 1830 were soon afterwards generally changed into quantities of corn payable at fiars prices, and nearly all the corn-growing farms of the district are held at such rents. The succession of deficient crops formerly noticed, and consequent distress amongst farmers, extended over the county generally, and arose from the severe drought of 1826, followed by the ravages of the wheat fly for several consecutive years, when the yield of wheat on some of the best farms did not reach 16 bushels per statute acre; and in 1828 the wheat crop on the farm of Wintonhill was offered to and refused by the incoming tenant at 12⅞ bushels, exclusive of the expense of harvesting and marketing the crop. About that time many farmers were impoverished, and without security of tenure from being in arrears of rent. With a view of meeting their pressing liabilities, retrenchment was carried into every department of the farm. The productive powers of the soil were drawn upon, fewer people were employed, the wages of labour fell, and depression overshadowed the industrial classes connected with agriculture. The change of money-rents into quantities of corn payable at fiars prices, coupled with the return of more productive seasons, altered the prospects and policy of farmers. Knowing that, under the altered terms of their contracts, security of tenure was restored, and that all the proceeds of augmented crops would not be absorbed in paying rent; and having experienced the evils of parsimonious management, they set about increasing the productiveness of their farm by every available means. To accomplish this object, soils were deepened, drained, and enriched, by employing more capital and labour; better crops were obtained, and the working-classes became enabled to purchase with the wages of labour a greater share of farm-produce.

"From what has been experienced in East Lothian, it would appear that when landowners for a length of time exacted too much rent, farmers employed little capital and labour, inferior crops were reaped, and the state of cultivation retrograded. On the other hand, when a moderate rent was paid, much capital and labour were employed, augmented crops were obtained, and agriculture was progressive.

"In the metayer system which prevails in some countries, the miserable crops are equally divided between the owner and occupier of the soil; and other parties are but little interested in the division. With an improved state of agriculture, such as now exists in East Lothian, matters became very different; and it is the province of the farmer to distribute the produce, or rather its money value, amongst the parties entitled to it. Every individual who aids the productive powers of the soil by his labour, or otherwise, becomes entitled first to be paid; and the landowner ought to receive as rent only what remains after disbursing the legitimate expenses of production. Much of the augmented produce of the present time goes to the non-agricultural population—such as ingenious mechanics and manure merchants. The results of high farming form a large fund for rewarding many classes of the community, and with a good understanding existing between the owners and occupiers of the soil, that fund will progressively increase.

"Viewing the farmer simply as a distributor of the fruits of the earth, it may appear that he has no pecuniary interest in the quantity gathered or the division of it beyond what falls to his own share. He will, however, find as a general rule, that without large crops his portion will be small, and that the larger the produce distributed amongst the number of individuals aiding in producing the crop, the greater will be the happiness diffused amongst the population."

## Appendix B.

After the foregoing article was partly put to press, we became aware that *the two gold medals offered by the Highland and Agricultural Society of Scotland, for the best plans of farm-buildings for large and small farms,* had been awarded to Mr James Cowie, Mains of Haulkerton. From the novelty of the principle adopted by Mr Cowie, and the skilful manner in which he has worked it out, we felt desirous to include an illustration of it in the present treatise. This he has kindly enabled us to do by placing at our disposal the specifications and descriptions of plans. (Plates XIV., XV., and XVI.)

"The plan, Plate XIV., is calculated for a farm of 400 acres, and can be erected at a cost of about L.1200, exclusive of carriages. I have given full sections and elevations along with a ground plan of it, accompanied by full specifications, which will enable readers to understand it fully, and in fact to make it available and ready for tradesmen to work by, if required. Notwithstanding, to those not accustomed to judge of buildings from drawings, a few explanations may not be unacceptable, as leading to a more ready understanding of the arrangements. It will be seen that the two granary lofts, upper and lower, are attached to the sheaf-loft and corn-room. The division between them can be made to shift, so as one can be lessened or enlarged as may be required. The adjacent house has, in the ground-floor, a boiling-house and hay or grass shed, which may extend above the water-wheel to the corn-room wall. The floor above can be occupied as an auxiliary sheaf-loft or granary, or for erecting machinery for bruising corn or other food, &c. The straw barn is placed in the centre of the building, and allows two kinds of straw to be deposited separately. The hay shed and infirmary, when not occupied, can serve as a store for straw or chaff if need be. The turnip sheds are placed quite adjacent to the cattle, which can be fed from a small waggon on a railway, by the arrangement adopted here, in nearly half the time required by employing the common wheel-barrow. The sheds or boxes for the loose cattle are placed four feet below the level of the rest of the interior, and are immediately behind the stalls, so as to admit of the dung being removed from the tied-up cattle with the least labour. The cow-byre is in a separate division, and the calves-house is in proximity to it. The stable, which has two doors opening externally for more ready access to the horses, is conveniently situated as regards proximity to the boiling-house, corn-room, straw-barn, dung-shed, and cart-sheds; and there is a room provided over the turnip-shed for a sleeping apartment for the persons in charge of the cattle and horses. There are two large loose boxes, carpenter's shop, pig-sties, an ample tool-house, and an enclosed shed, which is capable of containing two carts, or can be employed in a temporary way as a guano or potato house. The poultry-house has a yard, part of which can, as occasion may require, be staked off as an exterior area for an invalid beast requiring fresh air. The saddle-horse stable and gig-house may be simply referred to in concluding the description. This steading thus embraces within a comparatively compact circle, all the conveniences required for a farm of the size specified; and it is not the least recommendation to it that the farmer can see almost at a glance, in any part of the interior, all his 10 or 12 horses, his 50 stall cattle, his 60 shed cattle, and his 30 or more calves; and from the position of, and ready access to them all, he can at once see how they are supplied with food and litter. The whole homestead with its contents, live and dead stock, are in fact as much within the visible scope of its owner, and manual access of the servants, as anything of the kind can, or requires to be.[1]

"The plan, Plate XV., is that of a farm on the small property of Calvennan, in Wigtownshire. It was built last season at a cost of about L.500. It has three roofs, and the arrangements, which are similar to those in the plan just described, will be understood by a reference to the accompanying plan and sections."

### "Specification for Steading of Farm-Offices.

### "*Mason Work.*

"All necessary excavations will be performed by the tenant.

"The walls will be founded at the depth shown by the sections, or as much more as will insure a firm and solid foundation. The contractor must satisfy himself as to the extent of the necessary depths, as no addition will be allowed for extra building.

"The foundation course of the walls are to be laid with large flat-bedded stones laid close together, and their joints hard packed with stone-shivers and lime mortar, and having a toe or ledge from 3 to 4 inches broad, projecting beyond the thickness of the walls on each side. The walls are to be of good coursed and well banded and packed common rubble work. The stones composing the outside courses are to be well axe-dressed on the face, and to have beds of not less than 7 inches of breadth, and not to exceed 12 inches in height, having headers laid in each course at from 5 to 6 feet apart, extending at least two-thirds the thickness of the walls, and the whole to be particularly snecked on the outside, and back-snecked. All corners, outband door and window rybats, to be 26 inches in length, and squared on the ends; and inband rybats to go through the walls; and the whole to have heads not less than 8 inches broad. The rybats of the large doors will have checks $1\frac{1}{2}$ inches by $2\frac{5}{8}$ inches on the outside all round. All other doors opening to the outside will have checks $1\frac{1}{2}$ inch by $2\frac{1}{2}$ inches; and the other door and window rybats will have checks 2 inches deep, and one inch check on the lintels. All the corners of the buildings, door and window rybats, soles, and lintels, tabling and put stones, and arch stones, are to be well droved and jointed, and the pillars of the cart sheds are to be close jointed, and all rybats to have a margin of 3 inches round the outside faces, and on each of the external corners. The heel-posts of the byres are to be of stones 8 inches square, to be well droved, and to have a groove cut in each $1\frac{1}{2}$ inch square, for the travis-boards, and to be well sunk in the ground, 2 feet at least, and to stand $3\frac{1}{2}$ feet above the saddles as shown.

"The feeding-troughs of the byres are to be raised above the causewaying 6 inches, and bottomed with well droved and jointed stones; and the wooden posts of the stable and byres are to have proper stone bases. The urine under drains are to be laid with glazed socket-pipes to communicate with the urine tank, as shall be pointed out.

"The internal walls of the corn-room, sheaf-loft, and granaries are to have one good coat of plaster, and the walls of the same are to be beam filled between the couples.

"Such of the houses and passages as shall be pointed out for causewaying shall be done in a proper and sufficient manner by the contractor at the rate of threepence per yard.

[1] In Plate XIV. the plan of an ark for a water-mill is given, but should a steam-engine be required the erections for it can be made in place of the ark in the same situation.

"The foundation of the underground walls of the ark are to be laid with large flat-bedded stones, all well laid and packed, and the whole of the water walls are to be of well-sized stones squared up, axed on the face and well jointed, to have full beds, and built in courses, and every third stone to be a header of at least 2 feet in length. All openings are to have squared up scuncheons. There will be a projecting course laid at centre 9 inches thick, and at least 1 foot 9 inches in breadth, well droved and jointed. The bottom of the ark is to be slabbed with good quarry stones, and the tail race through an arched opening 3 feet square, the thickness of the wall. The size and form of the stones for hanging the machinery, and all the necessary cuttings, boring, and levellings, &c., must be executed at the sight, and to the satisfaction of the mill-wright or inspector.

"All the lime for the building is to be of the best English shells, well slaked and made into a stong composition of mortar with clean sharp sand, and all the joints of the outside work are to be well ripped out and pointed with Scotch lime mortar, in a proper season, and the ark is to be pointed with Roman cement.

"All necessary raggles are to be made, window frames bedded and pointed in, and the lead and the running in of the hinge crooks of the doors, also the laying of the urine-pipes, and all inferior jobs necessary for the completion of the mason-work, must be done at the sight, and to the satisfaction of the inspector without any additional charge.

### "*Carpenters' Work.*

**Lintels.** "Safe lintels throughout the buildings to have 1 inch of thickness to every foot of extreme length, and to have 9 inches of wall-hold, and closely fitted up to the out-side stone lintels. All inside doors to have wood lintels.

**Joists.** "Joists and sleepers to be laid as shown, 18 inches from centres. Joists to have 9 inches of wall-hold.

**Trimmers.** "To have one row of trimmers in centre 10 inches by 1.

**Mill-beams.** "Mill beams to be laid as shown, to have 12 inches of wall-hold; to be double mortised, and fixed with a $\frac{7}{8}$th-inch joining bolt.

**Roofs.** "The main couples on wide roofs will be framed as shown, and secured at the joinings with iron plates; the rafters to be placed 21 inches from centres, checked at joinings, and securely nailed.

"The wide roofs will be supported by cast-iron columns as shown. These columns to have large bases and capitals, and to have 6 inches diameter at the centre, and not less than $\frac{5}{8}$ inch thick of metal, fixed at the top to a dressed beam 11 inches square, and let into the stone base at the bottom $\frac{1}{4}$ inch. The other roofs to be framed up as shown—roofing to be checked at joinings, and properly nailed.

**Slate-lath.** "Slate-lath to be nailed on to answer slates 16 inches by 8 inches, or as near to that size as can be conveniently got.

**Gutters.** "Gutters between the roofs to be formed as shall be shown; all to be properly bracketed up and laid with ploughed flooring.

**Luffer windows.** Luffer-windows for granary and ventilators to have frames 3 inches by 2 inches, boards one inch thick, and made to open and shut with a rod and wood brackets, as shall be shown.

**Windows.** "The window-frames to be two inches thick, and to be made to open on pivots 12 inches from the top, and to be filled with strong rough plate glass.

**Doors.** "All the large doors to be in two halves, bound with four bars each, 7 inches by $1\frac{1}{8}$ inch, and all to have margin stiles in both edges $3\frac{1}{2}$ inches by $1\frac{1}{8}$ inch. Covering to be $\frac{7}{8}$ inch thick, ploughed, and all beeded on the joints. Each door to have two slipping bolts 18 inches long, $\frac{3}{4}$ inch diameter, made to work on strong iron plates; hinges to be $2\frac{1}{4}$ inches broad, $1\frac{1}{2}$ inch at neck, and each hinge to be two-thirds the width of the door, and to have three screw bolts each.

"Corn-room door to be cut across the centre horizontally. All the other outside doors to be in one piece, and all to be framed on the back-side with stiles and bars; stiles $3\frac{1}{2}$ inches, bars 7 inches by $1\frac{1}{8}$ inch. Each door to have four bars covered with $\frac{7}{8}$th inch deals, either to be ploughed and beeded on the joints, or plain joints separated $\frac{3}{8}$th inch between deals, as shall be required: hinges 2 inches broad, $\frac{1}{4}$ inch thick, and two-thirds the breadth of the door, and each to have a screw-bolt at neck. Such of the doors as shall be pointed out to have a sliding board 9 inches square at bottom to admit air at pleasure. All the doors to have strong ring latches, and those on the outside to have home-made locks of the value of 5s. each, to be put on with three screw bolts each. Keys of stable-doors to have rings. The doors for granaries and sleeping apartments to be made similar to the others, but hung on posts with good hinges, and to have locks same as the others. All the doors, luffer and other windows to have three coats of white lead paint, finished to a taint to be approved of.

**Crooks.** "Crooks to be feather-tailed, pins for large doors $1\frac{1}{8}$ inch, for small doors 1 inch.

**Flooring.** "Mill-loft and granaries to be floored with $1\frac{1}{8}$ inch thick deal, not broader than 7 inches, clean dressed on face, grooved and tongued, and nailed down with 14 lb. spikes, and the bye wood all cleaned off. Dressed skirting boards fixed to ducts round all the walls of granaries, corn-room, and sheaf-loft, 7 inches deep and 1 inch thick.

**Stable-mangers.** "The mangers to be 16 inches deep, and sloped from the back to 20 inches, and in addition to have a 3 inch deal biting tree of hard wood. The front and bottom to have $1\frac{3}{4}$ inch deal, the back 1 inch deal.

**Stable-posts.** "The posts to be octagon, 8 inches diameter at foot, and 7 inches at top, grooved for travis $1\frac{1}{2}$ inch deep and 2 inches broad; to be fixed at top to a run-joist 7 inches by $2\frac{1}{2}$ inches, with a large oak pin, and at bottom with an iron pin 5 inches long, 1 inch diameter. Front posts same size, split up the centre and similarly fixed. Posts and run-joists to be clean dressed.

**Stable-racks.** "Hay-racks to be fitted up in the stable 36 inches broad. The splits to be $2\frac{1}{4}$ inches by $1\frac{1}{8}$ inch, and to be 4 inches between. Rails to be 4 inches by 2 inches, and checked for splits, and properly nailed.

**Travis boards.** "Travis to be 2 inches thick, to be clean dressed, close jointed, each joint to have 3 iron dowels $\frac{3}{8}$th inch diameter; and to be fixed between the front posts by screw-bolts. The gable walls to be lined the length of the stalls with 1 inch deal, ploughed and fixed to straps 1 inch by 2 inches. Travis to be finished on the top with an ogee, and strapped with thick iron hoop.

**Harness pins.** "Harness-pins and saddle-rests to be fitted up as shall be pointed out, each post to have an iron hook for hanging harness. Two rings to be fixed into each post for binding horses.

**Corn-chests.** "Two corn-chests to be fitted up in recesses in walls of stable, of 1 inch ploughed deal, 4 feet long each, 2 feet wide inside, and 3 feet deep; provided with proper locks and hinges. One corn-chest 3 feet long for riding stable, similar to the others.

**Byre-troughs.** "Fronts and backs of byre-troughs to be 2 inches thick and 12 inches deep, to slope towards the cattle, and rounded on the edge.

**Byre-posts.** Post to be fitted up as shown, to be fastened at bottom and top same as stable, to be $5\frac{1}{2}$ inches diameter, champhered in corners. The front post to be grooved for receiving travis, the other one to be in two, and travis fixed to them same as stable. Run-joists to be 6 inches by 3 inches. Iron sliding rods 14 inches long, $\frac{3}{4}$ inch thick, to be fixed in the posts with screw-bolts for cattle bindings.

**Byre-racks.** "Racks to be fitted up 30 inches deep on the side next the cattle, and 24 inches on the other side. Same dimensions as stable racks, and fitted up in the same way; splits to be 6 inches between.

**Byre-travis.** "Travis boards to be $1\frac{1}{4}$ inch thick, $4\frac{1}{2}$ feet high at front, and 3 feet 3 inches at back; and front-bar 5 inches broad, and 2 inches thick, to be nailed to the front posts, and 2 feet above the edge of the troughs.

**Cattle-shed troughs.** "Troughs to be made into proper lengths for convenience in shifting. Sides to be 14 inches deep and 2 inches thick; bottom $1\frac{1}{2}$ inch, to be properly secured by longitudinal spars, nailed to bottom and framing, frame 3 inches by 2 inches, and made to stand on feet. Width of troughs to be $2\frac{1}{2}$ feet; all to be firmly nailed.

**Cribs.** "One straw-crib to be made for each division of sheds; posts to be 4 inches square, to have 3 rails on each side, 4 inches by 2 inches; to stand 4 feet high, 8 feet long, and 4 feet wide.

"Two traps to be made for corn-room, loft, and stable, of such length and dimensions as shall be pointed out.

"All scaffolding, centring, and moulds, are to be furnished to the contractor for the mason-work. All inferior jobs not specified, nor shown in sections necessary for the proper completion of the carpenter work, shall be done without any additional charge, unless from its nature and extent such shall be alllowed by the inspector of the work.

"All the timber shall be of good Baltic timber, or American red pine, and must be well seasoned.

"*Scantlings of Timber.*

"Sleepers, 6½ inches by 2½.

Joists, 10½ inches by 2½.

Rafters, narrow roof, 6 inches at bottom, 5 inches at top, 2½ inches thick.

Baulks or ties, 6½ inches by 2.

Cross beam for thrashing-mill, 10 inches by 14.

Longitudinal beams, 7 inches by 14.

Safe lintels for large shed-doors, 10 inches by 10.

Slate lath, 1½ inches by 1.

Rafters of main-couples, 5 inches by 8.

Tie beams of do. 9 inches by 5.

King posts of do. 5 inches by 5.

Spurs or anglers, 5 inches by 5.

Purlins, 5½ inches by 5½.

Intermediate rafters, wide roofs, 6 inches by 2.

"*Slater Work.*

"The roofs to be covered with blue Welsh slates, size 16 inches by 8 inches; to have 2-inch cover or overlap, and all to be fair and closely laid. To be nailed to laths with nails weighing eight pounds per thousand, steeped in oil when red hot, and each slate to have two nails. Skylights to be put in as shown, of strong sheet-glass of the size of 12 inches by 18 inches, fitted into zinc frames, weighing 16 ounces per square foot. The valley gutters to be covered with lead weighing 6 lb. per square foot, and 12 inches in breadth. The flat gutter between the roofs to be covered with lead weighing 6 lb. per square foot.

"The gutter at the narrow ends will be 9 inches in breadth, and the lead to rise up on the roof the usual height.

"Gutters will have declivities of 1½ inch on every 10 feet of length, and to have boxes formed where shown, 5 inches deep; to have 3-inch lead pipes soldered into the same, and carried through the beam below into the cast-iron columns. All the roofs to be upheld sound and water-tight for eighteen months after being finished.

"The whole of the work, including materials, but excluding carriages, must be performed by the day of in a most substantial and workmanlike manner, to the entire satisfaction of or any other person to be named by the employer. Any alterations that may be made in the progress of the work at the suggestion of the inspector shall be paid for, or deducted according to his estimate."

---

# AGRICULTURAL CHEMISTRY.

The application of chemistry to the development of the principles of agriculture, though it has only of late years attracted general attention, is by no means new. It dates as far back as the period at which agriculture, after remaining for ages almost stationary, received that stimulus which has led to its recent progress. The earliest reference to the composition of vegetables, and the source of their food, in an agricultural point of view, we owe to Jethro Tull; and though his conclusions are no doubt often erroneous, as indeed they could scarcely fail to be, in the then imperfect state of our knowledge of vegetable chemistry and physiology, and with his limited acquaintance with what was even then known, yet some of his observations are unquestionably both ingenious and valuable. They were, however, incidental merely, for he attributed the benefits of his improved method of culture to mechanical, and not to chemical principles, and deliberately denies the statement put forth by Van Helmont, and some of the chemists of his own time, that plants derive their food from the air.

While we thus fix the work of Jethro Tull as the earliest in which allusion is made, though only indirectly, to the chemical principles of agriculture, its effect was rather to turn attention from, than direct it to the investigation of the subject; and it was not till the close of the last century that its importance was brought distinctly before the agricultural public by the publication of Lord Dundonald's *Treatise on the intimate connexion between Chemistry and Agriculture.* Almost simultaneously with its publication appeared the earlier researches of De Saussure, which, extending over a long series of years, have the merit of laying the foundation of all that has been recently done, and of opening up the field which has been since so successfully cultivated. Saussure investigated, in every point of view, and with a care and accuracy which have never been surpassed, the principal phenomena of the life of plants, and directed attention to the important bearings which many of the facts he substantiated had upon the practice of Agriculture. Neither Saussure's investigations nor the work of Lord Dundonald, appear to have excited that attention which they deserved, or to have produced any immediate effects in the progress of agriculture; but a lively interest was excited by a course of lectures on agricultural chemistry given by Sir Humphry Davy, in the year 1812, at the instance of the Board of Agriculture, and afterwards published. These lectures, written with all the elegance and precision which characterised their author's style, brought prominently before the public the results of Saussure's experiments, and contained a number of useful practical suggestions, many of which have been adopted into our everyday practice, and become so thoroughly incorporated with it, that their scientific origin has been altogether forgotten. The interest which Sir Humphry Davy's work awakened was only temporary: it soon died out, and the whole subject lay in abeyance for a considerable number of years. The truth is, that at that time agriculture was not ripe for science, nor science ripe for agriculture. The necessities of a rapidly increasing population had not then begun to compel the agriculturist to use such means as would increase the amount of production to its utmost limit; and that branch of chemistry which treats of the nature and constitution of the various components of animals and vegetables was still entirely uncultivated, and the whole science in a comparatively imperfect state. We cannot be surprised, therefore, that matters remained with but little change during the comparatively long period of nearly thirty years. Indeed, with the exception of the investigation of soils by Schübler, and some other inquiries of minor importance, and which, in this country at least, excited no attention on the part of the agriculturist, nothing was done until the year 1840, when Liebig published his treatise on *Chemistry, in its application to Agriculture and Physiology.* Few works have ever created a more powerful impression. Written in a lively and attractive style, and essentially a popular work, dealing with scientific truths in a bold and original manner, and impressing, by its earnestness and the importance of its conclusions, it was at once received by the agricultural public, with the full conviction that the application of its principles was to be immediately followed by the production of immensely increased crops, and by a rapid advance in every branch of practical agriculture. The disappointment of those extravagant expectations, which *chemists* themselves foresaw, and for which they vainly attempted to prepare the agriculturist, was followed by an equally rapid reaction; and those who had embraced Liebig's views, and lauded them as the commencement of a new era, but who had absurdly expected an instantaneous effect, changed their opinion, and contemned, as strongly as they had before supported, the application of chemistry to agriculture. Taking all things into account, this effect is scarcely to be wondered at, and part of it is even to some extent attributable to Liebig himself; for in place of bringing always prominently before his reader the fact that agricultural chemistry was still in its early youth, and burthened with all the faults and errors of youth, he treated it too much as if it were already perfect in all its parts. Conclusions, ingenious, but founded on insufficient evidence, and sometimes altogether hypothetical, were stated as if they were fully demonstrated scientific truths; and when these proved, as they sometimes did, to be at variance with practice, it is not surprising that they should have produced a feeling of distrust on the part of persons incapable, from an imperfect and still oftener from no knowledge of science, of drawing the line of demarcation, which Liebig frequently omitted to do, between the positive fact and the ingenious hypothesis founded upon it. This omission, which would be of no consequence with scientific men, becomes a source of serious misapprehension in a work addressed to persons unacquainted with science, and who adopt indiscriminately both the facts and the hypotheses of the author. Be this as it may, Liebig's work, though rather too much of a popular character, has had perhaps all the more on that account a very powerful influence in awakening attention to the improvement of agriculture through means of science.

Liebig's work was followed, in the year 1844, by the publication of Boussingault's *Economie Rurale*, a work which, though it excited at the time infinitely less interest than Liebig's, is really quite as important a contribution to scientific agriculture, and in some respects even surpasses it; for it contains the accumulated results of a large number of investigations, both in the laboratory and the field, by the author himself, which have served to establish a great many important truths. Boussingault possesses the qualification, at present somewhat rare, of combining a knowledge of practical agriculture with extended scientific attainments; and his investigations, which have been made with direct reference to practice, and their results tested in the field, must be considered as the foundation of a large part of our correct knowledge of scientific agriculture.

The same year was marked by an event of equal importance in the history of scientific agriculture, namely, the foundation of the Agricultural Chemistry Association of Scotland, which was instituted through the exertions of a small number of practical farmers, for the purpose of pursuing investigations in agricultural chemistry, and affording to its members assistance in all matters connected with the cultivation of the soil. That institution has formed the model of similar associations in London, Dublin, Belfast, and in Germany, and it is peculiarly creditable to the intelligence, energy, and zeal of the practical farmers of Scotland, that with them commenced a movement, which has already found imitators in so many quarters, and has conferred so many benefits on agriculture. Within the last six or eight years, and mainly owing to the exertions of these associations, great progress has been made in accumulating facts on which to found an accurate knowledge of the principles of agricultural chemistry, and the number of chemists who have devoted themselves to agriculture, has considerably increased, though still greatly less than the exigencies of the subject require. Even now, we are but on the threshold of the subject, and are only, as the result of numerous and laborious investigations, becoming acquainted with the path which may be most advantageously followed in elucidating the applications of chemistry to agriculture. Much still remains to be done, and it behoves the agricultural public to adopt such measures as shall be most likely to advance the study of the principles of their art. What these means are will be afterwards indicated. Meanwhile it admits of no question, that with all the faults and errors of a science still in its infancy, the progress which has been made is sufficiently encouraging to induce practical men to turn their attention towards it.

## THE ORGANIC CONSTITUENTS OF PLANTS.

When a plant, or any of its parts, is exposed to a high temperature, it catches fire, burns, and is gradually consumed, until at length there is left behind a quantity of a white earthy matter, which undergoes no further change, however long the heat be continued. The action of heat thus divides the constituents of plants into two great classes, the *organic* constituents, contained in that part which is volatilised by burning, and the *inorganic* constituents which are found in the residual white matter or *ash*. All plants contain both classes of substances, and though their relative proportions vary considerably, the former greatly exceed the latter, and invariably form the principal part of the plant. The organic constituents are four in number:—

| | |
|---|---|
| Carbon. | Hydrogen. |
| Nitrogen. | Oxygen. |

The *inorganic* constituents, though smaller in amount, are much more numerous, not less than twelve having been observed as essential to the plant, while one or two others have been detected under certain circumstances, although they appear to be only accidentally present, and form no part of its living tissues. Those which have been clearly ascertained to be essential constituents are:—

| | |
|---|---|
| Potash. | Silicic Acid. |
| Soda. | Phosphoric Acid. |
| Lime. | Sulphuric Acid. |
| Magnesia. | Chlorine. |
| Peroxide of Iron. | |

and more rarely:—

| | | |
|---|---|---|
| Manganese. | Iodine. | Fluorine. |

None of these substances occur in the plant in their elementary or uncombined state, but exist as compounds of greater or less complexity formed by the union of two or more of them; which compounds are extremely varied in their properties, and are especially adapted for performing the various functions of the plant.

*The Organic Constituents of Plants.*—It would be out of

Agricultural Chemistry.

place to enter here into full details regarding the properties of the organic elements, which fall to be considered under the head of pure chemistry, but a few words regarding their more important characteristics, are essential to a right understanding of what is to follow.

*Carbon*, in the pure state, is found only in the diamond. It is left as charcoal in a less pure condition when vegetable and animal substances are heated in close vessels, and is then obtained as a black substance insoluble in water, which burns in the air, and, by its union with oxygen, is converted into a transparent and colourless gas called carbonic acid. Carbon is the largest constituent of plants, and forms, in round numbers, nearly 50 per cent. of their dry substance.

*Hydrogen* is only met with in nature in combination with other substances, and its principal compound is water, of which it forms one-ninth, the remaining eight-ninths being oxygen. It is separated from water by a well known process, and then appears as a transparent and colourless gas, remarkable for its lightness. It catches fire in the air, burns with a pale flame, and is converted into water by combining with oxygen. It is a constituent of all plants, and of all their parts, and though in much smaller quantity than carbon, is equally essential. Dry plants rarely contain more than 5 or 6 per cent. of hydrogen, and sometimes considcrably less.

*Nitrogen*, like hydrogen, is a gas, but unlike it, is found in great abundance in an uncombined state. It exists in large quantities in atmospheric air, of which it forms nearly four-fifths, or more correctly 79 per cent., of its volume. When separated from the oxygen with which it is mixed in the air, it forms a transparent gas, which is incombustible and extinguishes flame. It is a remarkably inert substance, and is incapable of directly entering into combination with the other elements, although it can be made to do so by indirect processes, a peculiarity which has very important bearings on many points which we shall afterwards have to consider. Nitrogcn is found in plants to the extent of from 1 to 4 per cent.

*Oxygen* is one of the most widely distributed of all the elements, and, from its powerful affinities, is the most important agent in almost all natural changes. It is found in the air, of which it forms 21 per cent., and in combination with hydrogcn and various other substances. When obtained in the pure state it possesses very remarkable properties. All substances burn in it with greater brilliancy than they do in atmospheric air, and its affinity for most of the elements is extremely powerful. It supports the respiration of animals, but only for a short time, for it excites a violent inflammation in the system, which proves fatal after the lapse of an hour or two. It is found in plants, in quantities varying from 30 to 36 per cent.

Now, in order that a plant may grow, all its four organic constituents must be presented to and absorbed by it, and that this absorption may take place, it is essential that thcy be presented to it in suitable forms. A seed may be planted in pure carbon, and supplied with unlimited quantities of hydrogen, nitrogen, oxygen, and inorganic substances, and it will not germinate; and a plant, under similar circumstances, will not only not increase, but will soon die. These substances cannot then be absorbed when in the *elementary* state, but when they have entered into certain forms of combination, they acquire the property of being readily taken up, and assimilated by the organs of the plant.

It has been ascertained by numerous experiments, that the forms of combination in which these elements must exist for this purpose, are by no means numerous; and though great difference of opinion formerly existed, it is now generally admitted that the most important compounds are—for the carbon, carbonic acid; for hydrogen, watcr; for nitrogen, ammonia and nitric acid; and for oxygen, water and carbonic acid. The properties and general chemical relations of these substances are fully treated of in the article CHEMISTRY, and need not be specially disscussed here; it will be enough to remind the reader that carbonic acid is a compound of carbon and oxygen, water a compound of hydrogen and oxygen, ammonia of hydrogen and nitrogen, and nitric acid of nitrogen and oxgen; and that all these substanccs, with the single exception of ammonia, may supply the plant with oxygen as well as with that element of which it is the particular source.

There are only two sources from which these substances can be obtained by the plant, viz. the atmosphere, and the soil, and it is necessary that wc should here consider the mode in which they may be obtained from these sourccs.

*The Atmosphere as a source of the organic constituents of Plants.*—Up to the middle of the last century the atmosphere was universally considered to be one of the great chemical elements, but at that time suspicions of its complex nature began to be entertained, which were afterwards substantiated by the experiments of Priestley, Rutherford, and other observers. It has been clearly established that the main bulk of the atmosphere is formed of a mechanical mixture of oxygen and nitrogen, along with certain other ingredients which, though in extremely minute proportion, are as essential to it as its larger constituents. It has been shown by many experiments that 100 volumes of air deprived of moisture and minor constituents, contain

| | |
|---|---|
| Oxygen | 21 |
| Nitrogen | 79 |
| | 100 |

Though only in mechanical mixture, the proportion of these ingredients is fixed and invariable. Experiments, entirely corresponding in their results, have been made by Humboldt, Gay-Lussac, and Dumas at Paris, by Saussure at Geneva, and by Lewy at Copenhagen; and similar results have also been obtained from air collectcd by Gay-Lussac during his ascent in a balloon at the height of 21,430 feet, and by Humboldt on the mountain of Antisano in South America at a height of 16,640 feet. In short, under all circumstances, and in all places, the relation subsisting between the oxygen and nitrogen is constant; and though no doubt many local circumstances exist which may tend to modify their proportions, these are so slow and partial in their operations, and are so counterbalanced by others operating in an opposite direction, as to retain a uniform proportion between the main constituents of the atmosphere, and to prevent any undue accumulation of one or other of them at any one point. It is different with the minor constituents, which are liable to have their proportion varied to some extent under different circumstances. Of these minor constituents the most important is carbonic acid.

*Carbonic Acid.*—The proportion of carbonic acid in the air has been carefully investigated by Saussure. From his experiments it appears that the mean quantity in 10,000 volumes of air, at the village of Chambeisy, near Geneva, amounts to 4·15 volumes; and this quantity was not constant, but varied between 3·15 and 5·75 volumes. The variations in question are dependent on different circumstances. It was found that the quantity was greater during the night than during the day, the mean quantity in the former case being 4·32, in the latter 3·38. The largest quantity found during the night was 5·74, during the day 5·4. Heavy and continued rain had the effect of diminishing the quantity of carbonic acid, by dissolving and carrying it down with it into the soil. Saussure found that in the month of July 1827, during the time when nine millimetres of rain fell, the average quantity of carbonic acid amounted to 5·18 volumes in 10,000; while in September 1829, when 254 millimetres fell, it was only 3·57. On the other hand, continued frosts, by retaining the atmosphere and soil in a dry state, had an opposite effect. High winds increase the carbonic acid to a small extent. It was also found to be greater over the cultivated lands than over the lake of Geneva; greater at the tops of mountains than at the level of the sea; in towns than in the country. The differences observed in all these cases are but small, but they are beyond the limits of error in the experiment, and have been confirmed by subsequent experimenters.

*Ammonia* is also an invariable constituent of the atmosphere, but in extremely minute quantity. Its amount appears to vary within wider limits than any of the other components; but it admits of question whether the very variable, and indeed almost conflicting, statements of different observers may not be to some extent dependent on the mode of experimenting, and the care which has been devoted to it. Our observations on this constituent of the air are less numerous than on any other; for though it has long been known that ammonia exists there, it is only recently that it has been ascertained to be invariably present, and that the recognition of its importance has led to the determination of its quantity. Dr Kemp determined the quantity present in 1,000,000 parts of air to be 3·68; Graeger found in the same quantity no more than 0·323; while Fresenius obtained only 0·098 parts by day, and 0·169 by night. The experiments of the latter observer appear to have been conducted with great care; those of Kemp probably give too high a result; but the number of experiments we at present possess is too small to permit us to draw any general conclusions as to the average proportion of ammonia, although they all concur in proving its invariable presence. It is easy to prove that it is present in the air, by collecting the first few drops of a shower, and applying to them the well-known tests for ammonia; but the accurate determination of its quantity is extremely difficult and tedious.

*Water.*—The air always contains a quantity of watery vapour, which varies greatly at different times and places, and is dependent to a great extent upon the atmospheric temperature, being largest in hot weather and least in cold. It is increased also by the proximity of the sea, of lakes and rivers, evaporation from which moistens the superincumbent air, and is diminished in dry districts. It is deposited on the surface of the earth in the form of rain and dew, and is connected with many very important natural changes. One thousand volumes of air contain, on the average, about eight volumes of watery vapour; but under certain circumstances this quantity may be greatly increased or diminished.

*Carburetted Hydrogen.*—Gay-Lussac, Humboldt, and Boussingault have shown, that when the whole of the moisture and carbonic acid have been removed from the air, it still contains a small quantity of carbon and hydrogen; and Saussure has rendered it probable that they exist in a state of combination as carburetted hydrogen gas. No definite proof of this position has, however, as yet been adduced, and the function of the compound is entirely unknown. It is possible that the presence of carbon and hydrogen may be due to a small quantity of organic matter; but, whatever be its source, its amount is certainly extremely small.

*Nitric Acid* is sometimes, but not invariably, found in the atmosphere. It has been detected after thunder-storms, during which it is apparently formed by the electric spark causing the combination of its elements. Its proportion is extremely minute.

*Sulphuretted Hydrogen and Phosphoretted Hydrogen.*—The proportion of these substances is almost infinitesimal; but they are pretty general constituents of the atmosphere, and are apparently derived from the decomposition of animal and vegetable matters.

From the preceding statements, it is apparent that the atmosphere may prove a source of all the organic constituents of plants; for not only does it contain nitrogen and oxygen in a pure state, but likewise in those forms of combination in which they are most readily absorbed; and it affords also a supply of carbon in the form of carbonic acid. No doubt the quantity of these substances appears trifling, but it is only relatively and not absolutely small; for, if we take into account the enormous mass of air surrounding the globe, it will be at once apparent, that even the minute fraction of ammonia, amounting, according to Fresenius, to less than a ten-millionth of the atmosphere, corresponds to a very large total quantity. It has been found, by a simple calculation, that the atmosphere must weigh in round numbers

5,050,000,000,000,000 tons,

and it must consequently contain

Carbonic acid,..............3,300,000,000,000 tons,
Ammonia, ................. 50,000,000 tons,

quantities sufficiently large to afford an abundant supply of these elements to all the plants on the surface of the earth.

*The Soil as a Source of the Organic Constituents of Plants.*—When a portion of soil is subjected to heat, it is found that it, like the plant, consists of a combustible and an incombustible part; but while in the plant the incombustible part or ash forms only a small proportion of the whole, the reverse is the case with the soil, which rarely contains more than 5 or 6 per cent. of organic matter, and sometimes much less. The organic matter exists in the state of what has been called humus, a substance which must be considered here as a source of the organic constituents of plants, independently of the general composition of the soil, which will be afterwards discussed.

The term *humus* is generic, and is applied by chemists to a rather numerous group of substances, very closely allied in their properties, of which several are generally present in all fertile soils. They have been submitted to examination by various chemists, but by none more accurately than by Mulder and Herman, to whom, indeed, we owe almost all the precise information we possess on the subject. The organic matters of the soil may be divided into three great classes; the first, containing those substances which are soluble in water; the second, those which are extracted by means of caustic potash; and the third, those which are insoluble in all menstrua. When a soil is boiled with a solution of caustic potash, a deep brown fluid is obtained, from which acids precipitate a dark brown flocculent substance, consisting of a mixture of at least three different acids, to which the names of humic, ulmic, and geic acids have been applied. The fluid from which they have been precipitated contains two substances, crenic and apocrenic acid, while the soil still retains what has been called insoluble humus.

The chemical characters of all the acids above named are pretty closely allied. They have, however, been divided into three groups, the humic, geic, and crenic groups, which present some differences in properties and composition. They are all compounds of carbon, hydrogen, and oxygen, and are characterised by their affinity for ammonia, which is so great that they are with difficulty obtained free from that substance, and generally exist in the soil in combination with it. They are all products of the decomposition of vegetable matters in the soil, and are produced in succession by the gradual progress of their decay. This decomposition may be easily traced by observing what takes place when a piece of wood, or any other vegetable substance is exposed to air and moisture. It first acquires a dark brown, and finally a black colour, and is then converted into two substances, named ulmin and humin. These are insoluble in alkalies, and are apparently identical with the insoluble humus of the soil. As the decay advances, the products become soluble in alkalies, and then contain humic, ulmic, and geic acids, and finally, by a still further progress, crenic and apocrenic acids are formed by a process of oxidation, which goes on during the decay.

In fact, these substances are representatives of the different stages of decomposition of plants; and that this is actually the source of all the humus compounds, is obvious from the fact that they are only found in the soil itself, that is to say, in the upper foot or two of the earth's surface, and only in those parts of it on which plants grow. Numerous analyses of the different substances already mentioned have been made, and have served to establish a number of minor differences in the composition even of those to which the same name has been applied; and these differences are manifestly attributable to the fact, that, as their production is the result of a gradual decomposition, at no time can it be possible to extract from the soil one pure substance, but only a variable mixture of several. For this reason it is that such discrepancies exist in the statements of the most careful observers. As far as the composition of these substances is concerned, little need be said, as we shall immediately see that it has no very direct bearing upon agricultural questions. It will suffice, therefore, to give the names and chemical formulæ of those which have been analysed and described,—

| | | | |
|---|---|---|---|
| Ulmic acid from long Frisian turf......... | $C_{40}$ | $H_{18}$ | $O_{16}$ |
| Humic acid from hard turf ................ | $C_{40}$ | $H_{15}$ | $O_{15}$ |
| Humic acid from arable soil ............... | $C_{40}$ | $H_{16}$ | $O_{16}$ |
| Humic acid from a pasture field ......... | $C_{40}$ | $H_{14}$ | $O_{14}$ |

| Apocrenic acid .............................. | $C_{48}$ | $H_{12}$ | $O_{24}$ |
| Crenic acid.................................... | $C_{24}$ | $H_{12}$ | $O_{16}$ |

Humus was formerly considered a much more important constituent of the soil than chemists are now inclined to suppose. It was believed to be the exclusive, or at all events the chief source of the organic constituents of plants, and by absorption through the roots to yield to them the greater part of their nutriment. This view is still supported by some chemists and vegetable physiologists, among whom Mulder is the most distinguished; but notwithstanding their authority, there is little doubt that humus is not a *direct* source of the organic constituents of plants, and is not absorbed as such by their roots; but it is so *indirectly*, in as far as the decomposition which it is constantly undergoing in the soil yields carbonic acid, which can be absorbed. The older opinion is refuted by many well-ascertained facts. As regards the exclusive origin of the carbon of plants from humus, it is easy to see that this at least cannot be true. The humus, as we have already stated, is itself derived solely from the decomposition of vegetable and animal matters; and if the plants on the earth's surface were to be supported by it alone, the whole of their substance would have to return to the soil as humus, in order to supply the generation which succeeds them. We know, however, that this is not the case; for the respiration of animals, the combustion of fuel, and many other processes, are annually converting a large quantity of these matters into carbonic acid; and if there were no other source of carbon but the humus of the soil, the amount of vegetable life would gradually diminish, and at length become entirely extinct. Schleiden, who has discussed this subject in full, has made an approximative calculation of the total quantity of humus on the earth's surface, and of the quantity of carbon annually converted into carbonic acid by the respiration of man and animals, the combustion of wood for fuel, and other minor processes; and he draws the conclusion that, if there were no other source of carbon except humus, the quantity of that substance existing in the soil would only support vegetation for a period of sixty years. So far from humus being the only source of carbon, it is obvious that a great part of it must be derived from other sources; for Boussingault has shown that cultivated crops carry off, on the average of years, about one ton more carbon than they receive in the manure applied to them, and without any corresponding diminution on the quantity of humus. A still more convincing evidence of the same nature is given by Humboldt. He states that an acre of land, planted with bananas, yields annually about 155,000 pounds weight of fruit, containing about 32,000 pounds, or upwards of 14 tons of carbon; and as this production goes on during a period of twenty years, there must be withdrawn in that time no less than 280 tons of carbon. But the soil on an acre of land weighs, in round numbers, 1000 tons, and supposing it to contain 4 per cent. of humus, the total weight of carbon in it would amount to little more than 20 tons.

It is manifest from these facts that the influence of humus must be very small, and while no one now supposes it to be the sole source of carbon, as was once believed, it has been contended, that there really is a certain, though small, absorption. Numerous facts are, however, at variance even with this opinion. It is found that the conditions which insure the solubility of the humus are by no means the most suitable to vegetation, though we should expect them to be so were humus absorbed. Peat soils, for instance, which contain large quantities of it in solution, so far from being favourable, are positively injurious to most plants. On the other hand, innumerable examples are found of plants growing luxuriantly in soils and places where no humus exists. The sands of the sea-shore, and the most barren rocks, have their vegetation, and the red-hot ashes which are thrown out by active volcanoes, are no sooner cool than a crop of plants springs up on them.

The conclusions to be drawn from these considerations have been further confirmed by the direct experiments of different observers. Boussingault sowed pease, which weighed 15·60 grains, in a soil composed of a mixture of sand and clay, which had been heated red-hot, and consequently contained no humus, and after 99 days growth, during which they had been watered with distilled water, he found the crop to weigh 68·72 grains, so that there had been a fourfold increase. Similar experiments have been made by Salm Horstmar, on oats and rape. He sowed them in a soil which had been previously ignited, and found that they grew readily and arrived at complete maturity. One oat straw grew to a height of three feet, and bore 78 grains; another bore 47; and a third 28, in all 153. These when dried at 212° weighed 46·302 grains, and the straw 45·6 grains. The most satisfactory experiments, however, are those of Weigman and Polstorff, who found that, provided care were taken to produce an artificial soil without humus, but having the *physical* characters of a fertile soil, it was possible to obtain a two-hundred-fold produce of barley. They prepared a mixture of six parts of sand, two of chalk, one of white bole, and one of wood charcoal; to this was added a small quantity of felspar, which had been fused up with marble and some soluble salts, so as to imitate as closely as possible the inorganic parts of a soil, and in it they planted twelve barley plants. The plants grew luxuriantly, reaching a height of three feet, and each bearing nine ears; the ears gave 22 pickles each. The grain of the twelve plants weighed 2040 grains, the straw 2449 grains. On the other hand, experiments have been made which show that even when present, humus is not absorbed. The first experiments of this sort we owe to Saussure, who allowed plants of the common bean and the Polygonum Persicaria to grow in solutions of humate of potash, and found a very trifling diminution in the quantity of humic acid present; but the value of his experiments is invalidated by his having omitted to ascertain whether the diminution of humic acid which he observed were really due to absorption by the plant. This omission has been supplied by Weigman and Polstorff. They grew plants of mint (Mentha undulata) and of Polygonum Persicaria in solutions of humate of potash, and placed beside the glass containing the plant, another perfectly similar, and containing only the solution of humate of potash. The solution, which contained in every 100 grains, 0·148 grains of solid matter, consisting of humate of potash, &c. was found to become gradually paler, and at the end of a month, during which time the plants had increased by 6½ inches, the quantity of solid matter in 100 grains had diminished to 0·132. But the solution contained in the other glass, and in which no plant had grown, had diminished to 0·136, so that the absorption could not have amounted to more than 0·004 grains for every 100 grains of solution employed. This quantity is so small as to be within the limits of error of experiment, and we are consequently entitled to draw the conclusion that humus, even under the most favourable circumstances, is not absorbed by plants.

While it appears, then, that humus is not directly a food of plants, it must not be supposed that it is altogether devoid of importance. The decompositions which it is constantly undergoing in the soil, make it a source of carbonic acid, which may be absorbed by the plants; and it consequently has indirectly an important bearing on their nutrition. Its functions in the soil are also important, but these we leave for future consideration.

Carbonic acid, ammonia, and water, are the great organic foods of plants. But while the plant has afforded to it an inexhaustible supply of the last, the quantities of the two former, both in the atmosphere and the soil, which are available as food, are limited, and insufficient to sustain its life for a prolonged period. It has been shown by Chevandrier, that an acre of land under beech wood accumulates annually about 1650 lb. of carbon. But the column of air resting upon an acre of land contains only about 15,500 lb. of carbon, and the soil may be estimated to contain 1 per cent., or 22,400 lb. per acre, and the whole of this carbon would therefore be removed, both from the air and the soil, in the course of little more than 23 years. But it is a familiar fact, that plants continue to grow with undiminished luxuriance year after year in the same soil, and they do so because neither their carbon nor their nitrogen are permanently absorbed; they are there only for a period, and when the plant has finished its functions and dies, they sooner or later return into their original state. Either the plant decays, in which case its carbon and nitrogen pass more or less rapidly into their original state, or it becomes the food of animals, and by the processes of respiration and secretion, the same change is effected. In this way a sort of balance is sustained; the carbon which at one moment is absorbed by the plant, passes in the next into the tissues of the animal, only to be again expired in that state in which it is fitted to commence again its round of changes.

But while there is thus, as it were, a continuous circulation of these constituents through both plants and animals, there are various changes which tend to diminish the quantities of carbonic acid and ammonia at the earth's surface, carbon being separated from plants and animals under certain circumstances in the elementary state, and the decomposition of nitrogenous matters yielding nitrogen, which is incapable of returning into the state of ammonia except in small quantity and by very circuitous processes. The elements carbon and nitrogen being, as we have already mentioned, incapable of direct absorption by plants, a gradual though slow diminution in the amount of vegetable life would necessarily occur were it not that nature has provided against this by establishing sources of carbonic acid and ammonia so as to sustain their quantity. The most important of these sources is perhaps volcanic action, both ammonia and carbonic acid being evolved from active volcanoes to an extent which may appear trifling when superficially examined, but is really very large. The production of nitric acid during thunder-storms, apparently by the combination of the nitrogen and oxygen of the atmosphere, which either directly or indirectly ministers to the growth of plants, is another mode in which the supply of these substances is sustained, and the small annual loss of the available food of plants counterbalanced.

*Source of the Inorganic Constituents of Plants.*—The nature of the inorganic constituents of plants, their being solid and fixed substances, sufficiently indicate that there can be but one source from which they may be derived. That source is the soil, which, as we shall afterwards see, contains all these substances in greater or less abundance, and has always been admitted to be the only substance capable of supplying them. The older chemists and physiologists, however, attributed no importance to these substances, and looking to the small quantities in which they are found in plants, imagined that they were there present merely as accidental impurities which had been absorbed from the soil along with the humus, which was at that time considered to be their organic food. This opinion, sufficiently disproved by the constant occurrence of the same substances, and in the same proportions, in the ash of each individual plant, has been further refuted by the experiments of Prince Salm Horstmar, who has established the fact of the origin of all these substances from the soil, and of their importance to vegetation, by experiments upon oats grown on artificial soils, in each of which one inorganic constituent was omitted. He found that, without silica, the grain vegetated, but remained small, pale in colour, and so weak as to be incapable of supporting itself; without lime, it died when it had produced its second leaf; without potash and soda, it grew only to the height of three inches; without magnesia, it was weak and incapable of supporting itself; without phosphoric acid, it was weak but upright; and without sulphuric acid, it was weak though normal in form, but produced no fruit.

*Manner in which the Constituents of Plants are Absorbed.*

*Water.*—The absorption of water by plants takes place in great abundance, and is connected with many of the most important phenomena of vegetation. It is absorbed by the roots alone, and passing into the tissues of the plant, a part of it is decomposed, and goes to the formation of certain of its organic compounds; but by far the larger quantity does not remain in the plant, but is again exhaled by the leaves. The extent to which this takes place is very large. Hales found that a sunflower exhaled in twelve hours about 1 lb. 5 oz. of water, but this quantity was liable to considerable variation, being greater in dry, and less in wet weather, and was greatly diminished during the night. Saussure made similar experiments, and found that the quantity of water exhaled by a sunflower amounted to about 220 lb. in four months. The subject of the exhalation of water by plants has recently been examined with great accuracy by Lawes. His experiments were made by planting single plants of wheat, barley, beans, pease, and clover, in large glass jars capable of holding about 42 lb. of soil, and covered with glass plates, furnished with a hole in the centre for the passage of the stem of the plant. Water was supplied to the soil at certain intervals, and the jars were carefully weighed. The result of the experiments, continued during a period of 172 days, is given in the following table, which shows the total quantity of water exhaled in grains:—

Wheat ........................................113,527
Barley ........................................120,025
Beans ........................................112,231
Pease ........................................109,082
Clover, cut 28th June .................... 55,093

It was found, further, that the exhalation was not uniform, but increased during the period of active growth of the plant, and diminished again when that period was passed. These variations are shown by the subjoined tables, of which the first gives the total exhalation during certain periods, and the second the average daily loss of water during the same periods.

TABLE I.—*Showing the Number of Grains of Water given off by the Plants during stated divisional Periods of their Growth.*

| Description of Plant. | 9 Days. From Mar. 19 to Mar. 28. | 31 Days. From Mar. 28 to Apr. 28. | 27 Days. From Apr. 28 to May 25. | 34 Days. From May 25 to June 28. | 30 Days. From June 28 to July 28. | 14 Days. From July 28 to Aug. 11. | 27 Days. From Aug. 11 to Sept. 7. |
|---|---|---|---|---|---|---|---|
| Wheat, | 129 | 1268 | 4,385 | 40,030 | 46,060 | 15,420 | 6235 |
| Barley, | 129 | 1867 | 12,029 | 37,480 | 45,060 | 17,046 | 6414 |
| Beans, | 88 | 1854 | 4,846 | 30,110 | 58,950 | 12,626 | 3657 |
| Pease, | 101 | 1332 | 2,873 | 36,715 | 62,780 | 5,281 | ... |
| Clover, | 400 | 1645 | 2,948 | 50,100 | ... | ... | ... |

TABLE II.—*Showing the average daily Loss of Water (in Grains) by the Plants, within several stated divisional Periods of their Growth.*

| Description of Plant. | 9 Days. From Mar. 19 to Mar. 28. | 31 Days From Mar. 28. to Apr. 28. | 27 Days. From Apr. 28 to May 25. | 34 Days. From May 25 to June 28. | 30 Days. From June 28 to July 28. | 14 Days. From July 28 to Aug. 11. | 27 Days. From Aug. 11 to Sept. 7. |
|---|---|---|---|---|---|---|---|
| Wheat, | 14·3 | 40·9 | 162·4 | 1177·4 | 1535·3 | 1101·4 | 230·9 |
| Barley, | 14·3 | 60·2 | 445·5 | 1102·3 | 1502·0 | 1217·6 | 237·5 |
| Beans, | 9·7 | 59·8 | 179·5 | 885·6 | 1965·0 | 901·8 | 135·4 |
| Pease, | 11·2 | 42·9 | 106·4 | 1079·8 | 2092·7 | 377·2 | ... |
| Clover, | 44·4 | 53·0 | 109·2 | 1473·5 | ... | ... | ... |

Similar experiments were made with the same plants in soils to which certain manures had been added, and with results generally similar. If, now, a calculation be made from these results of the quantity of water exhaled by the plants growing on an acre of land, it will be found greatly to exceed the annual fall of rain; but we know that of all the rain which falls only a small proportion can be absorbed by the plants growing on the soil, for a large quantity is carried off by the rivers, and never reaches their roots. It has been calculated, for instance, that the Thames carries off in this way at least one-third of the annual rain that falls in the district watered by it, and the Rhine nearly four-fifths. The exhalation which takes place to so great an extent must therefore be dependent on the repeated absorption of the same quantity of water, which, after being exhaled, is again deposited on the soil in the form of dew, and passes repeatedly through the plant. This constant percolation of water is of immense importance to the plant, as it forms the channel through which some of its other constituents are carried to it.

*Carbonic Acid.*—While thus the whole of the water which a plant requires is absorbed by its roots, exactly the reverse is the case with carbonic acid, of which only an inconsiderable quantity is so absorbed. It passes into the plant by the leaves, as has been clearly shown by Boussingault, by a very simple experiment. He took a large glass globe having three apertures, through one of which he introduced a branch of a vine, with twenty leaves on it. With one of the side apertures a tube was connected, by means of which the air could be drawn slowly through the globe, and into an apparatus in which its carbonic acid could be accurately determined. He found, in this way, that while the air which entered the globe contained 0·0004 of carbonic acid, that which escaped contained only 0·0001, so that three-fourths of the carbonic acid had been absorbed.

*Ammonia.*—The absorption of ammonia, so far as we at present know, takes place entirely by the roots; and although a quantity of it no doubt exists in the air, which is important to the plant, there is little doubt that even that reaches it through the root, being carried down by the rain, and absorbed in that way. The greater part of the ammonia, being derived from the organic matter of the soil, is undoubtedly absorbed by the roots.

*Inorganic Constituents.*—These are likewise absorbed by the roots; and it is as a solvent for these substances that the large quantity of water that passes through the plants is so important. The inorganic constituents exist in the soil in particular states of combination, in which they are only sparingly soluble; so much so, indeed, that many of them are considered to be almost absolutely insoluble in water. But in the soil their solubility is increased by the presence of carbonic acid, which being absorbed by the water causes it to dissolve, to some extent, substances otherwise insoluble. It is in this way that lime, which occurs in the soil principally as the insoluble carbonate, is dissolved and absorbed. Phosphate of lime is dissolved in water containing carbonic acid, or even common salt in solution; and generally we have some solvent substance always present. The amount of solubility produced by these substances is extremely small; but it is sufficient for the purpose of supplying to the plant as much of its mineral constituents as are required, for the quantity of water which, as we have already seen, passes through a plant is very large when compared with the amount of inorganic matters absorbed. It has been shown by Lawes that about 2000 grains of water pass through a plant for every grain of mineral matter fixed in it, so that there is no difficulty in understanding how the absorption takes place. There is no doubt that the substances, before they can pass into the plant, must be dissolved, experiment having distinctly shown that the spongioles or apertures through which this absorption takes place are too minute to admit even the smallest solid particle.

### THE PROXIMATE CONSTITUENTS OF PLANTS.

The substances which are absorbed by the plant undergo within it a series of complicated changes, and produce a number of complex organic compounds, of which the mass of the plant is composed. These substances may be divided into three great classes, of widely different properties, composition, and functions.

1*st*, *The Saccharine and Amylaceous Constituents.*—These substances are compounds of carbon, hydrogen, and oxygen, and all possess a certain degree of similarity in composition. The quantities of hydrogen and oxygen which they contain are always in the proportion to form water, so that they may be considered as compounds of carbon and water; not that it can be asserted that they actually do contain water, as such, for of that we have no evidence, but only that its constituents are there in the proportion to form it.

*Cellulose.*—This substance forms the fundamental part of all plants. It is the principal constituent of woody fibre, and is found in a state of purity in the fibre of cotton and flax, and in the pith of plants; but in wood it is generally contaminated with another substance, which has been called incrusting matter, as it is deposited in and around the cells, of which the plant is in part composed. Cellulose is insoluble in all menstrua, but, when boiled for a long time with sulphuric acid, is converted into a substance called dextrine. Cellulose consists of—

| | From pith of Elder-tree. | Spongioles of roots. |
|---|---|---|
| Carbon | 43·37 | 43·00 |
| Hydrogen | 6·04 | 6·18 |
| Oxygen | 50·59 | 50·82 |
| | 100·00 | 100·00 |

It is represented chemically by the formula, $C_{24}\ H_{21}\ O_{21}$, which shows it to be a compound of 24 atoms of carbon with 21 of hydrogen and 21 of oxygen.

*Incrusting matter.*—Of this substance, large quantities enter into the composition of all plants; but of its chemical nature little is known, as it cannot be obtained separate from cellulose. It is, however, of analogous composition, and probably contains hydrogen and oxygen in the proportion to form water.

*Starch.*—When a quantity of the flour of wheat, or of many other seeds, is exposed to a gentle stream of water, there is separated from it a fine white powder, which is common starch. This powder, when examined by the microscope, is found to be composed of minute grains, formed of concentric layers deposited on one another. These grains vary considerably in size and structure in different plants; but in the same plant they are generally so much alike as to admit of their recognition by a practised observer. These grains were formerly believed to be composed of an external coating of a substance insoluble in water, and containing in their interior a soluble kernel. This opinion has, however, been refuted, and distinct evidence been brought to show that the exterior and interior of the globules are identical in chemical properties. If boiled with water, starch dissolves to a thick fluid; and if heated in the dry state, to a temperature of about 390° Fahr., it becomes soluble in cold water. It is distinguished by giving a brilliant blue compound with iodine. Starch contains—

| | |
|---|---|
| Carbon | 44·47 |
| Hydrogen | 6·28 |
| Oxygen | 49·25 |
| | 100·00 |

and its composition is represented by the formula $C_{12}\ H_{10}\ O_{10}$. It differs, therefore, but little from cellulose in composition, but its chemical functions in the plant are extremely different. It is connected with some of the most important changes which occur in the growing plants, and by a series of remarkable transformations is converted into sugar and other important compounds.

*Lichen Starch* is found in most species of lichens, and is distinguished from common starch by producing a green colour with iodine. Its composition is the same as that of ordinary starch.

*Inuline.*—The species of starch to which this name is given is characterised by its dissolving in boiling water, and giving a white pulverulent deposit in cooling. It is found in the tuber of the dahlia, in the dandelion, and some other plants. Its composition is identical with that of cellulose, and its formula is $C_{24}\ H_{21}\ O_{21}$.

*Gum* is exuded from various plants in the form of a thick fluid, which dries up into a resinous mass. Its composition is the same as that of starch. It differs considerably in its properties when derived from different plants, but in all cases its chemical composition is the same.

*Dextrine.*—When starch is exposed to a heat of about 400°, or when treated with sulphuric acid, or with a substance extracted from malt called *diastase*, it is converted into dextrine. The same substance may also be obtained from cellulose by a similar treatment. The dextrine so obtained has the same composition as the starch from which it is obtained, but in its properties more nearly resembles gum. It is a highly important constituent of all plants, and may be converted into sugar on the one hand, and into starch on the other.

*Sugar.*—Under the general name of sugar are included four or five different substances which chemists have distinguished. Of these the most important are cane sugar, grape sugar, and an uncrystallisable sugar found in most plants.

*Cane Sugar* is met with in the sugar-cane, the maple, and many other plants. It is extremely soluble in water, and may be obtained in large crystals, as in common sugar-candy. Its composition is—

| | |
|---|---|
| Carbon | 42·22 |
| Hydrogen | 6·60 |
| Oxygen | 51·18 |
| | 100·00 |

and its chemical formula is $C_{12}\ H_{11}\ O_{11}$.

*Grape Sugar* is met with in the grape, and most other fruits. But it is also produced when starch is boiled for a long time with sulphuric acid, or treated with a large quantity of diastase. It is less soluble in water than cane sugar, and crystallises in small round grains. Its composition, when dried at 284°, is—

| | |
|---|---|
| Carbon | 40·00 |
| Hydrogen | 6·66 |
| Oxygen | 53·34 |
| | 100·00 |

and its formula is $C_{12}\ H_{12}\ O_{12}$.

The uncrystallisable sugar of plants is closely allied to grape sugar, and so far as we know, its composition is the same.

*Mucilage* is the name applied to the substance existing in linseed, and in many other seeds, and which communicates to them the property of swelling up and becoming gelatinous when treated with water. It is found in a state of considerable purity in gum tragacanth, and some other gums. Its composition is not known with absolute certainty, but it is either $C_{24}\ H_{19}\ O_{19}$, or $C_{12}\ H_{10}\ O_{10}$; and in the latter case it must be identical with starch and gum.

All the substances belonging to this class are obviously very closely related in chemical composition, some of them, indeed, as starch and gum, though easily distinguished by their properties, are identical in constitution, and the others only differ in the quantity of water, or of its elements which they contain. In fact, all these substances may be considered as compounds of carbon and water, and their relations are, perhaps, more distinctly seen when their formula are written so as to show this, as is done in the following table, in which they are all supposed to contain 24 equivalents of carbon, so as to make them comparable with cellulose:—

| | | | Water. |
|---|---|---|---|
| Grape sugar, | $C_{12}\ H_{12}\ O_{12}$ | $C_{24}\ H_{24}\ O_{24}$ | $C_{24} + 24$ |
| Cane sugar, | $C_{12}\ H_{11}\ O_{11}$ | $C_{24}\ H_{22}\ O_{22}$ | $C_{24} + 22$ |
| Cellulose, . | $C_{24}\ H_{21}\ O_{21}$ | $C_{24}\ H_{21}\ O_{21}$ | $C_{24} + 21$ |
| Inuline, . | $C_{24}\ H_{21}\ O_{21}$ | $C_{24}\ H_{21}\ O_{21}$ | $C_{24} + 21$ |

The differences being thus so slight, it will not be difficult to understand how one of these compounds may pass into the other. Thus, for instance, cellulose has only to absorb an atom of water to become cane sugar, or to lose an atom in order to be converted into starch; changes which, we have every reason to believe, actually do occur in the plant.

*Pectine and Pectic Acid.*—These substances are met with in many fruits and roots, as, for instance, in the apple, the carrot, and the turnip. They differ from the starch group of substances, in containing a larger quantity of oxygen than is required to form water along with their hydrogen; but their exact composition is still uncertain, and they undergo numerous changes during the ripening of the fruit.

2d, *Fatty Matters.*—The fatty constituents of plants form a rather extensive group of substances all closely allied, but distinguished by minor peculiarities in properties and differences in constitution. Some of them are of very frequent occurrence, but others are almost peculiar to individual plants. They are all compounds of carbon, hydrogen, and oxygen, and are at once distinguished from the preceding class, by containing oxygen in greatly less quantity than is required to form water with their hydrogen. The principal constituents of the fatty matters and oils of plants are three substances, called stearine, margarine, and oleine, the two former solids, the latter a fluid. These substances rarely if ever occur alone, but are mixed together in variable proportions, and the fluidity of the oils is due principally to the quantity of the last which they contain. If a quantity of olive oil be exposed to cold, it is seen partially to congeal; and if it be then pressed, a fluid flows out, and a crystalline solid remains, the former is oleine, though not absolutely pure, and the latter margarine. The separation of these substances involves a variety of troublesome chemical processes; and when it has been effected, it is found that each of them is a compound of a peculiar acid with another substance called glycerine, or the sweet principle of fats. Glycerine, as it exists in the fats, appears to be a compound of $C_3\ H_2\ O$, and its properties are the same from whatever source it is obtained. The acids separated from it are known by the names of margaric, stearic, and oleic acids.

*Margaric and Stearic Acids.*—These substances are white crystalline solids insoluble in water, and fusing at a low temperature. They were formerly believed to be different in composition, but the more accurate analyses of later chemists have shown, that they have both the following composition:—

| | |
|---|---|
| Carbon | 75·64 |
| Hydrogen | 12·71 |
| Oxygen | 11·65 |
| | 100·00 |

and are both represented by the formula $C_{34}\ H_{34}\ O_4$.

*Oleic Acid.*—Under this name two different substances appear to be included. It has been applied generally to the fluid acids of all oils, while it would appear that the drying and non-drying oils actually contain substances of different composition. The acid extracted from olive oil appears to have the formula $C_{36}\ H_{34}\ O_4$, while that from linseed oil is $C_{46}\ C_{38}\ O_6$, but this is still doubtful.

Other fatty acids have been detected in palm oil, cocoanut oil, &c. &c., but they are of minor importance, and so closely resemble margaric and stearic acids, as to be easily confounded with them, although their composition is undoubtedly different.

*Wax* is a substance closely allied to the fats. It consists of two substances, cerine and myricine, each of which is extremely complex in its composition. The former consists principally of an acid similar to the fatty acids, called cerotic acid, and containing $C_{54}\ H_{54}\ O_4$. The latter has the formula $C_{92}\ H_{92}\ O_4$. These substances are separated from one another by boiling with alcohol, in which the former is more soluble. The wax found in the leaves of the lilac and other plants appears to consist of myricine, while that extracted from the sugar-cane is said to be different, and to have the formula $C_{48}\ H_{50}\ O_2$. It is probable that other plants contain different sorts of wax, but their investigation is still so imperfect, that nothing definite can be said regarding them. Wax and fats appear to be produced in the plant from starch and sugar; at least it is unquestionable that the bee is capable of producing the former from sugar, and we shall afterwards see that a similar change is most probably produced in the plant.

3d, *Nitrogenous or Albuminous Constituents of Plants and Animals.*—The nitrogenous constituents of plants and animals are so closely allied, both in properties and composition, that they may be most advantageously considered together.

*Albumen.*—Vegetable albumen is found dissolved in the juices of most plants, and is abundant in that of the potato, the turnip, and wheat. In these juices it exists in a soluble state, but if its solution be heated to about 150° it coagulates into a flocky insoluble substance. It is also thrown down by acids and alcohol. Coagulated albumen is soluble in alkalies and in nitric acid. Animal albumen exists in the white of eggs, the serum of blood, and the juice of flesh; and from all these sources is scarcely distinguishable by its properties from vegetable albumen. The composition of both varieties is the same—

| | From Wheat. | From Potatoes. | From Blood. | From White of Egg. |
|---|---|---|---|---|
| Carbon | 53·7 | 53·1 | 53·4 | 53·0 |
| Hydrogen | 7·1 | 7·2 | 7·0 | 7·1 |
| Nitrogen | 15·6 | ... | 15·5 | 15·6 |
| Oxygen | 23·6 (Oxygen, Sulphur, Phosphorus) | ... | 22·1 | 22·9 |
| Sulphur | | 0·97 (Oxygen, Sulphur, Phosphorus) | 1·6 | 1·1 |
| Phosphorus | | ... | 0·4 | 0·3 |
| | 100·0 | | 100·0 | 100·0 |

Closely allied to vegetable albumen is the substance known by the name of *glutin*, which is obtained by boiling the gluten of wheat with alcohol. It appears to be a sort of coagulated albumen, and its composition is the same as that given above.

*Vegetable Fibrine.*—If a quantity of wheat flour be tied up in a piece of cloth, and kneaded for some time under water, the starch it contains is gradually washed out, and there remains a quantity of a glutinous substance called gluten. When this is boiled with alcohol, *glutin* above referred to is extracted, and vegetable fibrine is left. It dissolves in dilute potash, and on the addition of acetic acid is deposited in a pure state. Treated with hydrochloric acid, diluted with ten times its weight of water, it swells up into a jelly-like mass. When boiled or preserved for a long time under water, it cannot be distinguished by its properties from coagulated albumen.

*Animal Fibrine* exists in the blood and the muscles, and agrees in all its characters with vegetable fibrine, as is seen by the subjoined analyses—

| | Wheat Flour. | Blood. | Flesh. |
|---|---|---|---|
| Carbon | 53·1 | 52·5 | 53·3 |
| Hydrogen | 7·0 | 6·9 | 7·1 |
| Nitrogen | 15·6 | 15·5 | 15·3 |
| Oxygen | 23·2 | 24·0 | 23·1 |
| Sulphur | 1·1 | 1·1 | 1·2 |
| | 100·0 | 100·0 | 100·0 |

*Caseine.*—Vegetable caseine is abundantly found in most plants, and is met with in the juice from which albumen has been precipitated by heat, and may be separated from it in flocks by the addition of an acid. It has been obtained for chemical examination, principally from pease and beans, and from the almond and oats. That prepared from the pea has been called *legumine*, that from almonds *emulsine*, and that from oats *avenine;* but they are all three identical in their properties, although formerly believed to be different, and distinguished by these names. Vegetable caseine is best obtained by treating pease or beans with hot water, and straining the fluid. On standing, the starch held in suspension is deposited, and the caseine is retained in solution in the alkaline fluid; by the addition of an acid it is precipitated as a thick curd. Caseine is insoluble in water, but dissolves readily in alkalies; its solution is not coagulated by heat, but, on evaporation, becomes covered with a thin pellicle, which is renewed as often as it is removed.

*Animal Caseine* is the principal constituent of milk, and is obtained by the cautious addition of an acid to skimmed milk, by which it is precipitated as a thick white curd. It is also obtained by the addition of rennet, and the process of curdling milk is simply the coagulation of its caseine. It is soluble in alkalies, and is precipitated from its solution by acids, and in all other respects agrees with vegetable caseine.

The composition of animal caseine has been well ascertained, but considerable doubt still exists as to that of vegetable caseine, owing to the difficulty of obtaining it absolutely pure. The analyses of different chemists give rather discordant results, but we have given those which appear most trustworthy—

| | From Pease. | |
|---|---|---|
| Carbon | 50·6 | 50·7 |
| Hydrogen | 6·8 | 6·6 |
| Nitrogen | 16·5 | 15·8 |
| Oxygen | 25·6 | 23·8 |
| Sulphur | 0·5 | 0·8 |
| Phosphorus | ... | 2·3 |
| | 100·0 | 100·0 |

Other results differ considerably from these, and some observers have even obtained as much as eighteen per cent. of nitrogen and fifty-three of carbon.

The composition of animal caseine differs from this principally in the amount of carbon. Its composition is—

| | |
|---|---|
| Carbon | 53·6 |
| Hydrogen | 7·1 |
| Nitrogen | 15·8 |
| Oxygen | 22·5 |
| Sulphur | 1·0 |
| | 100·0 |

It will be at once manifest that a very close relation subsists between the different substances just described. Indeed, with the exception of vegetable caseine, they may be said all to present the same composition; and, as has been mentioned above, there are analyses of it which would class it completely with the others. While, however, the quantities of carbon, hydrogen, nitrogen, and oxygen are the same, differences exist in the small quantities of sulphur and phosphorus they contain, and which are indubitably essential to them. Much importance has been attributed to these constituents by various chemists, and especially by Mulder, and he has endeavoured to make out that all the albuminous substances are compounds of a substance to which he has given the name of *proteine*, with different quantities of sulphur and phosphorus. The composition of proteine, according to his newest experiments, is—

| | |
|---|---|
| Carbon | 54·0 |
| Hydrogen | 7·1 |
| Nitrogen | 16·0 |
| Oxygen | 21·4 |
| Sulphur | 1·5 |
| | 100·0 |

and is exactly the same from whatever albuminous compound it is obtained. Although the importance of proteine is probably not so great as Mulder supposed, it affords an important illustration of the close similarity of the different substances from which it is obtained. There is every reason to believe that the different albuminous compounds are capable of changing into one another, just as starch and sugar are mutually convertible; and the possibility of this change throws much light on many of the phenomena of nutrition in plants and animals. Indeed, it would seem probable that these compounds are formed from their elements by plants only, and are merely assimilated by animals to produce the nitrogenous constituents they contain.

*Diastase* is the name applied to a substance existing in malt, and obtained by macerating that substance with cold water, and adding a quantity of alcohol to the fluid, when the diastase is immediately precipitated in white flocks. It is produced during the malting process, and is not found in the unmalted barley. Its chemical composition is unknown, but it is nitrogenous, and is believed to be produced by the decomposition of gluten. If a very small quantity of diastase be mixed with starch suspended in hot water, the starch is found gradually to dissolve, and to pass first into the state of dextrine, then into that of sugar. The change thus effected takes place also in a precisely similar manner in the plant, for diastase is produced during the process of germination of all seeds and tubers, for the purpose of effecting this change, and to fulfil other functions less understood, but no doubt equally important. Diastase is found in the seeds only during the period when the starch they contain is passing into sugar; as soon as that change has taken place, its function is ended, and it disappears.

THE CHANGES WHICH TAKE PLACE IN THE FOOD OF PLANTS DURING THEIR GROWTH.

1*st*, *Changes which occur during germination.*—When a seed is placed in the soil under favourable circumstances, it becomes the seat of an important and remarkable series of chemical changes, which result in the production of the young plant. Experiment and observation have shown that heat, moisture, and air, are necessary to the production of these changes. In all instances these three requisites must be combined, with the further addition, that at the earliest period the seed must be protected from the light. The elevation of temperature required for germination is very different with different seeds; some germinate at a few degrees above the freezing point, and others require a tolerably high temperature. The presence of oxygen is also essential, for it has been shown that if seeds are placed in a soil exposed to an atmosphere containing no oxygen, or if they be buried so deep that the air does not reach them, they may lie for an unlimited period without sprouting; but so soon as they are exposed to the air, germination immediately takes place. This phenomenon is frequently observed where earth has been thrown up from a considerable depth, when it is often covered by plants unknown in the neighbourhood, and which have sprung from buried seeds.

When all the necessary conditions are fulfilled, the seed first absorbs moisture, swells up, and sends out a shoot which rises to the surface, and a rootlet which descends, to form the organ by which nourishment is by and by to be absorbed. Until this takes place, however, the young plant derives its

Agricultural Chemistry.

whole nutriment from the seed. When the seed begins to swell, oxygen is absorbed, and re-acting upon the gluten of the seed, causes its conversion into diastase. The diastase in its turn acts upon the starch, and converts it first into dextrine, and then into cellulose, which being deposited in the form of organised cells, produces the first little shoot of the plant. The germ continues to derive the whole of its nutriment from the seed until leaves are produced, and during this time the substances laid up in it undergo a series of complicated changes. From the first moment of growth oxygen is absorbed, and carbonic acid evolved, and at the same time water also is formed from the organic constituents of the seed, which gradually diminishes in weight. The amount of this diminution is different with different plants, but is always considerable. Boussingault found that the loss of dry substance in the pea amounted in 26 days to 52 per cent., and in wheat to 57 per cent. in 51 days. Against this, of course, is to be put the weight of the young plant produced, but this is always much less than the loss of weight of the seed, for Saussure found that a horse bean and the plant produced from it weighed, after 16 days, less by 29 per cent. than the seed before germination. The same phenomenon is seen in the process of malting, which is in fact the artificial germination of barley, the malt produced always weighing considerably less than the grain from which it was obtained. It was believed by Saussure, and the older investigators, that the carbonic acid evolved was entirely produced from starch and sugar. These substances, as we have already stated, may be looked upon as compounds of carbon and water, and the carbon was supposed to be simply oxidised to carbonic acid, and its water eliminated. The action cannot, however, be so simple as this, for the woody fibre contains more carbon than the sugar from which it is produced; and we have, moreover, every reason to believe that the nitrogenous substances are also oxidised. In fact, all the constituents of the seed appear to take part in this change, and the process of germination may in some respects be compared to decay or putrefaction, which, like it, is attended by the absorption of oxygen and evolution of carbonic acid; but while in the latter case the residual substances remain in a useless state, in the former they at once become part of a new organism.

*Changes which occur during the after-growth of the plant.*—So soon as the plant has exhausted the store of materials laid up for it in the seed, it begins to derive its subsistence from the surrounding air, and to absorb carbonic acid, water and ammonia, and to decompose and convert them into the different constituents of its tissues. Each of these substances, of course, undergoes a different series of changes, which we shall separately consider.

*Decomposition of Carbonic Acid.*—Carbonic acid is absorbed by the leaves and stems of plants, and in their interior is entirely decomposed, its carbon being retained, while its oxygen is again evolved in the gaseous state. For the production of this change, the influence of the sun's rays is essential, and the stronger the light the greater is the amount of oxygen exhaled, and consequently of carbonic acid decomposed. The separation of oxygen is observed only in the green parts of plants; the flowers and roots, and the fruits when approaching ripeness, produce an exactly opposite effect, absorbing oxygen and evolving carbonic acid. The absorption of carbonic acid and escape of oxygen has been proved by numerous direct experiments by Saussure and others, in which both atmospheric air and artificial mixtures containing an increased quantity of carbonic acid have been employed. Saussure allowed seven plants of periwinkle (*Vinca minor*) to vegetate in an atmosphere containing 7·5 per cent. of carbonic acid for 6 days, during each of which the apparatus was exposed for 6 hours to the sun's rays. The air was analysed both before and after the experiment, and the results obtained were—

| | Volume of the Air. | Nitrogen. | Oxygen. | Carbonic Acid. |
|---|---|---|---|---|
| Before the experiment, | 5746 | 4199 | 1116 | 431 |
| After „ | 5746 | 4338 | 1408 | 0 |
| Difference, | 0 | +139 | +292 | −431 |

There were therefore absorbed 431 volumes of carbonic acid, and 292 volumes of oxygen evolved. Had the whole oxygen of the carbonic acid been evolved, its volume would have been equal to that of the acid, or 431; so that the deficiency of 139 volumes of oxygen must have been retained in the organs of the plant. Similar results have been obtained with other plants, and in all of them it was observed that after the experiment the nitrogen was increased in amount. It might be supposed that this nitrogen had been produced from the nitrogenous constituents of the plant, but Saussure has effectually disproved this, and rendered it probable that it had simply been retained in the interstices of the plant, and dissolved in the water in which they grew. The absorption of carbonic acid takes place only during the day; at night or in the dusk, exactly the opposite occurs, oxygen being absorbed and carbonic acid evolved from all parts of the plant. Saussure found that the oak, the horse-chesnut, and other plants, absorb oxygen and give off carbonic acid in less volumes than the oxygen, while the house-leek, the cactus, and other plants, absorb oxygen without evolving carbonic acid. While then this action is exactly the reverse of that occurring during the day, it must not be supposed that it is due to the carbon which has been fixed during the day being again eliminated in absence of light. On the contrary, it appears to be a purely mechanical and not a chemical action. The carbonic acid is absorbed along with the moisture which day and night is passing into the plant by the roots, but in the absence of the sun it passes through the plant and is exhaled by the leaves without undergoing any change.

The absorption of oxygen during the night, however, appears to be a true chemical process; were it mechanical it would not be confined to oxygen alone, but would take place also with the other gases in contact with the plant. Moreover, the absorption is extremely different in different plants, in some scarcely appreciable, in others very abundant. The plants containing volatile oils, which pass readily into resins by absorption of oxygen, and those which contain tannine and other readily oxidisable substances, taking up the largest quantity. Thus the leaves of the *Agave americana* after 24 hours' exposure in the dark, have absorbed only 0·3 of their volume of oxygen. The leaves of the fir which contain abundance of volatile oil have absorbed 10 times as much, and those of the oak which contain much tannine, 18 times as much oxygen.

In the flowers, both by day and night, there is a constant absorption of oxygen and evolution of carbonic acid. In fact, an active oxidation is going on attended by the evolution of heat, which in the *Arum maculatum*, and some other plants, is so great as to raise the temperature 10° or 12° above that of the surrounding air.

*Decomposition of water in the Plant.*—In addition to the function which water performs in the plant, as the solvent of the different substances which form its food, and hence as the medium through which they pass into its organs, it serves also as a direct food, undergoing decomposition, and yielding hydrogen to the organic substances. Its constituents, along with those of the carbonic acid absorbed, undergo a variety of transformations, and form the principal part of the non-nitrogenous constituents. We have already stated that starch, sugar, and the other allied substances may

Agricultural Chemistry.

be considered as compounds of carbon with water, and their formation might be conceived to be effected by the carbonic acid losing all its oxygen, and then direct combination ensuing between the residual carbon, and a certain proportion of water. This, of course, would imply that no change takes place in the water, and though probably the simplest view of the case, it is by no means the most probable. It is much more likely that the carbonic acid is only partially decomposed, half its oxygen being removed, and, at the same time the oxygen being separated from a quantity of water, its hydrogen takes the place of the oxygen which has been removed from the carbonic acid. Thus, for instance, sugar may be produced from twelve equivalents of carbonic acid and twelve equivalents of water, twenty-four equivalents of oxygen being eliminated as thus represented:—

| | | | | | |
|---|---|---|---|---|---|
| 12 equivalents of Carbonic Acid, | $C_{12}$ | | $O_{12}$ | $O_{12}$ | |
| 12 „ Water, | | $H_{12}$ | $O_{12}$ | | |
| 1 „ Sugar. & 24 of Ox. | $C_{12}$ | $H_{12}$ | $O_{12}$ | | $+ O_{24}$ |

It cannot, of course, be positively asserted that sugar is really produced exactly in the manner here shown, but there are many facts which point to the probability of its occurring in a somewhat similar method. That water must be decomposed is evident from the fact established by analysis, that the hydrogen of the plant is generally larger than is required to form water with its oxygen, so that this excess at least must be produced by the decomposition of water. The hydrogen of the volatile oils, many of which contain no oxygen, and that of the fats, which contain only a small quantity of oxygen, must manifestly be obtained in a similar manner.

*Decomposition of Ammonia.*—The nitrogenous or albuminous compounds of vegetables must of necessity obtain their nitrogen from the decomposition of ammonia, experiment having distinctly shown that they are incapable of absorbing it in the free state from the atmosphere. It has been clearly ascertained, that the albuminous substances do not contain ammonia, and it is hence apparent that a complete decomposition of that substance must take place in the plant. In fact, carbonic acid, water, and ammonia, must simultaneously take part in these changes, which must of necessity be complicated; so much so, indeed, that in the present state of our knowledge we cannot attempt any distinct explanation of them.

It must be clearly understood, that while such changes as those described manifestly must take place, the explanations of them which have been attempted by various chemists are not to be accepted as determinately established *facts;* they are at present no more than hypothetical views which have been expressed chiefly with the view of presenting some definite idea to the mind, and are unsupported by absolute proof; they are only inferences drawn from the general bearings of known facts, and not facts themselves. Although, therefore, they are to be received with caution, they have advantages in so far as they present the matter to us in a somewhat more tangible form than the vague general statements which are all that could otherwise be made.

### THE INORGANIC CONSTITUENTS OF PLANTS.

The examination of the inorganic constituents or ash of plants has, of late years, formed the subject of a large number of laborious investigations which have served to give us pretty full information on this subject, and to refute several errors at one time prevalent. The proportion in which the inorganic constituents exist in many plants is so small that they were believed by the older chemists to be entirely fortuitous components, which were present merely because they had been dissolved along with the humus, which was then supposed to enter the roots in solution, and to form the chief food of the plant. This supposition which could only be sustained at a time when analysis was imperfect, has been long since disproved and abandoned, and it has been distinctly shown by repeated experiment that not only are these inorganic substances necessary to the plant, but that every one of them, however small its quantity, must be present if it is to grow luxuriantly and arrive at a healthy maturity. The experiments of Prince Salm Horstmar, before alluded to, have established beyond a doubt, that while a seed may germinate, and even grow, to a certain extent, in absence of one or more of the constituents of its ash, it remains sickly and stunted, and is incapable of producing either flower or seed.

While the necessity for a certain quantity of mineral matters is thus certain, it nevertheless appears that their relative and absolute quantities may vary within very wide limits. The total quantity of ash in different plants and parts of plants is extremely different, and the extent of this difference may be best seen from the table given below, which gives the quantity of ash in 100 parts of the different substances in a *dry* state.

*Table showing the quantity of inorganic matters in* 100 *parts of different plants dried at* 212 *degrees:—*

An examination of this table indicates, that though great differences exist in the proportion of ash in different plants, some general relations may be traced. It appears that the grains of the cerealia of all other seeds contain the smallest quantity of ash, and that the proportion is nearly the same in all, and may be stated in round numbers at two per cent. In the leguminous plants (pease, beans, &c.), the quantity is larger, amounting to about three per cent., while in rape-seed, linseed, and the other oily seeds, it reaches four per cent. In the stems and straws less uniformity exists, but if we except a few extreme cases, the quantity of ash in most of them approaches pretty closely to five per cent. Still more diversified are the results obtained from the entire plants; but this diversity is probably much more apparent than real, and must be, in part at least, dependent on the proportion existing between the stem and leaves; for, the leaves, as we observe under the next head, are peculiarly rich in ash, and a leafy plant must, of course, indicate a higher total per-centage of ash, although, if stems and leaves were separately examined, they might not show so conspicuous a difference.

The leaves of all parts of plants are richest in ash; the table shows that in some instances, as in the maple, the inorganic constituents exceed one-fourth of the whole of the weight of the dry matter. In other instances, and particularly in the coniferous plants, the quantity is much smaller. The average proportion of ash in the leaves amounts to about thirteen per cent., but where such variations exist, little value is to be attached to an average such as this, except as an indication of their general abundance.

Roots and tubers likewise show some variety, but, with the exception of the turnip and potato, all approach pretty closely to seven per cent.

The wood is that part of the plant which contains the smallest quantity of ash. In one case only does it reach five per cent., while the average scarcely exceeds one per cent., and in the fir the quantity amounts to no more than one six-hundredth of the dry matter. In the bark the quantity is much larger, and may be stated at seven per cent.

We have thus, in round numbers, the following proportions of ash in different parts of plants:—

| | |
|---|---|
| Wood | 1 |
| Seeds | 3 |
| Stems and straws | 5 |
| Roots and tubers | 7 |
| Bark | 7 |
| Leaves | 13 |

The differences which exist in the proportion of ash, are much more strikingly seen when we examine different parts of the same plant. In few instances, however, have analyses been sufficiently multiplied to give much information on this point. The oat, the orange tree, and the horse-chesnut, are the only plants in which it has been done. The results obtained with the oat are given in the following table:—

| | Hopetoun Oats, Northumberland. | Hopetoun Oats, Fifeshire. | Potato Oats, Northumberland. | Black Oats, Edinburgh. | Sandy Oats, Fifeshire. | Mean. |
|---|---|---|---|---|---|---|
| Grain | 2·14 | 1·81 | 2·22 | 2·11 | 1·76 | 2·00 |
| Husk | 6·47 | 6·03 | 6·99 | 8·24 | 6·03 | 6·75 |
| Chaff | 16·53 | 17·23 | 15·59 | 19·19 | 18·97 | 16 06 |
| Leaves | 8·44 | 7·19 | 14·59 | 10·29 | 15·92 | 10·88 |
| Upper part of straw | 4·95 | 5·44 | 9·22 | 8·25 | 11·0 | 7·77 |
| Middle part of straw | 6·11 | 5·23 | 7·41 | 6·53 | 9·01 | 6·66 |
| Lower part of straw | 5·33 | 5·18 | 9·76 | 7·11 | 7·30 | 6·93 |

from which it will be seen that though considerable variations occur, the relative proportions of ash in different parts of the plant are pretty constant.

The proportion of ash which a plant contains varies greatly at different periods of its growth, but the changes which it undergoes seem, so far as we at present know, to be governed by no general laws. It appears, however, generally, that during the period of active growth the quantity of ash is largest. Thus, it has been found that in early spring the wood of the young shoots of the horse-chesnut contains 9·9 per cent. of ash. In autumn this has diminished to 3·4, and the last year's twigs contain only 1·1 per cent., while in the old wood the quantity does not exceed 0·5. Saussure has also observed that the quantity of ash diminishes in certain plants when the seed has ripened. Thus, he found that the per-centages of ash, before flowering, and after seeding, were as follows:—

| | Before flowering. | With ripe seed. |
|---|---|---|
| Sunflower | 14·7 | 9·3 |
| Wheat | 7·9 | 3·3 |
| Maize | 12·2 | 4·6 |

Agricultural Chemistry.

On the other hand, the quantity of ash in the leaves of trees increases considerably in autumn, as shown by this table:—

| | Per-centage of ash in May. | September. |
|---|---|---|
| Oak leaves | 5·3 | 5·5 |
| Poplar | 6·6 | 9·3 |
| Hazel | 6·1 | 7·0 |
| Horse-chesnut | 7·2 | 8·6 |

In other cases, the proportion of ash appears to increase as the plant reaches maturity, and this is particularly seen in the oat, of which we have very complete analyses, at different periods of its growth:—

*Proportion of Ash in different parts of the Oat at different periods of its growth.*

| Date. | Stalks. | Leaves. | Chaff. | Grain with husk |
|---|---|---|---|---|
| 2d July | 7·83 | 11·35 | | 4·91 |
| 9th July | 7·80 | 12·20 | | 4·36 |
| 16th July | 7·94 | 12·61 | 6·00 | 3·38 |
| 23d July | 7·99 | 16·45 | 9·11 | 3·62 |
| 30th July | 7·45 | 16·44 | 12·28 | 4·22 |
| 5th August | 7·63 | 16·05 | 13·75 | 4·31 |
| 13th August | 6·62 | 20·47 | 18·68 | 4·07 |
| 20th August | 6·66 | 21·14 | 21·07 | 3·64 |
| 27th August | 7·71 | 22·13 | 22·46 | 3·51 |
| 3d September | 8·35 | 20·90 | 27·47 | 3·65 |

Here a rapid increase takes place in the quantity of ash in the leaves and chaff. In the stalks it remains nearly uniform at all periods of the growth. In the grain, again, there is a decided diminution; but this diminution is apparent, not real, and is due to the determination of the ash being made on the grain, with its husk, and the rapid increase in weight of the grain, which is poor in ash, while the husk remains nearly unchanged, causes an apparent diminution in its proportion.

The quantity of ash contained in a plant is also dependent upon the nature of the soil on which it grows. Of this an interesting illustration is given in the following table of the quantities found in the grain and straw of the same variety of the pea grown on fourteen different soils:—

| | Seed. | Straw. | | Seed. | Straw. |
|---|---|---|---|---|---|
| 1 | 2·30 | | 8 | 2·27 | 6·59 |
| 2 | 3·25 | 3·43 | 9 | 2·69 | 3·49 |
| 3 | 4·27 | 3·62 | 10 | 1·61 | 3·91 |
| 4 | 3·40 | 3·39 | 11 | 3·11 | 5·28 |
| 5 | 2·99 | 3·90 | 12 | 3·34 | 7·57 |
| 6 | 3·19 | 6·80 | 13 | 2·78 | 3·76 |
| 7 | 2·53 | 3·90 | 14 | 3·01 | 3·38 |

The differences, especially in the straw, are here very remarkable, but we are unable to connect them with the peculiarities in composition of the soils on which they grow; indeed it is obvious that they must be dependent on most complicated questions, which we cannot at present solve, for we see that the increase in the ash of the straw is not generally connected with any corresponding increase in that of the grain. Theoretically, we should anticipate the proportion to be greatest in those soils which contain the largest quantities of the substances which enter into the composition of the ash; but this is by no means invariably the case. In some instances, the variations certainly can be traced to this source, as in the following analysis of the fruit of the horse-chesnut, grown on a common fruit soil, and on a rich porphyry soil:—

| | Kernel of seed. | Green husk. | Brown husk. |
|---|---|---|---|
| Forest soil | 2·26 | 4·53 | 1·70 |
| Porphyry soil | 3·36 | 7·29 | 2·20 |

in which a very marked increase has occurred, in that grown on the rich soil. This, however, is only an isolated case, and in many instances no satisfactory connexion can be traced between the nature of the soil and the quantity of ash contained in the plants grown on it.

While it thus appears that the quantity of ash differs greatly in different plants, the proportion in which the individual components enter into these ashes is also variable. Within very wide limits this will be at once apparent, from the following table, in which are gathered together analyses of the ash of most of our common cultivated, and a few uncultivated plants:—

*Table of the Composition of the Ash of different Plants in* 100 *parts.*

*Note.*—Alumina and oxide of manganese are of so rare occurrence that separate columns have not been introduced for them, but when they occur their quantity is stated in a note at the end of the table.

| Radish root | 21·16 | ... | 1·29 | 7·07 | 8·78 | 3·53 | 1·19 | 41·09 | 7·71 | ... | 8·17 |

A simple inspection of this table leads to various interesting conclusions. It is to be observed that two at least of the constituents of the ash, viz. alumina, and oxide of manganese, occur rarely, and in small quantity, and must be of very little importance. They have indeed been altogether excluded by some chemists from the list of the true constituents of the ashes of plants, and their presence considered as purely fortuitous. Oxide of iron, of which the proportion is also very small, has sometimes been classed along with these substances as a fortuitous component; but it is invariably present, and the experiments of Prince Salm Horstmar leave no doubt that it is essential to the plant. Its function is unknown, but it is an important constituent of the blood of herbivorous animals, and may be present in the plant, less for its own benefit than for that of the animal of which it is destined to become the food.

*Soda* would appear also to be a comparatively unimportant constituent, being absent in some cases, and found in most plants in but small quantity. It is only in the cruciferous plants (turnip, rape, &c.) that it is found abundantly, and in them it appears to be an indispensable element; but in most other plants it admits of replacement by potash, and this replacement is probably in some instances the result of cultivation. It has at least been found that the proportions of the two alkalies vary greatly in cultivated and uncultivated specimens of the same plant, the proportion of soda being greatest in the uncultivated. This is conspicuously seen in the asparagus plant, which gave the following quantities of alkalies and chlorine:—

| | Wild. | Cultivated. |
|---|---|---|
| Potash | 18·8 | 50·5 |
| Soda | 16·2 | traced |
| Chlorine | 16·5 | 8·3 |

[1] Alumina, 1·02.

[2] Alumina. 0·63.

The soda having almost entirely disappeared in the cultivated plant, while a corresponding increase had taken place in the quantity of potash.

*Potash* is a most important constituent of plants, and generally forms a considerable proportion of their ash. It is most abundant in the roots and tubers, and sometimes forms more than half of their mineral constituents. It is also abundant in the seeds, while its proportion is small in the straws and stems, and particularly in the chaff, of our common grains. In general, it may be said to constitute a third part of the ash of most plants.

The proportions of *lime* and *magnesia* are liable to very great variations. As a general rule, the proportion of the former greatly exceeds that of the latter. An exception to this is found in the cereals, the grains of which are remarkably rich in magnesia; but, generally speaking, the quantity of magnesia is small, and rarely exceeds 4 per cent. Lime is most abundant in the leguminous plants, exceeding, in some instances, 30 per cent. of the ash. In the cereals it is remarkably small.

*Chlorine* is by no means an invariable constituent of the ash, although it is most commonly met with, and sometimes in considerable quantity. It appears to have some relation to the quantity of soda, and is always largest when that element is most abundant. A reference to the analyses of the wild and cultivated asparagus will render this obvious, and the same conclusions may be drawn from the table of the composition of ashes, where it will be seen that the chlorine exists to a great extent, as chloride of sodium, and conspicuously so in the ash of mangold-wurzel, where it amounts to almost exactly half of the mineral matter.

*Sulphuric Acid* is an essential constituent of the ash. But it is to be observed that it is in some instances entirely, and in all partially, a product of the combustion to which the plant has been submitted in order to obtain the ash. It is partially derived from the albuminous compounds, which all contain a certain quantity of sulphur, and which, being oxidised to sulphuric acid during the burning, remains in the ash. It is certain, however, that we thus obtain an imperfect estimate of the whole quantity of sulphur which the plant contains in its natural state; and for this reason experiments have been made, by treating the plants with nitric acid, so as effectually to oxidise the whole of their sulphur, and admit of its being accurately determined. From such experiments, the following table, showing the *total* amount of sulphur contained in 100 parts of different DRY plants, has been constructed.

| | | | |
|---|---|---|---|
| Poa palustris | 0·165 | Drumhead Cabbage | 0·431 |
| Lolium perenne | 0·310 | Wheat, grain | 0·068 |
| Italian Ryegrass | 0·329 | straw | 0·245 |
| Trifolium pratense | 0·107 | Barley, grain | 0·053 |
| repens | 0·099 | straw | 0·191 |
| Lucerne | 0·336 | Oats, grain | 0·103 |
| Vetch | 0·178 | straw | 0·289 |
| Potato tuber | 0·082 | Rye, grain | 0·051 |
| tops | 0·206 | Beans | 0·056 |
| Carrot, root | 0·092 | Pease | 0·127 |
| tops | 0·745 | Lentils | 0·110 |
| Mangold-Wurzel, root | 0·058 | Hops | 1·063 |
| tops | 0·502 | Gold of Pleasure | 0·253 |
| Swede, root | 0·435 | Black Mustard | 1·170 |
| tops | 0·458 | White Mustard | 1·050 |
| Rape | 0·448 | | |

*Phosphoric Acid* is found principally in the seeds of plants in which it amounts to from 30 to 50 per cent. The straws of the cereal plants contain it only in very small proportion, and the stems and leaves of other plants afford intermediate proportions.

*Silica* is an invariable constituent of the ash. It is only, however, in the grasses that it is abundant, and that principally in their stems. It there contributes to the strength of the straw, and by giving it additional rigidity prevents its being broken or injured by the weight of the ear.

The knowledge of the composition of the ash of plants leads to many important practical deductions. It enables us to explain why some plants will not grow upon particular soils on which others flourish. Thus, for instance, a plant which contains a large quantity of lime, such as the bean or turnip, will not grow in a soil in which that element is deficient, although wheat or barley, which require but little lime, may yield excellent crops. Again, if the soil be deficient in phosphoric acid, those plants only will grow luxuriantly which require but a small quantity of that element. An extension of this principle leads us to the conclusion that even where a soil contains a proper quantity of all its ingredients, the repeated cultivation of a plant which removes a large quantity of any one substance, may, in the course of time, so far reduce its amount, that the soil becomes incapable of any longer producing that plant, but if it be replaced by another which requires but little of the element thus removed, it may again produce an abundant crop. On this principle the rotation of crops is founded, and its success is dependent on the cultivation in successive years of plants which remove preponderating quantities of different substances.

It may be observed by a minute inspection of the table of ashes, that some plants are peculiarly rich in alkalies, others in lime, and others again in silica; and it would, of course, be the object of the farmer to employ, in succession, crops containing these elements in different proportions. Practical experience in this matter has led to conclusions in all respects identical with those of science, and the successive crops of a good rotation always belong to these different classes. It has been attempted to classify different plants under the heads of silica plants, lime plants, and potash plants, and the following table, extracted from Liebig's *Agricultural Chemistry*, in which the constituents of the ash are grouped under the three heads of salts of potash and soda, lime and magnesia, and silica, gives such a classification as far as it can be done:—

| | | Salts of Potash and Soda. | Salts of Lime and Magnesia. | Silica. |
|---|---|---|---|---|
| Silica Plants. | Oat straw with seeds | 34·00 | 4·00 | 62·00 |
| | Wheat straw | 22·50 | 7·20 | 61·50 |
| | Barley straw with seeds | 19·00 | 25·70 | 55·30 |
| | Rye straw | 18·65 | 16·52 | 63·89 |
| | Good hay | 6·00 | 34·00 | 60·00 |
| Lime Plants. | Tobacco | 24·34 | 67·44 | 8·30 |
| | Pea straw | 27·82 | 63·74 | 7·81 |
| | Potato plant | 4·20 | 59·40 | 36·40 |
| | Meadow Clover | 39·20 | 56·00 | 4·90 |
| Potash Plants. | Maize straw | 72·45 | 6·50 | 18·00 |
| | Turnips | 81·60 | 18·40 | — |
| | Beet root | 88·00 | 12·00 | — |
| | Potatoes | 85·81 | 14·19 | — |
| | Jerusalem Artichoke | 84·30 | 15·70 | — |

The special application of these facts must be left till we come to treat of the subject of the rotation of crops in full, for which a knowledge of the composition of soils is required.

It must be manifest that, as the crops which we remove from the soil contain a greater or less amount of inorganic matters, the quantity of these must, under any circumstances, be undergoing diminution. In many cases the soil contains an almost inexhaustible supply of those substances, but in other instances, where the quantity is small, a system of reckless cropping may reduce a soil to a state of absolute sterility. A remarkable illustration of this fact is found in the virgin soils of certain parts of America. The early settlers there reaped from these soils almost unheard-of crops, but, by repeated cultivation, they were soon exhausted and abandoned, new tracts being brought in and cultivated only to be in their turn exhausted and abandoned. The knowledge of the composition of the ash of plants shows us how this exhaustion may be avoided, and indicates the mode in which such soils may be preserved in a fertile state.

THE SOIL—ITS CHEMICAL AND PHYSICAL CHARACTERS.

No department of agricultural chemistry is surrounded with such difficulties and uncertainties as that relating to the properties of the soil. When chemistry began to be applied to agriculture it was from the determination of the composition of the soil that its principal advantages were anticipated, and it was certainly from it that the most striking results were at first obtained; for when analysis revealed, as it occasionally did, the absence of one or more of the essential constituents of the plant in a barren soil, it indicated at once the cause and the cure of the defect. The expectations naturally formed from the facts then observed have been but very partially fulfilled; for, as our knowledge has advanced, it has become apparent that it is only in rare instances that it is possible satisfactorily to connect together the composition and the properties of a soil, and with each advancement in the accuracy and minuteness of our analysis the difficulties have been rather increased than diminished. It has become more and more obvious that the question of the composition of a soil is one of extreme complexity, and we are now convinced that it will be necessary to commence again almost *de novo*, and, discarding many of the observations hitherto made, endeavour to determine the fundamental principles on which the fertility of a soil depends. It has been found that while in some instances it is possible to predicate with certainty that a particular soil is barren, in numerous others a barren and a fertile soil may approach so closely in composition that it is scarcely possible to distinguish them from one another; and so much is this the case that the analysis of a soil must, at the present moment, be considered as in many instances of comparatively little practical value. No doubt practical deductions of importance may occasionally be drawn from the careful analysis of a soil, but the great majority of those hitherto made fail to give the desired information. This may be partly owing to the imperfect analyses which have too often been made, but it is certainly mainly due to imperfect knowledge of the chemical conditions requisite for fertility; and until these are clearly known we cannot expect to derive from the analysis of a soil the important conclusions which it ought to, and at some future period certainly will, yield. Under the present circumstances, therefore, we can only detail such limited facts as are at present known, and of these we shall endeavour to give as clear and succinct an account as possible.

*Origin of Soils.*—The constituents of the soil, like those of the plant, may be divided into the great classes of organic and inorganic. The origin of the former of these we have already discussed. We have pointed out that they are derived from the decay of plants which have already grown upon the soil, and which, in various stages of decomposition, form the numerous class of substances grouped together under the name of humus. The organic substances may therefore be considered as in a manner secondary constituents of the soil, which have been accumulated in it as the consequence of the growth and decay of successive generations of plants, while the primeval soil consisted of inorganic substances only.

The inorganic constituents of the soil are obtained as the result of a succession of chemical changes going on in the rocks which protrude through the surface of the earth. We have only to examine one of these rocks to observe that it is constantly undergoing a series of important changes. Under the influence of air and moisture it is seen to become soft, to disintegrate, and to fall to powder, and is finally washed away by the rains. These actions, minute and trifling as they may at first sight appear, acting throughout many thousand years, are the source of the inorganic matters of all our soils. Geology points to a period at which the earth's surface must have been altogether devoid of soil, and have consisted entirely of hard crystalline rocks, such as granite and trap, by the disintegration of which, slowly proceeding from the creation down to the present time, all the soils which now cover the surface have been produced. But they have been produced as the result of very complicated processes; for these disintegrated rocks being washed away in the form of fine mud, or at least of minute particles, and being deposited at the bottom of the primeval seas, have there hardened into what are called sedimentary rocks, which being raised above the surface by volcanic action or other great geological forces have been again disintegrated to yield different soils. Thus, then, all soils are directly or indirectly derived from the crystalline rocks, those soils which overlie them being formed immediately by their decomposition, while those which overlie the sedimentary rocks may be traced back through them to the crystalline rocks from which they were originally formed. Such being the case, the composition of a soil must manifestly be dependent on the crystalline rocks from which it is derived. When we inquire into the matter, we find that these crystalline rocks are by no means numerous, and that they are made up of but a small number of different minerals. The great mass of our different rocks is made up of mixtures, in variable proportions, of quartz, felspar, mica, hornblende, augite, and zeolites. With the exception of quartz and augite, these names are, however, representatives of different classes of minerals. There are, for instance, not less than four different sorts of felspar, which have been distinguished by mineralogists by the names of orthoclase, albite oligoclase, and Labrador felspar; and there are, at least, two sorts of mica and hornblende, and many varieties of zeolites. The composition of those different minerals, with the exception of quartz, which is pure silica, is as follows, Thomsonite being given as a general illustration of the zeolites, which is a very numerous family:—

| | Felspars. | | | |
|---|---|---|---|---|
| | Potash. Orthoclase. | Soda. Albite. | Lime and Soda. Oligoclase. | Lime. Labrador. |
| Silica | 65·72 | 67·99 | 62·70 | 54·66 |
| Alumina | 18·57 | 19·61 | 23·80 | 27·87 |
| Peroxide of iron | traces | 0·70 | 0·62 | — |
| Oxide of manganese | traces | — | — | — |
| Lime | 0·34 | 0·66 | 4·60 | 12·01 |
| Magnesia | 0·10 | — | 0·02 | — |
| Potash | 14·02 | — | 1·05 | — |
| Soda | 1·25 | 11·12 | 8·00 | 5·46 |
| | 100·00 | 100·08 | 100·79 | 100·00 |

Agricultural Chemistry.

| | Mica. | | Hornblende. | | | |
|---|---|---|---|---|---|---|
| | Potash. | Magnesia. | Common. | Basaltic. | Augite. | Thomsonite. |
| Silica | 46·36 | 42·65 | 41·50 | 42·24 | 50·12 | 38·73 |
| Alumina | 36·80 | 12·96 | 15·75 | 13·92 | 4·20 | 30·84 |
| Peroxide of iron | 4·53 | — | — | — | — | — |
| Protoxide of iron | — | 7·11 | 7·75 | 14·59 | 11·60 | — |
| Oxide of manganese | 0·02 | 1·06 | 0·25 | 0·33 | — | — |
| Lime | — | — | 14·09 | 12·24 | 20·05 | 13·43 |
| Magnesia | — | 25·75 | 19·40 | 13·74 | 13·70 | — |
| Potash | 9·22 | 6·03 | — | — | — | 0·54 |
| Soda | — | — | — | — | — | 3·85 |
| Hydrofluoric acid | 0·70 | 0·62 | — | — | — | — |
| Water | 1·84 | 3·17 | 0·50 | — | — | 13·09 |
| | 99·47 | 99·35 | 99·24 | 97·06 | 99·67 | 100·48 |

It is very obvious that soils produced from the disintegration of those minerals must be very different in their composition and fertility. Potash felspar, for instance, must yield a soil of much greater value than albite or Labrador, as it contains abundance of potash which, in the foregoing section, we have seen to be so important a constituent of the ash of plants; in the same way mica ought to produce a valuable soil. On the other hand, Labrador, hornblende, and augite supply lime and magnesia, and in this respect may be said to surpass the other felspars. But the value of these different minerals is not dependent on their chemical constitution alone; the facility with which they disintegrate, and undergo decomposition so as to liberate their constituents in a state in which they may become available to the plant, is an important element of their value, and in this respect very marked differences are observable. The disintegration of these minerals occurs in two different ways: in those rich in the alkalies it depends on their gradual separation into a silicate of alumina, and an alkaline silicate; in those which contain little alkali, and much protoxide of iron it depends on the gradual absorption of oxygen by that substance, which causes the breaking up of the mineral into new compounds. These changes take place with very different degrees of rapidity. In potash and soda felspar they proceed apace, but in Labrador, owing to the absence of alkalies, they are extremely slow.

The changes which take place in felspar may be easily traced through all their stages. We observe, in the first place, that after a certain time the mineral loses its peculiar lustre, acquires a dull and earthy appearance, absorbs water, becomes gradually soft, and at length falls into a more or less white and soft powder, presenting the characters of common clay. The nature of this change will be best seen by the following analysis of the clay produced by the decomposition of felspar, which is employed in the manufacture of porcelain under the name of kaolin,—

| | |
|---|---|
| Silica | 46·80 |
| Alumina | 36·83 |
| Peroxide of Iron | 3·11 |
| Carbonate of Lime | 0·55 |
| Potash | 0·27 |
| Water | 12·44 |
| | 100·00 |

In this instance the decomposition of the felspar had reached its limit, a mere trace of potash being left, but if taken at different stages of the process, variable proportions of that alkali are met with. This decomposition of felspar is the source of the great deposits of clay which are so abundantly distributed over the globe; and it takes place with nearly equal rapidity with potash and soda felspar. It is only in rare instances complete, and the soils produced from it frequently contain a considerable proportion of undecomposed felspar, which continues for a long period to yield a supply of alkalies to the plants which grow on them.

Agricultural Chemistry.

Mica undergoes decomposition with extreme slowness, as is at once illustrated by the fact that its shining scales may frequently be met with entirely unchanged in the soil. Its persistence is dependent on the small quantity of alkaline constituents which it contains; and for this reason it is observed that the magnesian micas undergo decomposition less rapidly than those containing the larger quantity of potash. Eventually, however, both varieties become converted into clay, their magnesia and potash passing gradually into soluble forms. Hornblende and augite, as already mentioned, owe their decomposition to another cause, oxygen is absorbed, the protoxide of iron being converted into peroxide; lime and magnesia being separated, and a ferruginous clay produced. The zeolites are all rapidly decomposable minerals; like the felspars they yield a clay, while lime and alkalies are separated.

It is obvious from what has just been stated that all of these minerals may yield soils, but most of them would be devoid of many essential ingredients, while not one of them would yield either phosphoric acid, sulphuric acid, or chlorine. It has, however, been recently ascertained that certain of these minerals, or at least the rocks formed from them, contain minute, but distinctly appreciable traces of phosphoric acid, although in too small quantity to be detected by ordinary analysis; and small quantities of chlorine and sulphuric acid may also in most instances be found. Still it will be observed that most of these minerals would yield a soil containing only two or three of those substances, which, as we have already learned, are essential to the plant. Thus potash felspar, while it would give abundance of potash, would be but an inefficient source of lime and magnesia; and Labrador, which contains abundance of lime, is altogether deficient in magnesia and potash.

Nature has, however, provided against this difficulty, for she has so arranged it that these minerals rarely occur alone, the rocks which form our great mountain masses being composed of intimate mixtures of two or more of them, and that in such a manner that the deficiencies of the one compensate those of the other. We shall shortly mention the composition of these rocks.

Granite is a mixture of quartz, felspar, and mica in variable proportions. The quality of the soil it yields is dependent on the variety of felspar present, for both orthoclase and albite occur in it. When the former is the constituent, granite yields soils of tolerable fertility provided their climatic conditions be favourable; but it frequently occurs in high and exposed situations which are unfavourable to the growth of plants. Gneiss is a similar mixture, but characterised by the predominance of mica, and by its banded structure. Owing to the small quantity of felspar which it contains, and the abundance of the difficultly decomposable mica, the soils formed by its disintegration are generally inferior. Mica slate is also a mixture of quartz, felspar, and mica, but consisting almost entirely of the latter ingredient, and consequently presenting an extreme infertility. The position of the granite gneiss and mica slate soils in this country is such that very few of them are of much value; but in warm climates they not unfrequently produce abundant crops of grain. Syenite is a rock similar in composition to granite, but having the mica replaced by hornblende, which by its decomposition yields supplies of lime and magnesia more readily than they can be obtained from the less easily disintegrated mica. For this reason soils produced from the syenitic rocks are frequently possessed of considerable fertility.

The series of rocks of which *greenstone* is the type, and which are among the most widely distributed, are very different in composition from those already mentioned. They are divisible into two great classes, which have received the names of diorite and dolerite, the former a mixture of albite and hornblende, the latter of augite and Labrador, sometimes with considerable quantities of a sort of oligoclase containing both soda and lime, and of different kinds of zeolitic minerals. Generally speaking, the soils produced from diorite are superior to those from dolerite. The albite which the former contains undergoes a rapid decomposition, and yields abundance of soda along with some potash, which is seldom altogether wanting, while the hornblende supplies both lime and magnesia. Dolerite, when composed entirely of augite and labrador, produces rather inferior soils; but when it contains oligoclase and zeolites, and comes under the head of basalt, its disintegration is the source of soils remarkable for their fertility; for these latter substances undergoing rapid decomposition furnish the plants with abundant supplies of alkalies and lime, while the more slowly decomposing hornblende affords the necessary quantity of magnesia. In addition to these the basaltic rocks are found to contain appreciable quantities of phosphoric acid, so that they are in a condition to yield to the plant almost all its necessary constituents.

The different rocks now mentioned, with a few others of less general distribution, constitute the whole of our great mountain masses; and while their general composition is such as I have stated, they frequently contain disseminated through them quantities of other minerals which, though in trifling quantity, nevertheless add their quota of valuable constituents to the soils. Moreover, the exact composition of the minerals of which the great masses of rocks are composed is liable to some variety. Those which we have taken as illustrations have been selected as typical of the minerals; but it is not uncommon to find albite containing 2 or 3 per cent. of potash, Labrador with but 2 per cent., the remainder being replaced by magnesia, and zeolitic minerals containing several per cent. of potash, the presence of which must of course considerably modify the properties of the soils produced from them. The properties of the soils are also greatly altered by the mechanical influences to which the rocks are exposed. Situated for the most part in elevated positions, they are no sooner disintegrated than they are washed down by the rains. A granite, for instance, as the result of disintegration, has its felspar reduced to an impalpable powder, while its quartz and mica remain, the former entirely, the latter in great part, in the crystalline grains which existed originally in the granite. If such a disintegrated granite remains on the spot, it is easy to see what its composition must be; but if exposed to the action of running water, by which it is washed away from its original site, a process of separation takes place, the heavy grains of quartz are first deposited, then the lighter mica, and lastly the felspar. Thus there may be produced from the same granite soils of very different nature and composition, from a pure and barren sand to a rich clay formed entirely of the debris of the felspar.

The sedimentary rocks are too numerous and too varied in their composition to admit of much detail being given regarding their relations to the soil. Being derived, however, from the crystalline rocks, the observations which we have already made regarding the latter will apply in some sort to the former. In fact, the sedimentary rocks may to all intents and purposes be classed under the head of clays (embracing the different sorts of clay slates, shales, &c.), and sandstone, the former derived from felspathic, the latter from quartzose minerals. To these must be added limestone, which in various forms is one of the most important of the stratified rocks. Each of these forms many subdivisions, partly dependent on chemical differences, and partly on their position in the geological series. The purest clays, such as the fire clay of the coal formation, have manifestly been produced by the thoroughly complete decomposition of felspar, and in them almost nothing but its silica and alumina have been left; such clays yield almost absolutely barren soils. But when the decomposition has not proceeded so far, different sorts of clay slates and shales are produced, which, though of considerable hardness, disintegrate sometimes with great rapidity, and often produce soils of much value. As an illustration of the general composition of such rocks the following analyses of the fire clay of the coal formation, and of transition clay slate are given.

| | Transition Clay Slate. | Fire Clay. |
|---|---|---|
| Silica | 60·03 | 54·77 |
| Alumina | 14·91 | 28·61 |
| Peroxide of iron | 8·94 | 4·92 |
| Lime | 2·08 | 0·58 |
| Magnesia | 4·22 | 1·14 |
| Potash | 3·87 | 1·00 |
| Soda | ... | 0·24 |
| Carbonic acid } Water } | 5·67 | 8·24 |
| | 99·72 | 99·50 |

The sandstones require little mention; many of them consist of nearly pure silica, and these produce mere sandy soils, incapable of supporting vegetable life; but in other instances silica is only the principal constituent, and is mixed with a certain proportion of clay, and such sandstones may yield soils of better quality, but they are always light and poor. Where such sandstones occur interstratified with clays, still better soils are produced, the mutual admixture of the disintegrated rocks producing a soil of intermediate properties, and in which the heaviness of the clay is tempered by the lightness of the sandstone.

Limestone is one of the most widely distributed of the stratified rocks, and in different localities occurs of very different composition. Limestones are divided into two classes, common and magnesian; the former a nearly pure carbonate of lime, the latter a mixture of that substance with carbonate of magnesia. But while these are the principal constituents, it is not uncommon to find small quantities of phosphate and sulphate of lime, which, however trifling their proportions, are not unimportant in an agricultural point of view. The following analyses will serve to illustrate the general composition of these two sorts of limestone:—

| | Common. | | Magnesian. | |
|---|---|---|---|---|
| | Mid-Lothian. | Sutherland. | Sutherland. | Dumfries. |
| Silica | 2·00 | 7·42 | 6·00 | 2·31 |
| Peroxide of iron and alumina | 0·45 | 0·76 | 1·57 | 2·00 |
| Carbonate of lime, | 93·61 | 84·11 | 50·21 | 58·81 |
| Carbonate of magnesia | 1·62 | 7·45 | 41·22 | 36·41 |
| Phosphate of lime | 0·56 | ... | ... | ... |
| Sulphate of lime | 0·92 | ... | ... | 0·10 |
| Organic matter | 0·20 | ... | ... | ... |
| Water | 0·50 | ... | 0·69 | ... |
| | 99·86 | 99·74 | 99·69 | 99·63 |

These are pure limestones; but there occurs yet another sort, which is a mixture of carbonate of lime with variable quantities of clay. Limestone and chalk, when disintegrated, produce light and open soils; but when mixed with clay, they give rise to soils of high fertility. This is particularly the case with chalk, on which are found some of the most valuable of all soils. But it is true only of the common limestones, for experience has shown that those which contain magnesia in large quantity are generally prejudicial to vegetation, and yield barren or at best very inferior soils.

Such are the general characters of the three great classes of stratified rocks; any attempt to particularise the numerous varieties of each would lead us far beyond the limits of the present article. It is necessary, however, to remark, that in many instances the one variety passes into the other, or, more correctly speaking, sedimentary rocks occur, which are, so to speak, mixtures of two or more of the three great classes. Thus we have sandstones which contain much clay, clay slates and shales, which are rich in lime, limestone rocks with a large intermixture of clay. Such mixtures usually produce better soils than either of their constituents separately, and accordingly, in those geological formations in which they are abundant, the soils are generally of excellent quality. The same effect is produced where numerous thin beds of members of the different classes are interstratified, the disintegrated portions being gradually intermixed, and valuable soils formed. It may be stated generally that the soils of the clay slates are for the most part cold, heavy, and very difficult and expensive to work; those of sandstone light and poor, and of limestone generally poor and thin. These statements must, however, be considered as very general; for individual cases occur in which some of these substances may produce good soils. Such is the case with the lower chalk and with some of the shales of the coal formation. Little is at present known regarding the peculiar nature of these rocks, or their composition; and the cause of the differences in the fertility of the soil produced from them is a subject worthy of minute investigation.

*Chemical Composition of the Soil.*—We have already referred to the division of the constituents of the soil into the two great classes of organic and inorganic. When treating of the sources of the organic constituents of plants, we entered with some degree of minuteness into the composition and relations of the different members of the former class, and expressed the opinion that they did not admit of being directly absorbed by the plant. As a direct source of these substances, humus is unimportant; but it has other functions to perform which render it an essential constituent of all fertile soils. These functions are dependent on the power which it has of absorbing and entering into chemical composition with ammonia, and with certain of the soluble inorganic substances of the soil. Its effects in this way are strikingly seen in the manner in which ammonia is absorbed by peat soils; it suffices merely to pour upon some dried peat a small quantity of a dilute solution of ammonia to find its smell immediately disappear. This peculiar absorptive power extends also to the fixed alkalies, potash and soda, as well as to lime and magnesia, and has an important effect in preventing these substances being washed out of the soil—a property which, as we shall afterwards see, is possessed also by the clay contained in greater or less quantity in most soils.

In examining into the inorganic constituents of the soil, we find that it is not sufficient merely to inquire into the nature of these substances, but that the states of combination in which they exist is of the very highest importance. Two soils may, for instance, be found on analysis to yield exactly the same results, and yet the one may prove in practice to be fertile, the other barren; and these differences may be entirely dependent on the conditions in which their individual elements exist. To pass into the plant, these substances must be soluble in water, and, unless they are so, it matters not in what quantity the soil contains them; if they are insoluble, they are locked up from use, and the soil is left to hopeless infertility. Accordingly, it must be at once apparent that the determination of the total amount of each of the elements of the soil is not sufficient to establish its value. If the analysis is to be of any use, it ought to indicate also the conditions in which they exist, so that we may ascertain the ease or difficulty with which they may be absorbed. For this purpose it is necessary to determine, 1*st*, The substances soluble in water; 2*d*, The substances insoluble in water, but soluble in acids; 3*d*, The substances insoluble both in water and acids. If to these we add the organic constituents, we have four separate heads, under which the components of a soil ought to be classified. This classification is accordingly adopted in the most careful and minute analyses; but the difficulty and labour attending such analyses has hitherto precluded the possibility of making them except in a few instances; and, generally speaking, chemists have been contented with treating the soil with an acid, and determining in the solution all that is dissolved. Such analyses are at times useful for practical purposes, as, for example, when they show the absence of lime, or any other individual substance, by the addition of which we may rectify the deficiency of the soil; but they are of comparatively little scientific value, and throw but little light on the true constitution of the soil, and the sources of its fertility. Nor is it likely that we shall arrive at much satisfactory information until the number of minute analyses is so far extended as to enable us to establish the fundamental principles on which the various properties of the soil depends.

The separation of the constituents of a soil into the four great groups already mentioned is effected in the following manner:—A given quantity of the soil is boiled with three of four successive quantities of water, which dissolves out all the soluble matters. These soluble matters generally amount to about one-half per cent. of the whole soil, and consist of nearly equal proportions of organic and inorganic substances. In very light and sandy soils, it occasionally happens that not more than one or two-tenths per cent. dissolve in water, and in peaty soils, on the other hand, the proportion is sometimes considerably increased, principally owing to the abundance of soluble organic matters.

When the residue of this operation is heated with dilute hydrochloric acid, the portion soluble in acids is obtained in the fluid. This portion of the soil is liable to very great variations. In some soils of excellent quality, and well adapted to the growth of wheat, it does not exceed three per cent., while in calcareous soils, such as those of the chalk formation, it may reach as high as 50 or 60 per cent. In general, however, it amounts to about 10 per cent. The organic constituents are also very variable in amount; ordinary soils of good quality containing from 2 to 10 per cent., while in peat soils it is no uncommon thing for them to exceed 30 per cent., and in some instances to reach as high as 50. Such soils, however, cannot be considered *fertile* soils. The insoluble constituents are likewise subject to great variations. In the ordinary clay and sandy soils of this country, they generally form from 80 to 90 per cent. of the whole, but they are occasionally as low as 30, especially in such soils as are very rich in lime.

The distribution of the constituents under these different heads will be best illustrated by a few analyses of soils of good quality. The following are the analyses of two noted for the excellent crops of wheat they produce, and for their general fertility. The analyses were made from the upper 10 inches, and a quantity of the 10 inches immediately subjacent was analysed as subsoil. The first is the ordinary wheat soil of the county of Mid-Lothian, the other the alluvial soil of the Carse of Gowrie in Perthshire, so celebrated for the abundance and luxuriance of the crops it produces.

From an examination of these analyses, it is apparent that certain of the inorganic constituents of the soil are met with in each of the three heads under which they are arranged, while others are confined to one or two. Silica and the alkalies occur generally, though not invariably in all three. Chlorine is met with only in the part soluble in water, phosphoric acid only in that soluble in acids, while sulphuric acid occurs in both the last-named divisions. The part soluble in water is composed entirely of salts of the alkalies, lime, and magnesia; the acids being sulphuric acid, silica, and chlorine, the latter in very small quantity. All the substances met with in solution are important constituents of the ash of plants. It is different, however, with those soluble in acids, of which the larger proportion consists of alumina and oxide of iron, both of which are comparatively unimportant to the plant, but very important, as we shall afterwards see, in relation to the physical properties of the soil. The remainder of the substances soluble in acids, amounting to from 1 to 2 per cent., is composed of some of the most essential constituents of plants. Lime, magnesia, potash, and soda, appear again in larger quantity than in the soluble part, and along with them we have the phosphoric acid to the amount of from 0·2 to 0·4 per cent. of the whole soil, and sulphuric acid in much smaller quantity. The insoluble matters show a striking difference in the two soils, in regard to the proportion of alkalies they contain, the Mid-Lothian soil showing only 0·28 per cent. of potash, the subsoil none, while the Perthshire contains 2·45 and 2·00 respectively.

As a contrast with these soils, we have the following analysis of a soil from the island of Antigua, from which very large crops of sugar-cane are obtained. The soil is of great depth, and analyses of the subsoil at the depth of 18 inches and 5 feet are given. These last analyses are not so minute as that of the soil itself, the soluble matters not having been separately determined, but included in that soluble in acids.

In this soil there is a general resemblance in the composition of the portion soluble in water to those of the wheat soils. But the part soluble in acids is distinguished by the great abundance of carbonate of lime.

The soil of Holland from the neighbourhood of the Zuider Zee, which is an alluvial deposit from the waters of the Rhine, and produces large crops, gave the results which follow.

It is unnecessary to multiply analyses of fertile soils, those now given being sufficient to shew their general composition. They are all characterised by the presence in considerable quantity of all the essential constituents of plants, and by their presence in a state in which they may be readily absorbed. The absence of one or more of these substances immediately diminishes or altogether destroys the fertility of the soil; and the extent to which this occurs is illustrated by the following analysis of a soil from Pumpherston, Mid-Lothian, forming a small patch in the lower part of a field, and on which nothing would grow. Being naturally wet, it had been drained and sowed with oats, which died out about six weeks after sowing, and left a bare soil on which weeds did not show the slightest disposition to grow.

In this instance the barrenness of the soil is distinctly traceable to the deficiency of phosphoric acid, sulphuric acid, and chlorine. There is also a remarkably large quantity of oxide of iron, which, when dissolved by the humic acid, is well known to be highly prejudicial to vegetation. That this took place was shown by the fact that the drains, a couple of months after being laid, were almost stopped up by humate of iron. Still more striking are the following analyses:—

| | Moorland soil near Aurich East Friesland. | Sandy soil near Wettingen. | Soil from near Muhlhausen. |
|---|---|---|---|
| Silica and sand | 70·576 | 96·000 | 77·780 |

| Water | ... | ... | 4·095 |
| | 100·000 | 100·000 | 100·000 |

The results contained in these analyses are peculiarly remarkable, indicating as they do the almost total absence of all those substances which the plant requires. These must, however, be considered as in a great measure exceptional cases, as it is no doubt but rarely that so large a number of constituents is absent, and far more frequent to find the deficiency restricted to one or two substances. They are illustrations of barrenness dependent on different circumstances. The first shows the unimportance of the organic matters of the soil, which are here unusually abundant, without in any way counteracting the unfertility dependent on the absence of the other constituents. The second is that of a nearly pure sand; and the third, though it contains a greater number of the essential ingredients of the ash, is still rendered unfruitful by the deficiency of alkalies, sulphuric acid, and chlorine.

An examination of the foregoing analyses indicates pretty clearly the conditions of fertility of the soil. It must obviously contain all the constituents of the plants which are to grow upon it, and in a soluble state, so that they may admit of absorption by the plant. It is clear, however, that the part directly soluble in water embraces only a certain number of the constituents of the plant, and that only in small quantity. This becomes still more apparent if we estimate the quantities contained in an acre of soil. It is calculated that the soil on an imperial acre of land 10 inches deep weighs in round numbers about 1000 tons; and calculating from this, we find that the quantity of potash soluble in water in the Mid-Lothian wheat soil amounts only to about 70 lb. per acre. But a crop of hay carries off from the soil about 38 lb. of potash, and one of turnips, including tops, not less than 200 lb. Manifestly, therefore, if only the matters soluble in water could be taken up by the plant, such soils could not possess the amount of fertility which they actually do. But the soil is not an inert unchangeable substance; it is the theatre of an important series of chemical changes effected by the action of air and moisture, and producing a continued liberation of its constituents. The oxygen of the air acts upon the organic matters of the soil, and produces a constant though slow evolution of carbonic acid, which is absorbed by the moisture contained in the soil, and exerts a solvent action on its constituents. In fact, though a very feeble acid, carbonic acid, by continuous action, is constantly effecting the solution of new quantities of the constituents of the soil; and this action goes on so slowly that at any one moment, the quantity in a soluble condition is not sufficient to supply the total amount required by the plant; but by a beautiful provision of nature, they are brought into the soluble state only in proportion as they are required for the plant, and thus the loss which would take place by the rain falling upon a soil charged with soluble matters and washing them out, is effectually prevented.

Carbonic acid is therefore a most important agent in producing the chemical changes in the soil, and the organic matters are valuable, as affording a supply of that substance within the soil itself; but the carbonic acid of the atmosphere will itself effect these changes, although with different degrees of rapidity according to the character of the soil. In light soils of open texture it will act easily, but in stiff clay soils its action is very slow. The solvent action of the carbonic acid is, no doubt, principally exerted on the substances soluble in acids, but not entirely, for we know that the part insoluble in acids is gradually being disintegrated and made soluble; and hence it is that the composition of that part of the soil which resists the action of acids, and which at first sight might appear of no moment, is really important. We observe, in fact, that this circumstance must at once confer on the soil of the Carse of Gowrie a great superiority over those of Mid-Lothian and most other districts; for it contains in its insoluble part a quantity of alkalies which must necessarily form a source of continual fertility. Accordingly, experience has all along shown the great superiority of that soil, and of alluvial soils generally, which are all more or less similar to it. The facility with which these matters are attackable by carbonic acid is also an important element of the fertility of a soil, and it is to the existence of compounds which are readily soluble that we attribute the high fertility of the trap soils.

By a further examination of the analyses of fertile soils, it is at once apparent that the most essential constituents of plants are by no means the most abundant in the soil. In fact, phosphoric and sulphuric acids, lime, magnesia, and the alkalies, which in most instances make up nine-tenths of the ash of plants, form but a small portion of even the most fertile soils; while silica, which except in the grasses occurs in small quantity, oxide of iron which is a limited, and alumina a rare, constituent of the ash, form by far their larger part. Thus the total amount of potash, soda, lime, magnesia, phosphoric and sulphuric acids and chlorine contained in the Mid-Lothian wheat soil amounts only to 3·5888 per cent., and in the Perthshire to 6·4385, the entire remainder being substances which enter into the plant for the most part in much smaller quantity. Now, as these small quantities of the more important substances are capable of supplying the wants of the plant, it must be obvious that a very small fraction of the silica, oxide of iron, and alumina, which the soils contain, would afford to it the whole quantity of these substances it requires, and that the rest of these constituents must have some other functions to perform in the soil. Hitherto we have looked upon a soil merely as the source of the inorganic food of plants, but it has to act also as a support for the plant while growing, and to retain a sufficient quantity of moisture to support its life; and unless it possess the properties which fit it for doing so, it may contain all the elements of the food of plants, and yet be nearly or altogether barren.

If a quantity of a soil be shaken up with water and allowed to stand for a few minutes, we find that it rapidly deposits a quantity of grains which we at once recognise as common sand. If the water be now poured off into another vessel and allowed to stand for a longer time, there is deposited a quantity of a fine soft powder, having the properties and composition of common clay, while the clear fluid now contains the soluble matter. By a more careful treatment we can likewise distinguish and separate humus, and in soils lying on chalk or limestone, calcareous matter or carbonate of lime. We perform in this way a sort of mechanical analysis, and classify the components of the soil into four groups, a mixture of two or more of which in variable proportions is found in all soils.

The relative proportions in which these substances exist in a soil are intimately connected with its mechanical and physical properties, which have as important an influence in its fertility as its chemical composition; for a soil may contain all the necessary elements of the crops, and yet, from some defect in its physical characters, be nearly or altogether barren. In fact, it is impossible to examine a large number of analyses of soils without seeing that though in many instances they may give tolerably satisfactory information as to their relative values, yet we sometimes see two soils one fertile and the other barren although there is no appreciable difference in their *chemical* composition. An illustration of this is found in the following analyses of two soils both fertile, but in one of which red clover grows luxuriantly, in the other it invariably fails.

| | Clover fails. | Clover succeeds. |
|---|---|---|

| | 99·96 | 100·08 |
| Nitrogen | 0·15 | 1·15 |

In default of any explanation deducible from the composition of the soil, we are induced to attribute the differences here observed to differences in their physical properties.

Now it appears that the mechanical constituents of the soil mentioned above possess certain properties, partly mechanical and partly chemical, which exert an important influence on its fertility. Sand and clay, the most important of the four, confer on the soil diametrically opposite properties; the former, when present in large quantity, producing what are designated as light, the latter stiff or heavy soils. Sand, being composed of hard indestructible grains of silicious matter, forms a soil of an open texture, through which water readily permeates; while clay, from its fine state of division, and peculiar adhesiveness or plasticity, gives a close-textured and retentive soil; and the proper intermixture of the two produces a light fertile soil, each tempering the peculiar properties of the other. Indeed, their mixture is manifestly essential, for sand alone contains none of the essential ingredients of the plant; and if present in large quantity, the openness of the soil is excessive, water flows through it with rapidity, manures are rapidly destroyed, and the accession of drought soon causes the plants which grow upon it to languish and die. Clay, on the other hand, is by itself equally objectionable; the closeness of its texture prevents the spreading of the roots of plants, and the access of carbonic acid, which, as we have already seen, is so important an agent in the changes occurring in the soil. In fact a pure clay, that is to say, a clay unmixed with sand, even though it may contain all the essential constituents of the plant is absolutely unfertile. Practically, of course, these extreme cases never occur; the heaviest clay soils are mixtures of true clay with sand, and the most sandy soils contain their proportion of clay; but frequently the preponderance of the one over the other is so great, as to produce soils greatly inferior to those in which the mixture is more uniform.

We have spoken of those substances merely as mechanically affecting the soil; but clay possesses also a very remarkable property, apparently of a chemical nature, although to what extent it is so is as yet unknown, and which gives it a high importance in the soil. It possesses a remarkable power of absorbing the soluble constituents of the soil, and preventing them, in part at least, from being washed out by the rains. This peculiar effect of clay has long been recognised by chemists; but its special importance in an agricultural point of view has been shown by Mr Thomson; and to the extended investigation of Way we owe the greater part of our definite information regarding it. It appears that all ordinary arable soils possess, in a more or less marked degree, the power of removing from their solution ammonia, potash, soda, and phosphoric acid, to a considerable extent, and lime and magnesia in smaller quantity. The amount of this absorption is easily seen by a simple experiment. It suffices to take a tall cylindrical vessel open at both ends, and filled with the soil to be operated upon, which is retained by a piece of rag tied over its lower end. A quantity of a dilute solution of ammonia being then poured upon the surface of the soil, and allowed to percolate, the first quantity which flows away is found to have entirely lost its peculiar smell and taste; and in a similar manner the removal of potash and soda may be illustrated. Mr Way has found, that not only is ammonia absorbed by the soil in the free state, but also when in combination with different acids. In the latter case the absorption is attended with a true chemical decomposition, for the fluid which flows from the soil contains the whole of the acid of the ammonia salt in combination with lime. Thus, if sulphate of ammonia be employed, we have sulphate of lime in the fluid, and if muriate of ammonia, we have muriate of lime escaping. Mr Way's experiments have shown, that an ordinary soil is capable of absorbing and bringing into an insoluble condition about 0·3 per cent. of ammonia, when either ammonia itself, its sulphate, or muriate, is employed. It thus appears, as far as absorption goes, to be immaterial whether the ammonia is free or combined. But it is different with potash, which is absorbed from the nitrate to the extent of about 0·6 per cent., and from a caustic solution of potash to double that amount. In these cases the *acid* of the substance employed appears to combine with lime, and the whole of it is obtained in the solution. From this it may be gathered, that lime is not readily absorbed from solutions of its salts; indeed, it would appear that the only salt of lime which comes under the absorbent power of the soil is the bicarbonate, from which lime is taken to the extent of 1·4 per cent. by the soil. The absorption of lime from this salt, and of phosphoric acid, which takes place to a considerable extent, probably occurs, however, quite independently of the clay present in the soil, and is occasioned by its *lime*, which forms an insoluble compound with phosphoric acid, and by removing half the carbonic acid of the bicarbonate of lime converts it also into an insoluble state.

Mr Way attributes the entire absorptive effects of the soil to the clay which they contain, but it may be questioned whether it is the exclusive agent at work. We have remarked, that the absorption of phosphoric acid and of lime from the bicarbonate is probably dependent on lime itself. But as regards alkalies and ammonia, there is another absorptive agent in the organic constituents of the soil. So powerful indeed is the affinity of these substances for ammonia, that chemists are at one as to the difficulty of obtaining the humic and other acids pure, owing to the obstinacy with which they retain it; and there cannot be a doubt that in many soils these substances are in this point of view of much importance. This is particularly the case in peat soils, which, though naturally barren, may be made to produce good crops by the application of sand or gravel; and as neither of these can cause any absorption of the valuable matters, we must attribute this effect to the organic matter. That peat does absorb ammonia may be shown by a simple experiment. If a quantity of dry peat be taken and ammonia poured on it, we find that its smell disappears; and this may be continued until upwards of 1·5 per cent. of dry ammonia has been absorbed, and this quantity is *retained* by the peat. There is another point worthy of inquiry at the present time, and which may prove of much importance. It is certain that the soil, when shaken up with ammonia, withdraws from its solution a quantity of that substance; but what is the effect of withdrawing the remaining solution, and agitating with more water? May it not happen that the ammonia at first absorbed may be again washed out of the soil. The analyses of the soils given in page 393 show at least that the whole of the potash and soda is not in an insoluble condition in the soil; and though the quantity extracted by water is small, it is unequivocal; we know also, that the water which flows from the drains always contains a variety of alkaline and other salts in solution, manifestly derived from the soils through which it has percolated. In short, it must not be supposed that the substances absorbed are rendered absolutely insoluble; they become only relatively so; and it is probable that, under particular circumstances, a considerable proportion of them may be again removed. This is obviously the case in regard to ammonia, as absorbed by peat, for we find that the alkaline reaction is removed by that substance from a considerable quantity of dilute ammonia, although only a *portion* of it is retained when the soil has become dry. Here the presence of moisture appears to be of consequence, and no doubt other conditions, not at present understood, may have the effect of greatly modifying the phenomena.

The peculiarities hitherto alluded to are perhaps in some respects more chemical than mechanical, or at least partake to some extent of both; but the more strictly physical characters, such for instance as the relations of the soil to heat and moisture, &c., are not less important. It needs, indeed, only a moment's consideration to see how great must be the influence exerted by their power of absorbing heat and moisture. We know that in these respects soils differ greatly, and the possession of these properties in a high degree may cause two soils chemically identical to differ widely in productiveness. Thus, for instance, two soils may be identical in composition, but one may be highly hygrometric, that is, may absorb moisture readily from the air, while the other may be very deficient in that property. Under ordinary circumstances no difference will be apparent between the produce of the two soils, but in a dry season the crop upon the former may be in a flourishing condition, while that on the latter may be languishing and enfeebled merely from its inability to absorb from the air, and supply to the plant the quantity of water required for its growth. In the same way, a soil which absorbs much heat from the sun's rays will surpass another which has not that property; and though in many cases this effect may be comparatively unimportant, it may make the difference between successful and unsuccessful cultivation in soils which lie in an unfavourable climate or exposure.

The investigation of the physical characters of soils has attracted little attention except on the part of Schübler, who published, nearly 30 years ago, a very elaborate series of researches on this subject, from which all our present information is derived. He determined, 1*st*, The specific gravity of the soils; 2*d*, The quantity of water which they are capable of imbibing; 3*d*, The rapidity with which they give off by evaporation the water they have imbibed; that is, their tendency to become dry; 4*th*, The extent to which they shrink in drying; 5*th*, Their hygrometric power; 6*th*, The extent to which they are heated by the sun's rays; 7*th*, The rapidity with which a heated soil cools down, which indicates its power of *retaining* heat; 8*th*, Their tenacity, or the resistance they offer to the passage of agricultural implements; 9*th*, Their power of absorbing oxygen from the air. Each of these experiments was performed on several different soils, and on their mechanical constituents. Schübler's experiments are undoubtedly important, and though the methods employed are some of them not altogether beyond cavil, they have apparently been performed with great care. It is nevertheless desirable that they should be carefully repeated, for such facts ought not to rest on the authority of one experimenter, however skilful and conscientious, nor on a single series of soils, which may not give a fair representation of their general physical properties. In fact Schübler appears to imagine that having once determined the extent to which the sand, clay, and other mechanical constituents of the soil possess these properties, we are in a condition to predicate with regard to soils produced from their mixture in variable proportions, although this is by no means probable.

In examining these properties, Schübler selected for experiment, pure silicious sand, calcareous sand (carbonate of lime in coarse grains), finely powdered carbonate of lime, pure clay, humus, and powdered gypsum. He used also a heavy clay consisting of 11 per cent. of sand and 89 of pure clay, a somewhat stiff clay containing 24 per cent. of sand and 76 of clay, a light clay, with 40 per cent. of sand and 60 of pure clay, a garden soil consisting of 52·4 per cent. of clay, 36·5 of silicious sand, 1·8 of calcareous sand, 2 per cent. of finely divided carbonate of lime, and 7·2 of humus, and two arable soils, one from Hoffwyl, and one from a valley in the Jura, the former a somewhat stiff, the latter a light soil.

| | Specific gravity. | Water absorbed by 100 parts. Per cent. | Of 100 parts of water absorbed, there evaporate in four hours at 66°. | Diminution during drying of 100 parts of moist soil. | Quantity of hydrometric water absorbed by 77·165 grains of the soil spread on a surface of 141·48 square inches. | | | | Power of retaining heat. Calcareous sand, 100. | Tenacity of the soils, pure clay, 100. | Quantity of oxygen absorbed by 77·165 grains of the moist soil in 30 days, from 15 cubic inches of atmospheric air. Expressed in cubic inches. |

The experiments detailed in the preceding table speak in a great measure for themselves, and scarcely require detailed comment. It must be remarked, however, that all the characters determined are not equally important. Those illustrating the relations of the soil to water are perhaps the most important. The superiority of a retentive over an open soil is sufficiently familiar in practice, and though this superiority is no doubt partly due to the former absorbing and retaining more completely the ammonia and other valuable constituents of the manures applied to it, it is also dependent to an equal if not greater extent upon the power it possesses of retaining moisture. A reference to the table makes it apparent that this power is presented under three different heads, which are certainly related to one another but are not identical. In the second column of the table we have the quantity of water absorbed by the soil, when thoroughly moistened as a sponge is, and it may be considered as representing the quantity of water which will be retained by these different soils when thoroughly saturated by long continued rains. The column immediately succeeding gives the quantity of that water which escapes by evaporation from the same soil after exposure for four hours to dry air at the temperature of 66°. The fifth, sixth, seventh, and eighth columns indicate the quantity of moisture absorbed, when the soil, previously artificially dried, is exposed to moist air for different periods. These characters are dependent principally, though not entirely, on the porosity of the soil. The last may also be in some measure due to the presence of deliquescent salts in the soil, but is partially occasioned by their peculiar structure. It is to be remarked that clay and humus are two of the most highly hygrometric substances known, and it is peculiarly interesting to observe, that by a beneficent provision of nature, they also form a principal part of all fertile soils. The quantity of water imbibed by the soil is important to its fertility, in so far as it prevents it becoming rapidly dry after having been moistened by the rains. It is valuable also in another point of view, because if the soil be incapable of absorbing much water, it becomes saturated by a moderate fall of rain, and when a larger quantity falls, the excess of necessity percolates through the soil and carries off with it a certain quantity of the soluble salts. Important as this property is, however, it must not be possessed in too high a degree, but must permit the *evaporation* of the water retained with a certain degree of rapidity. Soils which do not admit of this taking place, become the cause of much inconvenience and injury in practice. By becoming thoroughly saturated during winter, they remain for a long time in a wet and unworkable condition, in consequence of which they cannot be prepared and sown until late in the season, and though chemically unexceptionable, such soils are always disadvantageous, and may in certain seasons prove absolutely valueless. The extent to which the imbibition of water takes place is extremely variable, and the rapidity of evaporation equally so, but apparently in the inverse ratio of the former; for we observe that silicious sand absorbs only one-fourth of its weight of water, and again gives off in the course of four hours four-fifths of that it had taken up, while humus, which absorbs nearly twice its weight, retains nine-tenths of that quantity after four hours exposure. Long-continued and slow evaporation of the water absorbed by a soil is injurious in another way, for it makes the soil "cold," a term of practical origin, but which very correctly expresses the peculiarity in question, which is due to the quantity of heat absorbed during evaporation, which prevents the soil acquiring a sufficiently high temperature from the sun's rays. The soils which have absorbed a large quantity of moisture shrink more or less in the process of drying, and form cracks, which often break the delicate fibres of the roots of the plants and cause considerable injury: the extent of this shrinking is given in the fourth column.

The relation of the soils to heat divides itself into two considerations: the amount of heat absorbed by the soil, and the degree in which it is retained. Of these the latter only is illustrated in the table. The former is dependent on so many special considerations that the results cannot be tabulated in a satisfactory manner. It is independent of the chemical nature of the soil, but varies to a great extent according to its colour and the angle of incidence of the sun's rays, and its state of moisture. It is, however, an important character, and has been found by Girardin to modify to a considerable extent the rapidity of ripening of the crops. He found in a particular year, that on the 25th of August 26 varieties of potatoes were ripe on a very dark-coloured sandy vegetable mould, 20 on an ordinary sandy soil, 19 on a loamy soil, and only 16 on a nearly white calcareous soil.

The tenacity of the soil is very variable, and indicates the great differences in the amount of power which must be expended in working them. According to Schübler, a soil whose tenacity does not exceed 10 is easily worked, but when it reaches 40 it becomes sufficiently difficult and heavy to work.

In looking at the tables, we see manifestly that there is one constituent of the soil to which a high importance must be attached in relation to its *physical* properties, and it is the more interesting to observe, as it is that to which we have attributed a minor *chemical* importance. It is humus, which will be observed to confer on the soil a high power of absorbing and retaining water, to diminish its tenacity and permit its being more easily worked, to add to its hygrometric power and property of absorbing oxygen from the air, and finally, from its dark colour to cause the more rapid absorption of heat from the sun's rays. It will be thus understood, that while humus does not directly supply food to the plant, it ministers indirectly in a most important manner to its well-being, and that to so great an extent that it must be considered an indispensable constituent of a fertile soil. But it is important to observe that it must not be present in too large a quantity, for an excess of it does away with all the good effects of a smaller supply, and produces soils notorious for their infertility.

Such are the important physical properties of the soil, and it is greatly to be desired that they should be more extensively examined. The great labour which this involves has, however, hitherto prevented its being done, and will, in all probability, render it impossible ever to do so except in a limited number of cases. Some of these characters are, however, of minor importance, and for ordinary purposes it might be sufficient to determine the specific gravity of the soil in the dry and moist state, the power of imbibing and retaining water, its hygrometric power, its tenacity and its colour. With these data we should be in a condition to draw probable conclusions regarding the others; for we find that the higher the specific gravity in the dry state, the greater is the power of the soil to retain heat, and the darker its colour the more readily does it absorb it. The greater its tenacity, the more difficult is it to work, and the greater difficulty will the roots of the young plant find in pushing their way through it. The greater the power of imbibing water, the more it shrinks in drying; and the more slowly the water evaporates, the colder is the soil produced. The hygrometric power is so important a character that Davy and other chemists have even believed it possible to make it the measure of the fertility of a soil; but though this may be true within certain limits, it must not be too broadly assumed, the results of recent experiments by no means confirming the opinion in its integrity, but indicating only some relation between the two.

*The Subsoil.*—The term soil is strictly confined to that portion of the surface turned over by the plough working at ordinary depth; which, as a general rule, may be taken at 10 inches. The portion immediately subjacent we call the subsoil, and it has considerable agricultural importance, and requires a short notice. In many instances, soil and subsoil are separated by a purely imaginary line, and no striking difference can be observed either in their chemical or physical characters. In such cases it has been the practice with some persons not to limit the term soil to the upper portion, but to apply it to the whole depth, however great it may be, which agrees in characters with the upper part, and only to call that subsoil which manifestly differs from it. This principle is perhaps theoretically the more correct, but great practical advantages are derived from limiting the name of soil to the depth actually worked in common agricultural operations. The subsoil is always analogous in its general characters to a soil, but it may be either identical with that which overlies it or not. Of the former, striking illustrations are seen in the wheat subsoils, the analyses of which have been already given. In the latter case we find that great differences may exist. Thus we may have a heavy clay lying on an open and porous sand, or on peat, and *vice versa.* Even where the characters of the subsoil appear the same as those of the soil, appreciable chemical differences are generally observed, especially in the quantity of organic matter, which is increased in the soil by the decay of plants which have grown upon it, and by the manure added. In general, then, all that we have said regarding the characters of soils both chemically and physically, will apply to the subsoils, except that, from the difficulty with which the air reaches the latter, some minor peculiarities are observed. The most important is the effect of the decay of vegetable matter, without access of air, which is attended by the reduction of the peroxide of iron to the state of protoxide, or more commonly by the production of sulphuret of iron, compounds which are extremely prejudicial to vegetation, and occasionally give rise to some difficulties when the subsoil is brought to the surface, as we shall afterwards have to notice.

The physical characters of the subsoil are often of much importance to the soil itself. As, for instance, where a light soil lies on a clay subsoil, in which case the value of the soil is much higher than if it reposed on an open or sandy subsoil. And in many similar modes is an important influence exerted; but these belong more strictly to the practical department of agriculture, and need not be mentioned here.

*Classification of Soils.*—Numerous attempts have been made to form a classification of soils according to their characters and value, but they have not hitherto proved very successful; and the result of more recent chemical investigations has not been such as to encourage a farther attempt. We have not at present data sufficient for the purpose, nor if we had, would it be possible to arrange any soil in its class except after an elaborate chemical examination. The only classification at present possible must be founded on the general physical characters of the soil; and the ordinary mode followed in practice of dividing them into clays, loams, &c. &c., which we need not here particularise, fulfils all that can be done until we have more minute information regarding a large number of soils. Those of our readers who desire more full information on this point are referred to the works of Thaer, Schübler, and others, where the subject is minutely discussed.

### THE MECHANICAL IMPROVEMENT OF THE SOIL.

In order that it may have the highest degree of fertility, a soil must possess the necessary physical properties and chemical composition in perfection. In comparatively few instances does this actually occur; for the greater proportion of soils, either from mechanical or chemical defects, are incapable of producing an abundant vegetation. These defects, however, admit of diminution, or even entire removal, by certain methods of treatment, the adaptation of which to particular cases is necessarily one of the most important branches of agricultural practice, as the elucidation of their mode of action is of its theory. The observations already made with regard to the characters of fertile soils, will have prepared the reader for the statement that these defects may be removed in two ways, either mechanically or chemically. The former method of improvement may at first sight appear to fall more strictly under the head of practical agriculture, of which the mechanical treatment of the soil forms so important a part, and that their improvement by chemical means should form the sole subject of our consideration here. But the line of demarcation between the mechanical and the chemical, which seems so marked, disappears on more minute observation, and we find that the mechanical methods of improvement are frequently dependent on chemical principles; and those which, at first sight, appear to be entirely chemical, are also in reality partly mechanical. It will be necessary for us, therefore, to consider shortly the mechanical methods of improving the soil.

*Draining.*—By far the most important method of mechanically improving the soil is by draining,—a practice the beneficial action of which is dependent on a great variety of circumstances. Its most obvious effect is probably that which it produces on the temperature of the soil. We have already remarked that the germination of a seed is dependent on the soil in which it is sown acquiring a certain temperature, and the rapidity of the after-growth of the plant is, in part at least, dependent on the same circumstance. The necessary temperature is speedily attained by the heating action of the sun's rays, when the soil is dry; but when it is moist, the heat is expended in evaporating the moisture with which it is saturated; and it is only after this has been effected that it acquires a sufficiently high temperature to produce the rapid growth of the seeds committed to it. But when the soil is drained, the superfluous moisture is drawn off, and it is ready to take advantage of the heating effect of the sun's rays in early spring; and thus the period of germination, and by consequence also that of ripening, is advanced. The extent to which this takes place is necessarily variable, but it is generally considerable; and in some districts of Scotland the extensive introduction of draining has made the harvest on the average of years from 10 to 14 days earlier than it was before. It is unnecessary to insist on the importance of such a change, which in upland districts may make cultivation successful when it was previously almost impossible. The removal of moisture by drainage affects the physical characters of the soil in another manner: it makes it lighter, more friable, and more easily worked; and this change is occasioned by the downward flow of the water carrying with it to the lower part of the soil the finer argillaceous particles, leaving the coarser and sandy matters above, and in this way a marked improvement is produced on heavy clays. The abundant escape of water from the drains acts chemically by removing any noxious matters the soil may contain, and by diminishing the amount of soluble saline matters, which sometimes produce injurious effects. It thus prevents the saline incrustation, which is frequently seen in dry seasons on soils which are naturally wet, and which is produced by the water, which rises to the surface by capillary attraction, depositing, as it evaporates, the soluble substances it contained, and leaving a hard crust which prevents the access of air to the interior of the soil. The access of air to the soil, which is one of the most important elements of its fertility, is promoted in a high degree by draining, as, by removing the water which stagnates in the lower part of the soil, it permits the air to reach it. It provides also for the frequent change of the air which permeates the soil; for every shower that falls expels from it a quantity of the air it contains, and as the moisture flows off by the drains, a new supply of air enters to take its place, and thus the important changes which the atmospheric oxygen produces on the soil, are promoted in a high degree. The air which thus enters acts on the organic matters of the soil, and produces the carbonic acid, which we have already seen is so intimately connected with many of its chemical changes. In the absence of atmospheric air, the organic matters undergo different decompositions, they pass into states in which they are slowly acted on, and are incapable of supplying a sufficient quantity of carbonic acid to the soil. They also act upon the peroxide of iron, contained in all soils, reduce it to the state of protoxide, or, with the simultaneous reduction of the sulphuric acid, they produce sulphuret of iron, forms of combination which are well known to be most injurious to vegetation.

The removal of water from the lower part of the soil, and the admission of air, which is the consequence of draining, submits that part of it to the same changes which take place in its upper portion, and has the effect of practically deepening the soil to the extent to which it is thus laid dry. The roots of the plants growing on the soil, which stop as soon as they reach the moist part, now descend to a lower level, and derive from that part of it supplies of nourishment formerly unavailable. The deepening of the soil has further the effect of making the plants which grow upon it less liable to be burned up in seasons of drought, a somewhat unexpected result of making a soil drier, but which manifestly depends on its permitting the roots to penetrate to a greater depth, and so to get beyond the surface portion, which is rapidly dried up, and to which they were formerly confined.

It is thus obvious that the drainage of the soil modifies its properties both mechanically and chemically. It exerts also various other actions in particular cases which we cannot here stop to particularise. It ameliorates the climate of districts in which it is extensively carried out, and even affects the health of the population in a favourable manner. The sum of its effects must necessarily differ greatly in different soils, and in different districts; but a competent authority[1] has estimated, that, on the average, land which has been drained produces a quarter more grain per acre than that which is undrained. But this can scarcely be said to exhaust the benefits derived from it, for draining is merely the precursor of further improvement. It is only after it has been carried out that the farmer derives the full benefit of the manures which he applies. He gains also by the increased facility of working the soil, and by the rapidity with which it dries after continued rain, which enables him to get on at their proper season with agricultural operations, which would otherwise have to be postponed for a considerable time.

We can scarcely be expected here to say much regarding the mode in which draining ought to be carried out, but we may remark that much inconvenience and loss has occasionally been produced by too close adhesion to particular systems. No rules can be laid down as to the depth or distance between the drains which can be universally applicable, but the intelligent drainer will seek to modify his practice according to the circumstances of the case. As a general rule, the drains ought to be as deep as possible, but in numerous instances it may be more advantageous to curtail their depth and increase their number. If, for instance, a thick impervious pan resting on a clay were found at the depth of three feet below the surface, it would serve no good purpose to make the drains deeper; but if the pan were thin, and the subjacent layer readily permeable by water, it might be advantageous to go down to the depth of four feet, trusting to the possible action of the air which would thus be admitted, gradually to disintegrate the pan, and increase the depth of soil above it. It is a common opinion that if we reach, at a moderate depth, a tenacious and little permeable clay it is no use making the drains deeper than this; but this is an opinion which should be adopted with caution, both because no clay is absolutely impermeable, even the most tenacious admitting of the passage of water, and because the clay may have been brought down by water from the upper part of the soil, and may have stopped there merely for want of some deeper escape for the water, and which drains at a lower level might supply. It may even happen that it might be necessary to vary the depth of the drains in different parts of the same field, and the judicious drainer may sometimes save a considerable sum by a careful observation of the peculiarities of the different parts of the ground to be drained.

*Subsoil and Deep Ploughing.*—It frequently happens, when a soil is drained, that the subsoil is so stiff as to permit the passage of water imperfectly, and to prevent the tender roots of the plant from penetrating it, and reaching the new supplies of nourishment which are laid open to it. In such cases the benefits of subsoil ploughing and deep ploughing are conspicuous. The mode of action of these two methods of treatment is similar but not identical. The subsoil plough merely stirs and opens the subsoil, and permits the more ready passage of water and the access of air and of the roots of plants, the former to promote the necessary decompositions, the latter to avail themselves of the valuable matters set free. Deep ploughing again produces more extensive changes; it brings up new soil to the surface, mixes it with the original soil, and thus not only brings up new supplies of valuable matters to it, but frequently changes its chemical and mechanical characters, rendering a heavy soil lighter by the admixture of a light subsoil and *vice versa*. Both are operations which are useless unless they are combined with draining, for it must manifestly serve no good purpose to attempt to open up a soil unless the water which lies in it be previously removed. In fact, subsoiling is useless unless the subsoil has been made thoroughly dry, and it has been found by experience that no good effects are obtained if it be attempted immediately after draining, but that a sufficient time must elapse, in order to permit the escape of the accumulated moisture, which often takes place very slowly. Without this precaution, the subsoil, after being opened by the plough, soon sinks together, and the good effects anticipated are not realised. The necessity for allowing some time to elapse between draining and further operations is still more apparent in deep ploughing, when the soil is actually brought to the surface. In that case it requires to be left for a longer period after draining, in order that the air may produce the necessary changes on the subsoil; for if it be brought up after having been for a long time saturated with moisture, and containing its iron in the state of protoxide, and the organic matter in a state in which it is not readily acted upon by the air, the immediate effect of the operation is frequently injurious in place of being advantageous. One of the best methods of treating a soil in this way is to make the operation a gradual one, and by deepening an inch or two every year gradually to mix the soil and subsoil; as in this way from a small quantity being brought up at a time no injurious effects are produced. Deep ploughing may be said to act in two ways, *firstly*, by again bringing to the surface the manures which have a tendency to sink to the lower part of the soil, and, *secondly*, by bringing up a soil which has not been exhausted by previous cropping, in fact a virgin soil.

The success which attends the operation of subsoiling or deep ploughing must manifestly be greatly dependent on the character of the subsoil, and good effects can only be obtained when its chemical composition is such as to supply in increased quantity the essential constituents of the plant; and it is no doubt owing to this that the opinions entertained by practical men, each of whom speaks from the results of his own experience, are so varied. The effects produced by deep ploughing on the estates of the Marquis of Tweeddale, are familiarly known to most Scottish agriculturists, and they are at once explained by the analyses of the soil and subsoil here given, which show that the latter, though poor in some important constituents, contains more than twice as much potash as the soil.

| | Soil. | Subsoil. |
|---|---|---|
| Insoluble silicates | 87·623 | 82·72 |
| Soluble silica | 0·393 | 0·12 |
| Alumina and peroxide of iron | 4·129 | 8·60 |
| Lime | 0·341 | 0·18 |
| Magnesia | 0·290 | 0·24 |
| Sulphuric acid | 0·027 | 0·03 |
| Phosphoric acid | 0·240 | trace |
| Potash | 0·052 | 0·12 |
| Soda | 0·050 | 0·04 |
| Water | 1·956 | 3·26 |
| Organic matter | 5·220 | 4·02 |
| | 100·321 | 99·33 |

In addition to the difference in the amount of potash, something is probably due to the difference in the quantity of alumina and oxide of iron in the subsoil, which on this account must probably be more tenacious than the soil itself, which appears to be rather light. In many other instances, the use of the subsoil plough has occasioned much disappointment, and has led to its being decried by many practical men; but of late years its use having become better understood its merits are more generally admitted. We believe that, in all cases in which the soil is deep, more or less marked good effects must be produced by its use, but of course there must be cases in which, from the defective com-

[1] Mr Dudgeon of Spylaw. *Highland Society's Transactions*, vol. xii. p. 505.

position of the subsoil or other causes, it must fail. It may sometimes be possible *a priori* to detect these cases, but in a large majority of them we suspect our knowledge is much too limited to enable us to do so.

*Improving the Soil by Burning.*—It has long been familiarly known, that a decided improvement has been produced on some soils by burning. Its advantages have chiefly been observed on two sorts, heavy clays, and peat soils; and on these varieties it has been practised to a great extent. The action of heat on the heavy clays appears to be of a two-fold character, depending partly on the change effected in its physical properties, and partly on a chemical decomposition produced by the heat. The operation of burning is effected by mixing the clay with brushwood and vegetable refuse, and allowing it to smoulder for some time. It is an operation of some nicety, and its success depends on the temperature being kept as low as possible. It has been further found that its success is by no means equal in all clays, but that there are some which are rather injured than benefited by it. The cause of its beneficial action appears to depend on a change which takes place in the state in which the potash exists in the soil, as a consequence of which it becomes more soluble than it was before. It has been found, that after heating, a dilute acid will extract from clays improved by burning a much larger quantity of potash than it did before; and as we know that the substances not extractable by acids are in a state in which they are unavailable to the plant, or at least can only be slowly obtained by it, we can easily understand how such a soil should be improved by burning, and also how some clays which contain little or no potash should not be affected by the process. The necessity for preserving the temperature of the burning mass of clay as low as possible is also rendered obvious; for it has been found by direct experiment, that at high temperatures another change occurs, whereby the potash, which at lower temperatures becomes soluble, passes again into an insoluble state. A part of the beneficial effects is no doubt also due to the change produced in the physical characters of the clay by burning, which makes it lighter and more friable, and by mixture with the unburnt clay ameliorates the whole. This improvement in the physical characters of the clay also requires that it shall be burnt with as low a heat as possible; for if it rises too high, the clay coheres into hard masses which cannot again be reduced to powder, and the success of the operation of burning may always be judged of by the readiness with which it falls into a uniform friable powder.

The improvement of peat by burning has been practised to some extent in Scotland, though less frequently of late years than formerly; but it is still the principal method of reclaiming peat soils in many countries, and particularly in Finland, where large breadths of land have been brought into profitable cultivation by means of it. The *modus operandi* of burning peat is very simple; it acts by diminishing the superabundant quantity of humus or other organic matters, which, in the previous section we have seen to be so injurious to the fertility of the soil. It *may* act also in the same way as it does on clay, by making part of the inorganic constituents more really soluble, although it is not probable that its effect in this way can be very marked. Its chief action is certainly by destroying the organic matters, and by thus improving the physical character of the peat, and causing it to absorb and retain a smaller quantity of water than it naturally does. For this reason it is that it proves successful only on thin peat bogs, for if they be deep the inorganic matters soon sink into the lower part, and the surface relapses into its old state of infertility. It is probably for this reason that the practice has been so much abandoned in Scotland, the more especially as other and more economical modes of treating peat soils have come into use.

*Mixing of Soils.*—The mixing of soils is a very obvious method of improving those which are defective, and nothing but its expense limits its utility. It has been applied to the improvement of heavy soils and of peats, the former being mixed with sand or marl so as to diminish its tenacity; the latter with clay or gravel to add to its inorganic matters, and in both instances it has proved successful. The admixture of peat with open sandy soils and with heavy clays has also been tried, although to a small extent, and we are not aware of the results obtained. It is very probable that the practice of mixing soils might be judiciously extended if we had sufficiently accurate information regarding the chemical composition of those mixed. It must be manifest, indeed, that the admixture of a highly fertile soil, even in moderate quantity, with another of inferior quality, must of necessity be attended with some effect. We believe, indeed, that the rich trap soils of some parts of Scotland have been mixed with those of inferior quality, but the extent of the benefit derived from the practice has not been made public.

### MANURES.—THEIR CHEMICAL COMPOSITION AND MODE OF ACTION.

It is obvious from the statements we have made in a previous section, that even fertile soils contain many of the essential constituents of plants in limited and some of them in very small quantity; and the necessary consequence is, that the growth of successive generations of plants would soon exhaust the whole supply of these substances which they are capable of affording. In a state of nature, the plant which grows upon a soil dies there, or annually sheds its leaves, and returns to it the substances it had drawn into its system, in a state in which they are ready to afford nourishment to the next year's vegetation. But under the artificial circumstances of cultivation, when the crops produced are more or less completely removed from the soil, exhaustion would sooner or later take place if the substances removed from it were not again returned in the form of manure.

The action of a manure, however, is more complicated than this statement would lead us to suppose; for it is not confined to the mere addition to the soil of the substances required to sustain its fertility, but they exert an influence upon the soil itself, promote the changes which are continually in progress within it, and cause the liberation of a larger quantity of its valuable constituents than the atmosphere alone could do. It is clear that different manures may effect these objects in different ways and to different extents. Some may confine their influence to the mere addition of the necessary elements of the plants, others may exert a powerful influence on the changes occurring in the soil. Some again may supply all the constituents of the plants, others only one or two. The former of these is a very obscure and ill-understood branch of the action of manures; the latter is better known, and is an important element in our estimation of their value, those manures necessarily having the highest value which contain the greatest number of substances required by the plant, and those which afford only one or more having their value regulated by the difficulty which the plant has in obtaining the constituents these manures contain in abundance. There has thus arisen the distinction between general and special manures, a distinction which is important both in theory and practice, and which ought never to be lost sight of.

*General Manures.*—General manures, then, are those which are capable of supplying to the plant *all* or nearly all its constituents, and this is necessarily done in the most effectual manner by farm-yard manure, to which theory and practice concur in giving the highest rank.

*Farm-Yard Manure.*—Farm-yard manure is a mixture of the dung and urine of domestic animals with the straw which has been used as litter, and its composition and value will of course depend on that of these substances, which we must first consider. The dung of animals consists of that part of their food which passes through the intestinal canal without undergoing assimilation; the urine contains that portion which has been assimilated and is again excreted in consequence of the changes which are proceeding in the tissues of the animal. Their composition is naturally very different, and must be separately considered.

*Urine.*—Urine consists of a variety of earthy and alkaline salts, and of certain organic substances, generally rich in nitrogen, dissolved in a large quantity of water. The composition in the different domestic animals has been examined by different chemists; we quote the analyses of Fromberg, as giving the most complete view of the subject.

| | Horse. | Swine. | Ox. | Goat. | Sheep. |

Human urine has been accurately examined by Berzelius. His analysis gives the following numbers:—

| | Natural. | Dry Residue. |
|---|---|---|
| Urea ...................................... | 3·010 | 44·70 |
| Lactic acid, lactate of ammonia, and extractive matters......... | 1·714 | 25·58 |
| Uric acid ................................ | 0·100 | 1·49 |
| Mucus .................................... | 0·032 | 0·48 |
| Sulphate of potash.................... | 0·371 | 5·54 |
| Sulphate of soda....................... | 0·316 | 4·72 |
| Phosphate of soda .................... | 0·294 | 4·39 |
| Biphosphate of ammonia ............ | 0·165 | 2·46 |
| Chloride of sodium.................... | 0·445 | 6·64 |
| Muriate of ammonia ................. | 0·150 | 2·46 |
| Phosphates of magnesia and lime... | 0·100 | 1·49 |
| Silica ...................................... | 0·003 | 0·05 |
| Water ..................................... | 93·300 | ... |
| | 100·000 | 100·00 |

Among the special organic constituents of the urine are three substances of much importance, as they contain a large quantity of nitrogen, which they yield in the form of ammonia, as a consequence of certain changes to which they are liable. The composition of these substances is as follows:—

| | Urea. | Uric Acid. | Hippuric Acid. |
|---|---|---|---|
| Carbon .................. | 20·00 | 36·0 | 60·7 |
| Hydrogen ............... | 6·60 | 2·4 | 5·0 |
| Nitrogen ................ | 46·70 | 33·4 | 8·0 |
| Oxygen .................. | 26·70 | 28·2 | 26·3 |
| | 100·00 | 100·0 | 100·0 |

It is evident from these analyses that the urines of different animals must differ greatly in value, those of the ox, swine, and goat, containing a very much smaller quantity of solids than the others. They differ also in regard to their saline ingredients; and while salts of potash and soda form the principal part of the ash of the urine of the ox, sheep, goat, and horse, and phosphoric acid and phosphates are entirely absent, that of the pig contains a considerable quantity of the latter substances, and in this respect more nearly resembles the urine of man. Human urine is also much richer in urea and nitrogenous constituents generally, and has a higher value than any of the others.

*Dung.*—The solid excrement of animals is equally variable in composition. That of the domestic animals which had the ordinary winter food was found to have the following composition:—

| | Horse. | Cow. | Sheep. | Swine. |
|---|---|---|---|---|
| Per-centage of water in the fresh excrement.......... | 77·25 | 82·45 | 56·47 | 77·13 |
| Ash in the dry excrement......... | 13·36 | 15·23 | 13·49 | 37·17 |

100 parts of ash contained—

| | Horse. | Cow. | Sheep. | Swine. |
|---|---|---|---|---|
| Silica.................................. | 62·40 | 62·54 | 50·11 | 13·19 |
| Potash................................ | 11·30 | 2·91 | 8·32 | 3·60 |
| Soda .................................. | 1·98 | 0·98 | 3·28 | 3·44 |
| Chloride of sodium................. | 0·03 | 0·23 | 0·14 | 0·89 |
| Phosphate of iron ................. | 2·73 | 8·93 | 3·98 | 10·55 |
| Lime ................................ | 4·63 | 5·71 | 18·15 | 2·63 |
| Magnesia .......................... | 3·84 | 11·47 | 5·45 | 2·24 |
| Phosphoric acid ..................... | 8·93 | 4·75 | 7·52 | 0·41 |
| Sulphuric acid ...................... | 1·83 | 1·77 | 2·69 | 0·90 |
| Carbonic acid........................ | ... | trace | trace | 0·60 |
| Oxide of manganese ............... | 2·13 | ... | ... | ... |
| Sand ................................. | ... | ... | ... | 61·37 |
| | 99·80 | 99·29 | 99·64 | 99·82 |

Human fæces contain about 73 per cent. of water, and leave about 1 per cent. of ash, of which the composition is—

| | |
|---|---|
| Potash..................................... | 6·10 |
| Soda........................................ | 5·07 |
| Lime........................................ | 26·46 |
| Magnesia.................................. | 10·54 |
| Oxide of iron ............................ | 2·50 |
| Phosphoric acid.......................... | 36·03 |
| Sulphuric acid............................ | 3·13 |
| Carbonic acid............................. | 5·07 |
| Chloride of sodium...................... | 4·33 |
| | 99·23 |

It is to be observed that the urine and dung of animals differs conspicuously in the composition of the ash, the urine being characterised by the abundance of alkaline salts, the latter containing only a small proportion of these, but being rich in earthy matters, and especially in phosphoric acid. The difference in the quantity of nitrogen they contain is also very marked, and is distinctly shown by the following analyses by Boussingault, which give the quantity of carbon, hydrogen, nitrogen, and oxygen in the dung and urine of the horse and the cow.

| | Horse. | | | | Cow. | | | |
|---|---|---|---|---|---|---|---|---|
| | Natural. | | Dry. | | Natural. | | Dry. | |
| | Urine. | Dung. | Urine. | Dung. | Urine. | Dung. | Urine. | Dung. |
| Carbon | 4·46 | 9·56 | 36·0 | 38·7 | 3·18 | 4·02 | 27·2 | 42·8 |
| Hydrogen | 0·47 | 1·26 | 3·8 | 5·1 | 0·30 | 0·49 | 2·6 | 5·2 |
| Nitrogen | 1·55 | 0·54 | 12·5 | 2·2 | 0·44 | 0·22 | 3·8 | 2·3 |
| Oxygen | 1·40 | 9·31 | 11·3 | 37·7 | 3·09 | 3·54 | 26·4 | 37·7 |
| Ash | 4·51 | 4·02 | 36·4 | 16·3 | 4·68 | 1·13 | 40·0 | 12·0 |
| Water | 87·61 | 75·31 | 0·0 | 0·0 | 88·31 | 90·60 | 0·0 | 0·0 |
| | 100·00 | 100·00 | 100·0 | 100·0 | 100·00 | 100·00 | 100·0 | 100·0 |

It thus appears that the urine of the horse, in its natural state, contains three times as much nitrogen as its dung, and that of the cow twice as much; and the difference, especially in the horse, becomes still more conspicuous when they are dry.

Taking the facts just mentioned into account, it is obvious that the quality of farm-yard manure must depend, 1. On the kind of animal from which it is produced; 2. On the quantity of straw which has been used as litter; 3. On the nature of the food with which the animals have been supplied; and, 4. On the care which has been taken to prevent the escape of the urine, or of the ammonia produced by its decomposition. The extent to which these different circumstances modify the quality of farm-yard manure has not been very fully determined by analyses; nor is it probable that its composition varies very greatly, indeed, the analyses which we possess, although they are not very numerous, show a great degree of similarity in the farm-yard manure of different places, when prepared in the same manner. The results obtained by different analyses are contained in the following table, which, in addition to the ordinary farm-yard manure, gives also the composition of that produced by feeding cattle in boxes and of stable dung. The authority is given with each analysis.

| | Farm Yard Manure. | | | | | Box Manure. | Stable Dung. |
|---|---|---|---|---|---|---|---|
| | Nisbet. | | Liebig. | Boussingault. | Way. | Way. | Richardson. |
| Water | 70·0 | 70·0 | 65·0 | 79·3 | 71·4 | 71·0 | 65·2 |
| Organic matter | 20·8 | 20·4 | 24·0 | 14·0 | 28·6 | 29·0 | 24·7 |
| Ash | 9·2 | 9·6 | 11·0 | 6·7 | | | 10·1 |
| | 100·0 | 100·0 | 100·0 | 100·0 | 100·0 | 100·0 | 100·0 |
| Nitrogen | ... | ... | ... | 0·4 | 0·4 | 0·6 | 0·6 |

The composition of the ash of farm-yard manure in 100 parts is:

| | Farm-Yard Manure. Nisbet. | | Liebig. | Stable Dung. Richardson. |
|---|---|---|---|---|
| Potash | 3·3 | 5·1 | 2·7 | 3·2 |
| Soda | 0·9 | 1·7 | 2·7 | 2·7 |
| Lime | 6·9 | 12·3 | 8·2 | 8·7 |
| Magnesia | 0·6 | 0·8 | 1·0 | 1·9 |

| Carbonic acid | ... | ... | 4·5 | 4·9 |
| Sand and silica | 79·9 | 71·9 | 66·4 | 59·0 |
| | 100·0 | 100·0 | 100·0 | 96·9 |

The value of farm-yard manure must manifestly depend on the quantity of all the constituents of the plant contained in it. If, however, we examine minutely into the action of the individual elements, it becomes obvious that two present a much higher value than the others, and may, in most cases, be taken as the measure of the value of any manure. These substances are nitrogen and phosphoric acid. Now, it is to be observed, that though both exist in the soil, they are present in but small quantity, even in those of the highest fertility. But this is not all, for the condition in which they are met with is far from being that in which they are readily available to the plant. The phosphoric acid of our soils is not only in an insoluble state, but in one in which it is not readily reached or dissolved by the roots of the plant, and, consequently can only become available as it is liberated by the continuous and slow decomposition constantly occurring in the soil. As regards nitrogen, we have already very distinctly referred to the fact that it can only be absorbed in the state of ammonia or of nitric acid, and most abundantly and readily in the former condition. But the soil contains its nitrogen in the form of vegetable debris, which do not contain that element in the form of ammonia, but only yield it as the result of decompositions, which, like all those occurring in the soil, proceed with extreme slowness. The importance of having the phosphoric acid in a soluble state, and the nitrogen in the form of ammonia, is conspicuously seen from the marked effects obtained from the use of superphosphate of lime (in which a large quantity of the phosphoric acid is soluble) and the salts of ammonia, to which we shall afterwards have to advert. By reference to the analyses of the urine and dung of our domestic animals in the previous page, we see that they do not contain ammonia as such, although they are rich in substances capable of yielding it, and that soluble phosphates are found only in the urine of man and the pig. The value of farm-yard manure is to be estimated by the abundance of these elements; but for all ordinary purposes, in considering the matter, we may put the phosphoric acid out of the question, and confine our attention to the nitrogen.

In the production of farm-yard manure of the highest quality, the object of the farmer must be, first, to produce a manure containing the largest possible amount of nitrogen; and secondly, to convert that nitrogen more or less completely into ammonia. In regard to the first of these points, it will be at once seen from what we have said of the comparative composition of the dung and urine, that the more effectually the latter is collected and its escape from the dung preserved, the higher will be the value of the manure; and it is for this reason that chemists have so anxiously impressed upon the agricultural public the great importance of preserving, and, if possible, retaining in the mass the fluid that drains from the dung heap, which must necessarily contain a considerable quantity of the nitrogenous constituents of the urine. This may be managed to a considerable extent, by arranging the manure heap in such a manner that the fluid which drains from it can be again pumped up over the solid matter, so that the latter may be saturated by it. A still more effectual plan is to mix the dung with some substance which may absorb the urine. For this purpose it is desirable that the absorbent substance shall be one which has an affinity for ammonia, so that it may not only retain the urine mechanically, but, by combining chemically with the ammonia produced by its decomposition, may prevent the escape of that substance into the air, which, from its volatility, it is of course very liable to do. Many substances, such as gypsum, sulphate of iron, chloride of manganese, sulphate of magnesia, and sulphuric acid, have been proposed for this purpose, and have occasionally been used, though not extensively. They all answer the purpose of *fixing* the ammonia, that is, of preventing its escaping into the air more or less effectually, but they do not add sufficiently to the porosity of the manure heap to enable it to absorb the fluid, which is a matter of some importance. For this purpose clay, or the vegetable refuse of the farm, may be employed. But by far the best substance, when it can be got, is dry peat, which not only absorbs the fluid, but will serve to fix the ammonia without the addition of any other substance. We have already referred to the absorbent power of peat in the section on soils, but we may mention here that accurate experiment has shown that a particular peat will absorb about 2 per cent.[1] of ammonia, and when dry will still retain from 1 to 1·5 per cent., or nearly three times as much as would be yielded by the whole nitrogen of an equal weight of farm-yard manure. Peat charcoal has been recommended for the same purpose, but careful experiment has shown that it *does not absorb ammonia*, although it removes putrid odour; and though it may be usefully employed when it is wished to deodorise the manure heap, it must not be trusted to as an absorbent of ammonia.

In addition to these methods of managing farm-yard manure, we have of late years had the introduction of box-feeding, one of the great advantages of which is said to be the production of a manure of superior quality to that obtained in the old way. In box-feeding none of the dung or urine is removed from under the animals, but is trampled down by their feet, and new quantities of litter being constantly added, the whole is consolidated into a compact mass, by which the urine is entirely retained. That, under these circumstances, the manure should be of high quality is certainly consistent with theory, and the analysis of box manure given above confirms the opinion. It is, however, a solitary analysis, and until confirmed by more extended analyses too much dependence must not be placed upon it. The value of box manure must mainly depend upon the solid retaining the whole of the liquid manure; but this is exactly the point on which practical men differ, the keen supporters of box-feeding asserting that it does, while others find that a certain quantity escapes. Should this prove to be frequently the case, the advantages of box-feeding, as a means of producing good manure, will be less than its supporters imagine.

Whether box manure is really superior to that prepared by the ordinary method is very questionable, but there is no doubt that it surpasses a large proportion of that actually produced. It is more than probable, however, that the more careful management of the manure heap may produce equally good effects. It is manifest that the same number of cattle, fed in the same way, and on the same food, and supplied with the same quantity of litter, must always excrete the same quantities of valuable matters, and the only question to be solved is, whether these valuable matters are more effectually preserved in the one way than the other. It will be readily seen that this cannot be done by the analysis of the manure alone, but we must conjoin with it a determination of the total weight of manure produced; for though, weight for weight, box manure may be better than ordinary farm-yard manure, the total quantity obtained from a given number of cattle may be so much greater that the deficiency in quality may be compensated for. At the present time our knowledge is too limited to admit of a definite opinion on this subject, but it is highly deserving of the combined investigation of the farmer and the chemist.

The value of the manure produced is also dependent on the nature of the food supplied to the cattle, and the period of the fattening process at which it is collected. When lean beasts are put up to fatten they at first exhaust the food much more completely then they do when they are nearly fattened, and the manure produced is very inferior at first, and goes on gradually improving in quality as the animal becomes fat. That the quality of the food affects the value of the manure is an opinion which has long been entertained by practical men, and it is no doubt correct, though not to the extent which some persons believe. It is held by some farmers, that while cattle are fed with oil-cake, the increased value of the manure is equal to from one-half to one-third that of the oil-cake. This is certainly an exaggeration, but there cannot be a doubt that some increase of value must take place; for when oil-cake is employed, the quantity of nutritive matters consumed by the animal is larger than when it is fed on turnip alone; but it is not possible at present to estimate the difference, for want of experiments especially directed to this point. From analyses made some time since, we have come to the conclusion that, weight for weight, the dung and urine of cattle fed with oil-cake are richer in valuable matters than those fed on turnips alone; but the experiments were not sufficiently extensive to enable us to draw a definite conclusion, and no determination of the total quantity excreted could be made.

Supposing the conditions which produce the manure containing the largest quantity of nitrogen to have been fulfilled, we have now to consider those which affect its evolution in the form of ammonia. This change is effected by *fermentation*. When a quantity of manure is left to itself for some time it is found to become hot, and gradually to diminish in bulk, and if it be now turned over it is found to evolve the smell of ammonia more or less distinctly. This ammonia is produced, in the first instance, from the urine, the nitrogenous constituents of which are rapidly decomposed, and the fermentation thus set up in the mass of manure extends to the solid dung, and finally to the straw of the litter, and gradually proceeds until a large quantity of ammonia is produced. The same change occurs in the manure if mixed with the soil, but in that case it is much slower, and experience has shown that much greater effects are produced if the manure has been fermented previous to being used. Science at once explains the necessity for the process, and shows that by its means the nitrogen is converted into a state in which the crop it is applied to can rapidly absorb it, and that the practice of applying well-fermented dung to the quickly growing crops, and fresh dung to those which come slowly to maturity, is consistent with theory. But it points out also that the method of doing this

[1] Report on the economic uses of peat. *Highland Society's Transactions*, N.S., vol. iv. p. 549.

by fermentation is, in so far, defective, that it cannot be effected without some loss of ammonia, however carefully it may be managed; and though up to the present time the fermentation of a manure has been deemed essential to its success, it may be questioned whether, now that we have other sources of ammonia, it might not be more economical to apply farm-yard manure in an unfermented state, so as to avoid the loss of ammonia which takes place during the process, and to supply the quantity required for the early growth of the plant by the use of some of the salts of ammonia or other ammoniacal manures. This is a speculative opinion, which must be submitted to experiment, and its value must depend on the amount of loss which takes place by fermentation in the manure heap, regarding which we have at present no information.

*Liquid Manure.*—This term is applied to the urine of the animals fed on the farm, and to the drainings from the manure-heap, which, in place of being returned to it, are in some instances allowed to drain away, and are collected in tanks, from which they are distributed according to the old plan by a watering-cart, or according to the method recently introduced in Ayrshire, by pipes laid under-ground in the fields, and through which the manure is either pumped by steam-power, or, where the necessary inclination can be obtained, is distributed by gravitation. That liquid manure must necessarily be valuable, is an inference which may be at once drawn from the analyses of the urine of different animals already given, and which, when it is collected apart from the solid matters, may be taken as representing the composition of liquid manure. It will be at once seen from these analyses, that liquid manure so obtained must be extremely rich in ammonia, but deficient in phosphates; and as the nitrogenous matters of urine pass with great rapidity into the form of ammonia, it must act quickly, and produce its best effects on those crops which admit of being rapidly forced on to maturity. The deficiency of phosphates in the urine of the common domestic animals is an objection to the use of that fluid alone. But where the drainings of the manure-heap are employed, this difficulty is done away with, for they generally contain a certain quantity of phosphates, either in solution, or more probably in suspension in the fluid. The following analyses by Professor Johnston give the composition, No. 1 of the drainings of the manure-heaps when exposed to rain; No. 2 of the drainings when moistened with cows' urine pumped over it. The numbers give the quantities in grains contained in a gallon of the fluid:—

| | No. 1. | No. 2. |
|---|---|---|
| Ammonia | 9·6 | 21·5 |
| Organic matter | 200·8 | 77·6 |
| Ash | 268·8 | 518·4 |
| Total solids in a gallon | 479·2 | 617·5 |
| The ash contained,— | | |
| Alkaline salts | 207·8 | 420·4 |
| Phosphates | 25·1 | 44·5 |
| Carbonate of lime | 18·2 | 31·1 |
| Carbonate of magnesia, and loss | 4·3 | 3·4 |
| Silica and alumina | 13·4 | 19·0 |
| | 268·8 | 518·4 |

The method of liquid manuring employed by Mr Kennedy at Myremill, the results of which have excited so much interest, is different from liquid manuring in its *strict* sense, for not only are the drainings of the manure-heap employed, but the whole solid excrements are mixed with water in a tank, and rape-dust and other substances occasionally added, and distributed through the pipes.

No system of manuring has produced more striking effects than liquid manuring; and especially on grass-lands, the rapidity of its action is such as to produce an extremely abundant vegetation, much greater, indeed, than could be produced by the application of the solid manure. The luxuriance of the growth of grass by its means is, however, apt to lead us to overrate its general effects; and it is by no means so certain that it can be advantageously applied to the general operations of the farm. Its effect on the cereals is certainly much less marked than that on ryegrass and root-crops, and we have not yet seen the effects of its continued use. Experience and theory concur in holding that a supply of solid matters capable of evolving carbonic acid, is essential to the fertility of the soil, so that, by acting on the mineral matters, it may cause their continuous decomposition. The objection to liquid manure is, that it does not supply these substances in sufficient quantity. This difficulty is no doubt got rid of, to some extent, in the Ayrshire plan, which, after all, is rather a new method of applying the *solid* manure of the farm than strictly *liquid* manuring; but still, as no litter is employed, the quantity of organic matters capable of evolving ammonia is greatly less than it is by the old method; and we must consider the Ayrshire mode of liquid manuring as a great experiment of which all will await the results with interest. Of course the pecuniary question is also of much importance in this method; but that is a matter which we only indicate here, as it is treated of in full in the article on Practical Agriculture.

*Vegetable Manures.*—Many vegetable substances are employed as manures, and their value is variable, and must be estimated in the same manner as that of farm-yard manure, the quantity of nitrogen and phosphoric acid greatly exceeding in importance that of the other constituents. Although like farm-yard manure they may be made to undergo fermentation so as to convert their nitrogen into ammonia, they are generally, indeed almost invariably, applied in the unfermented state, seldom alone, and most commonly conjoined with farm-yard manure.

*Rape-Dust, Castor-Cake, Poppy-Cake,* &c.—Rape-dust has long been employed as a manure, and the success which has attended its use has led to the introduction of the refuse cake from some other oil seeds, such as that of the castor-oil seed, which cannot be employed for feeding. Like the seeds of all plants, these substances are rich in nitrogen, and their ash, containing of course all the constituents of the plant, supplies the necessary inorganic elements. The following are analyses of these substances, which, in addition to the amount of nitrogen and phosphates, show also that of water and oil, to which we shall have occasion afterwards to refer in relation to the feeding value of some of them.

| | Rape-Cake. | Poppy-Cake. | Cotton-seed cake. | Castor-Cake. |
|---|---|---|---|---|
| Water | 10·68 | 11·63 | 11·19 | 12·31 |
| Oil | 11·10 | 5·95 | 9·08 | 24·32 |
| Albuminous compounds | 29·53 | 31·16 | 25·16 | 21·91 |
| Ash | 7·79 | 12·98 | 5·64 | 6·08 |
| Other constituents | 40·90 | 38·18 | 48·93 | 35·38 |
| | 100·00 | 100·00 | 100·00 | 100·00 |
| Nitrogen | 4·38 | 4·94 | 3·95 | 3·20 |
| Silica | 1·18 | 3·36 | 1·32 | 1·96 |
| Phosphates | 3·87 | 6·93 | 2·19 | 2·81 |
| Phosphoric acid in combination with alkaline | 0·39 | 3·27 | 0·15 | 0·64 |

A general similarity will be observed in the composition of all these substances; they are all rich in nitrogen, and contain as much of that element as is found in about ten times their weight of farm-yard manure, and a somewhat similar proportion exists in the amount of phosphates and probably of their other constituents. They have all been employed with success, but the most accurate experiments have been made with rape-dust, which has been longer and more extensively used than any of the others. It has been employed alone for turnips, or mixed with farm-yard manure, and also as a top-dressing to cereals. The most marked advantage is derived from it when applied in the latter way on land which has been much exhausted, on which its effects are often very striking. Several circumstances are essential to the production of its full effects. It requires moisture, and hence it often proves a failure in very dry seasons, and on dry soils. It must not be applied in too large a quantity, experience having shown that after a certain point has been reached, an increase in the quantity not only does not increase but positively diminishes the crop. The most advantageous application is found to be from five to seven cwt. per acre. The observations in regard to the use of rape-dust probably apply with equal force to the other substances of the same class; but their application being more recent and more limited, the results of their use have not been made public.

*Malt-Dust, Bran, Chaff,* &c.—All these substances have been applied as manures, and their value is principally dependent on the quantity of nitrogen they contain, which in malt-dust amounts to 4·5 per cent. of nitrogen, and in bran to about 3·2. They must therefore be made to rank with rape-dust in point of value.

*Straw* has been occasionally employed as a manure, and sometimes even as a top-dressing for grass land. It is generally admitted, however, that its application in the dry state, and especially as a top-dressing, is a practice not to be recommended, as it decomposes too slowly in the soil; and it is always desirable to ferment it in the manure heap, so as to facilitate the production of ammonia from its nitrogen. Still circumstances may occur in which it becomes necessary to employ it in the dry state, and it will generally prove most valuable on heavy soils, which it serves to keep open, and so promotes the access of air, and enables it to act on the soil. On light sandy soils it generally proves less advantageous, as its tendency of course is to increase the openness of the soil, and render it less able to retain the essential constituents of the plant. The manurial value of straw alone is low, as it contains only about 0·2 per cent. of nitrogen, or about half as much as farm-yard manure.

*Saw-Dust* has little value as a manure, as it undergoes decomposition with extreme slowness. It is a good *mechanical* addition to heavy soils, and diminishes their tenacity; and though its manurial effects are small, it sooner or later undergoes decomposition, and yields what valuable matters it contains. It is a useful absorbent of liquid manure, and may be advantageously added to farm-yard manure for that purpose.

*Manuring with Fresh Vegetable Matter.—Green Manuring.*—The term green manuring is applied to the ploughing in of green vegetable matter which has been grown on the soil for that purpose. The success which attends it, especially on soils poor in organic matter, is very marked. Its utility is manifestly dependent on its affording to the soil a supply of matter which by its decomposition may yield carbonic acid to act on the soil, as well as nitrogen and inorganic matters. The action is not, however, confined to this, for it serves also as a means of bringing up from the lower parts of the soil the valuable matters it contains, and of mixing them again with the surface part. Many of the plants found most useful for green manuring send down their roots to a considerable depth; and when they are ploughed in, all the substances which they have brought up are of course deposited in the upper few inches of the soil. Plants when ploughed in in the fresh state also decompose rapidly, and are therefore able immediately to improve the subsequent crop; and as this decomposition takes place in the soil without the loss of ammonia and other valuable matters, which infallibly occurs when they are fermented on the dung-heap, it will be obvious that in no other mode can equally good results be obtained by the use of these plants.

Many plants have been employed as green manure, and different opinions have been expressed as to their relative values. In the selection of any one for the purpose, that should of course be taken which grows most rapidly, and produces within a given time the largest quantity of valuable matters. No general rule can be given for the selection, as the plant which fulfils those conditions best will differ in different soils and climates. The plants most commonly employed in this country are spurry, white mustard, and turnips. Rye, clover, buck-wheat, white lupins, rape, borage, and some others, have been largely employed abroad. Some of these are obviously unfitted for the climate of the British Islands; and the others, although they have been tried occasionally, do not appear to have been very extensively employed. The turnip is sown broadcast at the end of harvest, and ploughed in after two months. White mustard and spurry are employed in the same way as a preparation for winter wheat, and with the best results. The latter is sometimes sown as a spring crop in March, ploughed in in May, and another crop sown which is ploughed in in June, and immediately followed by a third. The effect of this treatment is such that the worst sands may be made to bear a remunerative crop of rye.

*Sea-Weed.*—Sea-weeds are very extensively employed on the coasts of Scotland and England, in quantities varying from 10 to 20 tons per acre as a manure. Their action is necessarily similar to that of green manure ploughed in, as they contain all the ordinary constituents of land plants. Their nitrogen usually amounts to about 2·1 per cent. of the dry substances, and they are much richer in ash than ordinary land plants. The dry fucus saccharinus contains 28 per cent., and fucus vesiculosus about 20 per cent. The following are analyses of the ash of three species of sea-weeds from the Firth of Forth.

| | Laminaria digitata. | Fucus serratus. | Fucus nodosus. |
|---|---|---|---|
| Potash | 31·812 | 30·870 | 14·320 |
| Chloride of potassium | 19·764 | 6·148 | 29·885 |
| Iodide of potassium | 1·365 | ... | ... |
| Chloride of sodium | 23·986 | 25·859 | 15·557 |
| Lime | 5·351 | 7·927 | 7·647 |
| Magnesia | 3·454 | 6·368 | 5·636 |
| Peroxide of iron | 1·333 | 0·230 | 0·135 |
| Sulphuric acid | 9·598 | 17·870 | 24·812 |
| Phosphoric acid | 3·287 | 2·480 | 0·848 |
| Silica | 0·050 | 2·248 | 1·160 |
| | 100·000 | 100·000 | 100·000 |

The great value of sea-weed is dependent on the rapidity with which it decomposes. In fact, when spread on the land, it is seen to soften and disappear in a very short time. It is therefore a rapid manure, and its effects are almost entirely confined to the crop to which it is applied. It may be used as a top-dressing to grass land; but it is most beneficial when ploughed in green, or when made into a compost with lime and earth. On the western coast of Scotland and in the Hebrides sea-weed is the chief manure. It gives excellent crops of potatoes, but they are said to be of inferior quality, unless marl or shell sand is employed at the same time.

The observations which have been made regarding the manurial value of these substances, immediately lead to the inference that all vegetable matters possess a certain value, and that they ought to be carefully collected and preserved. In fact, the careful farmer adds every thing of the sort to his manure heap, where, by undergoing fermentation along with the manure, their nitrogen becomes immediately available to the plant; while during the fermentation the seeds of weeds are destroyed, and the risk of the land being rendered dirty by their springing up when the manure is used, is prevented.

*Animal Manures.*—Animal substances generally contain a much larger quantity of nitrogen than vegetables, and as they undergo decomposition and yield it in the form of ammonia more rapidly, their value is much higher.

*Flesh* is an important manure. That of horses is prepared and sold to some extent. The dead animal after being skinned is cut up and boiled in large cauldrons until the flesh separates from the bones. The latter are removed, and the flesh dried upon a flat stove. The flesh as sold has the following composition:—

| | |
|---|---|
| Water | 12·17 |
| Organic matter | 78·44 |
| Phosphate of lime, &c. | 3·82 |
| Alkaline salts | 3·64 |
| Sand | 1·93 |
| | 100·00 |
| Nitrogen | 9·22 |
| Ammonia to which the nitrogen is equivalent | 11·20 |

Another sort of "flesh manure" has been recently imported from South America. It is a mixture of the flesh and smaller bones of cattle which have been slaughtered for their tallow, and remains in the vats in which the separation of the tallow is effected by steaming. Owing to the variable proportion of bones and flesh, and to the mixture of sand, which takes place, owing to the careless way in which it has been preserved, it varies somewhat in composition. Its composition is,

| | |
|---|---|
| Water | 9·05 |
| Fat | 11·13 |
| Animal matter | 39·52 |
| Phosphate of lime | 28·74 |
| Carbonate of lime | 3·81 |
| Alkaline salts | 0·57 |
| Sand | 7·18 |
| | 100·00 |
| Nitrogen | 5·56 |
| Ammonia to which the nitrogen is equivalent | 6·67 |

Another sample contained 5·77 of nitrogen, 17·16 of phosphate of lime, and 18·78 of sand.

Considerable difference must necessarily exist in the effects of these two manures, owing to the difference of their composition. The first must owe its value entirely to nitrogen, the quantity of phosphate of lime and alkaline salts being too small to exert any influence of importance. In the South American manure, however, the quantity of bones raise that of phosphate of lime in the first instance to above a fourth, and in the second to nearly a fifth, of the whole weight, and must therefore cause it to act, to a great extent, in the same manner as bones, to the manurial value of which we shall presently refer.

*Fish* have been employed in considerable quantity as a manure. That most extensively employed in this country is the sprat, which is occasionally caught in enormous quantities on the Norfolk coast, and used as an application for turnips. They are sold at 8d. per bushel, and their composition is,—

| | |
|---|---|
| Water | 64·6 |
| Organic matter | 33·3 |
| Ash | 2·1 |
| | 100·0 |
| Nitrogen | 1·90 |
| Phosphoric acid | 0·91 |

The refuse of herring and other fish curing establishments, whales' blubber, and similar fish refuse are all useful as manure, and are employed whenever they can be obtained. They are not usually employed alone, but are more advantageously made into composts with their own weight of soil, and allowed to ferment thoroughly before being applied.

*Blood* is a most valuable manure, but it is not much employed in this country, at least in the neighbourhood of large towns, as there is a demand for it for other purposes, and it can rarely be obtained by the farmer in large quantity. In its natural state it contains about 3 per cent. of nitrogen, and after being dried up the residue contains about 15 per cent. It is best used in the form of a compost with peat or mould, and this forms an excellent manure for turnips, and is also advantageously applied as a top-dressing to wheat.

*Hair, Skin, and Horn.*—The refuse of manufactories in which these substances are employed, are frequently used as manures. They are all highly nitrogenous substances, and owe their entire value to the nitrogen they contain, their inorganic constituents being in too small quantity to be of any importance, wool and hair having only 2 per cent., and horn 0·7 per cent. of ash. In the pure and dry state, and after subtraction of the ash, their composition is,—

| | Skin. | Human Hair. | Wool. | Horn. |
|---|---|---|---|---|
| Carbon | 50·99 | 50·65 | 50·65 | 51·99 |
| Hydrogen | 7·07 | 6·36 | 7·03 | 6·72 |
| Nitrogen | 18·72 | 17·14 | 17·71 | 17·28 |
| Oxygen | 23·22 | 20·85 | 24·61 | 24·01 |
| Sulphur | ... | 5·00 | | |
| | 100·00 | 100·00 | 100·00 | 100·00 |

The refuse actually obtained is always moist and often mixed with foreign matters, and is consequently inferior to this. Refuse horse hair generally contains 11 or 12 per cent. of nitrogen. Wool contains very different quantities according to the kind of refuse. Woollen rags contain 12·7 per cent. of nitrogen; woollen cuttings about 14; and what is called shoddy only 5·5 per cent. Horn shavings are extremely variable in their amount of nitrogen. When pure they sometimes contain as much as 12·5 per cent., but a great deal of the horn shavings from comb manufactories, &c., contains much sand and bone dust, by which their percentage of nitrogen is greatly diminished, and it sometimes does not exceed 5 or 6 per cent.

All these substances are highly valuable as manures, but as they undergo decomposition more slowly than flesh or blood they are more applicable to slow growing crops, and to those which require a strong soil. Woollen rags have been largely employed as a manure for hops, and are believed to surpass every other substance for that crop. As a manure applicable to the ordinary purposes of the farm they have scarcely met with that attention which they deserve, probably because their first action is slow and the farmer is more accustomed to look to immediate than to future results; but they possess the important qualification of adding permanently to the fertility of the soil.

*Urate and Sulphated Urine.*—We have already discussed the urine of animals, in reference to farm-yard manure. But human urine, the composition of which was then stated, is of much higher value than that of the lower animals, and many attempts have been made to preserve and convert it into a dry manure. Urate is prepared by adding gypsum to urine, and collecting and drying the precipitate produced. It contains a considerable quantity of the phosphoric acid of the urine, but very little of its ammonia; and as the principal value of urine depends on the latter, it is necessarily a very inefficient method of turning it to account. A better method has been proposed by Dr Stenhouse, who adds lime-water to the urine, and collects the precipitate, which, when dried in the air, contains 1·91 per cent of nitrogen, and about 41 per cent. of phosphates. This method is subject to the same objection as that by which urate is made, namely, that the greater part of the ammonia is not precipitated. This might probably be got over to some extent by the addition of sulphate of magnesia, or, still better, of chloride of magnesium, which would throw down the phosphate of magnesia and ammonia. By much the best mode of employing urine is in the form of sulphated urine, which is made by adding to urine a sufficient quantity of sulphuric acid to neutralise its ammonia, and evaporating to dryness. In this form all the valuable constituents are retained, and excellent results are obtained from it. Its effects, though mainly attributable to its ammonia, are also in part dependent on the phosphates and alkaline salts which it contains; and it is therefore capable of supplying to the plant a larger number of its constituents than the animal matters already mentioned.

*Night-Soil and Poudrette.*—The value of night-soil as a manure is well known. It depends, of course, partly on the urine, and partly on the fæces of which it is formed. Its disagreeable odour has prevented its general use, and various methods have been contrived both for deodorising and converting it into a solid and portable form. The same difficulties which beset the conversion of urine into the solid form are found here, and in most of the methods employed the loss of ammonia is great. It is sometimes mixed with lime or gypsum, and dried with heat, and sometimes with animal charcoal or peat charcoal. By none of these methods, however, is it obtained of high quality; and a good method of making it portable at small expense is still a desideratum. It usually contains about 2 per cent. of nitrogen, and 6 of phosphoric acid.

*Guano* is the solid excrement of carnivorous sea-birds, which is accumulated in immense quantities on the coasts of South America and other tropical countries. It has been used as a manure in Peru from time immemorial, but the accounts given by the older travellers of its marvellous effects were considered to be fabulous, until Humboldt, from personal observation, confirmed all their statements. It was first imported into this country in 1840, in which year a few barrels of it were brought home; and from that time its importation rapidly increased. Soon after large deposits of it were found in Ichaboe; and it has since been brought from many other localities.

The value of guano differs greatly according to the locality from which it is obtained. That from the rainless districts of Peru contains the ingredients of the dung comparatively little changed, a considerable proportion of the uric acid and ammonia of the urine existing in some instances in its natural state, and a small quantity only having undergone decomposition. But that from other districts has suffered a more or less complete decomposition according to the moisture of the climate, which reduces the quantity of organic matters and ammonia, until, in some varieties, they are so small as to be of little importance. The following are minute analyses of three specimens of Peruvian guano, showing all the different constituents it contains, and the amount of difference which may exist:—

| | I. | II. | III. |
|---|---|---|---|
| Urate of ammonia | 10·70 | 9·0 | 3·24 |
| Oxalate of ammonia | 12·38 | 10·6 | 13·35 |
| Oxalate of lime | 5·44 | 7·0 | 16·36 |
| Phosphate of ammonia | 19·25 | 6·0 | 6·45 |
| Phosphate of magnesia and ammonia | ... | 2·6 | 4·20 |
| Sulphate of potash | 4·50 | 5·5 | 4·23 |
| Sulphate of soda | 1·95 | 3·8 | 1·12 |
| Sulphate of ammonia | 3·36 | ... | ... |
| Muriate of ammonia | 4·81 | 4·2 | 6·50 |
| Phosphate of soda | ... | ... | 5·29 |
| Chloride of sodium | ... | ... | 0·10 |
| Phosphate of lime | 15·56 | 14·3 | 9·94 |
| Carbonate of lime | 1·80 | ... | ... |
| Sand and alumina | 1·59 | 4·7 | 5·80 |
| Water | 9.14 | 32·3 | 23·42 |
| Undetermined humus-like organic matters | 10·00 | | |
| | 100·48 | 100·0 | 100·00 |

These analyses illustrate two points—*first*, that in different samples the decomposition may have advanced to different extents; for we observe that the quantity of uric acid, or rather of urate of ammonia, is greatly less in the last analysis than in the other two, and much smaller than in the fresh dung, which contains from 50 to 90 per cent. of uric acid; and *secondly*, that guano is rich in all the constituents of the plant, but especially in ammonia, the best form in which nitrogen can be supplied in uric acid, which, by decomposition, yields ammonia, and in phosphoric acid. But such analyses are too elaborate for ordinary purposes; and a less complete analysis is usually made, in which the total quantity of ammonia, with that which exists ready formed, and will be yielded by the uric acid. the quantity of water, the loss by ignition (that is, the total quantity of organic matter and ammoniacal salts), the water, sand, and alkaline salts, are determined. The subjoined tables give the average composition of different sorts of guano determined in this way. They are mostly averages deduced from a very large number of analyses, excepting those of recent Ichaboe, and of old Bolivian. In the second table are given the analyses of a number of other sorts of guano, but some of them only from a single analysis, so that they probably do not accurately represent the average, although they may give some idea of the composition of each sort. Two of the sorts—old Ichaboe and old Bolivian—are not now imported, the supplies being exhausted.

*Table showing the Average Composition of different varieties of Guano.*

| | Angamos. | Peruvian. | Ichaboe. | | Bolivian. | | | Latham Island. | Saldanha Bay. | Australian. | Patagonian. | Chilian. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|

Agricultural Chemistry.

*Table showing the Composition of some of the less common varieties of Guano.*

*Note.*—The numbers in this Table are mostly derived only from a single analysis, and have no value as determining the *average* composition of these Guanos, but they serve to give a general idea of their value.

| | Sea Bear Bay. | Holmes's Bird Island. | Ascension Island. | Possession Island. | Algoa Bay. | New Island. | Bird's Island. |
|---|---|---|---|---|---|---|---|

As with farm-yard manure, the value of guano is estimated by the quantity of nitrogen and phosphates which it is capable of yielding to the crop. As the nitrogen, however, exists in great part as ammonia, and the remainder in a state in which it readily passes into that substance, it is customary in the analysis to state the quantity of ammonia and not that of nitrogen, but it is easy to calculate the amount of the latter by bearing in mind that 17 parts of ammonia correspond to 14 of nitrogen.

By examining the tables given above, it is obvious that guanos may be divided into two classes, the one characterised by the abundance of ammonia, the other by that of phosphates; and which, for convenience sake, may be called ammoniacal and phosphatic guano. Peruvian and Angamos are characteristic of the former, and Saldanha Bay and Bolivian of the latter class. Of course the value of these varieties is very different; and as guano is an expensive manure, it is of much importance that some ready means of estimating the value of different samples should be known to the farmer. The principles that guide the chemist in making such an estimate are very simple. As the value of a guano depends on the quantity of ammonia and phosphates it contains, and as these are commercial articles, which have a definite value in the market, all that is necessary is to ascertain that value, and to calculate from it that of the guano. Now when sulphate of ammonia is bought, we find by calculation from its price, that the dry ammonia contained in it costs very nearly 6d. per pound, and in bones the cost of phosphate of lime is about ¾d. per pound.

In addition to this, we have also a certain quantity of phosphoric acid in the alkaline salts, which is equal in round numbers to double its weight of phosphate of lime. But this phosphoric acid being in a soluble state is worth more than twice as much as phosphate of lime. It is somewhat difficult to estimate its exact value, but we shall probably not be far wrong in assuming it at 3d. per lb. If we calculate the value of Peruvian guano upon this principle we obtain the following results per ton:—

| | L. | s. | d. |
|---|---|---|---|
| 17·5 per cent. of ammonia equal to 392 lb. per ton, value at 6d per lb., | L.9 | 16 | 0 |
| 23·48 per cent. of phosphates equal to 526 lb. at ¾d. per lb., | 1 | 13 | 0 |
| 2·5 per cent. of phosphoric acid equal to 56 lb. per ton at 3d. per lb. | | 14 | 0 |
| Total value per ton, | L.12 | 3 | 0 |

But the price of Peruvian guano is from L.9, 10s. to L.10 per ton; and this being the case, either it must be bought for its ammonia alone or else we buy ammonia in guano at a cheaper rate that we do in any other form. The latter is probably the most correct view of the case; and if so we find that the price paid for ammonia in Peruvian guano is rather less than 5d. per lb. Calculated on this principle, the value of a ton of average Peruvian guano is L.9, 13s. 8d., which is almost exactly the price at which it is sold. By calculating in this way, then, we can at once estimate the value of any sample of guano. A very simple method of effecting the calculation is the following:—If a pound of ammonia be worth 5d., a *ton* will be worth L.45; in the same way we find that a ton of phosphates is worth L.7, and of phosphoric acid in the alkaline salts L.28. If then we multiply the per-centage of ammonia by 45, that of phosphates by 7, and of phosphoric acid by 28, the sum of the products will give the price in pounds sterling of 100 tons of guano, and then dividing by 100 and doubling the first decimal, we have the price of a ton within a shilling or two. Applying this method of calculation to the Government Bolivian guano we find its value to be as follows:—

| | | |
|---|---|---|
| Phosphates | 56·09 × 7 = | 392·6 |
| Phosphoric acid | 3·11 × 28 = | 87·0 |
| Ammonia | 2·57 × 45 = | 115·6 |
| Value of 100 tons | | 593·2 |

The value of a ton will therefore be about L.5, 18s. But the usual selling price of Bolivian guano is about L.8 per ton, so that it actually sells at a much higher price than its value calculated in this way would warrant. By a similar calculation we find the value of Saldanha Bay would be L.4, 13s., its selling price at present being L.6, 10s.

This method of calculation, therefore, while it may be used with advantage for the comparison of different ammoniacal guanos, is not applicable to the phosphatic class, as it gives a lower value than that at which they are sold. It may be urged that these guanos are sold at a higher price than the value of their constituents warrants, but the question is not limited to this point. The two classes of guanos are bought for different purposes, the ammoniacal guanos for the sake of their ammonia principally, the phosphatic for their phosphates, and these prices would not be given for the latter sorts of guano unless the farmer found his advantage by it. We shall see afterwards that though Peruvian guano is generally the best, there are certain soils on which the phosphatic guanos nearly or altogether equal it; and on these soils, of course, Bolivian guano at L.8 is actually cheaper than Peruvian at L.9, 10s.; but this is only the case in particular instances, and taken as a whole it may be said that Peruvian, notwithstanding its high price, is the cheapest of all guanos.

In purchasing guano particular precautions are required on the part of the farmer, in order to avoid the risk of obtaining an adulterated article. He ought to attend to the following points in regard to *Peruvian* guano.

1*st*, The guano should be light coloured. If it is dark, the chances are that it has been damaged by sea-water.

2*d*, It should be dry, and when a handful is well squeezed together it should cohere very slightly.

3*d*, It should not have too powerful an ammoniacal odour.

4*th*, It should contain lumps which, when broken, appear of a paler colour than the powdery part of the sample.

5*th*, When rubbed between the fingers it should not be gritty.

These characters must not, however, be too implicitly relied on, for they are all imitated with wonderful ingenuity by the skilful adulterator, and they are applicable only to Peruvian guano; the others being so variable that no general rules can be given for determining whether they are genuine. With them as well as with Peruvian guano, the only safe mode of detecting adulteration is by analysis; and it is desirable even where there is no chance of adulteration having been practised, to determine in this way the value of the guano, as different cargos of the same sort differ materially in this respect. In the table above we have given the *average* composition of the different guanos, but in order to show how much individual cargos may differ from the mean, we give here analyses of samples of the highest and lowest quality of the genuine guanos of most importance.

| | Angamos. | | Peruvian. | | Bolivian. | |
|---|---|---|---|---|---|---|
| | Highest. | Lowest. | Highest. | Lowest. | Highest. | Lowest. |
| Water | 12·60 | 7·09 | 10·37 | 21·49 | 11·53 | 16·20 |
| Organic matter and ammoniacal salts | 65·62 | 50·83 | 55·73 | 46·26 | 11·17 | 12·86 |
| Phosphates | 10·83 | 8·70 | 25·20 | 18·93 | 62·99 | 52·95 |
| Alkaline salts | 7·50 | 16·30 | 7·50 | 10·64 | 9·93 | 13·83 |
| Sand | 3·45 | 17·08 | 1·20 | 2·68 | 4·38 | 4·16 |
| | 100·00 | 100·00 | 100·00 | 100·00 | 100·00 | 100·00 |
| Ammonia | 25·33 | 17·15 | 18·95 | 14·65 | 1·89 | 2·23 |

Calculating, in the manner before given, the value of these two samples of Peruvian guano, we find the highest to be worth L.10, 6s. per ton, the lowest no more than L.7, 18s. Something would have to be added for the phosphoric acid in the alkaline salts which have not been determined in these analyses, but this would not materially alter their *relative* values.

The adulteration of guano is carried on to a very large extent, and we are certainly within bounds in asserting that one-half of all the guano sold in this country is adulterated. The chief adulterations are a sort of yellow loam, very similar in appearance to guano, sand, gypsum, common salt, and apparently also ground coprolites. The extent to which it is adulterated may be estimated from the following analyses taken at random from those of a large number of guanos, all of which were sold as first-class Peruvian.

| | | | | | |
|---|---|---|---|---|---|
| Water | 12·85 | 15·19 | 12·06 | 27·86 | 6·32 |
| Organic matter and ammoniacal salts | 26·84 | 44·31 | 34·14 | 30·41 | 27·42 |
| Phosphates | 15·54 | 20·95 | 22·08 | 22·17 | 33·61 |
| Sulphate of lime | ... | ... | 11·08 | ... | 22·11 |
| Alkaline salts | 6·07 | 9·40 | 12·81 | 7·92 | 22·50 |
| Sand | 38·70 | 10·15 | 7·83 | 1·64 | 10·15 |
| | 100·00 | 100·00 | 100·00 | 100·00 | 100·00 |
| Ammonia | 9·34 | 13·90 | 9·77 | 8·64 | 9·76 |

In all these cases a very large depreciation in value has taken place; the first of them, by calculation, being worth only L.5, 5s. per ton. Large quantities of similarly adulterated guanos are annually sold at the price of the genuine article. The adulteration is principally carried on in London, but it is believed that it is also practised, though not so largely, in other places. In most instances these guanos are sold without analysis, and with the assurance on the part of the seller that they are genuine guano, which some farmers seem to consider all that is required. Others are sold with analysis, and sometimes it occurs that large quantities of adulterated and inferior guanos are sold by the analysis of a genuine sample, but of course this is the practice of the fraudulent dealer only. In order to insure obtaining a genuine guano, none should ever be purchased without an analysis, a comparison of which with the average composition of good guano, enables the buyer to ascertain its quality, and when the supply is obtained another sample should be selected of which an analysis should be obtained, in order to ascertain that the stock corresponds with the analysis by which it was sold—a very necessary precaution. It may be objected that this involves expense, but surely the cost of an analysis is a very trifling matter when a farmer buys perhaps L.100 or L.200 worth of a manure which adulteration may reduce to half its value.

The value and use of guano are now so well understood, that it will scarcely be necessary to enlarge on the mode of its application. Although owing its chief value to ammonia and phosphates, it contains also all the other ingredients of the plant, and everything required in a manure except the large quantity of organic matters capable of producing carbonic acid, on the importance of which to the soil we have already enlarged. It is capable of entirely replacing farm-yard manure, and excellent crops of turnips and potatoes have been raised by it alone, and at less cost than by farm-yard manure. But though this can be done, it is a practice not to be recommended, for the quantity of valuable matters in an ordinary application of guano is much smaller than in farm-yard manure, and not sufficient permanently to sustain the fertility of the soil. Five cwt. of Peruvian guano, which is a fair application to an acre, contains about 97 lb. of ammonia and 138 of phosphates, but 30 tons of farm-yard manure contain about 280 of ammonia and 360 of phosphates, and consequently the effects of the guano must be much more rapidly exhausted than those of the farm-yard manure. In fact guano is a rapidly acting manure, and its effects are principally observed on the crop to which it is applied. It is not of course to be denied that a certain effect will be experienced on the subsequent crops, but it must of necessity be small. The inference from these facts is, that, though guano may at an emergency be used as an entire substitute for farm-yard manure, the practice is one to be generally avoided. But the rapidity of action of guano makes it a most important auxiliary to farm-yard manure, and it is as an auxiliary that the greatest benefit has been derived from it. Experience has shown that one-half the farm-yard manure may be replaced by guano with the production of a larger crop than by the former alone in its full quantity. The proportion of guano usually employed is from three to five cwt., and it is said that a much larger quantity produces prejudicial effects on the subsequent crop, although it is not very easy to see on what it depends.

Guano has also been most advantageously employed as a top-dressing to grass land and to young corn.

In selecting the variety to be employed, several circumstances must be attended to. It will be found as a general rule that on strong soils, under good cultivation, the best effects are obtained from the ammoniacal guanos, but on light soils these guanos are less applicable, as the soluble ammoniacal compounds they contain are rapidly washed out, and much of their effects lost. On such soils the phosphatic guanos come up to, or even surpass, the others. No definite rules can be given for determining the soils on which these different varieties are most applicable, but each individual must determine by experiment that which best suits his own farm; and the inquiry is of much importance to him, as, of course, if the phosphatic guanos will answer as well as the ammoniacal, there is a large saving in the cost of the manure. A very excellent practice is to employ a mixture of equal parts of the two sorts of guano.

*Pigeons' Dung.*—The dung of all birds, which more or less closely resembles guano, may be employed with much advantage as a manure, but that of the pigeon and the common fowl are the only ones which can be got in quantity. Pigeons' dung, according to Boussingault, contains 8·3 per cent. of nitrogen, equivalent to 10·0 of ammonia. Its value, therefore, will be more than half that of guano, but it varies greatly, and a sample imported from Egypt into this country, and analysed by Professor Johnston, contained only 5·4 per cent. of ammonia. Hens' dung has not been accurately analysed, but its value must be about the same as pigeons'.

*Bones.*—Bones appear to have been employed agriculturally to a considerable extent in the last century as a dressing to old exhausted pasture lands in Cheshire; but it is only during the present century that they have been employed on arable land. The bones employed as a manure are always moist, and vary to some extent in quality. The following is an analysis of a very excellent sample, consisting, we believe, mostly of the bones of the horse:—

| | |
|---|---|
| Water | 6·20 |
| Organic matter | 39·13 |
| Phosphate of lime | 48·95 |
| Lime | 2·57 |
| Magnesia | 0·30 |
| Sulphuric acid | 3·15 |
| Silica | 0·30 |
| | 100·60 |
| Ammonia which the organic matter is capable of yielding, | 4·80 |

In general, bones may be said to contain about half their weight of phosphate of lime, and 10 or 12 per cent. of water. But besides these, bones are met with in other forms in commerce, in which their organic matter has been extracted either by boiling or burning. The latter is especially common in the form of the spent animal charcoal of the sugar refiners, which usually contains from 70 to 80 per cent. of phosphate of lime, but of course does not yield ammonia, the organic matters having been entirely destroyed by heat.

From the analysis given above, it is obvious that the manurial value of bones is dependent partly on their phosphates and partly on the ammonia they yield. It has been common to attribute their entire effects to the former, but this is manifestly erroneous. It is true that in some instances this may be the case, but there is no doubt that the ammonia must generally be of importance, and ought to be taken into account in estimating their value. When bones are applied for the sake of their phosphates alone, burnt bones or the spent animal charcoal of the sugar-refiners are to be preferred.

At the first introduction of bones they were applied in large fragments, and in quantities of from 20 to 30 cwt. per acre. As their use became more general they were gradually employed in smaller pieces, until at last they were reduced to dust, and it was found that, in a fine state of division, a few hundredweights produced as great an effect as the larger quantity of the unground bones. Even the most complete grinding which can be attained, however, leaves the bones in a much less minute state of division than guano, and they necessarily act more slowly than it does, the more especially as they contain no ready-formed ammonia. They may be still further reduced by fermentation, which acts by decomposing the organic matter, and causing the production of ammonia. Or by solution in sulphuric acid, which converts the insoluble phosphate of lime into a soluble state.

*Dissolved Bones.*—The method of dissolving bones in sulphuric acid has proved a very important boon to agriculture. It depends upon the fact that there exists a phosphate of lime containing half as much lime as that which is found naturally in the bones, and which is artificially produced by the sulphuric acid, which withdraws one-half of the lime, forming with it sulphate of lime, while the whole of the phosphoric acid of the bones remains in combination with the other half, and in a soluble form. By employing a sufficiently large quantity of sulphuric acid, the whole quantity of phosphoric acid in the bones may be thus brought into a soluble state, but in actual practice it is found preferable to leave part of it in both states; as where it is entirely soluble, its effect is too great during the early part of the season, and deficient at its end. In order to dissolve bones, we employ from one-half to one-fourth of their weight of strong sulphuric acid; but one-third will be found to be the quantity most generally applicable. The bones are put into a vessel of wood, stone, or lead (iron is to be avoided, as it is rapidly corroded by the acid), and mixed with one-third their weight of water, which may with some advantage be used hot. One-third their weight of sulphuric acid is then added, and mixed as uniformly as possible with the bones. Considerable effervescence takes place, and the mass becomes extremely hot. At the end of two or three days it is turned over with the spade, and after standing for some days longer, generally becomes pretty dry. Should it still be too moist to be sown, it must be again turned over, and mixed with some dry substance to absorb the moisture. For this purpose all substances containing lime or its carbonate must be carefully avoided, as they bring back the phosphates into the insoluble state, and undo what the sulphuric acid has done. Dry loam, peat, decaying leaves, or similar substances may be used. An excellent plan is to sift the bones before dissolving, and, applying the acid only to the coarser part, to mix in the finer dust which has passed through the sieve, to dry up the mass. Considerable trouble attends the manufacture of superphosphate on the small scale, and large manufactories have sprung up in which it is manufactured for sale, and is sold at about L.7 per ton. This probably exceeds the cost at which superphosphate can be prepared at the farm, but the saving of trouble induces many persons to purchase it. Since the introduction of coprolites, that substance has come into general use among manufacturers as a substitute for bones, owing to its cheapness and the large quantity of phosphates it contains. But as it is devoid of nitrogenous matters, and is consequently incapable of yielding ammonia, a certain quantity of bones is always employed along with it, or sulphate of ammonia, or some other ammoniacal salt is added to the mixture. The following are analyses of different samples of commercial superphosphate of fair quality. The first and second are made entirely from bones, the third apparently from coprolites alone. We have added also a single analysis of an inferior sort.

| | | | | Inferior. |
|---|---|---|---|---|
| Water | 10·50 | 23·97 | 10·43 | 7·37 |
| Organic matter | 26·47 | 16·18 | 3·61 | 13·99 |
| Phosphates | 34·29 | 27·18 | 37·59 | 20·96 |
| Sulphate of lime | 12·14 | 11·39 | 25·63 | 45·43 |
| Sulphuric acid | 14·40 | 12·93 | 4·69 | traces. |
| Alkaline salts | 0·72 | 2·54 | 7·71 | 2·67 |
| Sand | 1·48 | 5·81 | 10·34 | 9·58 |
| | 100·00 | 100·00 | 100·00 | |
| Ammonia | 3·17 | 1·32 | 0·54 | 0·44 |
| Soluble phosphates | 22·97 | 19·58 | 13·72 | |

These analyses give the total quantity of phosphates in the body of the analysis, and below the proportion of these phosphates which is rendered soluble by acids, as well as the quantity of ammonia contained in the organic matter. The two first of them are rather above the average quality, and it may be stated generally that the farmer must expect to find in a good superphosphate, about 30 per cent. of phosphates, of which from 12 to 15 ought to be in the soluble state; and about 1·5 per cent. of ammonia if the superphosphate is made from bones, a smaller quantity if from coprolites. Many superphosphates, however, are sold of greatly inferior quality, and containing little or no soluble phosphates; and these are generally made from coprolites and with a deficient quantity of sulphuric acid. Of this the last analysis is an example, but it is no uncommon thing to see samples which prove to contain *no* soluble phosphates, but even some per cent. of carbonate of lime, which is incompatible with their existence. The farmer should lay it down as a rule, never to purchase a superphosphate in the analysis of which carbonate of lime or of magnesia occurs.

The manurial value of bones depends principally, but not entirely, on their phosphates, and it is for these almost exclusively that they are employed. They were first made use of in Cheshire as an application to old pasture lands, on which their effects were truly marvellous. That here, at least, the phosphates alone were the cause of their beneficial effects is very clear. These lands had been from time immemorial pastured by milch cows; and in the milk and cheese removed, a large quantity of phosphoric acid is carried off, and so the pasture at length became deteriorated. The bones supplied this element, and hence their good effects. The principal use of bones at the present time is in the culture of the turnip, and it is on that crop that dissolved bones have proved so beneficial. They exert a remarkable influence in forcing on the plant through the early period of its growth, and so bringing it out of the stage during which it is most liable to suffer from the attacks of insects and other risks; and are best applied in conjunction with farm-yard manure or with guano; although the turnip can be raised with them alone. Dissolved bones are a rapid manure, and the greater part of their influence is exerted on the first crop. But undissolved bones are very permanent, and their effects have been observed many years subsequent to a liberal application.

Many other substances have been used as manures, but those to which we have referred are of much greater importance than any others. It is at once obvious from the remarks already made, that manures vary greatly in quality, and it is most desirable that some means should be contrived for estimating their comparative values. Considerable difficulties stand in the way of doing this effectually. Boussingault, who has paid much attention to this subject, is of opinion that the value of a manure may be determined solely from the quantity of nitrogen it contains, irrespective of its other constituents, and in his *Rural Economy* he has given a table constructed on this principle, of which the following is an abridgment.

| | Nitrogen in moist state, per cent. | Equivalent. |
|---|---|---|
| Farm-yard manure | 0·41 | 100 |
| Dung from inn-yard | 0·79 | 51 |
| Wheat straw | 0·24 | 167 |
| Rye straw | 0·17 | 235 |
| Oat straw | 0·28 | 143 |
| Pea straw | 1·79 | 22 |
| Potato tops | 0·37 | 108 |
| Withered beet-root leaves | 0·5 | 80 |
| Carrot leaves | 0·85 | 47 |
| Oak leaves | 1·18 | 34 |
| Fucus digitatus | 0·86 | 46 |
| Salt cod fish | 6·70 | 6 |
| White lupin seed | 3·49 | 11·5 |
| Malt grains | 4·51 | 9 |
| Hemp seed cake | 4·21 | 9·5 |
| Poppy cake | 5·36 | 7·5 |
| Cider apple refuse | 0·59 | 68 |
| Cow dung | 0·42 | 125 |
| Horse dung | 0·55 | 73 |
| Cows' urine | 0·44 | 91 |
| Horses' urine | 2·66 | 15·5 |
| Poudrette of Belloni | 3·85 | 10·3 |
| ... Montfaucon | 1·56 | 25·5 |
| Pigeons' dung | 8·30 | 5 |
| Guano (Peruvian) | 13·95 | 3·0 |
| Silkworm litter | 3·29 | 12 |
| Dried muscular flesh | 13·04 | 3 |
| Dried blood | 12·18 | 3·2 |
| Liquid blood | 2·95 | 13·3 |
| Bones (fresh) | 5·31 | 7·5 |
| Sugar-refiners' black | 13·75 | 2·9 |
| Animal black | 1·06 | 3·8 |
| Sugar scum | 0·54 | 7·5 |
| Feathers | 15·24 | 2·5 |
| Woollen rags | 17·98 | 2·0 |
| Horn shavings | 14·36 | 3·0 |
| Coal soot | 1·35 | 30·0 |
| Wood soot | 1·15 | 35 |

In this table the first column gives the quantity of nitrogen in 100 parts of the moist manure. The second gives the equivalent, that is, the quantity of any manure which may be substituted for another, farm-yard manure being taken at 100. Thus, to give an example of its use, suppose the farmer wished to employ a certain quantity of dried blood in place of farm-yard manure, he finds in the table that for every 100 lb. of the latter, he requires only 3·2 lb. of the former. It is evident, however, that this principle cannot be accurately carried out with all manures. In the comparison of farm-yard manure with straw and other analogous substances it probably approximates very closely to the truth; but with bones, guano, and other substances, much of the value of which is certainly dependent on their phosphates, it must manifestly give incorrect results, and with the phosphatic guanos especially we should obtain values much less than practical experience has shown them to possess. Moreover, no account is taken of the state in which the nitrogen exists, although we have already seen that this is far from unimportant. Still some value attaches to such a table, and except with those manures which contain phosphates or other substances in larger quantity, it may often prove useful.

### *Mineral Manures.*

All the substances to which we have hitherto alluded are capable of adding to the soil all, or the greater part of, the essential constituents of the plant. Even bones supply not merely ammonia and phosphates, but contain quantities of alkaline salts and other matters, which, though small, are not to be neglected. But many substances are also employed which contain only a single constituent, and their use is found to be followed by very remarkable results. We shall mention these substances in succession, commencing with those which yield nitrogen.

*Sulphate and Muriate of Ammonia.*—These and other salts of ammonia have been tried experimentally as manures, and it has been ascertained that they may all be used with equal success; and as the sulphate is by much cheaper, it is that which probably will always be employed to the exclusion of every other. It contains, when pure, 25·7 per cent. ammonia. That which is now manufactured for agricultural purposes is of very excellent quality, and when genuine, contains almost exactly the proper quantity of ammonia. Its purity may always be roughly estimated, by putting a small quantity on a shovel and heating it over a fire, when it ought to volatilise completely, or leave only a trifling residue. Some care, however, is necessary in applying this test, as in the hands of inexperienced persons it is sometimes fallacious. The salts of ammonia may be applied in the same way as guano; but they are most advantageously employed as a top-dressing, and principally to grass lands. In this way very remarkable effects are produced, and within a week after the application, the difference between the dressed and undressed portions of a field is already conspicuous. Experience has shown that success is best insured when the salt is applied during or immediately before rain, so that it may be at once incorporated with the soil; as when used in dry weather little or no benefit is derived from it. It seems also to exert a peculiarly beneficial effect upon clover; and hence it ought to be employed only on clover-hay, as where ryegrass or other grasses form the whole of the crop we have better manures.

*Ammoniacal Liquor of the Gas Works, and of the Ivory-Black Manufacturers.*—Both of these are excellent forms in which to apply ammonia, when they can be obtained. The ammoniacal liquor of the gas-works is very variable in quality, but contains generally from 4 to 8 ounces of dry ammonia per gallon, which corresponds in round numbers to from 1 to 2 lb. of sulphate of ammonia. It is best applied with the watering-cart, but must be diluted before use with three or four times its bulk of water, as if concentrated it burns up the grass. It is also well to use it during wet weather. The ammoniacal liquor of the ivory-black works contains above 12 per cent. of ammonia, or about four or five times as much as gas liquor. It has been used in some parts of England, made into a compost, and applied to the turnip and other crops, and, it is said, with good effect. *Bone oil,* which distils over along with it, has also been used in the form of a compost; it contains a large quantity of ammonia and of nitrogen in other forms of combination; the total quantity of nitrogen it contains being 9·04 per cent., which is equivalent to 10·98 of ammonia. Only part of this nitrogen is actually in the state of ammonia; and some circumstances connected with the chemical relations of the other nitrogenous compounds in this substance render it probable that they may pass very slowly into ammonia, and may therefore be of inferior value; but the substance is worth a trial, as it is very cheap. It must be carefully composted with peat, and turned over several times before being used.

*Nitrates of Potash and Soda.*—Nitrate of potash has been frequently employed as a manure, but its place is now entirely taken by nitrate of soda, which, from its superior cheapness, will always be preferred. Like the ammoniacal salts, it is a source of nitrogen, of which it yields about 16 per cent., and is therefore richer in that element than Peruvian guano. It is employed as a top-dressing to grass lands and to young corn, and with the most striking effects, even when the quantity employed has been extremely small. In a recent experiment, Mr Pusey found 42 lb. per acre to increase the produce of barley by 7 bushels per acre, and very favourable results have been obtained by other experimenters. The beneficial effects of nitrate of soda appear to be almost entirely confined to the grasses and cereals. At least experience here has shown that it produces little or no effect on clover; and one farmer has stated, that having recently adopted the practice of sowing clover with a very small proportion of ryegrass only, he has been led to abandon the use of nitrate of soda, which he formerly employed abundantly, when ryegrass formed a principal part of his crop. The action of nitrate of soda is very remarkable, not only in this respect, but also because a given quantity of nitrogen in it *appears* to produce a greater effect than the same quantity in sulphate of ammonia or guano. At the same time, this statement must be taken as very general, for our experiments are still too few to permit us to state it as a definite fact. Nitrate of soda is best conjoined with common salt, which checks its tendency to make the grain crops run to straw, and prevents their lodging, which, when it is employed alone, they are very apt to do. With hay this precaution is less necessary, and it is better to conjoin the nitrate with an equal quantity of sulphate of ammonia, the combination of the two giving better results than either separately.

*Salts of Potash and Soda.*—The substances just mentioned may be considered to owe all their value to their nitric acid, but other salts of the alkalies have been employed as manures, although, with the exception of common salt, to a limited extent. Sulphate of soda has been tried on clover and grass, but mixed with nitrate of soda, and with good effect, although we cannot tell how much may have been due to the nitrate.

*Chloride of Sodium, or Common Salt,* has at different times been employed as a manure, but its effects are so variable and uncertain, that its use, in place of increasing, has of late years rather diminished, it having frequently been found that on soils in all respects similar, or even on the same soil, in different years, it will sometimes prove advantageous, at others positively injurious. It appears, however, to be a valuable addition to other manures, especially to guano and nitrate of soda, as it prevents the tendency which crops manured with these substances have to lodge. The mode in which this effect is produced is obscure; and, so far as we know, no explanation has yet been given of it. It is supposed to cause the plant to absorb more silica from the soil; but this is a speculative explanation of its action, and has not been supported by definite experiment. Although little effect has been observed from salt, it deserves a more accurate investigation, as notwithstanding the extent to which it has been employed, we are singularly deficient in definite experiments with it.

*Silicates of Potash and Soda* have been employed with the view of supplying silica to the plant, but the results have been far from satisfactory. Good effects have been observed from the application of silicate of soda to the potato; but our experience of it is much too limited to enable us to form any estimate of its general value.

*Carbonates of Potash and Soda* have only been tried experimentally, and that to a small extent. The remarks we have made in the section of the ashes of plants regarding the subordinate value of soda, will enable the reader to see that greater effects are to be anticipated from the former than from the latter of these salts. They *may*, however, exert a chemical action in the soil, altogether independent of their absorption by the plant, but its nature and amount are still to determine.

*Sulphate of Magnesia* can be obtained at a low cost, and has been used as a manure in some instances with very marked success. It has been chiefly applied as a top-dressing to clover hay, but it seems probable that it might prove of use to the cereals, the ash of which is peculiarly rich in magnesia.

Many other saline substances have been tried as manures; but in most instances to too limited an extent to permit any definite conclusions as to their value. The experiments have also been too frequently performed without those precautions necessary to exclude fallacy, so that the results already arrived at must not be accepted as establishing facts, but rather as indications of the direction in which further experiments would be valuable. There is little doubt that many of these substances might be usefully employed, if the conditions necessary for their successful application were eliminated; and no subject is at present more deserving of elucidation by careful and well-devised field experiments.

Various mixtures of saline manures have been employed, and frequently with good effects. The most marked, however, have been from those of vegetable origin. Thus, wood ashes and peat ashes have been employed with more or less success, and their utility is clearly attributable to their affording a supply of all the inorganic constituents of the plant. Wood ashes, when they can be obtained, are a most valuable manure; coal and peat ashes appear to be inferior as a general rule; but in Belgium and Holland the use of peat ashes is common, and the effects are said to be excellent. They have at different times been imported into this country, but do not appear to have established a reputation as a manure.

It has been held by some chemists, and particularly by Liebig, that, provided we apply to the soil the mineral constituents of the plant, without adding either nitrogen or organic matters, we fulfil all the conditions necessary to the growth of the plant. This opinion has certainly not been confirmed by experiment in this country; the presence of ammonia, or at all events of nitrogen, in some form or other, having always been found necessary, and the application of the mineral matters, even when their proportions have been regulated by reference to the composition of the ash of the plant to which they have been applied, has proved a failure. Notwithstanding this, Liebig still holds to this view, which he has found supported by experiments of his own. It is extremely difficult to reconcile these discordant statements and facts; but we suspect strongly that something must depend on climate and soil; we know at least as regards one manure, superphosphate, that climate has its effect. In England dissolved coprolites have been successfully employed as a manure for the turnip, but in Scotland they have proved by no means so successful. An addition of ammonia is necessary in the moister and colder climate of Scotland; and this is so well known to some manufacturers that they avoid sending to our market any superphosphates made from coprolite alone, but take care to add a sufficient quantity of nitrogenous matters to satisfy the wants of the climate. It is not impossible that the different requirements of the climates may be the real cause of these differences of opinion and that Liebig may be right for the climate of Giessen, as our experimenters are for this country. Boussingault, who first insisted on the importance of ammonia or nitrogen in manures, has had his opinion fully confirmed by the valuable researches of Lawes, to which we must refer our readers for a very full discussion of the whole subject.

*Lime.*—Lime is by far the most important of the mineral manures, and is an almost indispensable agent in all agricultural improvement. It has been employed in the form of chalk, limestone, marl, shell-sand, and as quick and slaked lime. To the composition of limestones we have already referred when treating of the origin of soils, and have pointed out that they are divisible into two classes—one consisting of nearly pure carbonate of lime, the other of a mixture of carbonate of lime and magnesia. It will be unnecessary, therefore, to refer further to this subject. Chalk is a nearly pure carbonate of lime; marl is a pulverulent deposit of carbonate of lime, sometimes nearly pure, at others mixed with a variable proportion of clay and sand; and shell-sand is the debris of shells which has been cast up on the seashore, and which contain a greater or less admixture of sand.

Pure carbonate of lime contains exactly 56 per cent. of *lime*, and a good limestone ought to contain from 90 to 95 per cent. of the carbonate, equivalent to 50·40 per cent. of lime. It may therefore be said generally, that a good limestone should contain about half its weight of lime. When limestone is exposed to heat, its carbonic acid is driven off, and the lime is left in the quick state; and the quick lime, by exposure to the air, absorbs moisture from it and *slakes*; and if it be exposed for a longer time, it also absorbs carbonic acid, and passes back, more or less completely according to the length of time it is exposed, into the state of carbonate. While lime may be applied in the state of carbonate, either as chalk, marl, or pounded limestone, and with a certain amount of advantage, much greater effects are obtained from the use of the lime itself in the quick or slaked state. These advantages are dependent partly on the mechanical effect of the burning and slaking, which enable us to reduce the lime to a much more minute state of division, and consequently to incorporate it more uniformly and thoroughly with the soil, and partly on the more powerful chemical action of the quick or caustic lime, by which a greater effect is produced upon the soil. Other minor advantages are also secured, such as the production of a certain quantity of sulphate of lime, &c., which, though comparatively trifling, may, under particular circumstances and in some soils, be of considerable importance.

The action of lime is of a complicated character. Like all the inorganic constituents of plants, it may of course serve as food for those growing in the soil to which it is added. But this is manifestly a very subordinate part of its action,—1*st*, Because no soil exists which does not contain lime in sufficient quantity to supply that element to the plants. 2*d*, Because its effects are not restricted to those soils in which it exists naturally in small quantity; and, 3*d*, Because it is found that a small application, such as would suffice for the wants of the crops, is not sufficient to produce its best effects. In fact, by far the most important action of lime is that which it exerts on the chemical and mechanical properties of the soil; and it is this which necessitates its application in very large quantities.

The proportion of lime applied varies very greatly in different places. As much as ten tons per acre have frequently been applied, and in some instances much more. Of late years, however, we believe that these very large applications have become less common, because it is found that better effects are produced by a smaller quantity more frequently repeated. Its quantity depends greatly on the nature of the soil; on heavy clays, especially if undrained, very large applications are required; on light soils much smaller; even the depth of a soil must be considered, and a smaller quantity will suffice when it is shallow. The geological origin of the soil is also not without its influence; for we find that its beneficial effect is peculiarly seen on granite, porphyry, and gneiss soils, both because these are naturally deficient in lime, and because they undergo very slowly those decompositions which liberate their active constituents.

The greater part of the action of lime is indeed dependent on its exerting a chemical decomposition on the soil; and it acts equally on both the great divisions of its constituents, the inorganic and the organic. On the former, it acts by decomposing the silicates, which form the main part of the soil, and by liberating the alkalies they contain, it causes a larger supply of these substances to become available to the plant. On the organic constituents its effects are principally expended in promoting the decomposition which converts their nitrogen into ammonia; and thus a supply of food, which might remain for a long period locked up, is set free in a state in which the plant can at once absorb it. But these chemical decompositions are attended by a corresponding change in the mechanical characters of the soil. Heavy clays are observed to become lighter and more open in their texture; and those which are too rich in organic matter have it rapidly reduced in quantity, and the excessive lightness which it occasions diminished.

The effects of an application of lime are not generally observed immediately, but become apparent in the course of one or two years, when it has had time to exert its chemical influence on the soil; but from that time its effects are seen gradually to diminish and finally to cease entirely. The period within which this occurs necessarily varies with the amount of the application and the nature of the soil, but it may be said generally that lime will last from ten to fifteen years. The cessation of its effects is due to several circumstances, partly of course to the absorption of lime by the plants, partly to its being washed out of the soil by the rains, and partly to its tendency to sink to a lower level in the soil, a tendency which most practical men have had opportunities of observing. In the latter case, deep-ploughing often produces a marked effect, and sometimes makes it possible to postpone for a year or two the reapplication of lime. All these circumstances have their influence in bringing to an end its action, but the most important is, that after a time it has exhausted its decomposing effect on the soil, having destroyed all the organic matter, or liberated all the insoluble mineral substances which the quantity added is competent to do, and so the soil passes back to its old state. It does even more, for unless active measures are taken to sustain the fertility of the soil by other means, it is found that its fertility is apt to become less than it was before the use of lime. And that it should be so is manifest, if we consider that the lime added has liberated a quantity of inorganic matter, which, in the natural state of the soil, would have become slowly available to the plant, and that it must have acted chiefly in those very portions which, from having already undergone a partial decomposition, were ready to pass into a state fitted for absorption, and thus as it were, must have anticipated the supplies of future years. This effect has been frequently observed by farmers, and is indeed so common, that it has passed into a proverbial saying, that "lime enriches the fathers and impoverishes the sons." But this is true only when the soil is stinted of other manures, for when it is liberally treated the exhausting effect of lime is not observed, and it must be laid down as a practical rule that the use of lime necessitates a liberal treatment of the soil in all other respects. But when lime has been once employed, it becomes almost necessary to resort to it again; and generally so soon as its effects are exhausted a new quantity is applied, not so large as that which is used when the soil is first limed, but still considerable. When this is done very frequently, however, bad effects ensue; the soil gets into a particular state in which it is so open that the grain crops become uncertain, and such land is said, in practical language, to be overlimed. The explanation commonly assumed by those unacquainted with chemistry is, that the land has become too full of lime; but a moment's consideration of the very small fraction of the soil, which even the largest application of lime forms, will serve to show that this cannot be the cause. And analyses of overlimed soils have proved that the lime does not exceed the ordinary quantity found in fertile soils. The explanation of the phenomenon probably is, that the rapid decomposition of organic matter by the lime, and its escape as carbonic acid has so opened the pores of the soil as to give it the peculiar appearance so well known in practice. The cure for overliming is found to be the employment of such means as consolidate the soil, such as eating off with sheep, rolling, or laying down to permanent pasture.

The immediate effect of lime on the vegetation of the land to which it is applied is very striking. It immediately destroys all sorts of moss, makes a tender herbage spring up, and eradicates a number of weeds. It improves the quantity and quality of most crops, and causes them to arrive more rapidly at maturity. The extent to which it produces these effects is due to the form in which it is applied. In general they are produced more distinctly and more rapidly when it is applied in the quick state, more slowly if it be in the mild state, that is to say, quick lime which has been exposed for a long time to the air, and still more slowly as marl or chalk. The particular circumstances under which these different forms of lime are best employed is a very extensive subject, and would lead us beyond our limits; and for further information we must refer the reader to Professor Johnston's treatise on the use of lime in agriculture.

*Sulphate of Lime, or Gypsum.*—Gypsum has been applied in large quantity as a manure, and is found to exert a very remarkable influence upon clover, and leguminous crops generally. It is used in quantities varying from 2 cwt. per acre up to a very large quantity, and almost invariably with good results, in some instances even with the production of double crops. Much speculation has taken place as to the cause of this action which is so specific in its character, and from Sir Humphry Davy down to the present time, many chemists and agriculturists have considered the matter. Sir Humphry Davy attributed its action to its supplying sulphur to those plants which, according to him, contain a larger quantity of that element than other plants. That opinion has been since entertained by others, but it can scarcely be considered as well founded, for the more accurate experiments recently made do not point to any conspicuous differences between the quantities of sulphur contained in these and other plants. It is, moreover, to gypsum alone that these effects are due, and if it were merely as a source of sulphur that it was employed, there are other salts which could be equally, perhaps more advantageously, used; such, for instance, as sulphate of soda. It is more probable that the action of sulphate of lime may depend on its value as an absorbent of ammonia, and to its taking the atmospheric ammonia, and supplying it to the plants. Great difficulties unquestionably surround this explanation, and though supported by some persons, much may be said against it; as, for instance, why should its effect be so very marked on particular plants. In fact, while we have experiments which prove in the most unquestionable manner the utility of gypsum, we require others made with the express object of elucidating the cause of its action.

*Phosphate of Lime.*—In treating of bones we have alluded sufficiently to the value of phosphate of lime, but when conjoined with animal matters, ammonia, and other valuable substances. We have now simply to refer to the existence of certain varieties of mineral phosphates, some of which have been used, and others proposed, as manures. The apatite of Estremadura was some years since proposed as a manure, and a commission was sent by our Government to inquire into the extent of the supplies, and the possibility of its being imported, but it was found to be limited in extent and too inaccessible to be of much importance, and we believe no attempt has been made to import it. The same mineral is met with in New Jersey and other districts of America, and has been sent to this country, but its price was too high to admit of its being employed. Phosphate of lime also occurs in England, principally in Suffolk, in the form of what are called coprolites, although it is doubtful whether they really deserve that name, which was originally given by geologists to very different substances. The coprolites are now collected in very large quantities, and some thousand tons must be annually employed. They are extremely hard, and require very powerful machinery to reduce them to powder, and hence their price is considerable, we believe about L.3 per ton. From this hardness they are also less easily attacked by the plant, and are consequently best employed dissolved in sulphuric acid. Coprolites have the following composition:—

| | |
|---|---|
| Phosphate of lime | 57·33 |
| Carbonate of lime | 23·89 |
| Sulphate of lime | 2·03 |
| Sand | 12·70 |
| Organic matter | 2·23 |
| Water | 1·82 |
| | 100·00 |

They are therefore rich in phosphates, containing, in fact, more of these substances than guano; but as they are hard, and not easily dissolved by the plant, an inferior value must be attributed to them. Much coprolite of inferior quality, and containing a larger proportion of carbonate of lime, is sold; and the purchaser must ascertain by analysis that the article he buys is good.

### THE ROTATION OF CROPS.

It is a necessary consequence of the facts detailed in the previous sections, that a crop growing on any land must necessarily exhaust it more or less; that is, must remove from it a certain quantity of the elements which confer fertility upon it. That this is the case has been long admitted in practice, and it has also been established that the exhausting effects of different species of plants are very different; that while some rapidly impoverish the soil, others may be cultivated for a number of years without material injury, and others even *apparently* improve it. Thus, it is a notorious fact that white crops exhaust, while grass improves the soil; but the improvement in the latter case is really dependent on the fact, that when the land is laid down in pasture, nothing is removed from it, the cattle which feed on its produce returning again all that they had removed; so that, when we take into account the fact that the plants derive a part, and in some instances a very large part, of their nutriment from the air, the fertility of the soil must manifestly be improved, or at all events supported in its previous state.

When, however, the plant, or some of its parts, is removed from the soil, there must be a reduction in the amount of its fertility dependent on the quantity of its valuable constituents which each plant contains; and thus it occurs that when a plant has grown on any soil, and has removed from it a large quantity of nutritive matters, that it becomes incapable of producing an equally large crop of the same species; and if the attempt is made to grow it in successive years, the land becomes incapable of producing it at all, and is then said to be thoroughly exhausted. But if the exhausted land be allowed to lie for some time without a crop, it is found, more or less rapidly according to circumstances, to regain its fertility, and to produce again the same substance in remunerative crops. The observation of this fact led to the introduction of naked fallows, which, up to a comparatively recent period, were an essential feature in agriculture. But after a time it was observed that the land which had been exhausted by successive crops of one species was not absolutely barren, but was still capable of producing a luxuriant growth of other plants. Thus pease, beans, clover, or potatoes, might be cultivated with success on land which would no longer sustain a crop of grain, and these plants came into use in place of the naked fallow under the name of fallow crops. On this was founded the rotation of crops; for it was clear that a judicious interchange of the plants sown might enable the soil to regain its fertility for one crop at the time when it was producing another; and when exhausted for the second, it might be again ready to bear crops of the first.

The necessity for a rotation of crops has been explained in several ways. The oldest is that of Decandolle, who founded his theory on the fact that the plants excrete certain substances from their roots. He found that when a plant was grown in water, a substance was excreted from the roots; and he believed that this extrementitious substance was thrown out *because* it was injurious to the plant, and that, remaining in the soil, it acted as a poison to those of the same species, and so prevented the growth of another crop. But this excretion, though poisonous to the plants from which it was excreted, he believed to be nutritive to those of another species which thus grew luxuriantly where the others failed. Nothing can be more simple than this explanation, and it was readily embraced at the time it was propounded and considered fully satisfactory. But when more minutely examined, it becomes apparent that the facts on which it is founded are of a very uncertain character. Decandolle's observations regarding the radical excretions of plants have not been confirmed by subsequent observers. On the contrary, they have found that though some plants, when growing in water, do excrete a particular substance in small quantity, that nothing of the sort appears when they are grown in a silicious sand. And hence the inference is, that the peculiar excretion of plants growing in water is rather the result of disease than a natural product. But even admitting the existence of these matters, it would be impossible to accept the explanation founded upon them, because we know that, on individual soils, the repeated growth of particular crops is perfectly possible, as, for instance, on the virgin soils of America, from which many successive crops of wheat have been taken; and in these cases the alleged excretion must have taken place without producing any deleterious effect on the crop. Besides, it is in the last degree improbable that these excretions, consisting of soluble organic matters, should remain in the soil without undergoing decomposition, as all similar substances do; and even if they did, we cannot, with our present knowledge of the food of plants, admit the possibility of the direct absorption of any organic substance whatever. We believe, indeed, that the idea of radical excretions, as an explanation of the rotation of crops, must be considered as being entirely abandoned.

We now seek for its explanation in the different quantities of valuable matters which different plants remove from the soil, and more especially to their mineral constituents. To the great differences which exist in the composition of the ash of different plants we have referred in the section on that subject; and we have pointed out that a distinction has been made between lime, potash, and silica plants. This distinction has its origin in the explanation of the rotation of crops, to which we now refer. In fact, it is believed that if, to take a particular instance, a plant which requires a large quantity of potash be grown on a soil, it will, in a greater or less time, exhaust all, or nearly all, the potash which that soil contains in an *available* form, and will consequently cease to produce a luxuriant crop of it. But if we replace it by another plant which requires only a small quantity of potash and a large quantity of lime, it will flourish, because it finds what is necessary to its growth. In the meantime, the changes which are proceeding in the soil, are liberating new quantities of the inorganic matters from those forms of combination in which they are not immediately available, and when after a time the plant which requires potash is again sown on the soil, it finds a sufficient quantity to serve its purpose. We have already, in treating of the ashes of plants, pointed out the extent of the differences which exist; but these will be made more obvious by the annexed table, giving the quantity of the different mineral matters contained in the produce of an imperial acre of the different crops. We have omitted the oxide of iron and manganese as unimportant, and have added the quantity of nitrogen, which is of considerable interest, though of course not directly important as regards rotation.

*Table showing the number of Pounds of Mineral Matters and Nitrogen removed from an Acre of Land by average Crops of different Grains, &c.*

| | Silica. | Potash. | Soda. | Lime. | Magnesia. | Chloride of Potassium. | Chloride of Sodium. | Phosphoric Acid. | Sulphuric Acid. | Nitrogen. |
|---|---|---|---|---|---|---|---|---|---|---|
| Wheat, grain..... | 1·2 | 10·5 | 1·0 | 1·2 | 4·1 | ... | ... | 15·3 | 0·1 | 38·0 |

From an inspection of this table, we at once perceive the difference of effects which different crops must produce on the soil. Thus, a wheat crop (grain and straw) removes from the soil 98 lb. of silica; and as we know that that substance exists in small quantity in an available state in most soils, we understand how a succession of wheat or other grain crops (some containing even a larger quantity of silica than wheat) should fail to flourish, unless a sufficient quantity of that element be annually set free to supply the loss; while a crop of turnips removing only 4 lb. of silica may be produced, and at the same time permit the accumulation of a quantity of soluble silica ready for another crop of grain. The turnip again, which carries off no less than 112 lb. of potash, soon exhausts the soil of that element; and when a grain crop, removing only from 17 to 37 lb. according to circumstances, replaces it, we have the conditions necessary for the restoration of that which the turnip had removed. So with the other elements we find that the turnip removes 40 lb. of sulphuric acid, wheat only 4·7; and clover requires above 135 lb. of lime and magnesia, and wheat only 19 of the two. And thus the small quantity of individual substances removed by one plant, compensates for the large quantity withdrawn by another; and by a judicious interchange we have the soil always in a condition to supply a sufficient quantity of the elements necessary for any crop which grows on it.

Viewed in this light, we see that there are several important practical deductions to be drawn from these observations regarding the principles of rotation. We observe that the quantities of mineral matters withdrawn by the plants of the same class are generally similar, and thus we infer that we ought as much as possible to cause crops of the most opposite class to alternate with one another, and to repeat each plant as seldom as possible, so that even when we are obliged to return to the same class we should, if circumstances permit, employ a different member of it. Thus, for instance, in place of immediately repeating wheat, when we wish another grain crop, it would theoretically be preferable to employ oats or barley, and to replace the turnip by mangold-wurzel or some other root. It is obvious, however, that this system cannot be carried out in practice to its full extent; for the superior value of individual crops causes their repetition more frequently than that of those which make a less return. But experience has so far concurred with theory, that it has taught the farmer the advantage of long rotations; and we have had the successive introduction of the three, four, five, and six course shift, and even of longer periods in some instances.

In all this the farmer only imitates the practice of nature; for it has been long observed that when one generation of plants dies out, it is immediately replaced by another. In the forests of Sweden we have a remarkable illustration of this, for when a pine forest is felled and the land left to itself, there spring up not pines but birch trees; and every one is familiar with the fact that when a gap occurs in a thorn-hedge it is useless to attempt to fill it up by putting in a young thorn, but that some other plant must be used.

Such is the theory of rotation; but is it absolutely necessary that it should be rigidly adhered to? We think not. Because in the art of agriculture we place the plants in artificial circumstances, and instead of allowing them to depend entirely on the soil we supply them with a quantity of manure containing all the elements of the plant, and if it be used in sufficiently large quantity we may grow year after year the same crop. And accordingly the order of rotation which is theoretically the best may be, and every day is, violated in practice. This must necessarily be done at the expense of a certain quantity of the valuable matters of the manure added, and is so far a practice which ought theoretically to be avoided. But in actual practice the matter is to be decided on other grounds. The object then is, not to produce the largest crops, but those which make the largest money return, and thus it may be practically economical to grow a crop of high commercial value more frequently than is theoretically advantageous. The farmer must therefore seek to do away as far as possible with the disadvantages which such a course entails, and this he will endeavour to do by a liberal treatment of the soil, and by as careful a management of the other crops of this nature as possible.

But while the farmer may do this to some extent, he must bear in mind that the frequent repetition of some crops cannot be practised with impunity, for they are liable to certain diseases, which have been attributed more or less correctly to this cause. Such is the case with clover, which, when frequently repeated on light soils, fails entirely; and the potato and turnip disease have also, though with less foundation, been attributed to the same cause. Whether this is the sole origin of these diseases is questionable, but there is no doubt that they are aggravated by frequent repetition, and hence a strong argument in favour of rotation. We have been told by great authorities in high farming, that with the command of manures we now have, rotations may be done away with; but this is an opinion to which science gives no countenance, and he would be a rash man who attempted to carry it out in practice.

### THE FEEDING OF THE ANIMALS ON THE FARM.

The feeding of cattle, once a subordinate part of the operations of the farm, has now become one of its most important departments, and the principles of its most successful and economical practice have been elucidated by the recent investigations of chemists and physiologists, by which much light has been thrown on many matters which would otherwise have remained obscure.

It scarcely requires to be stated at the outset, that the food must contain all the different elements which enter into the composition of the animal body. When we examine what these are, we find them identical with those of plants; their organic part consisting of carbon, hydrogen, nitrogen, and oxygen, and their ash of the same ingredients as that of plants. The organic elements are not only the same, but they are united together in a similar manner, and we have them existing, on the one hand, as nitrogenous matters, in the form of fibrine, albumen, and caseine, which, as we have pointed out when treating of the proximate constituents of plants, are identical in chemical composition and properties with the substances extracted from plants, and described under the same names; and, on the other hand, as fatty matters, which correspond in all respects with those found in plants. It has hence been inferred, and is supported by many other facts which our limits will not permit us to detail, that the animals simply absorb the substances which have been formed by the plant, and deposit them in their tissues. It has been distinctly ascertained that the whole nutriment of animals is derived from their food, and that neither nitrogen nor any other element is derived from the air. Now, of the food consumed, a part only is absorbed; the remainder passes through the intestinal canal and is excreted in the form of fæces, while the absorbed portion goes to fulfil two different functions; one quantity being deposited in the tissues to supply that waste which we learn from physiological facts is constantly occurring; the other being employed in supporting the process of respiration, combining with the oxygen of the air inspired, and converting it partly into carbonic acid. If the supply of food be properly apportioned to the animal, the loss occasioned by the waste of the tissues and the process of respiration is exactly sufficient to counterbalance the gain of food, and the animal remains with its weight unchanged; but if it be larger than is required for this purpose, an increase of weight takes place, and a quantity of fat and flesh is laid up as a sort of reserve against future deficiencies of supply. In a state of nature an equilibrium subsists between the supply and the waste, which prevents the animal ever increasing greatly in weight; and it is the object of the feeder, by placing the animal in artificial circumstances, and increasing the supply of food, to raise this reserve to the greatest extent compatible with the health of the animal. In order to this, he must consult nature, and endeavour to imitate her processes as closely as possible, to give food consonant with her principles, and to fulfil all those conditions which are likely to diminish the waste of the tissues.

*The Food of Animals.*—In examining the conditions which must be attended to in the food of animals, we may with advantage take an example from that which nature has provided for the sustenance of their young. The milk may, in fact, be considered as a typical food, and necessarily the best fitted to fulfil the purposes for which it is intended. Now, we find it, exclusive of its inorganic constituents, to contain three different classes of nutritious matters. 1st, Nitrogenous or albuminous substances; 2d, Fatty matters; 3d, Sugar; the first adapted to the production of flesh, the second to the formation of the fat of the body, and the third going partly to supply the respiratory process, and partly to be converted into fat. Now, to sustain the animal in its usual state, a sufficient quantity of those substances must be given to supply the waste of the tissues, and the process of respiration, along with a quantity which is never absorbed, but passes through the alimentary canal. In round numbers this latter quantity amounts to not less than half the whole nutritive matters. The quantity of albuminous substances absorbed and used to supply the waste of the tissues varies very greatly according to circumstances shortly to be mentioned, but in an experiment of Boussingault's on a cow, amounted to about 18 ounces. The consumption of sugar, starch, and similar substances, to maintain respiration is much larger; for it has been ascertained that in the course of 24 hours an ox will convert into carbonic acid by respiration, from 4 to 5 lb. of carbon, to supply which from 10 to 12 lb. of sugar or starch are required. It is necessary, therefore, that the food to be supplied should contain these substances, and a sufficiency of them for the purpose; and what we have already said of the composition of vegetables shows that all do contain these substances, though their quantity is very variable. In comparing the value of different sorts of food, it is necessary to consider the quantity of nitrogenous and other matters which they contain. But we find by experience, that all these substances are not of equal importance, some being supplied in sufficient quantity for all purposes, others being found in many sorts of food in comparatively small quantity. It appears, indeed, that the nitrogenous constituents are by much the most important, and for many purposes the value of the food may be estimated almost entirely from them. But these substances are the flesh-forming element of the food only; the production of fat is dependent partly on the fatty matter, and partly on the starch and sugar of the plant. At one time it was believed that the presence of fatty matters in the food was essential to the production of fat in the animal; but careful experiments have entirely refuted this opinion, and have shown that the fat may be produced from sugar or starch alone, and hence some chemists and physiologists have even gone so far as to hold that the fat of the food does not go to form the fat of the animal. We apprehend, however, that this is an extreme view of the case, and it can scarcely be doubted that the fat must be of importance, though it may not be absolutely essential. Now, in comparing different sorts of food, we come to the conclusion, that those are most valuable which contain the largest quantity of albuminous substances, oil and saccharine matters; but there are few or no foods which do not contain these latter substances in sufficient quantity to supply the wants of any animals which feed upon them. We may therefore take the quantities of albuminous matters and oil as the measure of the nutritive value of any sort of food. That this is borne out by practice, we may see at once by selecting any two sorts of food: let us take the turnip and linseed-cake. Now the former of these is very poor in nutritive matters, and hence requires to be supplied in large quantity to the animal; the latter is rich both in albuminous and oily matters, and only a small quantity of it is required. The practical farmer, when he gives cattle linseed-cake,

Agricultural Chemistry.

generally considers that he may replace 100 lb. weight of turnips by 5 lb. of cake; and that with this apparently trifling quantity the cattle fatten better than they did with the large quantity of turnip. Now, when we inquire into the relative quantities of nitrogenous and oily matters contained in these two substances, we have at once an explanation of the observed fact. Analysis shows us, that the quantities of albuminous matters and of oil contained in 100 parts of those two substances are as follows:—

| | Oil-Cake. | Turnip. |
|---|---|---|
| Albuminous matter | 27·69 | 1·27 |
| Oil | 12·79 | 0·20 |

If we calculate from these results, we find that 100 lb. of turnips contain the same quantity of albuminous matter as 4·5 lb. of oil-cake, and no more oil than is supplied by 1·5 lb. of oil-cake, so that the 5 lb. of oil-cake contain a larger quantity of nutritive matter than the large quantity of turnip for which they are a substitute.

The consideration of these facts is of much importance in the economic feeding of animals, for it is manifest that very great differences must exist in the nutritive value of different sorts of food; and now that the farmer finds it desirable to use other substances than those produced on the farm, it is of importance that he should possess some means of estimating the relative value of different sorts of food. We give here, as an assistance in doing so, a table showing the per-centage of albuminous and oily matters contained in 100 parts of different crops.

| | Albuminous Matters. | Oil. |
|---|---|---|
| Poppy cake | 31·46 | 5·75 |
| Rape cake | 29·53 | 11·10 |
| Crambolina cake | 28·79 | 9·50 |
| Common Scotch tares | 28·57 | 1·30 |
| Hopetoun tares | 28·32 | 1·49 |
| Linseed cake | 27·69 | 12·79 |
| Field beans | 27·05 | 1·58 |
| Winter tares (foreign) | 26·73 | 1·58 |
| Spring tares (foreign) | 26·54 | 1·26 |
| Cotton seed cake | 25·16 | 9·08 |
| Beans (65 lb. per bushel) | 24·70 | 1·59 |
| Linseed | 24·44 | 34·00 |
| Lentils (foreign) | 24·57 | 1·51 |
| Lentils (Scotch growth) | 24·25 | 1·79 |
| Gray pease | 24·25 | 3·30 |
| Foreign beans | 23·49 | 1·51 |
| Kidney beans | 20·06 | 1·22 |
| Maple pease | 19·43 | 1·72 |
| Clover hay, second crop | 13·52 | ... |
| Sunflower seed | 12·70 | 29·98 |
| Oats | 10·16 | 6·12 |
| Buckwheat | 9·84 | 2·69 |
| Guinea corn | 9·27 | 3·46 |
| Wheat | 9·01 | 1·99 |
| Common Scotch bean straw | 8·25 | ... |
| Barley | 7·74 | 1·88 |
| Hay (new) | 6·16 | ... |
| Winter bean straw | 5·71 | ... |
| Hay (old) | 4·00 | ... |
| Crimson clover | 3·30 | ... |
| Yellow clover | 3·26 | ... |
| Lucerne | 3·11 | ... |
| Cow grass | 2·75 | ... |
| Red clover | 2·59 | ... |
| Chevalier barley straw | 1·90 | ... |
| Early Angus oat straw | 1·50 | ... |
| Red wheat straw | 1·50 | ... |
| White wheat straw | 1·37 | ... |
| Turnip | 1·27 | 0·20 |

The blank spaces in the second column occur where the oil is in too small quantity to admit of accurate determination.

A simple inspection of this table gives a great deal of information; but by the use of the rule of three it is easy to calculate the quantity of one substance which corresponds in albuminous or in oily matters to another. It is to be observed, however, that the substances containing the former in large quantity, do not necessarily, or even frequently contain a proportionate amount of the other, so that, practically, in making the comparison, we must rely upon one only, and we commonly select the quantity of albuminous matters as the most important. It will be understood, that while these two constituents are the most important as regards the estimation of the value of any food, they are not the only substances *essential* to its nutritive value. On the contrary, the non-nitrogenous, or, as they are sometimes called, the respiratory elements, because they supply the carbon consumed in the process of respiration, and each individual inorganic substance is essential; but as these substances are met with in abundance in all sorts of food, they are unimportant in the estimation of their relative value.

The values as deduced from these numbers must be considered as an approximation only; but they are very close approximations when the substances are of analogous characters; as, for instance, in the case of different sorts of grain. They are, however, liable to modification, by a number of different circumstances: thus, for example, rape-cake has, according to the table, a higher value than linseed-cake, but it possesses a peculiar bitter flavour, which makes it unpalatable to the cattle; and it also frequently produces scouring, so that it may not always give as good effects as might be anticipated from it. Something also is to be attributed to the general nature of the substance, and to the condition in which its constituents exist; and it would appear that the presence of a large quantity of woody fibre reduces the value of food, by enveloping its nitrogenous and other matters, and preventing their absorption during their passage through the intestines of the animal; and it is probably on this account that straw, though richer in nitrogenous matters, has a much lower nutritive value than the turnip.

The nutritive effects obtained from the food, are also increased by mixing together different sorts. Indeed this is found to be an exceedingly important point; for as we have seen that the milk which nature supplies as the appropriate food of the young animal, contains a mixture of all the different classes of nutritive elements, so it appears the best effects are produced by an imitation of this also. But few of the substances which we employ contain all the necessary elements of the food in proper proportion; we find one deficient in fatty matters, another in albuminous, and so on, and in order to produce a food of the most suitable kind, we require to mix together several substances; and when this is judiciously done so as to insure a proper relation between the individual nutritive elements, a higher effect is obtained than could have been got by the use of these substances separately. Thus the farmer who is feeding with bean-meal in considerable quantity, will generally find that a better effect is obtained by replacing a part of it with some of the more oleaginous seeds or cakes. There is, however, another circumstance independent of chemical composition which modifies the nutritive value of the different sorts of food. It is necessary in order to its proper digestion, that the food shall have a certain bulk, for without it the peristaltic motions of the intestines are not properly performed, digestion is incomplete, and a quantity of nutritive matter is wasted. For this reason the highly nutritive foods must always be conjoined with those which occupy a large bulk in the stomach. But, on the other hand, the bulk of the food must not be excessive, for then the stomach is overloaded, digestion and absorption of the food are checked, and the health of the animal becomes impaired.

*The circumstances which diminish the waste of the Food.*—We have already remarked that there are three great purposes to which the food swallowed is appropriated; the increase of weight in the animal—the object the feeder has in view and desires to promote—the supplying the waste of the tissues, and the process of respiration, both of which are sources of waste of food, and which it must necessarily be his aim to diminish as much as possible. The circumstances which must be attended to in order to do this are sufficiently well understood. It has been clearly established that the natural heat of the animal is sustained by the consumption of a certain quantity of its food in the respiratory process, during which it undergoes exactly the same change as those which occur during combustion. In fact, a certain quantity of the food is no more than so much fuel intended to sustain the heat of the body. We observe, however, that the temperature of the body is always the same, whatever be that of the surrounding air. Now it is obvious that if the temperature of the animal is to remain the same in winter as in summer, a larger quantity of fuel (*i.e.*, food) must be consumed for this purpose, just as a room requires more fire to keep it warm in winter than in summer, and hence it naturally follows that if we keep the animal in a warm locality we economise the fuel. In order to do this, then the housing of the cattle is a matter of importance, and here practice has arrived at conclusions strictly concordant with science. The old feeders kept their cattle in large open courts, where they were exposed to every vicissitude of the weather. But as intelligence advanced, we find them substituting, first, what are called hammels and then stalls, in which the animals are kept, during the whole time of fattening, at an equable temperature. The effect of this is necessarily to introduce a considerable economy of the food required to sustain the animal heat; but it also effects a saving in another way, for it diminishes the waste of the tissues. It has been ascertained in the most conclusive manner, that this waste is dependent on the amount of muscular exertion. Thus if we sit still for an hour a certain amount of waste in our tissues takes place, but if we run or engage in any violent muscular exertion, we increase this waste, and consequently require a larger quantity of food to supply it. The confining the animals in stalls has the effect of diminishing the amount of muscular action, and introduces an important economy in the food. Even the making the houses dark, and thus preventing the attention of the animal being disturbed by various objects, has its effect in promoting this economy.

An extension of the same principle has led to the use of the food artificially heated, but it is doubtful whether the advantages derived from it are commensurate to the increased expenses of the process; at least opinions differ among the best informed practical men on this subject.

The rapidity of fattening is dependent on many other circumstances. One of the most important is the breed, and universal experience has shown that the short-horn manifests in this respect a marked superiority. This and many similar facts are, however, less chemical than physiological, and could not be considered here without entering upon many matters not connected with our subject.

### CONCLUDING REMARKS.

We have thus endeavoured to give our readers as full an account of the present state of agricultural chemistry as our limits permit. In a science so new, and embracing so many minute facts, the task is not without difficulty. It has been our object, however, as far as possible to avoid details, and to give rather such principles as have been established, and to illustrate them by what appeared to be the most satisfactory and best observed facts. In many branches of the subject these are but few, and the conclusions founded on them must necessarily be uncertain, and in some instances may possibly be proved erroneous by further observations. That a department of science cultivated for so short a period, and requiring for its proper pursuit the co-operation of two classes of men, the farmer and the chemist, who have hitherto had so little in common, should be imperfect, is not to be wondered at. On the contrary, we are of opinion that the progress made within the last few years, considering all the disadvantages under which it has been placed, from the rash and unweighed theories with which it has been overloaded, the excessive and imprudent zeal of its supporters, the opposition of another class, and the equally fatal lukewarmness of a third, a great deal has been done. Facts of much practical value have been elicited, and an immense stimulus has been given to careful observation and inquiry into principles on the part of the farmer. That this is already beginning to bear its fruit is unquestionable, and it is impossible to look at the opinions and practice of modern farmers of the best class, without observing how much they are influenced by science. That much, however, still remains to be done, is only too obvious from many of the statements we have made, and even in what we consider familiar matters, the chemist is frequently stopped by the want of field experiments sufficiently definite to support or refute his positions. Indeed there are few departments of scientific agriculture that would not be benefited by experiments of a more minute and careful nature than those which, in a less advanced state of the art, and for purely practical purposes, were sufficient. We doubt much, however, whether this can be carried out in detail until a regular professional education in the principles as well as the practice of agriculture is provided for the young farmer, a want which is every day becoming more felt, and the fulfilment of which cannot long be postponed.

AGRIGENTUM, in *Ancient Geography*, a city of Sicily, part of the site of which is now occupied by a town called *Girgenti*, from the old name. See GIRGENTI. According to ancient authors, Dædalus, the most famous mechanician of fabulous antiquity, fled to this spot for protection against Minos, and built many wonderful edifices for Cocalus, king of the island. Long after his flight, the people of Gela sent a colony hither 582 years before the birth of Christ, and, from the name of a neighbouring stream, called the new city *Acragas*, whence the Romans formed the word *Agrigentum*. These Greeks converted the ancient abode of the Siculi into a citadel to guard the magnificent city which they erected on the hillocks below. An advantageous situation, a free government, with all its happy effects, and an active commercial spirit, exalted their commonwealth to a degree of riches and power unknown to the other Greek settlements, Syracuse alone excepted. But the prosperity of Agrigentum appears to have been but of short duration, and tyranny soon destroyed its liberties. Phalaris was the first who reduced it to slavery. His name is familiar to most readers on account of the cruelty with which he tortured his enemies. See PHALARIS. Phalaris met with the common fate of tyrants, and after his death the Agrigentines enjoyed their liberty for sixty years; at the expiration of which term Thero usurped the sovereign authority. The moderation, justice, and valour of this prince preserved him from opposition while living, and have rescued his memory from the obloquy of posterity. He joined his son-in-law Gelo, king of Syracuse, in a war against the Carthaginians; in the course of which victory attended all his steps, and Sicily saw herself for a time delivered from her African oppressors. Soon after his decease, his son Thrasydeus was deprived of the diadem, and Agrigentum restored to her old democratical government, which she retained till the Carthaginian invasion in 406 B.C., a period of more than sixty years. During this interval of prosperity were executed most of those splendid public works which excited the admiration of succeeding ages, and caused their citizen Empedocles to remark, "that the Agrigentines built their dwellings as though they should exist for ever, and indulged in luxury as if they were to die on the morrow." The total number of the inhabitants at this period was estimated by Diodorus at 200,000. But their prosperity was not entirely without interruption; for the Agrigentines having engaged in hostilities with the mountain chief Ducetius, the conduct of the Syracusans towards that chieftain occasioned a war between these two rival states, which terminated in the signal defeat of the Agrigentines at the river Himera. But a more terrible reverse awaited them: they were attacked by the Carthaginians in 406 B.C., and by this enemy their armies were routed, their city taken, their race almost extirpated, and scarce a vestige of magnificence was left. It appears, however, that some of the fugitive inhabitants availed themselves of permission to return to the ruined city, and after a few years were even able to shake off the yoke of Carthage, and attach themselves to the cause of Dionysius. But the city was so far from having recovered its previous importance, that Timoleon, after his triumph over the Carthaginians B.C. 340, found it necessary to re-colonize it with citizens from Velia in Italy. This measure was crowned with astonishing success; for Agrigentum rose from its ashes with such a renewal of vigour, that in a very short time we find it engaged in the bold scheme of seizing a lucky moment, when Agathocles and Carthage had reduced Syracuse to the lowest ebb, and arrogating to itself supremacy over all the Sicilian republics. Xenodocus was appointed the leader of this arduous enterprise; and had his latter operations been as fortunate as his first campaign, Agrigentum would have acquired such a preponderance of reputation and power, that the rival states would not have even dared to attack it. But a few brilliant exploits were succeeded by a severe overthrow; the Agrigentines lost courage, disagreed in council, and humbly sued for peace to Agathocles. This commonwealth afterwards took a strong part with Pyrrhus; and, when he left Sicily to the mercy of her enemies, threw herself into the arms of Carthage. During the first Punic war Agrigentum was the headquarters of the Carthaginians, and was besieged by the Roman consuls, who, after eight months' blockade, took it by storm. It nevertheless changed masters several times during the contests between these rival states, and in every instance suffered most cruel outrages. After this period very little mention of it occurs in history, nor do we know the precise time of the destruction of the old city and the building of the new one.

The hospitality and parade for which the Agrigentines are celebrated in history were supported by an extensive commerce: by means of which, the commonwealth was able to resist many shocks of adversity, and always to rise again with fresh splendour. It was, however, crushed by the general fall of Grecian liberty: the feeble remnants of its population, which had survived so many calamities, were at length driven out of its walls by the Saracens, and obliged to lock themselves up for safety among the bleak and inaccessible rocks of the present city.

Agrigentum occupied a hill of considerable extent, but small elevation, rising between the small rivers Acragas and Hypsas, and was remarkable for its strength as a fortress. The whole space comprehended within the walls of the ancient city abounds with traces of antiquity, foundations, brick arches, and little channels for the conveyance of water. Of its many celebrated edifices, the most magnificent was the temple of Olympian Jupiter, which, according to Diodorus, was 340 feet long, 160 broad, and 120 in height, without including the basement; each fluting of the columns being of capacity sufficient to admit the body of a man. Of this vast structure nothing remains but the basement and a few fragments of the columns and entablature; but these, and many other monuments less ruinous, attest the ancient wealth and magnificence of the Agrigentines.

AGRIONIA, in *Grecian Antiquity*, festivals annually celebrated by the Bœotians in honour of Bacchus. At these festivals the women pretended to search after Bacchus as a fugitive, and, after some time, gave over their inquiry, saying that he had fled to the Muses, and was concealed among them.

AGRIOPHAGI (αγριος, and φαγω), in *Antiquity*, a name given to those who fed on wild beasts. The name is given, by ancient writers, to certain people, real or fabulous, said to have fed altogether on lions or panthers. Pliny and Solinus speak of *Agriophagi* in Ethiopia, and Ptolemy of others in India on this side the Ganges.

AGRIOPUS, a genus of Acanthopterygious fishes in the system of Cuvier. The best known, *A. Torvus*, is found at the Cape of Good Hope.

AGRIPPA, CORNELIUS, born at Cologne in 1486, a man of considerable learning, and by common report a great magician; for the monks at that time suspected every thing of heresy or sorcery which they did not understand. He composed his treatise of the *Excellence of Women* to insinuate himself into the favour of Margaret of Austria, governess of the Low Countries. He accepted of the charge of historiographer to the emperor, which that princess gave him. The treatise of the *Vanity of the Sciences*, which he published in 1530, enraged his enemies extremely; as did that of *Occult Philosophy*, which he printed soon after at Antwerp. He was imprisoned in France for having written something against the mother of Francis I. On being liberated, he went to Grenoble, where he died in 1535.

AGRIPPA, *Herod*, the son of Aristobulus and Berenice, and grandson to Herod the Great, was born A.M. 3994, ten years before the vulgar era. After the death of Aristobulus his father, Josephus informs us that Herod, his grandfather, took care of his education, and sent him to Rome to make his court to Tiberius. The emperor conceived a great affection for Agrippa, and placed him near his son Drusus. He very soon won the favour of Drusus, and of the empress Antonia. On the death of Drusus, Agrippa, who had indulged his inclination to liberality, was obliged to leave Rome, overwhelmed with debt, and retired to the castle of Malatha, where he lived rather like a private person than a prince. Herod the tetrarch, his uncle, who had married Herodias, his sister, assisted him for some time with great generosity. He made him principal magistrate of Tiberias, and presented him with a large sum of money; but growing weary of assisting him, and reproaching him with his bad economy, Agrippa left Judea, and some time afterwards returned to Rome. Upon his arrival he was received into the good graces of Tiberius, and commanded to attend Tiberius Nero, the son of Drusus. Agrippa, however, having more inclination for Caius, the son of Germanicus, and grandson of Antonia, chose rather to attach himself to him; as if foreseeing the future elevation of Caius, who, at that time, was universally beloved. The great assiduity and agreeable behaviour of Agrippa so far won upon this prince, that he kept him continually about him.

Agrippa being one day overheard by Eutyches, a slave whom he had made free, to express his wishes for Tiberius's death and the advancement of Caius, the slave betrayed him to the emperor; whereupon Agrippa was loaded with fetters, and committed to the custody of an officer. Tiberius soon after died, and Caius Caligula ascended the throne. The new emperor heaped wealth and favours upon Agrippa, changed his iron fetters into a chain of gold, set a royal diadem upon his head, and gave him the tetrarchy of Batanæa and Trachonitis, which Philip the son of Herod the Great had formerly possessed. To this he added that of Lysanias; and Agrippa returned very soon into Judea to take possession of his new kingdom.

On the assassination of Caligula, Agrippa, who was then at Rome, contributed much by his advice to maintain Claudius in possession of the imperial dignity, to which he had been advanced by the army; and while he made a show of being in the interest of the senate, he secretly advised Claudius to maintain his good fortune with firmness. The emperor, as an acknowledgment for his kind offices, gave him all Judea; and the kingdom of Chalcis, at his request, was given to his brother Herod. Thus Agrippa became of a sudden one of the greatest princes of the East, and was possessed of as much, if not more territory than had been held by Herod the Great, his grandfather. He returned to Judea, and governed it to the great satisfaction of the Jews. But the desire of pleasing them, and a mistaken zeal for their religion, impelled him to acts of cruelty, the memory of which is preserved in Scripture, Acts xii. 1, 2, &c.; for about the feast of the passover, in the year of Jesus Christ 44, St James major, the son of Zebedee, and brother of St John the Evangelist, was seized by his order and put to death. He proceeded also to lay hands on St Peter, and imprisoned him, delaying his execution till the close of the festival. But God having miraculously delivered St Peter from the place of his confinement, the designs of Agrippa were frustrated. After the passover, he went from Jerusalem to Cæsarea, and there had games performed in honour of Claudius. Here the inhabitants of Tyre and Sidon waited on him to sue for peace. Agrippa being come early in the morning to the theatre to give them audience, seated himself on his throne, dressed in a robe of silver tissue, which reflected the rays of the rising sun with such lustre as to dazzle the eyes of the spectators. When the king had delivered his address, the parasites around him shouted out that it was not the voice of a man but of a god. The vain Agrippa received the impious flattery with complacent satisfaction; but in the midst of his elation, looking upwards he saw, with superstitious alarm, an owl perched over his head. During his confinement by Tiberius, he had been startled by a like omen, which had been interpreted as portending his speedy release, with the warning, that whenever he should behold the same sight again, his death was to follow within the space of five days. Seized with terror, he took to his bed, and after a few days of excruciating torment, died, according to the Scripture expression, "eaten up by worms." Such was the death of Herod Agrippa, after a reign of seven years, in the year of Christ 44.

Agrippa II., son of the preceding, was made king of Chalcis; but three or four years after, he was deprived of that kingdom by Claudius, who gave him instead of it other provinces. In the war which Vespasian carried on against the Jews, Herod sent him a succour of 2000 men; by which it appears, that though a Jew by religion, he was yet entirely devoted to the Romans, whose assistance indeed he wanted to secure the peace of his own kingdom. He lived to the third year of Trajan, and died at Rome A.D. 100. He was the seventh and last king of the family of Herod the Great. It was before him and Berenice his sister that St Paul pleaded his cause at Cæsarea.

Agrippa, *Marcus Vipsanius*, according to Tacitus, was born of humble parents about 69 years B.C.; yet he could scarcely have been of very mean birth, as at the age of 18 he was the chosen companion at Apollonia of Octavius, the nephew and successor of Julius Cæsar; many of whose successes were mainly due to the courage and military talents of Agrippa. On the assassination of the dictator, Agrippa accompanied his friend to Italy, and rendered essential service in the conduct of the first war against M. Antonius, which terminated in the capture of Perusia, into which L. Antonius, the younger brother of the triumvir, had thrown himself. He appears to have had no part in the atrocious butcheries that followed the capture of that city, which cast such a deep stain on the character of Octavius. The event took place 40 years B.C. Three years after this Agrippa was made consul, and had the command in Gaul; when he defeated the Aquitani, and led the Roman eagles beyond the Rhine, to punish the aggressions of the Germans on the province of Gaul. But Agrippa was soon summoned to Italy by the critical state of the affairs of Octavius; where the whole coasts were commanded by the superior fleets of Sex. Pompeius. His first care was the formation of a secure harbour for the ships of Octavius; and this he accomplished by uniting the Lucrine lake with the sea by means of a fortified canal through a narrow slip of land called the Barrier of Hercules. He made an inner haven also by joining the lake Avernus to the Lucrine by another cut. In these secure ports the fleets were equipped, and 20,000 manumitted slaves were sedulously trained to rowing and naval manœuvres, until they were able to cope with the seamen of Pompeius. Agrippa was thus enabled in the following year to defeat S. Pompeius in the naval action of Mylæ, in which he captured 30 ships from his opponent; and soon after gave him a more signal defeat near Naulochus, sinking 28, and capturing or burning 250 of his ships. This victory gave Octavius the empire of the Mediterranean, and secured to him Sicily, the granary of Rome, after an easy triumph over his feeble colleague Lepidus; and it prepared the way for the overthrow of the power of M. Antonius the other triumvir. The whole merit of these successes is due to Agrippa; for Octavius scarcely exhibited common courage in any of these transactions.

In the year 33 B.C. Agrippa filled the useful office of ædile; and he signalized the tenure of his office by fresh proofs of the activity and perseverance of his character, by the great improvements in the city of Rome, in the repairs and construction of aqueducts and fountains neglected or injured during the civil wars, and in the reformation of the sewers of the capital, which he repaired and enlarged until they became what Pliny has described them,—"Operum omnium maximum, suffossis montibus, atque urbe pensili, subterque navigatâ." He appears also on this occasion to have introduced an effectual mode of *flushing* those sewers by conducting into them the united waters of several different streams.

From these useful labours he was again called away in the year 31 B.C. to command the Roman fleet, which by the victory at Actium fixed the empire of the world on the unworthy Octavius. The services of Agrippa made him a special favourite with the former, who gave him his niece Marcella in marriage, 27 B.C., when for a third time he was consul; and in the following year the servile senate bestowed on Octavius the imperial title of AUGUSTUS. In this same year Agrippa, in commemoration of the naval victory of Actium, dedicated to Jupiter and all the other gods the pantheon, now called *Rotunda*. The inscription on its portico still remains, M. AGRIPPA L. F. CONSUL TERTIUM FECIT. But it is probable that he only added the magnificent portico to a much more ancient building; as a minute examination of the architecture of the structure appears to indicate. In the year 25 B.C. we again find this eminent man employed in Spain; where he reduced the insurgent Cantabri, the ancestors of the present Biscayans.

The friendship of Augustus and Agrippa seems to have been clouded by the jealousy of Marcellus, who had married Julia the daughter of Augustus by Scribonia. This coolness was probably fomented by the intrigues of Livia, the second wife of Augustus, who probably dreaded his influence with her husband. The consequence was that Agrippa left Rome; and though, to cloak his retirement, he was appointed to the distant government of Syria, he repaired to Mytilene. But Marcellus dying within a year, Agrippa was recalled to Rome; and at the desire of Augustus was divorced from Marcella, and became the husband of the widowed Julia, who was no less distinguished by her beauty and abilities, than afterwards by her shameless profligacy.

In 19 B.C. we find Agrippa again at the head of an army in Spain, where he subdued the Cantabri, who had been for two years in insurrection against the Romans. After that he was a second time made governor of Syria; where by his justice and wise administration he obtained general commendation, especially from the Hebrew population of his province, of which Judea formed a part.

The last military employment of this great and good man was in Pannonia, where his character for equity alone sufficed to put down insurrection, without bloodshed. In fact he was the greatest military commander of Rome since the days of Julius Cæsar, and the most honest of Roman governors in any province. His character is well described by V. Paterculus, "Virtutis nobilissimæ, labore, vigiliâ, periculo invictus, parendique sed uni scientissimus, aliis sane imperandi cupidus, et per omnia extra dilationes positus, consultisque facta conjungens."

This great man returned to Italy, where he lived greatly honoured, and died two years before his imperial father-in-law.

Agrippa left several children; by his first wife—Pomponia Vipsania, who became the first wife of Tiberius, and was the mother of Drusus: he had no children by Marcella; but by Julia he was the father of Caius and Lucius Cæsar; of Julia, married to Lepidus; of Agrippina the elder, wife of Germanicus; and of Agrippa Posthumus.—See *Dio Cassius; Appianus; Suetonius; Velleius Paterculus;* Fergusson's *R. Rep.* (T. S. T.)

AGRIPPINA, THE ELDER, the virtuous, heroic, but unfortunate offspring of M. Agrippa by a very abandoned mother, and herself the parent of a still more profligate and guilty daughter of the same name. She was early married to Germanicus, the son of Drusus and Antonia the niece of Augustus. On the death of Augustus, she joined her husband in his German campaigns, where she had several opportunities of showing her intrepidity, sharing with Germanicus his toils and his triumphs. The love which the army showed for this leader was the cause of his recal from the Rhine by the suspicious Tiberius. He was soon afterwards sent into Syria, where he died at Antioch, from the effects, as was believed, of poison administered to him by Piso, the governor of Phœnice.

On his deathbed, Germanicus implored his wife for heaven's sake, and that of their numerous children, to submit with resignation to the evil times on which they were fallen, and not to provoke the vengeance of the tyrant Tiberius. But unhappily this prudent advice was not followed by this high-spirited woman; who, on landing at Brundusium, went straight to Rome, and entered the city bearing the urn of her deceased husband in her arms, and was received amid the tears of the citizens and the soldiery, to whom Germanicus was dear. She boldly accused Piso of the murder of her husband; and that bad man, to avoid public infamy, committed suicide. She continued to reside at Rome, watched and suspected by Tiberius, who for some time dreaded to glut his vengeance on the widow and family of so popular a prince as Germanicus. She soon had the temerity to upbraid the tyrant with his hypocrisy in pretending to worship at the tomb of Augustus. He began by putting to death both men and women who had shown attachment to the family of Germanicus; and finally he arrested Agrippina and her two eldest sons, Nero and Drusus, and deported them to the isle of Pandataria, where her mother Julia had perished; and there she was starved to death. Tiberius also ordered the execution of her two eldest sons. Yet it is remarkable that, by his will, the emperor left her youngest son Caius, better known by the name of *Caligula*, as one of the heirs of the empire. Agrippina was murdered in the 33d year of our era. (T. S. T.)

AGRIPPINA, daughter of Germanicus, sister of Caligula, and mother of Nero; a woman of wit, but licentious and cruel. She was thrice married, the last time to Claudius, her own uncle, whom she poisoned to make way for Nero, her son. Nero afterwards caused her to be murdered in her chamber, when she bid the executioner stab her first in the belly, that had brought forth such a monster.

AGRIPPINA COLONIA UBIORUM, in *Ancient Geography*, now *Cologne;* so called from Agrippina, the daughter of Germanicus and mother of Nero, who had a colony sent thither at her request by the Emperor Claudius, to honour the place of her birth. See COLOGNE.

AGRONOMI, *in Antiquity*, rural police, frequently mentioned by Plato.

AGROSTIS, a genus of grasses. See BOTANY.

AGROTERAS THUSIA, an annual festival at Athens, in honour of Artemis or Diana, in consequence of a vow made before the battle of Marathon to offer in sacrifice as many goats as there should be slain of the enemy. The number was afterwards restricted to 500.

AGUAS CALIENTES, a well-built town of Mexico, in the province of Guadalaxara, containing about 500 families of Spanish descent, besides numerous others of mixed races. It takes its name from the hot-springs in its vicinity. The climate is fine, and the extensive and beautiful gardens

Agudo || Aguesseau.

surrounding the town produce abundance of olives, figs, grapes, &c. Much maize also is raised. It has a great cloth manufactory, and the general trade is considerable. Lat. 22. N. Long. 101. 50. W.

AGUDO, a well-built town of La Mancha, in Spain, with a population of 1240, chiefly engaged in agriculture and cattle-breeding.

AGUE. See Medicine.

AGUEDA, the *Æminium Flumen* of the Romans (Pliny), a river of Spain in the province of Salamanca. It rises in the Sierra de Gata, and passing by Ciudad Rodrigo, falls into the Douro, on the Portuguese frontier, after a northward course of 70 miles.

Agueda, *Santa*, a small village in the province of Guipúzcoa, in Spain, celebrated for its sulphurous baths, which for 300 years have been esteemed for their efficacy in the cure of cutaneous and other diseases.

AGUESSEAU, Henri Francois d', Chancellor of France, illustrious for his virtues, learning, and talents, was born at Limoges on the 27th of November 1668. His father, at that time intendant of Languedoc, and afterwards a counsellor of state, was a man of great worth and abilities. He seems to have taken the sole charge of his son's education; and having destined him for the bar, he took uncommon pains to exercise him in every branch of knowledge which could contribute to his success in that profession. His care was rewarded with the happiest success. Young D'Aguesseau gave early indications of uncommon abilities; and such was his thirst for knowledge, and his habits of application, that he soon acquired the reputation of an almost universal scholar. He had a particular relish for poetry, which, he used to say, "was the only passion of his youth;" but this passion was so far from withdrawing him from severer studies, that it was allied in his mind with a nearly equal taste for mathematics. He studied law with the zeal of an antiquary, and the spirit of a philosopher; and, in order to form his taste as a pleader, he employed a whole year in repeated perusals of the most esteemed productions of ancient eloquence. After this thorough course of preparation, he became an advocate in 1690; and by the interest of his father, who then resided in Paris, he was soon furnished with opportunities of distinguishing himself, and of rising to the highest honours of the profession. When little more than 21 years of age, he was appointed one of the three *Advocates-General*,—an office which imposed the duty of assisting in those causes where the king, the church, or the public was concerned. The king, Louis XIV., in appointing him, yet untried, to this situation, acted solely upon the recommendation of the elder D'Aguesseau, "who was incapable," said Louis, "of deceiving him, even to advance his own son." D'Aguesseau's first appearances as an advocate-general were such as amply to fulfil the expectations of his father, and to warrant the appointment which he had obtained from the king. Denis Talon, an old lawyer, who had long officiated with great reputation in the same capacity, was heard to say, that "he should have been glad to have finished his career as that young man had begun."

D'Aguesseau held this office for ten years, during which period he greatly distinguished himself, both for learning in his profession, and for a superior style of forensic eloquence. The society which he chiefly frequented was well adapted to improve his taste; for the chosen companions of his leisure hours were Racine and Boileau, the latter of whom has frequently mentioned him with praise in his writings.

It was D'Aguesseau's opinion, that no one could rise to distinguished eminence as an orator, who did not labour to enlarge his mind, and to improve his taste, by the study of philosophy, and by exercises of literature; and he accordingly employed several of those stated discourses which the usages of France required from the advocates-general at the opening of the Sessions, to impress these views upon the minds of the younger members of the bar.

Aguesseau.

In the year 1700 he was appointed *Procurator-General;* an office of higher dignity, and of more various and extensive duties, than that of advocate-general. He filled this office for seventeen years with the most splendid reputation; adding, by his lenity in criminal cases, and by his care of the public hospitals, the praise of humanity and benevolence to his other claims to the respect and admiration of his countrymen.

It had been early predicted of D'Aguesseau, that he would one day fill the place of Chancellor; and this prediction was at length realised in 1717, upon the death of Voisin, who then held the seals. Though he was yet only forty-eight years of age, his nomination to this high dignity gave general satisfaction, and was, indeed, intended as a popular measure by the Duke of Orleans, who had lately assumed the regency. D'Aguesseau soon began to experience the difficulties and perils attendant upon his elevation; for he had not been installed above a year, when he was deprived of the seals, and exiled to his estate. His steady opposition to the delusive projects of the famous John Law, with which the regent and his ministers were wholly intoxicated, was the honourable cause of this first reverse of fortune. In 1720, when the ruinous consequences of these schemes had filled the nation with distress and alarm, the chancellor was recalled from banishment; and he contributed not a little, by the firmness and sagacity of his counsels, to calm the public discontents, and repair the mischiefs which had been committed.

Law himself had acted as the messenger of his recal; and it is said that D'Aguesseau's consent to re-accept the seals from the hand of this adventurer was much blamed by the literary corps, with which he had hitherto stood in high favour, as well as by the parliament. But his reputation appears to have sustained a much severer shock, when he endeavoured to prevail with the latter body to register the declaration of the late king in favour of the bull *Unigenitus*,—a measure which they held in great abhorrence, and which he had himself firmly opposed during the life of Louis. The regent's favourite, Dubois, then Archbishop of Cambray, had moved his master to insist upon this act of registration, in the hope that he might thereby obtain a cardinal's hat; and it seems to have been thought that the chancellor had yielded his better opinion in compliance with the wishes of this worthless minion. Be this as it may, it is certain that he opposed the favourite with firmness, when he attempted, after being made prime minister, to take precedence in the council; and he was in consequence, in 1722, sent a second time into exile.

He now passed five years on his estate at Fresnes; and he always spoke with delight of this tranquil period, when he was left free from the cares of professional duty, and the distractions of public life, to cultivate his mind. The Scriptures, which he read and compared in various languages, and the Jurisprudence of his own and other countries, formed the subjects of his more serious studies: the rest of his time was devoted to philosophy and literature, and the improvement of his park, where he was sometimes to be seen employed with a spade.

From these noble and congenial occupations he was again recalled, by the advice of Cardinal Fleury, in 1727; but the seals were not restored to him till ten years thereafter. During the intervening period he had endeavoured to mediate in the new disputes which had arisen between the court and the parliament; but his interference seems to have given satisfaction to neither party,—the one reproaching him with desertion from their cause, and the other with too great a leaning towards it. When the seals were at last restored to him, he completely withdrew from all affairs of state, and devoted himself entirely to his duties as chancellor, and to the introduction of those reforms which had long occupied his inquiries and meditations.

Besides some important enactments regarding Donations, Testaments, and Successions, he introduced various regulations for improving the forms of procedure, for ascertaining the limits of Jurisdictions, and for effecting a greater uniformity in the execution of the laws throughout the several provinces. These reforms constitute an epoch in the history of the jurisprudence of France, and have associated his name with those illustrious benefactors of her Civil Code, L'Hôpital and Lamoignon.

In 1750, when upwards of eighty-two years of age, he besought the king to accept his resignation; and he was accordingly permitted to retire, the king continuing to him the honours of his office as a special mark of his approbation. He died in the following year, and was interred, according to his own request, in the common burial-place of the village of Auteuil, where the remains of his wife, who died there in 1735, had been deposited. The name of this lady, whom he married in 1694, and by whom he had several children, was Anne Lefèvre d'Ormesson.

This great man has not, in all respects, been equally praised by those who have attempted to transmit his character to posterity. Saint-Simon and others reproach him with a degree of tardiness and indecision, which sometimes greatly obstructed the course of justice. His own answer to this charge has been recorded by Duclos, and is worthy of notice: "When I recollect," said he, "that a decision of the chancellor makes a law, I think myself warranted in taking a long time for consideration." In summing up his character, all must agree with Laharpe, that he was "a man who did honour to France, to the magistracy, and to letters, by his virtues, his talents, his profound and various learning, and his enlightened views in the science of jurisprudence."—*Cours de Littérature*, tom. xiv. c. 1.

His published writings form a collection of thirteen volumes quarto, of which the first was published at Paris in 1759, and the last in 1789. The far greater part of these volumes relates to matters connected with his professional occupations and studies; but they also contain a variety of pieces upon other subjects. Besides the already mentioned discourses, an elaborate treatise on money, and some theological pieces, there is a life of his father,—interesting from the view which it affords of his own early education under that excellent person; and Metaphysical Meditations, written in vindication of the grand truth, that independently of all revelation, and all positive law, there is that in the constitution of the human mind which renders *man a law to himself*.—See *Histoire des Hommes Illustres de Regnes de Louis* XIV. *et de Louis* XV. par le Duc de Saint-Simon; *Mémoires Secretes*, par Duclos; *Les Loisirs d'un Ministre d'Etat*, par D'Argenson; *Eloge de D'Aguesseau*, par Thomas. (M. N.)

AGUILAR *de la Frontera*, a very fertile district of the province of Cordova in Spain, with a population of 18,844, chiefly engaged in agriculture, cattle breeding, and the manufacture of oil and pottery.

Its chief town, of the same name, stands near the river Cabra, seven leagues S.S.E. of Cordova. The houses are well built, and distinguished by their cleanness and regularity, both external and internal. The principal buildings are the parish church, the chapter-house, the prison, and the markets. There are two convents, two public schools, a charity-hospital, and a house of refuge. Near the church are the ruins of a once magnificent castle. The principal products are wine and oil. Pop. 11,836.

AGUILAS, San Juan de las, a seaport of Murcia in Spain, with 4832 inhabitants. Its harbour is small but secure; and England, France, and Portugal maintain vice-consuls there.

AGUILLANEUF, or Auguillaneuf, a form of rejoicing used among the ancient Franks on the first day of the year. The word is compounded of the French *a*, to, *gui*, misletoe, and *l'an neuf*, the new year. Its origin is traced from a druidical ceremony. In the sacred month of December every year, the priests went in solemn procession to gather the misletoe of the oak. The prophets marched in front, singing hymns in honour of the gods; after them came a herald with a caduceus in his hand; these were followed by three druids abreast, bearing the things necessary for sacrifice; last of all came the chief or arch druid, accompanied by the train of people. The chief druid, ascending the oak, cut off the misletoe with a golden sickle, and the other druids received it in a white cloth. On the first day of the year they distributed it among the people, after having blessed and consecrated it by crying *A gui l'an neuf*, to proclaim the new year.

AGUILLON, or Aguillonius, Francis, a Jesuit, born at Brussels. He was rector of the Jesuit college at Antwerp, and eminent for his skill in mathematics. He was the first who introduced that science among the Jesuits in the Low Countries. He wrote a book of Optics, and was employed in finishing his Catoptrics and Dioptrics when he died in 1617.

AGUIMES, a town in the Great Canary Island, 1100 feet above the sea level, with a population of 3073, and manufactures of palm and olive oil, linen, cloth, &c.

AGUIRRE, Joseph Saenz d', a Benedictine, and one of the most learned men of the 17th century, was born at Logroño, March 24, 1630. He was censor and secretary of the supreme council of the inquisition in Spain, and interpreter of the Scriptures in the university of Salamanca. He printed three volumes in folio upon Philosophy, a commentary upon Aristotle's ten books of Ethics, and other pieces. He attained to the dignity of cardinal, and died at Rome on the 19th August 1699.

AGULHAS, Cape, the most southern point of Africa, 100 miles eastward of the Cape of Good Hope, in Lat. 34. 51. 30. S. Long. 19. 55. 30. E. It rises 155 feet above the sea; and in 1849 a lighthouse was opened on it nearer the water. An immense bank, the *Agulhas Bank*, extends from the Cape of Good Hope along this coast to the great Fish River, a distance of 560 miles, with a general breadth of 100: but opposite to the Cape it projects 100 miles more southward. The great oceanic current from the Indian Ocean to the Atlantic sets along its outward edge, and has sharply defined it. The soundings on the bank westward of Cape Agulhas show a muddy hollow in the bottom of the sea; but eastward it is sandy, with a mixture of comminuted shells. The oceanic current has such velocity that ships are often set far to the westward, and round the Cape of Good Hope, even against a smart breeze. The bank abounds with fish; and the approach to it is denoted by the appearance of many toothed whales such as the dolphin, sharks, seals, and innumerable sea-birds.

AGURAH, in *Jewish Antiquity*, the name of a silver coin, otherwise called *gerah* and *keshita*, value $1\frac{1}{2}$d.

AGUSADURA, in *Ancient Customs*, a fee due from vassals to their lord for the sharpening of their agricultural implements. Of old the tenants in some manors were not allowed to have them sharpened by any but those whom the lord appointed, for which an acknowledgment was to be paid, called *agusadura*, in some places *agusage;* which some take to be the same with what was otherwise called *reillage*, from the ancient French *reille*, a ploughshare.

AGYEI, in *Antiquity*, a kind of obelisks, sacred to Apollo, erected in the vestibules of houses, by way of security.

AGYNIANI (α priv. and γυνη), in *Church History*, a sect who condemned marriage and the use of flesh, as not instituted by God, but introduced at the instigation of the devil. They are sometimes also called *Agynenses*, and *Agynii;* and are said to have appeared about the year 694. It is not surprising that they soon became extinct. Their tenets coincide in a great measure with those of the Abelians, Gnostics, Cerdonians, and other preachers of chastity and abstinence.

AGYRIUM, the ancient name of a Sicilian town, in the Val di Demona, near the River Semetus, now called San Filippo d'Argiro, containing 6500 inhabitants. It was the birth-place of the historian Diodorus.

AGYRTÆ (αγειρω, I congregate), in *Grecian Antiquity*, a kind of strolling imposters, who went about the country to pick up money, by telling fortunes at rich men's doors; pretending to cure diseases by charms, sacrifices, and other religious mysteries; also to expiate the crimes of their deceased ancestors, by virtue of certain odours and fumigations; to torment their enemies, by the use of magical verses, and the like. The *Agyrtæ* corresponded to the *Æruscatores* of the Latins, and to our modern gypsies.

AHAB, son of Omri, and seventh king of Israel, reigned twenty-one years, from B.C. 918 to 897. Many of the evils of his reign may be ascribed to the close connection he formed with the Phœnicians, between whom and the Jews there had long been a beneficial commercial intercourse. Having married Jezebel, the daughter of Ethbaal, or Ithobaal, king of Tyre, Ahab was entirely under her control, and sanctioned the introduction, and eventually established the worship, of the Phœnician idols, and especially of the sun-god Baal. Hitherto the golden calves in Dan and Bethel had been the only objects of idolatrous worship in Israel, and they were intended as symbols of JEHOVAH. But all reserve and limitation were now abandoned. The king built a temple at Samaria, and erected an image, and consecrated a grove to Baal. Idolatry became the predominant religion; and so strong was the tide of corruption, that it appeared as if the knowledge of the true God was soon to be for ever lost among the Israelites. But Elijah the prophet boldly opposing himself to the regal authority, succeeded in retaining many of his countrymen in the worship of the true God. At length the judgment of God on Ahab and on his house was pronounced by Elijah, that, during the reign of his son, his whole race should be exterminated. Ahab died of the wounds he received in a battle with the Syrians, according to a prediction of Micaiah, which he refused to credit, yet endeavoured to avert, by disguising himself in the action.—1 Kings xvi. 29, xxii. 40.

AHALA, a noble Roman family of the gens Servilia, which produced many distinguished men. Of these the most celebrated is C. Servilius Structus Ahala, master of the horse to the dictator Cincinnatus, B.C. 439. He signalised himself by his boldness in slaying in the forum with his own hand the popular agitator Sp. Mælius, for refusing to appear before the dictator on a charge of conspiracy against the state. For this act of violence Ahala was afterwards brought to trial. He saved himself from condemnation by retiring into voluntary exile.

AHANTA, a district on the Gold Coast of Africa, on the Gulf of Guinea, in Lat. 5. N. and Long. 3. W.—See *Bowdich's Travels.*

AHASUERUS, or ARTAXERXES, the husband of Esther and, according to Archbishop Usher and F. Calmet, the Scripture name for Darius, the son of Hystaspes king of Persia. Scaliger supposed Xerxes to have been the husband of Esther, or the Ahasuerus of Scripture: and Dr Pridcaux believes him to be Artaxerxes Longimanus. See History of PERSIA, and ESTHER.

AHAUS, a circle in the department of Munster, and Prussian province of Westphalia, formed out of the old lordships of Bocholt and Horstmar. It is 264 square miles, or 168,960 acres, in extent, comprehending four cities, three market towns, and 11 villages, with 40,069 inhabitants. The soil is moderately fertile, and yields corn, buck-wheat, and flax. It is watered by the Aa, the Berkel, the Bechta, the Dinkel, and several smaller streams. The most valuable products are cattle, and especially sheep. There is some little spinning and weaving of linen; but the higher wages paid in Holland induce the labourers to go to that country, in the seasons of hay and corn harvest, to save the means of subsistence for the winter.—The chief city of the circle, of the same name, is the residence of the Prince of Salm-kyrburg; and contains, besides his castle, 271 houses, and 1658 inhabitants. Long. 7. 4. 34. E. Lat. 52. 4. 36. N.

AHAZ, king of Judah, the son of Jotham, remarkable for his vices and impieties. He made one of his sons pass through the fire, to do honour to the idol Moloch; and he offered sacrifices and incense upon the high places, upon hills, and in groves. Rezin, king of Syria, and Pekah, king of Israel, invaded Judah in the beginning of the reign of Ahaz; and having defeated his army and pillaged the country, they laid siege to Jerusalem. When they found that they could not make themselves masters of that city, they divided their army, plundered the country, and made the inhabitants prisoners of war. Rezin and his part of the confederate army marched with all their spoil to Damascus; but Pekah, with his division of the army, having attacked Ahaz, killed 120,000 men of his army in one battle, and carried away men, women, and children, without distinction, to the number of 200,000. But as they were carrying those captives to Samaria, the prophet Oded, with the principal inhabitants of the city, came out to meet them, and by their remonstrances prevailed with them to set their prisoners at liberty. At the same time the Philistines and Edomites invaded other parts of his kingdom, killed multitudes of the people, and carried off much booty. In this distressed condition, Ahaz sent ambassadors to Tiglath-pileser, king of the Assyrians; and to engage him to his interest, he stripped the temple and city of all the gold he could find, and sent it as a present. Tiglath-pileser marched to the assistance of Ahaz, attacked Rezin, and killed him, took his capital Damascus, destroyed it, and removed the inhabitants to Cyrene.

The misfortunes of this prince had no influence in amending his character; for in the times of his greatest affliction, he sacrificed to the Syrian deities, whom he looked upon as the authors of his calamities, and endeavoured thus to propitiate. He broke in pieces the vessels of the house of God, shut up the gates of the temple, and erected altars in all parts of Jerusalem. He set up altars likewise in all the cities of Judah, with a design to offer incense on them. His body, after his death, was refused a place in the sepulchres of the kings of Judah. Hezekiah his son succeeded him in the year of the world 3278, B.C. 726.

AHAZIAH, the son and successor of Ahab, king of Israel, reigned two years in conjunction with his father. Ahaziah imitated Ahab's impieties (1 Kings xxii. 52, *seq.*), and paid his adoration to Baal and Astarte, the worship of whom had been introduced into Israel by Jezebel, his mother. The Moabites, who had been always obedient to the kings of the ten tribes ever since their separation from the kingdom of Judah, revolted after the death of Ahab, and refused to pay the ordinary tribute. Ahaziah, however, had not leisure or power to reduce them. By an accidental fall, about this time, from a lattice of his palace, he received such injury as to put his life in danger. He despatched messengers to Ekron to inquire of the god Baalzebub whether or not he should recover. A more faithful oracle came to him in the person of the prophet Elijah, who forewarned him of his speedy death. This took place A.M. 3108, and Jehoram his brother succeeded to the throne. (2 Kings i.)

Ahaziah, king of Judah, the son of Jehoram and Athaliah, succeeded his father in the kingdom of Judah, A.M. 3119. He walked in the ways of Ahab's house, to which he was allied. He reigned only one year, and was slain by Jehu the son of Nimshi.

A-HEAD, a sea-term, signifying farther onward than the ship, or at any distance before her, lying immediately on that point of the compass to which her stem is directed. It is used in opposition to *a-stern*, which expresses the situation of any object behind the ship.

AHENOBARBUS, the name of a plebeian Roman family of the gens Domitia, which rose in the course of time to considerable distinction. The emperor Nero was of this family. The name was derived from the red beard and hair by which many of the family were distinguished.

AHIGAL, a town of Estremadura in Spain, with a population of 1370, and manufactories of soap, linen, oil, &c.

AHIJAH, or Ahiah, a prophet residing in Shiloh in the times of Solomon and Jeroboam. He appears to have put on record some of the transactions of the former reign. (2 Chron. ix. 29). It devolved on him to announce and sanction the separation of the ten tribes from the house of David, as well as the foundation (1 Kings xi. 29–39), and, after many years, the subversion, of the dynasty of Jeroboam. (1 Kings xiv. 7–11.)

AHIMELECH (*brother of the king*, i. e. *the king's friend*,) was the son of Ahitab, and brother of Ahiah, who was most probably his predecessor in the high priesthood. When David fled from Saul, he went to Nob, a city of the priests in Benjamin, where the tabernacle then was; and by representing himself as on pressing business from the king, he obtained from Ahimelech some of the sacred bread which had been removed from the presence-table. He was also furnished with the sword which he had himself taken from Goliah, and which had been laid up as a trophy in the tabernacle. (1 Sam. xxi. 1–9.) These circumstances were witnessed by Doeg, an Edomite in the service of Saul, and were so reported by him to the jealous king as to appear acts of connivance at, and support to David's imagined disloyal designs. Saul immediately sent for Ahimelech and the other priests then at Nob, and laid this crime to their charge, which they repelled by declaring their ignorance of any hostile designs on the part of David towards Saul or his kingdom. The king, however, commanded his guard to slay them. Their refusal to fall upon persons invested with so sacred a character might have brought even Saul to reason; but he repeated the order to Doeg himself, and was too readily obeyed by that malignant person, who, with the men under his orders, not only slew the priests then present, eighty-six in number, but marched to Nob, and put to the sword every living creature it contained. The only one of the priests that escaped was Abiathar, son of Ahimelech, who fled to David, and afterwards became high priest. (1 Sam. xxii.)

AHITHOPHEL (*brother of foolishness*, i. e. *foolish*), the very singular name of the man who, in the time of David, was renowned throughout all Israel for his worldly wisdom. He was of the council of David; but at the time of Absalom's revolt, was at Giloh, his native place, whence he was summoned to Jerusalem; and it shows the strength of Absalom's cause in Israel that a man so capable of foreseeing results, and estimating the probabilities of success, took his side in so daring an attempt. (2 Sam. xv. 12.) The news of this defection appears to have occasioned David more alarm than any other single incident in the rebellion. He earnestly prayed God to turn the sage counsel of Ahithophel "to foolishness" (probably alluding to his name); and being immediately after joined by his old friend Hushai, he induced him to go over to Absalom with the express view that he might be instrumental in defeating the counsels of this dangerous person. (xv. 31–37.) Hushai interposed with his plausible advice, the object of which was to gain time to enable David to collect his resources. When Ahithophel saw that his counsel was rejected for that of Hushai, he gave up the cause of Absalom for lost; and he forthwith returned to his home, and hanged himself, B.C. 1023. (ch. xvii.) This is the only case of suicide which the Old Testament records, unless the last acts of Samson and Saul may be regarded as such.

AHJOLI, a city on the bay of Borgas, in the Black Sea, surrounded with many wind-mills, and of commercial consequence from its copious salt-springs. It is in the Turkish province of Silistria, a part of ancient Bulgaria.

AHMEDABAD. See Amedabad.

AHMEDPOORA. The name of several towns in Hindustan.

AHRWEILER, a circle in the department of Coblentz, and the Prussian province of the Lower Rhine. It extends over 143 square miles, or 91,520 acres; and has 32,820 inhabitants, viz. 31,657 Catholics, 651 Protestants, 512 Jews, in three cities, three market towns, and 74 villages. The Rhine washes its eastern border, and receives the water of the Ahr, which issues out of a fertile valley, near Sinzig, whence some good wine from the sides of the hills is produced. The rest of the district is poor in agriculture, and indifferently furnished with cattle, game, fish, wood, and stone. The capital is a small city of the same name. It is on the banks of the Ahr, and contains 438 houses, and 2880 inhabitants, chiefly tanners, curriers, and makers of wine.

A-HULL, in naval language, the situation of a ship when all her sails are furled on account of the violence of the storm, and when, having lashed her helm on the lee-side, she lies nearly with her side to the wind and sea, her head being somewhat inclined to the direction of the wind.

AHUYS, a town of Sweden, in the principality of Gothland, and territory of Christianstadt, near the Baltic Sea, about ten miles from Christianstadt. It is small, but very strong in situation, and has a good port. Long. 14. 10. E. Lat. 55. 55. N.

AI (Sept. Ἀγγαί, Ἀγγαΐ, and Γαΐ; Vulg. *Hai*) a royal city of the Canaanites, east of Bethel. It existed in the time of Abraham, who pitched his tent between the two cities (Gen. xii. 8; xiii. 3); but it is chiefly noted for its capture and destruction by Joshua (vii. 2–5; viii. 1–29). At a later perion Ai was rebuilt, and is mentioned by Isaiah (x. 28), and also after the captivity. The site was known, and some scanty ruins still existed, in the time of Eusebius and Jerome (*Onomast.* in *Agai*), but Dr Robinson was unable to discover any certain traces of either. He remarks (*Bib. Researches*, ii. 313), however, that its situation with regard to Bethel may be well determined by the facts recorded in Scripture. That Ai lay to the east of Bethel is distinctly stated; and the two cities were not so far distant from each other but that the men of Bethel mingled in the pursuit of the Israelites as they feigned to flee before the king of Ai, and thus both cities were left defenceless (Josh. viii. 17). A little to the south of a village called Deir Diwan, and one hour's journey from Bethel, the site of an ancient place is indicated by reservoirs hewn in the rock, excavated tombs, and foundations of hewn stone. This, Dr Robinson inclines to think, may mark the site of Ai, as it agrees with all the intimations as to its position.

AIBAR, a Spanish town in a valley of the same name, in the province of Navarre, the scene of a bloody battle between the Spaniards and the Moors in 885. Pop. 1360.

AID-DE-CAMP, in *Military Affairs*, an officer employed to receive and carry the orders of a general.

AIDAN, a king of the Dalriad Scots, about the end of the 6th century.—See *Boece's History*.

AIDAN, *St*, a famous Scottish bishop of Lindisfarne or Holy Island, in the 7th century, was employed by Oswald, king of Northumberland, in the conversion of the English, in which he was very successful. He was a monk in the monastery of Iona, and died in 651.

AIDS, *Auxilia*, a pecuniary tribute under the feudal system, paid by a vassal to his lord on particular occasions; originally a mere gift, which, in process of time, became a demandable right. The aids of this kind were chiefly three, viz.:—1*st*, When the lord made his eldest son a knight; 2*d*, To provide a dower when he gave his eldest daughter in marriage; 3*d*, To ransom his lord when taken prisoner. The amount of the first two was limited by statute, but the last was, of course, uncertain.

AIGLE, a bailiwick in the territory of Romand in Switzerland, consists of mountains and valleys, the principal of which are the Aigle and Bex. Through these is the great road from Valais into Italy. In passing by Villeneuve, which is at the head of the lake of Geneva, the traveller enters into a deep valley three miles wide, bordered on one side by the Alps of Switzerland, on the other side by those of Savoy, and crossed by the river Rhone. Six miles from thence he arrives at Aigle, a town of 1900 inhabitants, situated in a wide part of the valley, adorned with vineyards, fields, and meadows. The governor's castle is on an eminence overlooking the town, and has a lofty marble tower. This government has nine large parishes; and is divided into four parts, Aigle, Bex, Olon, and Ormont. This last is among the mountains, and adjoins Rougemont. It is a double valley, abounding in pasture lands. Ivorna, in the district of Aigle, was in part buried by the fall of a mountain, occasioned by an earthquake, in 1584.

AIGLE, L', a city in France, in the arrondissement of Mortagne, and department of the Orne. It is situated on the river Rille, which divides it into three parts; one on each side of the river, and one in an island formed by two of its channels. It contains 844 houses, and 4720 inhabitants. It is an industrious place, with manufactures of linen, cotton, paper, leather, cutlery, needles, bottles, and other wares.

AIGUE PERSE, a town of France, in the department of Puy de Dome, twelve miles N.N.E. of Riom. In its vicinity are mineral springs, and the Château de la Roche, where the Chancellor de l'Hôpital was born. Pop. 2671.

AIGUES MORTES, a town of France, in the department of Gard, 20 miles south-west of Nismes. It was once a seaport town, and here St Louis embarked on his two expeditions to Africa; but it is now four miles distant from the coast, being connected with it by the Roubine canal. The surrounding marshes render it very unhealthy. Pop. 3365.

AIGUILLON, a town in the department of Lot and Garonne, in France, at the conflux of the rivers Garonne and Lot, containing 3919 inhabitants.

AIGUISCE, in *Heraldry*, denotes a cross with its four ends sharpened, but so as to terminate in obtuse angles. It differs from the cross fitchee, inasmuch as the latter tapers by degrees to a point, and the former only at the ends.

AIKEN, JOHN, M.D., born at Warrington in Lancashire, was the only son of the Rev. Dr John Aiken, who, for many years, was one of the masters in the Dissenting Academy at Warrington, before its removal to Hackney. The son received his elementary education at that seminary: his medical studies he prosecuted in the university of Edinburgh, and in London under the celebrated Dr William Hunter. He commenced his professional career as a surgeon at Chester; but not succeeding in that episcopal city, he tried to establish himself in his native town. Finally, he went to Leyden, took the degree of M.D. in that university, and attempted to establish himself as a physician in London. His success in this new field does not seem to have been considerable; partly owing to his delicate health, and partly from the singleness of purpose and keenness with which he entered into the engrossing political questions of the day, especially the grand principle of liberty of conscience. Hence he began at an early period to devote himself to literary pursuits. Dr Aiken's reputation now chiefly rests on his endeavours to popularise scientific inquiries, by rendering them easy of comprehension to the general reader. In conjunction with his sister, Mrs Barbauld, he commenced the publication of a series of volumes on this principle, entitled *Evenings at Home*, the sixth and last volume of which appeared in 1796. This attempt to popularise scientific inquiries was a favourate object of Dr Aiken; and the work obtained a great reputation. It is chiefly commendable for the purity of the principles it inculcates, and the pleasing views it gives of human nature. His love of nature, and his power in delineating her features, are well illustrated in *The Natural History of the Year*, as well as in his miscellaneous *Essays*.

In 1798 Dr Aiken retired from professional life, and devoted himself with great industry to literary undertakings of varied and numerous kinds, among which his valuable *Biographical Dictionary* holds a conspicuous place. In this he was assisted by Enfield. It appeared in ten quarto volumes, from 1799 to 1815. Besides these he published *Lives of John Selden and Archbishop Usher, Memoirs of Huet Bishop of Avranches, Geographical Delineations of All Nations*, &c. &c.

A stroke of apoplexy terminated his life on the 7th of December 1822. The following is a list of the principal works of Dr Aiken.—1. Essay on the Legation of Arlerias, 1771.—2. Thoughts on Hospitals, 1771.—3. Observations on the external use of preparations of Lead, 1771.—4. Essay on the application of Natural History to Poetry, 1777.—5. Essay on the Plan and Character of Thomson's Seasons, 1778.—6. Biographical Memoirs of Medicine in Britain, 1780.—7. Poems, 1791.—8. A view of the character and public services of John Howard, Esq., 1792.—9. Description of the country round Manchester, 1795.—10. Evenings at Home, 6 vols. finished in 1796.—11. Natural History of the Year.—12. Letters to a Son, 1796.—13. General Biography, 10 vols. 4to. 1799 to 1815.—14. Letters to a Son, 2 vols. 1806.—15. Essays on Song-Writing, 1810.—16. Annals of the Reign of George III., from 1760 to 1815.—17. England Described, 1818.—18. Works of the British Poets, 1820. (T. S. T.)

AIKMAN, WILLIAM, a painter of considerable eminence, was born in Scotland, October 24. 1682. He was the son of William Aikman, Esq. of Cairney, and was intended by his father to follow his own profession, which was that of an advocate at the Scottish bar. But the genius of the son led him to other studies. He devoted himself to the fine arts, especially that of painting; and having for some time prosecuted his studies in Britain, in the year 1707 he went to Italy, resided in Rome for three years, afterwards travelled to Constantinople and Smyrna, and in 1712 returned to his own country. About the year 1723 he fixed his residence in London, where he followed the profession of painting, and had the good fortune to be patronised by the Duke of Argyll, the Earl of Burlington, Sir Godfrey Kneller, and other liberal encouragers of the arts. He painted many portraits of persons of the first rank in England and Scotland, and a large picture of the royal family for the Earl of Burlington, now in the possession of the Duke of Devonshire, which was unfinished at his death. Some of his portraits painted in Scotland are in the possession of the Duke of Argyll, the Duke of Hamilton, and others. Mr Aikman died in London, June 4. 1731. Six months previous to his death he had lost a son at the age of 17. The remains of both were removed to Edinburgh, and interred in the Greyfriars' churchyard on the same day. Somerville the author of *The Chase*, Mallet, Allan Ramsay the author of *The Gentle Shepherd*, and Thomson, were among Mr Aikman's intimate acquaintance; and the muse of each, in elegiac numbers, offered a warm tribute to the memory of their departed friend. The following epitaph, from the pen of Mallet, was engraved on his tomb:

> Dear to the good and wise, disprais'd by none,
> Here sleep in peace the father and the son;
> By virtue, as by nature, close ally'd,
> The painter's genius, but without the pride;
> Worth unambitious, wit afraid to shine,
> Honour's clear light, and friendship's warmth divine.
> The son, fair rising, knew too short a date;
> But, oh! how more severe the father's fate!
> He saw him torn untimely from his side,
> Felt all a father's anguish—wept, and died.

Aikman's style of painting was an imitation of the pleasing simplicity of nature. It is distinguished by softness of light, mellowness of shade, and mildness and harmony of colouring. His compositions have more placid tranquillity of ease than boldness of touch and brilliancy of effect. His portraits are supposed to have some resemblance to those of Kneller, not only in the imitation of the dresses of the time, but in the similarity of tint and manner of working.

AILANA, Ailath, or Aheloth, anciently a town of Arabia Petræa, situated near the Sinus Elanites of the Red Sea. It is also called *Eliath*, and *Eloth* (Stephanus, Strabo, Moses), and is the same with *Elana*. See Akabah.

AILESBURY. See Aylesbury.

AILMER, or Æthelmare, Earl of Cornwall and Devonshire in the reign of King Edgar. It is not known of what family he was. His authority and riches were great, and so also in appearance was his piety. He founded the abbey of Cernel, in Dorsetshire; and had so great a veneration for Eadwald, the brother of St Edmund the Martyr, who had lived a hermit in that country, near the Silver Well, that, with the assistance of Archbishop Dunstan, he translated his relics to the old church of Cernel. In 1016, when Canute invaded England, Earl Ailmer, together with the traitorous Eadric Streone, Earl of Mercia, and Earl Algar, joined the Dane against their natural prince, Edmund Ironside, which contributed greatly to the ruin of the Saxon cause. Ailmer died not long after.

AILRED, or Ealred, an English historian who lived in the reigns of Stephen and Henry II. He was born in 1109, of a noble family, and educated in Scotland with Henry, the son of King David. Embracing a religious life, he became, first abbot of Revesby, in Lincolnshire, and afterwards of the celebrated abbey of Rievaux. He died on the 12th of January 1166, aged 57, and was buried in his monastery. "He was," says Leland, "in great esteem during his life; celebrated for the miracles wrought after his death; and admitted into the catalogue of saints." He was author of several works, most of which were published by Gilbo the Jesuit, at Douay, 1631: part of them may be also found in the *Bibliotheca Cisterciensis*, and *Bibliotheca Patrum*. His principal work is the *Speculum Charitatis*. Leland, Bale, and Pits, mention several manuscripts of his which never were published.

AILSA, an insulated rock on the western coast of Scotland, between the shores of Ayrshire and Cantyre. It is of a conoidal form, with an irregular elliptic base, and rises abruptly from the sea to the height of 1139 feet. Its area is estimated by Macculloch at 3300 by 2200 feet. The only part at which the rock can be ascended is on the east side, where there is a spit of rolled pebbles; the other sides are insurmountable, and for the most part perpendicular. The south-west and north-west are perpendicular, and generally present grand columnar forms, which, though not so regular as those of Staffa, are far more lofty, and in some parts are about 400 feet high. The rock is a greenstone or syenite, with a basis of grayish compact felspar, with small grains of quartz and hornblende. There is no difference between the columnar and massive portions of the rock; but it is traversed by numerous trap veins. A fine columnar cave of 50 feet by 12 feet, and 30 feet high, exists towards the north end. About one-fifth up on the east side are the remains of a tower, with several vaulted rooms. The ascent is laborious, as the fragments of rock are interspersed with the tall vegetation of the common nettle, of *Lychnis dioica*, and *Silene amœna*. Two springs occur on the eastern slopes, where *Hydrocotyle vulgaris* grows to a great size. The scanty grass affords subsistence to a few goats and numerous rabbits; but the rocks are the favourite abode of innumerable gannets, gulls, puffins, and auks. Lat. 55. 15. 13. N. Long. 5. 7. W. (T. S. T.)

AIN, one of the departments in the east frontier of France, deriving its name from a river so called, a part of the ancient province of Burgundy. It is bounded on the north by the departments of Saone-Loire and Jura; on the east by Switzerland and Savoy, from which the Rhone divides it; on the south by the department of Isere, separated also by the Rhone; and on the west by the departments of the Rhone and the Saone-Loire, from both which the Saone divides it. The extent is 2257 square miles, or 1,444,480 acres. The eastern part is very mountainous, being a protraction of the Jura group. The western part is hilly, but interspersed with marshes. Some tracts of valuable land are found in the intervals. The chief products are rye, maize, wheat, some wine, a little salt, and oil. The dairy yields good butter and cheese. The department is divided into five arrondissements, 35 cantons, and 446 communes; and contains 22 cities, 403 market-towns and villages, 1467 hamlets, and 7000 insulated houses. The population in 1851 amounted to 372,939, all Catholics, except in the arrondissement of Gers, where the greater part are Reformed Protestants.

AINSWORTH, a township and chapelry in the parish of Middleton and hundred of Salford, in the county of Lancaster. Pop. in 1841, 1598, and in 1851, 1781.

Ainsworth, *Dr Henry*, an eminent nonconformist divine, who about the year 1590 distinguished himself among the Brownists, which involved him in so much trouble that he was obliged to retire to Holland, and became minister of a church at Amsterdam. His skill in the Hebrew language, and his excellent Annotations on the Holy Scriptures, which are still highly esteemed, gained him great reputation. He also wrote several pieces in defence of the Brownists, and some other works.

Ainsworth, *Robert*, born at Woodyale in Lancashire in 1660, was master of a boarding-school at Bethnal Green, from whence he removed to Hackney, and to other places in the neighbourhood of London. After acquiring a moderate fortune, he retired, and lived privately to the time of his death, which happened in 1743. We are indebted to his industry for a Latin and English Dictionary, which has been much used in schools. It was first published in 1736, and was, after the author's death, enlarged by various hands to 2 vols. 4to, in which form it has been several times reprinted.

AINTAB, a large garrison town on the northern frontier of Syria, in the pashalic of Aleppo. Lat. 36. 58. N. Long. 37. 13. E., 65 miles north of Aleppo, 50 miles E. of Scanderoon, and 30 miles west of Bir on the Euphrates. Pop. 25,000 to 30,000.

AIR, in *Physics*. See ATMOSPHERE, METEOROLOGY, and PNEUMATICS.

AIR, in *Painting*, &c., denotes the manner and verisimilitude of action; or it is that which expresses the disposition of the agent. It is sometimes also used in a synonymous sense with gesture or attitude.

AIR, in *Music*. See MUSIC.

*AIR-Gun*, a pneumatic machine for propelling bullets, &c., with great violence. See PNEUMATICS.

*AIR-Jacket*, a sort of jacket formerly made of leather, in which were several bags or bladders, composed of the same material, communicating with each other. These were filled with air through a leather tube having a brass stop-cock accurately ground at the extremity, by which means the air blown in through the tube was confined in the bladders. The jacket is now superseded by a tubular belt of cloth, made air-tight by a solution of caoutchouc in naphtha, buckled round the breast, by the help of which the person is supported in the water, without making the efforts used in swimming.

*AIR-Pipes*. See VENTILATORS.

*AIR-Pump*, a machine by which the air contained in a proper vessel may be exhausted or drawn out. See PNEUMATICS.

*AIR-Shafts*, among *Miners*, denote holes or shafts descending from the open air to meet the adits and furnish fresh air. The damps, deficiency, and impurity of air which occur when adits are wrought 30 or 40 fathoms long, make it necessary to sink air-shafts, in order to give the air liberty to play through the whole work, and thus discharge vitiated air, and furnish good air for respiration: the expense of which shafts, on account of their great depths, hardness of the rock, drawing of water, &c., sometimes equals, nay, exceeds, the ordinary charge of the whole adit.

*AIR-Threads*, or *Air Gossamer*, a name given to the long filaments so frequently seen in autumn floating about in the air.

These threads are the work of spiders, especially of that species called the *aranea obtextrix*, which, having mounted to the summit of a bush or tree, darts from its tail several of these threads, till one is produced capable of supporting the creature in the air. On this it mounts in quest of prey, and frequently rises to a very considerable height.

*AIR-Vessels* are spiral ducts in the leaves, &c. of plants, supposed to be analogous to the lungs of animals, in supplying the different parts of a plant with air.

AIRANI, in *Church History*, an obscure sect of Arians in the fourth century, who denied the consubstantiality of the Holy Ghost with the Father and the Son. They are otherwise called *Airanists;* and are said to have taken their name from one *Airos*, who distinguished himself at the head of this party in the reigns of Valentinian and Gratian.

AIRDRIE, a thriving town of Lanarkshire, eleven miles east of Glasgow, and thirty-one from Edinburgh. Pop. in 1851, 14,435. The extensive coal and iron mines in the vicinity afford employment to a considerable part of its population, and have been the means of raising it, since the commencement of the century, from the insignificance of a village to its present prosperity. The town contains one principal street, from which others diverge, and is well-built, paved, and lighted with gas. It has a handsome town-hall with a spire and clock, three Established, and three Free Churches, an Independent, a Baptist, a Roman Catholic, and other places of public worship; three branch banks, a mechanics' institute, an academy, and other schools; a cotton factory, gas-works, iron-founderies, distilleries, breweries, &c. A considerable number of its inhabitants are also engaged in the weaving of cotton goods for the Glasgow manufacturers. By the Reform Act it was created a parliamentary borough; and it unites with Lanark, Hamilton, Linlithgow, and Falkirk, in sending a member to Parliament. The municipal government, under a charter dated 1833, is vested in a provost, three bailies, and twelve councillors. Airdrie is connected with Glasgow by railway, and also by the Monkland canal.

AIRE, a city of France, head of a canton of the same name, in the circle of St Omer, and department of Pas de Calais. It is situated on the river Lys. The population amounts to 5088 persons, who are chiefly employed in making cotton and woollen goods, hardware, and large quantities of oil from seeds. Long. 2. 24. E. Lat. 50. 38. N.

AIRE, a town of France, in the department of Landes, and circle of St Sever, on the river Adour. It was at one time the capital of the Visigoths, and has been since the fifth century the seat of a bishopric.

AIRE, a river of England in Yorkshire, one of the affluents of the Humber, from which it is navigable for a sloop of 100 tons as far up as Leeds, a distance of forty miles.

AIRY, or AERY, among *Sportsmen*, the nest of a hawk or eagle.

*AIRY Triplicity*, among *Astrologers*, denotes the three signs, Gemini, Libra, and Aquarius.

AISLE, in *Architecture*, is the term applied to the *wing* of a building; but it is chiefly used to designate the lateral divisions of a Gothic building divided by two longitudinal rows of piers. The space between these piers is sometimes inaccurately termed the *middle aisle;* but properly it is the *body* or middle of the nave, choir, or transept.

AISNE, a department in the north-east division of France, on a river of the same name, formed out of divisions of the ancient provinces of Picardy and Isle of France. It is bounded on the N. by the department of the Nord and the kingdom of the Netherlands, on the E. by the departments of the Ardennes and Marne, on the S. by the Marne and Seine-Marne, and on the W. by the Oise and Somme. The extent is 2812 square miles, or 1,799,680 acres. The whole department is a plain, with few hills of much elevation. The soil is generally calcareous, except in the northern part, where it becomes clayey, and in some spots slaty. It is of various degrees of fertility, but for the most part adapted to the growth of corn. Wine, cider, and flax, are the other agricultural products. The manufactures are cotton, linen, and hosiery. The department is divided into five arrondissements, 37 cantons, and 840 communes. Its population in 1851 was 558,989. The chief city of the department is Laon. St Gaubain is celebrated for its mirrors, which are the largest in the world; and Folembray is said to manufacture annually 8,000,000 of wine bottles. Both these towns are in the arrondissement of Laon.

AITOCZU, a considerable river of Lesser Asia, which rises in Mount Taurus, and falls into the south part of the Euxine Sea.

AITON, WILLIAM, an eminent botanist and gardener, was born at a village near Hamilton in Scotland in 1731. Having been regularly trained to the profession of a gardener, he travelled to England in the year 1754, and soon obtained the notice of the celebrated Philip Miller, then superintendent of the physic garden at Chelsea, who engaged him as an assistant. His industry and abilities recommended him to the princess-dowager of Wales as a fit person to manage the botanical garden at Kew. In 1759 he was appointed to this office, in which he continued during life, and which was the source of his fame and fortune. The garden at Kew, under the auspices of his Majesty George III., was destined to be the grand repository of all the vegetable riches which could be accumulated by regal munificence, from researches through every quarter of the globe. These treasures were fortunately committed to the hands of Mr Aiton, whose care and skill in their cultivation, and intelligence in their arrangement, acquired him high reputation among the lovers of the science, and the particular esteem of his royal patrons. Under his superintendence many improvements took place in the plan and edifices of Kew gardens, which rendered them the principal scene of botanical culture in the kingdom. In 1783 his merit was properly rewarded with the lucrative office of managing the pleasure and kitchen gardens of Kew, which he was allowed to retain with the botanical department. In 1789 he published his *Hortus Kewensis*, or a Catalogue of the Plants cultivated in the Royal Botanical Garden at Kew, in 3 vols. 8vo, with 13 plates; a work which had been the labour of many years. The number of species contained in this work amounted to between five and six thousand, many of which had not before been described. A new and curious article in it relates to the first introduction of particular exotics into the English gardens. The system of arrangement adopted is the Linnæan, with improvements, which the advanced state of botanical science required. Mr Aiton, with candour and modesty, acknowledges the assistance he received in this work from the two Swedish naturalists, Dr Solander and Mr Jonas Dryander. Indeed, his character was such as secured him the friendship and good offices of the most distinguished names in science of his time. He was for many years honoured with the friendship of Sir Joseph Banks, the president of the Royal Society. The *Hortus Kewensis* was received with avidity by the botanic world, and a large impression was soon disposed of. The best edition is in 5 vols.

Notwithstanding his great activity and temperance, Mr Aiton fell into that incurable malady, a scirrhous liver, of which he died in 1793, in his 62d year. His eldest son, devoted to the same pursuits, was, by the king's own nomination, appointed to all his father's employments. Mr Aiton's private character was highly estimable for mildness, benevolence, piety, and every domestic and social virtue. He was interred in the churchyard of Kew.

AIUS Locutius, the name of a deity to whom the Romans erected an altar. The following circumstance gave occasion to this. One M. Ceditius, a plebeian, acquainted the tribunes that, in walking the streets by night, he had heard a voice over the temple of Vesta announcing to the Romans that the Gauls were coming against them. The intimation was, however, neglected; but after the truth was confirmed by the event, Camillus acknowledged this voice to be a new deity, and erected an altar to it under the name of *Aius Locutius*.

AIX, an ancient city of France, the chief place of the arrondissement of the same name, in the department of the Mouths of the Rhone. It was, before the revolution of 1789, richly endowed with ecclesiastical establishments, which have since then been secularized. It stands on a plain surrounded by hills, which produce abundance of most excellent olives, which, with wine and fruits, form the most important branches of agricultural industry. There are manufactories of various rich silk goods, linen, and hardware. The ancient springs, known to the Romans, but disused till again discovered in 1704, are slightly warm, but their efficacy is not now highly valued. In 1846 the inhabitants amounted to 24,165. This city is celebrated for having given birth to two famous naturalists, Adanson and Tournefort, and to the painter Vanloo.

The arrondissement of the same name comprehends 846 square miles, or about 541,740 acres, divided into ten cantons and 59 communes, with, in 1846, 112,254 inhabitants.

Aix, a small island on the coast of France, between the isle of Oleron and the Continent. It is twelve miles north-west of Rochefort, and eleven south-south-west of Rochelle. Long. 1. 4. W. Lat. 46. 5. N.

Aix, a river of France, in the department of the Lower Loire, which joins the Ysable, and falls into the Loire.

AIX-LA-CHAPELLE, or in German Aachen, a district in the Prussian province of the Lower Rhine, with an area of 1600 square miles. It comprehends 10 circles, 15 cities, 12 market-towns, 789 villages, 65,401 dwelling-houses, and in 1849 contained 411,525 inhabitants, of whom 395,416 were Roman Catholics, 2685 Jews, and the remainder Protestants. The circle of the same name extends over 124 square miles, and has a population of 63,458.

Aix-la-Chapelle, the chief town of the district and circle of the same name, lies between the Rhine and the Meuse, in a pleasant valley surrounded by beautiful hills, about eighteen miles east of Mæstricht, and thirty-eight west of Cologne, with which last it is connected by railway. By the census of 1849 it had 3125 houses, 8869 families, and a population of 50,533, of whom 47,489 were Catholics, 2734 Protestants, and 310 Jews. It has a public library, a gymnasium, a school for artisans, a commercial school, a collection of models, and a picture gallery; and is the seat of a bishop, of a district court, a court of justice, and a commercial court. It is celebrated for its woollen manufactures, which give employment to many thousands, as also for its needle and pin works. It has also several tanworks, and a considerable trade, particularly in cloth and wool. Among the public buildings the most remarkable are the town-house, erected in 1353, on the site of Charlemagne's palace, in which the peace of 1748 was ratified, and in front of which, in the market-place, is a beautiful fountain; the cathedral, founded by Charlemagne, containing the marble seat on which the kings sat at their coronation, and many popish relics, which are only exhibited once in seven years, when great numbers of votaries resort to the city; and there is also an elegant theatre. Aix-la-Chapelle was for a long time the capital of the German empire, and the usual place of coronation. In 1668 and 1748 treaties of peace were concluded here; and from this town the celebrated congress of 1818 derives its name. This was the favourite residence of Charlemagne, and in the cathedral is his tomb. In the latter part of the last century it was opened, and his body, clothed in the imperial robes, was found seated on a throne of state. The whole crumbled into dust on being touched; but the diamond clasp that fastened his mantle is still preserved at Vienna.

Its thermal sulphureous baths are celebrated over Europe for the cure of rheumatic and arthritic pains. These waters have the high temperature of 136° Fahr., and contain 5·5 cubic inches of sulphuretted hydrogen per English pint. Aix-la-Chapelle is the Aquæ Sextiæ of the Romans.

AJACCIO, or Adjazzo, an arrondissement in the island and department of Corsica, in the Mediterranean, containing 12 cantons and 72 communes, with 53,463 inhabitants. Its extent is 736 square miles, or 471,000 English acres. The capital, which bears the same name, and is the best built town in the island, is situated in a fertile territory, which produces excellent wines. It has a small citadel and an excellent harbour, and contains 10,460 inhabitants. It is celebrated as the birthplace of Napoleon Bonaparte, to whose memory a column has been here erected.

AJALON, in *Ancient Geography*, a Levitical city of the tribe of Dan, in the valley of which Joshua commanded the moon to stand still. The site of Ajalon is occupied by the modern village of Yâlo.

AJAN, a maritime country of Africa on its eastern coast, extending from Cape Guardafui to Zanguebar, between Lat. 4° to 11° N. It abounds with all the necessaries of life, and produces a very good breed of horses. The whole sea-coast, from Zanguebar to the strait of Babelmandeb, is called the coast of Ajan; and a considerable part of it is styled the Desert coast.

AJAX, the son of Telamon, king of Salamis, was, next to Achilles, the most valiant of the Grecian generals at the siege of Troy. He performed many great actions, and proved himself no mean match for Hector in single combat. When the arms of Achilles were adjudged by Agamemnon to Ulysses, Ajax was so transported with rage and jealousy that he lost his senses. In his madness he fell upon the sheep in the Grecian camp, among which he committed great slaughter. On coming to his senses he was so overcome with shame that he killed himself with the sword which had been given to him by Hector. The Greeks paid great honour to him after his death, and erected a magnificent monument to his memory upon the promontory of Rhetium.—Iliad, Dictys. Cret., Ovid. Met., B. xiii.

AJAX, surnamed *Oïleus*, and the *Lesser* (to distinguish him from the former), the son of Oïleus, king of the Locrians, was one of the principal heroes at the siege of Troy. He is said, after the taking of Troy, to have ravished Cassandra the daughter of Priam, in the temple of Minerva, whither she had fled for refuge. On his return home he was shipwrecked and perished on the coast of Eubœa. Philostratus records of him that he had a tame serpent 5 cubits in length, which ate at his table, and followed him like a dog. The Locrians held the memory of Ajax in great veneration and honoured him in some degree as a tutelar deity.

AJAX, in *Grecian Antiquity*, a furious kind of dance, intended to represent the madness of the hero of that name after his defeat by Ulysses, to whom the Greeks had given the preference in his contest for Achilles's arms. Lucian, in his treatise of Dancing, speaks of dancing the *Ajax*.—There was also an annual feast called *Ajantia*, Αιαντεια, consecrated to that prince, and observed with great solemnity in the island of Salamis, as well as in Attica; where, in memory of the valour of Ajax, a bier was exposed, set out with a complete set of armour.

AJMERE, the ancient appellation of the whole of Rajpootana, but more recently restricted to the limits of a British district in the centre of that province. It is bounded on the N.W. by the Rajpoot state of Joudpore; on the east by the Rajpoot states of Kishenghur and Jeypore; on the south by that of Odeypore; and on the S.W. by the British district of Mhairwarra. It extends from Lat. 25. 43. to Lat. 26. 42, and from Long. 74. 22. to Long. 75. 33, and has an area of 2029 square miles. In the north and north-west portions of the district, the mountains attain considerable elevation. Taraghur, immediately overlooking the town of Ajmere, rises a thousand feet from the plain below, and three thousand above the level of the sea. Its principal summit sustains the celebrated fort of Ajmere. The Mudar range, east of the city, is little inferior in elevation. In their geological character, the rocks composing these ridges bear a near resemblance to each other, all being of primitive formation, and generally schistose.

Copper mines have been worked on Taraghur, and lead, manganese, and iron, are discovered in abundance. The soil is, for the most part, light and sandy, and in many localities impregnated with mineral salts. The only stream which has any pretension to be styled a river is the Kharee Nuddee. This river skirts the district to the south, separating it from the native state of Odeypore, and subsequently intersects the territory of Ajmere in a north-easterly direction to its confluence with the Banas; but its waters are unpalatable, except during the rains, in consequence of the quantity of carbonate of soda which they hold in solution. The other streams of Ajmere, including even the Looni, which derives its source from the Ana Sagur Lake, may be characterised rather as rain torrents, their channels being completely devoid of water during the dry season. Nor is the dearth of running water compensated by any abundant supply from springs; no natural lakes exist in the province; and as the wet season is of brief duration, there are no means by which an adequate supply of water can be secured to the inhabitants, but by the aid of tanks, which are filled by the mountain torrents during the rains. These abound in every village. Some of these reservoirs are of considerable magnitude, and one, indeed, the Ana Sagur, is deserving of special notice from its enormous dimensions. This artificial lake is in the immediate vicinity of the town, and owes its construction to Ana Rao, who ruled in Ajmere prior to the invasion of Mahmood of Ghuzni at the commencement of the eleventh century. The excavation is, however, rather the work of nature than of art, and required nothing for its completion as a reservoir but the erection of a dam across a valley bounded on all other sides by steep ridges. The waters of several rain torrents are thus collected into this vast basin; the extent of which, after the rains, exceeds six miles in circumference. It furnishes the means of irrigation to a large district on its banks, is full of fish, and affords excellent water to the inhabitants of the town.

The climate of Ajmere, though characterised by great aridity, is considered salubrious. During the season of the hot winds which prevail from March to June, the temperature is high and the heat oppressive. In the month of May in the year 1838, the thermometer marked during the night 110 degrees. The temperature might be diminished by encouraging the growth of trees. The hills are now bare of timber. Formerly extensive tracts were covered by forests and brushwood, but these were destroyed during Mahratta rule. Refreshing breezes set in with the rains, which continue from June till the end of September; but the showers are lighter and far less continuous than in tracts further to the south and east. After the rains, the climate becomes agreeable and invigorating, and in the clear nights of December, January, and February, the thermometer sinks below the freezing point, and ice is abundantly formed.

Ajmere is scarcely mentioned in history prior to the establishment of the dynasty of Ghuzni in Cabul. It appears, however, to have enjoyed an early independence, as the eighth prince in succession from its founder is represented as having reigned in the year 695. The earliest incursion of the Mahometans into India took place in 664; it was followed from time to time by successive irruptions; until in 997 the Hindu Rajah of Lahore became in his turn the assailant, and led an army through Peshawur into Cabul. He was met by Sebektegin, the father of Mahmood of Ghuzni; but before any encounter had taken place, the Hindu became disheartened, acceded to humiliating conditions, and withdrew. In the following year, Sebektegin advanced to Lahore to enforce the fulfilment of the treaty; and among the princes who united their forces to resist the Mussulman, was the Rajah of Ajmere. The confederated forces were totally routed. Three years later, in Mahmood's first expedition to India, the sultan encountered the old Rajah of Lahore, whom he defeated and took prisoner. After this, Mahmood allowed little repose to himself, or respite to his neighbours. In the tenth year of his reign, he undertook his fourth expedition against India. The princes of Hindustan, instigated by Anang Pal, the Rajah of Lahore, combined their forces, and advanced to the Punjaub, to resist the progress of the Mahometan arms. The Rajah of Ajmere had again joined the confederacy, but their renewed efforts were ineffectual, and Mahmood was again victorious. The part taken by the Rajah of Ajmere was not, however, forgotten by Mahmood; and in his last irruption into Hindustan, which was directed against the temple of Somnath, he marched his troops through the province of Ajmere, ravaged the country, and plundered the city. The Rajah took refuge in his fortress, and Mahmood pursued his course to Somnath. Thenceforward the power and resources of the Rajahs of Ajmere rapidly increased, and half a century later, their possessions constituted one of the four kingdoms into which Hindustan was then distributed. The three remaining kingdoms were those of Delhi, Canouj, and Guzerat; but the king of Delhi dying without male issue, his dominions lapsed to Pritwi Rao, the chief of Ajmere, who thus held sway over the half of India. Pritwi Rao, however, had no sooner gained this accession of power, than a new competitor presented himself for the imperial sceptre. This was Shahabudin, afterwards Mohammed Ghoory. In 1191 he had conquered the Punjaub, and threatened an advance upon Delhi. Pritwi Rao was not unprepared for the struggle. The two armies met at Tirouri, near Thanesur in Northern India, where a decisive battle was fought, in which the Hindu potentate prevailed, and the rout of Mohammed was complete. Pritwi Rao derived from this victory but a brief interval of repose. Mohammed reunited his army, and two years after reappeared at Thanesur, to try once again the chances of battle. Upon this occasion, fortune favoured Mohammed, and Pritwi Rao, being taken prisoner, was put to death. The conquest of Ajmere followed. Mohammed left his new possessions in charge of his general Kootb-ood-deen, who, upon the dissolution of the Ghorian empire, raised himself to the throne of Delhi, and established the line of SLAVE KINGS of India; so called from their founder having risen from the condition of a Turkistan slave to sovereignty. From this time Ajmere appears to have remained for a considerable period in various degrees of dependence upon the Mahometans. It was wrested in 1527 by Baber from Rajah Sanga, who had aspired to independence. Acbar, in recovering the dominions of which his father had been stripped by Shir Shah, obtained Ajmere without a battle, and under this emperor it became the principal place of an extensive province. On the decline of the Mogul empire, Ajmere fell into the hands of the Mahrattas, who retained it from the middle of the last century until the year 1818, when it was formally ceded to the British government by Scindia. The district of Ajmere has been distributed into ten subdivisions, and has a population of 224,891 inhabitants. The principal places are Ajmere, Kekree, Poshkur, Pesangun, Shapoora, Sawur, and the military cantonment of Nusseerabad.

AJMERE, a city of Hindustan, in the district of the same name, situate on the slope of a hill, and surrounded by a wall of stone. It was nearly ruined in the long period of anarchy and misgovernment which prevailed in Central India prior to 1818; but since its acquisition by the British, it has greatly improved. Bishop Heber, who visited it in 1825, describes it as a well-built town of moderate size. Its principal streets are broad and convenient, and among the mansions more recently erected, some are stated to have been constructed upon so grand a scale as to form imposing objects even from the outside of the city walls. Above, on the mountain top, is a very remarkable fortress called Taraghur, nearly two miles in circuit, but of irregular shape and surface. It consists of a plain stone wall along the edge of a mountain, strengthened with a few round bastions; and it has an abundant supply of good water in all seasons from cisterns cut in the rock. The fortress was dismantled in 1830, and the works are going to decay. The most beautiful of the buildings of Ajmere is an antique Jain temple on the lower part of the mountain Taraghur. Though much injured by time, or by the hands of the Mussulmans, the relics are not excelled in beauty of architecture and sculpture by any remains of Hindu art. The columns supporting the roof are forty in number; but no two are alike, and great fertility of invention, as well as much taste, is manifested in the execution of the ornaments. The portion of this building which has survived the attacks of time or hostile feeling, has been converted into a mosque. Ajmere is renowned as a place of pilgrimage, the great attraction being the tomb of Khoja-Moyen-ud-Deen, famed as a great Mahometan saint, whose miracles are celebrated all over India. The tomb is of white marble, but remarkable neither for style nor beauty of architecture. To this place the emperor Acbar made a pilgrimage on foot from Agra, a distance of upwards of 200 miles, to implore at the sainted tomb the blessing of male offspring. Outside the city wall is the ruinous palace of Shah Jehan, and another of Acbar, now converted into an arsenal. In 1849 a school having an English department was opened, but the results have not yet been reported. The town is well supplied with water from the Ana Sagur Lake; its population in 1837 was estimated at 23,000 inhabitants, and is believed to be progressively improving. Ajmere is distant from Delhi 258 miles; from Calcutta 1039. Lat. 26. 29. Long. 74. 43. (E. T.)

AJOFRIN, a town of Spain, nine miles south of Toledo, with a pop. of 2883, principally employed in the making of coarse cloth, blankets, serge, and matting.

AKABAH. This gulf, the *Sinus Elanites* of antiquity, is the eastern estuary at the upper extremity of the Red Sea, extending N.N.E. from Lat. 28. to 29. 32. N., a distance of about 100 miles, and varying from about 12 to 17 miles in breadth. The navigation is rendered dangerous by the number of coral reefs, and the heavy squalls that sweep from the adjacent mountains, many of which rise perpendicularly to the height of 2000 feet. Tiran, and several other small islands, lie at its mouth. Its only well-sheltered harbour at the present day, according to Lieut. Wellsted, is that of Meenap-el-Dsahâle, or the Golden Port (so called from the colour of its sand) on the western shore, nearly opposite to Mount Sinai. The castle of Akabâh, which stands about $2\frac{1}{2}$ miles from the head of the gulf, on the east side, 150 yards from the beach, is a massive bastioned quadrangle, erected by the Sultan el-Ghûry of Egypt in the sixteenth century, and is situated, as its Arabic name imports, on a steep declivity, in Lat. 29. 30. 58. N. Long. 35. 0. 54. E. It is surrounded with groves of the date-palm, and immediately behind it rises the lofty Jebel el-Ashhab. A few soldiers garrison the castle, which serves as a depôt to supply provisions to the troops and the Hajj Caravan in its progress from Cairo to Mecca. Within its walls are several Arab dwellings, and deep wells of good water. Fresh water is also obtained on the shore by digging a little way into the sand. The adjacent plain is rich in pasturage, though near the sea it is strongly impregnated with salt. The fierce predatory character of the neighbouring Bedouins is a serious impediment to travellers.

Though now a place of little importance, Akabâh is not devoid of historical interest: it is supposed to occupy the site of the Elath of Scripture, from which an extensive commerce was carried on in remote ages with Rhinocolura, now *El Arish*, on the Mediterranean, 116 miles distant. It was the Aila or Elana of the Romans; and during the Crusades it was taken by the Christians, and again wrested from them by Saladin, through means of ships transported on camels from Cairo. Midway between Akabâh and Kaszer el-Bedawy (a dilapidated castle standing southward one hour's journey on the east side of the gulf) there are ruins in the sea, consisting of houses, walls, and columns, visible only at low water, and rendered difficult of access by the shallows. They are supposed to be the remains of the Scripture Eziongeber "which is beside Eloth," where king Solomon made a navy of ships, which brought gold from Ophir (1 Kings ix. 26, 28; 2 Chron. viii. 17), and was probably the port to which his fleet returned from Tarshish once every three years, bringing "gold and silver, ivory, and apes, and peacocks." (2 Chron. ix. 21.) The mention of peacocks would seem to indicate that Tarshish was some part of the coast of India, as this bird is indigenous to that country: and it may likewise be inferred, from several other passages, that the Israelites were not a maritime people, as Solomon's ships, we are told, were manned by Hiram with Tyrian sailors. The "Akrabbim" (*i. e. steep of scorpions*), mentioned in Numbers xxxiv. 4, is supposed by Burckhardt to be the acclivity of the mountain-chain westward from the plain of Akabáh.—Burckhardt's *Travels in Syria:* Robinson's *Biblical Researches in Palestine:* Wellsted's *Travels in Arabia.*

AKEN, a Prussian town in the government of Magdeburg on the Elbe. Its chief manufactures are cloth, leather, and tobacco. Pop. in 1849, 4685.

AKENSIDE, Mark, was of respectable though humble parentage, his father being a butcher in Newcastle-upon-Tyne, where the poet was born on the 9th November 1721. His parents intended him for the Dissenting Church, and from an educational fund connected with his denomination, he received aid to prosecute the necessary studies at the university of Edinburgh. Subsequent reflection directed his aims to the study of medicine, and he afterwards honourably repaid to his denomination the sum which he had not devoted to the purpose for which it was bestowed. In 1741 he went to Leyden, to complete his medical curriculum. There he acquired the friendship of his afterwards munificent patron, Jeremiah Dyson, Esq. He received his degree of Doctor of Physic, and returning to England in 1744, published his *Pleasures of Imagination*, which was received with unbounded applause. He settled as a physician at Northampton, but found the field already pre-occupied. "Akenside tried the contest a while," says Johnson, "but, having deafened the place with clamours of liberty, he removed to Hampstead, and subsequently fixed himself in London, the proper place for a man of accomplishments like his." As medicine did not seem likely to earn for him the maintenance of a gentleman, his generous friend Mr Dyson, with whom he resided, settled on him an annuity of L.300 a-year. He used every means, however, of advancing his reputation in his profession, by the publication of medical treatises, by obtaining a degree from Cambridge, by becoming a member of the Royal Society, and of the College of Physicians; and by the acceptance of public lectureships. "He advanced gradually in medical reputation, but never attained to any great extent of practice, or eminence of popularity." Sir John Hawkins alleges that he defeated his own efforts by "the high opinion he everywhere manifested of himself, and the little condescension he showed to men of inferior endowments." He was certainly a man of solid ability and extensive scholarship, but the warmth of his temperament intensified his vanity and arrogance to a ludicrous extent, and often placed him in mortifying circumstances. The humbleness of his birth was a thorn in his flesh, which his opponents loved to irritate. His manners were formal and strainedly dignified. He was a brilliant and pleasing companion, but exacting and pedantic in conversation. In Smollett's *Peregrine Pickle* Akenside is the ode-writing doctor who gives the feast after the manner of the ancients. His features were manly and expressive; his temper, though irritable, was kind and benevolent. He continued to write and wrangle amidst the literary society of London till the year 1770, when he died of a putrid fever, while he was engaged in re-casting his great poem; bequeathing to his patron Dyson the office of his literary executor. He is buried in the parish church of St James's, Westminster.

The *Pleasures of Imagination* is certainly a remarkable effort of a young man between twenty and twenty-three years of age; though it cannot compare in profoundness of reflection with Pope's *Essay on Man*, nor in simple warmth of natural feeling with Campbell's *Pleasures of Hope*, both composed at the same period of life. Its design, as he himself explains, is "to give a view of these (pleasures), in the largest acceptation of the term; so that whatever our imagination feels from the agreeable appearances of nature, and all the various entertainment we meet with, either in poetry, painting, music, or any of the elegant arts, might be deducible from one or other of those principles in the constitution of the human mind, which are here established and explained." The poem has the fault of youth, in diffuseness and obscurity of expression in a train of subtle thinking; but its effect is brilliant and spirit-stirring; it is full of aspirations after the lofty, the liberal, and the good, and is coloured with the Attic graces resulting from a warm sympathy with the Grecian spirit. Of its philosophy the poet Gray speaks contemptuously as "infected with the Hutcheson jargon." Dr Thomas Brown has largely used its pictorial portions as illustrations in his ethical lectures. Of its poetry Johnson remarks that "his images are forms fantastically lost under a superfluity of dress.

"Pars minima est ipsa puella sui.

The words are multiplied till the sense is hardly perceived; attention deserts the mind and settles in the ear. The reader wanders through the gay diffusion, sometimes amazed, sometimes delighted, but after many turnings in the flowery labyrinth, comes out as he went in. He observed little, and laid hold of nothing." The following is Professor Spalding's estimate: "A vivid fancy, a warm susceptibility of fine emotion, and an alluring pomp of language, are lavished on a series of pictures, illustrating the feelings of beauty and sublimity. The mischief is, that the poet, theorizing and poetizing by turns, loses his hold of his readers more than other writers whose topics are less abstract. The philosophical thinker finds better teaching elsewhere; and the poetical student, unless he is also metaphysically inclined, has his enthusiasm chilled by the intrusive dissertations."—*History of English Literature.*

Akenside's profusion of odes, hymns, epistles, and inscriptions, follow the artificial fashion of the eighteenth century. Most of these possess no great merit, but Johnson's condemnation of them appears too severe. This may possibly be in part owing to the spirit of freedom many of them breathe. For in his "hot youth," Akenside was a theoretical republican, and he continued throughout life a Whig, so far as the term implies what we understand by liberal principles. "Whether, when he resolved not to be a Dissenting minister," says Johnson, in speaking of Akenside's politics, "he ceased to be a Dissenter, I know not. He certainly retained an unnecessary and outrageous zeal for what he called and thought liberty; a zeal which sometimes disguises from the world, and not rarely from the mind which it possesses, an envious desire of plundering wealth, or of degrading greatness." The *Epistle to Curio*, which he afterwards spoiled by converting it into the *Ode to Curio*, is a bitter stricture on Pulteney's desertion of his principles after the fall of Walpole. The *Hymn to the Naiads*, and the *Hymn to Science*, are perhaps the finest of Akenside's minor works.

The *Pleasures of Imagination*, his capital work, was first published in 1744. Extraordinary though it was, as the production of a man who had not reached his 23d year, he was afterwards sensible that it wanted revision and correction;

and he went on revising and correcting it for several years; but finding this task to grow upon his hands, and despairing of ever executing it to his own satisfaction, he abandoned the purpose of correcting, and resolved to write the poem over anew upon a somewhat different and enlarged plan. He finished two books of his new poem, a few copies of which were printed for the use of the author and certain friends; of the first book in 1757, of the second in 1765. He finished also a good part of a third book, and an introduction to a fourth; but his most munificent and excellent friend, conceiving all that was executed of the new work too inconsiderable to supply the place and supersede the republication of the original poem, and yet too valuable to be withheld from the public, caused them both to be inserted in the collection of his poems. (D. S.)

AKERBLAD, Jan David, a learned Swede, who greatly distinguished himself by his profound researches in Runic, Coptic, Phœnician, and ancient Egyptian literature. His researches on the hieroglyphics of the latter are held in much estimation. After having travelled much in the east, he retired to Rome, where he had a pension from the late Duchess of Devonshire, and died there, in the prime of life, in 1819.

AKERMAN, a circle in the Russian province of Bessarabia, extending along the banks of the Black Sea, where the Dneister forms an estuary. It is nearly destitute of population, except the capital, of the same name, which is built on a tongue of land projecting into the estuary. It is the ancient Roman colony of Alba Julia. It is surrounded with strong walls and ditches, contains a castle, two public baths, five churches, several mosques, and a synagogue for Jews. The population, of various nations, religions, and languages, amounts to about 25,000. Its situation renders it a place of considerable trade. It is in Long. 30. 24. 15. E. and Lat. 46. 11. 45. N. Here the treaty with Turkey was concluded in 1826.

AKHALIES, a class of religious warriors among the Sikhs, and the most dissolute and most turbulent members of the Sikh community. They are both fanatics and fatalists, and admit proselytes from the lowest dregs of society. They acknowledge no God, but make fate the cause of all things.

AKHALZIKE, a fortress on the south-west frontier of Russian Georgia, formerly the capital of a Turkish pashalic. Lat. 41. 35. N. Long. 42. 45. E. The adjoining town is supposed to have a population of 15,000. The neighbourhood produces silk, honey, and wax, with excellent raisins, peaches, apricots, figs, and other fruits.

AKHALZIKH, or Akiska, a city of Georgia, in Asiatic Russia, on an affluent of the Kur, 110 miles west of Tiflis. Lat. 41. 40. N. Long. 43. 1. E. It was formerly the capital of a pashalic, and carried on an active trade in white slaves, now entirely suppressed. It has a strong castle, a college, and library, a fine mosque, and a considerable trade in silk, honey, and wax. Pop. about 12,000.

AKHBAR, or Ukhbar, called also Acbar or Acber, or Akbar or Akber, the greatest and the best of the Mogul emperors of Hindustan, was the son of Humayun, the son of Baber, the founder of the empire. He was born at the foot of Anercote, in the desert of Sinde, on 14th October 1542; ascended the throne 15th February 1556, and died at Agra, 13th October 1605, after a chequered, but generally prosperous, reign of nearly fifty years. He established his dominion over all Hindustan, or Northern India, and was, in fact, the real founder of the empire; his two predecessors having commenced the conquest of India without complete success, and Humayun having lost nearly all that his father had gained. Although almost continually occupied with enemies abroad, and rebellions and revolutions at home, he found time to cultivate the arts of peace, and gave the most anxious and most enlightened attention to every-

thing that seemed calculated to promote the welfare of his people. He encouraged trade and commerce, reduced taxation, and kept a strict watch over the conduct of his officers. But what most of all distinguished him from other Mahometan rulers was his spirit of toleration. Professing no dogmatic faith himself, he not only did not persecute the adherents of any creed, but showed the same benevolent attention to the interests of all his subjects, whether Moslem or Hindu. The mildness of his character, his strict impartiality, magnanimity, and personal courage, are mentioned with praise even by the Jesuits, who visited India during his reign; and the memory of his good qualities and deeds still lives among the people of Hindustan. His body was deposited in a splendid mausoleum, which remains entire at Secundra, a ruinous village six miles north of Agra; and is considered to be one of the finest architectural monuments of India, inferior only to the Taj-Mehal at Agra. It is built of red stone, and consists of several tiers of arcades and galleries, on the top of which is a small platform, surrounded by a marble screen richly carved, and affording an extremely fine view of the surrounding country. In the centre of the platform is Akbar's monument, of white marble, with these words:—"*The god Akbar, may his glory be magnified*;" an inscription that is thought to countenance the charge made against him, that he had aspired to divine honours. The body reposes in a plain sarcophagus, under a lofty dome, on the ground floor. See Abulfazl.

AKHISSAR, the ancient Thyatira, a city of Natolia, in Asia, situate in a plain 18 miles broad, which produces plenty of cotton and grain. The inhabitants, who are reckoned to be about 8000, are Greeks, Armenians, and Turks. The houses are built of earth or turf dried in the sun, and are very low and ill constructed; but there are six or seven mosques which are all of marble. There are remarkable inscriptions on marble in several parts of the town, which are part of the ruins of the ancient Thyatira. It is on a branch of the river Hermus, 50 miles from Pergamos. Long. 28. 30. E. Lat. 38. 50. N.

AKHMETSCHET. See Simferopol.

AKHTIAR. See Sevastopol.

AKIBA, a famous rabbi, flourished a little after the destruction of Jerusalem by Titus. He kept the flocks of a rich citizen of Jerusalem till the fortieth year of his age, and then devoted himself to study in the academies for twenty-four years; and was afterwards one of the greatest masters in Israel. According to the Jewish accounts, he had 24,000 scholars. He declared for the impostor Barcochebas, whom he owned as the Messiah; and not only anointed him king, but took upon himself the office of his master of the horse. The troops which the emperor Hadrian sent against the Jews, who, under the conduct of this false Messiah, had committed horrid massacres, exterminated this faction. Akiba was taken, and put to death with great cruelty. He lived 120 years, and was buried with his wife in a cave upon a mountain not far from Tiberias. According to tradition, his 24,000 scholars were buried around bim. It is said that he invented a supposititious work under the name of the patriarch Abraham.

AKOND, an officer of justice in Persia, who takes cognisance of the causes of orphans and widows, of contracts, and other civil concerns. He is the head of the school of law, and gives lectures to all the subaltern officers. He has his deputies in all the courts of the kingdom, who, with the second *sadra*, make all contracts.

AKYAB, a town and seaport of Arracan, in the East Indies, situate on the eastern side of the island of the same name, and at the mouth of the river Kuladyne. Previous to its occupation by the British, in 1826, Akyab was a petty village, consisting of a few fishermen's huts; but since that period it has gradually increased in importance, and has now become the most flourishing place of the province. The town is regularly built, with broad streets running at right angles to each other; the houses are spacious and substantial, and the shops are said to be well supplied with native goods and British manufactures. Rice is the principal article of export; and so abundant is the supply, that Akyab is called the granary of Arracan. The harbour, though inferior to that of Khyouk Phyoo, has the advantage of being surrounded by a fertile tract of vast extent, and of communicating with the rivers which form the outlets for the export of the surplus produce of the province. The soil of the island is of a sandy description, which soon becomes dry after rain, and the atmosphere is consequently devoid of that humidity to which the interior of the province is subject; and the heat which there is found so oppressive is here tempered by refreshing sea-breezes. The population of the town in 1841 amounted to 5000. Akyab was ceded to the British by the Burmese, under the provisions of the treaty concluded at Yandaboo on the 24th February 1826. Lat. 20. 9. Long. 92. 56. (E. T.)

AL, an Arabic particle prefixed to words, and signifying much the same with the English particle *the*. Thus they say, alkermes, alkoran, &c., *i. e.* the kermes, the koran, &c.

AL, or ALD, a Saxon term, frequently prefixed to the names of places, denoting their antiquity; as, Aldborough, Aldgate, &c.

ALA, a Latin term, properly signifying a wing; from a resemblance to which several other things are called by the same name. Thus,

ALA is a term used by botanists for the hollow of a stalk, which either the leaf or the pedicle of the leaf makes with it; or it is that hollow turning, or sinus, placed between the stalk or branch of a plant and the leaf, whence a new offspring usually issues. Sometimes it is used for those parts of leaves otherwise called *lobes* or *wings*.

ALÆ, the plural number, is used to signify those petals or leaves of papilionaceous flowers placed between those others which are called the *vexillum* and *carina*, and which make the top and bottom of the flowers. Instances of flowers of this structure are seen in those of pease and beans, in which the top leaf or petal is the vexillum, the bottom the carina, and the side ones the alæ.

ALÆ is also used for those extremely slender and membranaceous parts of some seeds which appear as wings placed on them. It likewise signifies those membranaceous expansions running along the stems of some plants, which are therefore called *alated stalks*.

ALÆ, in *Anatomy*, a term applied to the lobes of the liver, the cartilages of the nostrils, &c.

ALÆ, in the *Roman Art of War*, were the two wings or extreme parts of the army drawn up in order of battle.

ALABAMA, one of the United States of North America, lying between Lat. 30. and 35. N. and Long. 85. and 88. W. It is bounded by Florida and the Gulf of Mexico on the south, the state of Mississippi on the west, Tennessee on the north, and Georgia on the east. Its length is 330 miles, breadth 174, and area 50,722 square miles. The country, to the extent of more than 50 miles from the coast, consists of uneven lands, of a poor sandy soil, bearing little except pines, but interspersed with marshes and alluvial tracts on the sides of the streams, which are extremely fertile. Higher up, the country becomes fertile and beautiful, and it bears that aspect as far as the mountains occupying the northern part of the state. These mountains are about 50 miles in breadth, and are supposed to exceed 1500 feet in height, but have peaks rising much higher. They are covered with a stony soil, but on their southern side are many rich and beautiful valleys, clothed with forests of oak, hickory, walnut, gum, and maple. The country abounds in coal and iron ore, with numerous marble and hard and soft limestone quarries. The climate in the southern and low-lying parts of the country is very warm, but in the more elevated parts mild and salubrious. Its principal river, the Alabama, is formed by the junction of the Coosa and the Tallapoosa, and flowing S.S.W., unites with the Tombeckbee, 45 miles above Mobile Bay, to form the river Mobile. The population of this state has rapidly increased during the last forty years, being in 1810 only 20,845, and in 1850, 779,001; of whom 344,323 were slaves. Its commercial prosperity has fully kept pace with the increase of its population; for in the year ending 30th June 1851, the value of its exports amounted to $18,528,824, being greater than that of any of the other states, with the exception of New York and Louisiana. Its imports for the same period amounted to $413,446. The following are the principal of its agricultural productions for the year 1850:—560,360 bales of ginned cotton; 637,829 lb. of wool; 292,429 bushels of wheat; 28,485,966 bushels of Indian corn; 163,605 lb. of tobacco; 3,961,592 lb. of butter; 30,423 lb. of cheese; and 31,801 tons of hay. In the same year the quantity of improved land amounted to 4,387,088 acres; the value of its farming implements and machinery was $5,066,814; and of its live stock $31,558,686. It enjoys great facilities for commerce from its rivers being navigable to a great distance from the sea, as also from its railroads, of which, in January 1852, 121 miles were open, and 190 miles in progress; and besides these, it has 52 miles of canals. Several large cotton factories have been established, and the people are now beginning to direct their attention to the mineral wealth of the country: coal-mining is carried on to a considerable extent, and several iron forges have recently been erected. The facilities presented for shipbuilding are likewise beginning to attract notice. By the last census (1850) the representative population was 631,272, who send seven members to Congress. The government is vested in a governor, senate, and house of representatives, who meet biennially at Montgomery. The senate consists of 33 members, elected for four years, one-half going out every two years: the house of representatives consists of 100 members elected for two years. The members of both houses receive $4 a-day each, and the governor has a salary of $2500. In 1847, the public records and offices were removed from Tuscaloosa to Montgomery, where the meetings of the legislature are now held. The Capitol was destroyed by fire in 1849, but another has been erected on its site, completed in November 1851. The judges of the supreme and chancery courts are elected by the joint vote of both houses of the General Assembly for a period of six years: and by an amendment in the jurisdiction ratified in January 1850, the people elect the judges of the circuit courts for a similar period. The jurisdiction of the circuit courts extends to all civil and criminal causes in the state, and that of the supreme court to hearing and deciding in appeals from the inferior courts. A well-endowed university has been founded at Tuscaloosa, and there is also a Baptist, a Catholic, and a Methodist college. This state is divided into fifty-three counties. It was admitted into the Union as an independent state, by an act of Congress in 1819.

ALABARCHA, in *Antiquity*, a kind of magistrate among the Jews of Alexandria, whom the emperor allowed them to elect, for the superintendence of their policy, and the decision of differences and disputes.

ALABASTER, WILLIAM, an English divine, was born at Hadley, in the county of Suffolk. He was one of the doctors of Trinity College in Cambridge; and attended the Earl of Essex as his chaplain in the expedition to Cadiz in the reign of Queen Elizabeth. Apparently from pique at not being advanced in the English Church according to his own estimation of his merits, he there joined the Romish communion. Disappointed, however, in his expectations, he returned to England in order to resume his former religion. He obtained a prebend in the cathedral of St Paul, and after that the rectory of Therfield in Hertfordshire. He was well skilled in the Hebrew tongue; but wasted his ingenuity in the study of the Cabala, as is testified by his theological writings. He was also a poet, and is honoured with the praises of Spenser and Herrick. He died in the year 1640.

Alabaster, in *Natural History*, a mineral substance whose base is calcareous earth. It differs from marble in being combined, not with the carbonic, but with the sulphuric acid. The *oriental alabaster* of the antiquary and sculptor is a fibrous carbonate of lime.

Alabaster, in *Antiquity*, a term used for a vase wherein odoriferous liquors were anciently put. The reason of the denomination is that vessels for this purpose were frequently made of the alabaster stone, which Pliny and other ancients represent as peculiarly proper for this purpose.

Alabaster is also said to have been used for an ancient liquid measure, containing ten ounces of wine, or nine of oil. In this sense the alabaster was equal to half the sextary.

ALABASTRUM Dendroide, a kind of laminated alabaster, beautifully variegated with the figures of shrubs, trees, &c., and found in great abundance in the province of Hohenstein.

ALACRANES, a reef or shoal in the Gulf of Mexico, off the north coast of Yucatan, from which it is 80 miles distant. It extends 14 miles from N. to S., and 11 from E. to W. On the south side there is a secure harbour, well sheltered by dry reefs. On the 12th of February 1847, the mail steamship Tweed was wrecked on this reef; and in January 1849 a similar disaster befell the Forth, another steamer belonging to the same company. Lat. of the port, 22. 23. 6. N. Long. 89. 49. W.

ALADINISTS, a sect among the Mahometans, answering to freethinkers among us.

ALADSCHAHISSAR, a Turkish pashalic (Sandschah), part of the ancient Bulgaria, a mountainous district, in which the river Moravia rises in two branches, and runs into the Danube. It extends from Long. 21. 45. to 22. 30. E. and from Lat. 42. 30. to 43. 20. N. The great road from Belgrade passes through the northern part of the province. It is productive of wine, feeds much cattle, and has some rivers near Camplina. The capital, of the same name, sometimes called Krusechevarz, is the seat of a Greek bishop, and has a castle, once the residence of the predatory chief Von Serf, and wrested from him by the Sultan Murad the Second. It is near the east bank of the river Moravia.

ALADULIA, or Adadeul, a considerable province of Turkey in Asia, in that part called Natolia, between the mountains of Antitaurus, which separate it from Amasia on the north, and from Caramania on the west. It has the Mediterranean Sea on the south; and the Euphrates divides it on the east from Diarbekir. It comprehends the Lesser Armenia of the ancients, and the east part of Cilicia. Formerly it had kings of its own; but the head of the last king was cut off by Selim I. emperor of the Turks, who had conquered the country. It is now divided into two parts: the north, comprehended between Taurus, Antitaurus, and the Euphrates, is a beglerbeglie, which bears the name of Marash, the capital town; and the south, seated between Mount Taurus and the Mediterranean, is united to the beglerbeglie of Aleppo. The country is rough, rugged, and mountainous; yet there are good pastures, and plenty of horses and camels. The people are hardy and thievish. The capital is Malatia.

ALAEJOS, a Spanish town in the province of Valladolid, with two fine churches of Doric architecture, a convent, a hospital, and four schools. The chief manufacture is linen. Pop. 3255.

ALAGON, a Spanish town in the province of Zaragoza, near the confluence of the Ebro and the Jalon. Pop. 1932.

Alagon, a river of Spain, rising in the province of Salamanca, on the southern side of the Sierra de Herreros, and flowing through the provice of Caceres. After a course of 90 miles from N. to S. and S.W. it falls into the Tagus near Alcantara.

ALAIN, Chartier, secretary to Charles VII. king of France, born in the year 1386. He was the author of several works in prose and verse; but his most famous performance was his Chronicle of King Charles VII. Bernard de Girard, in his preface to the History of France, styles him "an excellent historian, who has given an account of all the affairs, particulars, ceremonies, speeches, answers, and circumstances, at which he was present himself, or had information of." Giles Coroxet tells us that Margaret, daughter to the king of Scotland, and wife to the Dauphin, passing once through a hall where Alain lay asleep, she stopped and kissed him before all the company who attended. Some of them telling her, that it was strange she should kiss a man who had so few charms in his person, she replied, "I did not kiss the man, but the mouth from whence proceed so many excellent sayings, so many wise discourses, and so many elegant expressions." Fontenelle, among his Dialogues of the Dead, has one upon this incident, between the princess Margaret and Plato. Pasquier compares Alain to Seneca, on account of the great number of beautiful sentences interspersed throughout his writings.

ALAIS, an arrondissement in the department of the Gard, in France, extending over 529 square miles, or 338,900 acres. It is divided into nine cantons and ninety-five communes, and in 1846 contained 98,133 inhabitants.

Alais, the chief city of the arrondissement of the same name. It is situate on the river Gardon, at the foot of the Cevennes. It contains 16,983 inhabitants, who are employed in manufacturing ribbons, sewing-silk, silk-hosiery, cotton-goods, glass, porcelain, and other articles. Long. 3. 29. 40. E. Lat. 44. 7. N. It has mines of coal and iron.

ALAJAR, a town of Spain, in the province of Huelva, with a population of 1995.

ALAMAGAN, one of the Ladrone or Marianne islands, in the Indian Ocean, is situated in Long. 146. 47. E. Lat. 18. 5. N. It is of an irregular form, and about 12 miles in circumference. The land in some places of this island is pretty high, so that it may be seen at the distance of 12 or 14 leagues. Near the north end of the island there is a volcano, which emitted an immense body of smoke in the year 1799, when it was visited by Captain Bass. The volcano is in a mountain close to the sea, rising above its level 1200 or 1500 feet. The high parts of the island are rugged and sterile. In the lower parts there is a profusion and luxuriance of vegetation. These abound with cocoa-nut trees, several kinds of stone-fruit, and the mellora or bread-tree of the Nicobar islands. Some small sugar-canes, some banana trees, and one bread-fruit tree, were discovered. Lizards, land-crabs, large partridges, quails, pigeons, owls, thrushes, and bullfinches, are numerous. But no fresh water, which was the object of Captain Bass's visit, could be found.

ALAMANNI, or Alemanni, Luigi, an Italian statesman and poet, was born at Florence in 1495. Having taken part in an unsuccessful conspiracy against Giulio de Medici, afterwards Pope Clement VII., he was obliged to take refuge in Venice, and afterwards in France. The Florentines having in the meantime recovered their liberty, Alamanni returned to his country, and took a prominent part in the affairs of the state. On the occurrence of a new revolution he was again banished, and retired into France. Here he composed the greater part of his works. He was greatly esteemed by Francis I., who, after the peace of Crespi in 1544, sent him as ambassador to Charles V. It is related that in the course of his address before the emperor, having spoken with complimentary emphasis of the imperial eagle, Charles quickly interrupted him with the words,

"l'aquila grifagna,
Che per più devorar, duoi rostri porta."

The lines were the ambassador's own, written with satirical allusion to the imperial crest. Alamanni replied that these were the words of a poet, and spoken in the heat of youth, but that now he spoke as an ambassador, uttering the words of truth and soberness. Charles was pleased with this ready reply, and congratulated him on enjoying the patronage of so distinguished a monarch as Francis I. After the death of Francis, Alamanni was still retained in the favour of his successor, Henry II., who in 1551 sent him as his ambassador to Genoa. He died at Amboise in 1556. He wrote a large number of poems distinguished by the purity and elegance of their style: the best of these is his didactic poem, entitled *La Coltivazione*. He is also the author of notes on the Iliad and Odyssey: those on the Iliad are inserted in the Cambridge edition of 1689, and in Barnes' fine edition of 1711.

ALAMOS, Balthasar, a Spanish writer, born at Medina del Campo, in Castile. After having studied the law at Salamanca, he entered into the service of Anthony Perez, secretary of state under Philip II. He was in high esteem and confidence with his master, on which account he was imprisoned after the disgrace of this minister. He was kept in confinement 11 years, when Philip III. coming to the throne, set him at liberty, according to the orders given by his father in his will. Alamos continued in a private capacity till the duke of Olivarez, the favourite of Philip IV., called him to public employments. He was a man of excellent wit as well as judgment. He died in the 88th year of his age. His Spanish translation of Tacitus, and the aphorisms which he added in the margin, gained him great reputation. This work was published at Madrid in 1614, and was to have been followed, as mentioned in the king's privilege, with a commentary, which, however, has never yet appeared. The author composed the whole during his imprisonment.

ALAN, Cardinal William, was born at Rossal in Lancashire, in the year 1532. He went to Oxford at the age of 15, and in 1550 was elected fellow of Oriel College. In 1556, being then only 24 years old, he was chosen principal of St Mary's Hall, and one of the proctors of the university. In 1558 he was made canon of York; but, upon Queen Elizabeth's accession to the throne, he left England, and settled at Louvaine, in an English college, of which he became the chief support. In 1565 he visited his native country; but on account of his extreme activity in the propagation of the Roman Catholic religion, he was obliged to fly the kingdom in 1568. He went first to Mechlin, and then to Douay, where he was made doctor of divinity. Soon after he was appointed canon of Cambray, and then canon of Rheims. In 1587 he was created cardinal with the title of *St Martin in Montibus*, and obtained from the king of Spain a rich abbey in the kingdom of Naples, and afterwards the bishopric of Mechlin. It is supposed to have been by his advice and instigation that Philip II. attempted to invade England. He died on the 20th of October 1594, aged 63, and was buried in the English college at Rome. He was a man of considerable learning, and an elegant writer. He wrote many books in defence of the Romish religion. The most remarkable are, 1. *A defence of the Twelve Martyrs in one Year*. Tho. Alfield was hanged for bringing into England and publishing this and others of Alan's works in the year 1584. 2. *A Declaration of the Sentence of Sextus V.*, &c.; a work intended to explain the pope's bull for the excommunication of Queen Elizabeth, and to exhort the people of England to take up arms in favour of the Spaniards. Many thousand copies of this book, printed at Antwerp, were put on board the Armada; but the enterprise failing, they were afterwards destroyed. 3. *Of the Worship due to Saints and their Relics*, 1583. This treatise, which was answered by Lord Burleigh, is esteemed the most elegant of the cardinal's writings.

ALAND, a group of islands at the entrance of the Gulf of Bothnia, between Lat. 59. 50. and 60. 32. N. and Long. 19. 10. and 21. 7. E. It consists of more than 80 inhabited, and more than 200 uninhabited islets, and rocks, most of which rise to a considerable elevation above the level of the sea. The surface is either a thin layer of clay, a rich mould, slate-stone, or sand. The arable soil produces rye and barley sufficient for home consumption, with hops, potatoes, and various culinary vegetables. The pasture grounds are generally very poor, yet they maintain considerable numbers of sheep, goats, and beeves. The fisheries are also productive, and waterfowl abound. The climate, though keen, and often severe, is more temperate than that of Finland. The inhabitants amount to about 14,000, mostly Swedes; 9000 of them being settled in Aland, the largest of the group. These islands were ceded by Sweden to Russia in 1809. Several of the harbours have been fortified, and are the station of a large military force, and a numerous flotilla.

ALANJE, a small town of Spain, 33 miles from Badajoz, with medicinal baths, which in 1844 afforded relief or cure to 388 out of 427 patients.

ALANT, in *Heraldry*, is a mastiff dog with short ears.

AL ARAF, in the *Mahometan Theology*, the partition wall that separates heaven from hell. The word is plural, and is derived from the Arabic verb *arafa*, to distinguish; in the singular it is written *al arf*. It gives the denomination to the seventh chapter of the Koran, wherein mention is made of this wall. Mahomet seems to have borrowed this idea either from the great gulf of separation mentioned in the New Testament, or from the Jewish writers, who also speak of a thin wall dividing heaven from hell. Mahometan writers differ extremely as to the persons who are to be found on Al Araf. Some take it for a sort of limbus for the patriarchs, prophets, &c.; others place here those whose good and evil works so exactly balance each other that they deserve neither reward nor punishment; others imagine this intermediate space to be possessed by those who, going to war without their parents' leave, and suffering martyrdom there, are excluded paradise for their disobedience, yet escape hell because they are martyrs.

ALARIC I., a celebrated general of the Visigoths, sprung from one of the noblest families of that people, and afterwards elected their king. He is first noticed in history as the leader of the Gothic auxiliaries of Theodosius the Great, A.D. 394. After the death of that emperor, the Goths revolted from his son, and Alaric entered Greece at the head of 200,000 men. His march was arrested by the Thessalians on the river Peneus, but he forced his way into Greece, and returned into Epirus laden with spoil. Five years afterwards he marched through Pannonia into Italy, where he was defeated by Stilicho in the bloody battle of Pollentia. Driven out of Italy, he obtained from Honorius the præfecture of Illyricum. On the murder of Stilicho, Alaric, A.D. 400, again invaded Italy, and sat down before the walls of Rome; but he accepted a ransom and raised the siege. After a fruitless negotiation with the feeble Honorius, he raised a competitor to the purple, whom he soon degraded, and obtained possession of Rome by the treachery of the slaves and domestics of the Romans. The imperial city was given up to be plundered by his followers, and though ecclesiastical writers have celebrated the piety and clemency of Alaric, it cannot be denied that the unfortunate inhabitants sustained the greatest outrages from this ruthless barbarian. This memorable event took place on the 24th August 410. The rest of Italy was also ravaged, and the conqueror intended to pass into Sicily, when death put an end to his career at Cosenza in 411. The inhuman rites attending his funeral have been forcibly described by Gibbon.—See *Zosimus; Claudian; Jornandes; Gibbon;* and the article Roman History.

Alaric II., eighth king of the Visigoths in Spain, succeeded his father Evaric in 484. He was careful to maintain the peace which his father had concluded with the Franks; but the ambitious Clovis, eager to possess himself of the rich Gothic provinces in Gaul, took arms against him, and in a battle near Poitiers, gained a complete victory, slaying Alaric with his own hand, A.D. 507. With Amalaric his son ended the Gothic dynasty in France.

During the reign of Alaric, and under his authority, was compiled the digest of laws known as the *Breviarium Alaricianum*, or Code of Alaric.

ALARM, in the *Military Art*, denotes either the apprehension of being suddenly attacked, or the notice thereof signified by firing a cannon, firelock, or the like. False alarms are frequently made use of to harass the enemy, by keeping them constantly under arms. Sometimes also this method is taken to try the vigilance of the picquet-guard, and what might be expected from them in case of real danger.

Alarm, in *Fencing*, is the same with what is otherwise called an appeal or challenge.

*Alarm-Bell*, that rung upon any sudden emergency, as a fire, mutiny, or the like.

ALARO, a town in the island of Minorca, with a population of 4081, and manufactures of oil, brandy, soap, linen, &c. In the neighbourhood is an air volcano, called *el Buflador*, or the Blower.

ALASCANI, in *Church History*, a sect of Anti-Lutherans, whose distinguishing tenet, besides their denying baptism, is said to have been this, that the words, *This is my body*, in the institution of the eucharist, are not to be understood of the bread, but of the whole action or celebration of the Supper. They are said to have taken the name from Alasco, superintendent of the foreign church in England. See the next article.

ALASCO, John, a Polish nobleman of the 16th century, who, imbibing the reformed opinions, was expelled his country, and became preacher to a Protestant congregation at Embden; but foreseeing persecution there, he came to England about the year 1551, while the reformation was carrying on under Edward VI. The publication of the *Interim* driving the Protestants to such places as afforded them toleration, 380 were naturalised in Britain, and obtained a charter of incorporation, by which they were erected into an ecclesiastical establishment, independent of the church of England. The church of the Augustin friars was granted them, with the revenues, for the maintenance of Alasco as superintendent, with four assistant ministers, subject to the approval of the king. This congregation lived undisturbed until the accession of Queen Mary, when they were all banished. They were kindly received, and permitted to settle at Embden; and Alasco at last, after an absence of twenty years, returned, by the favour of Sigismund, to his own country, where he died in 1560. Alasco was much esteemed by Erasmus, and the historians of his time speak greatly in his praise. He wrote a considerable number of theological treatises in defence of the doctrines of the Swiss Reformers. His real name was *Lascki*.

ALA-SHER. See Philadelphia, in Asiatic Turkey.

ALASHKA, or Aliaska, a long narrow peninsula on the north-west coast of North America, forming apparently a continental continuation of the chain of the Aleutian islands. It consists mostly of a ridge of steep rocky mountains, which in some parts attain a great elevation. At its eastern extremity, N. Lat. 60°, there is an active volcano 14,000 feet in height, and at the western extremity there are several cones of great elevation, which have been seen burning, and are covered for two thirds of their upper portions with perpetual snow. At the same extremity, the island of Unimak, separated only by a narrow strait, has enormous volcanoes, one of them named Chichaldinsk, rising in a regular cone to the height of 8083 feet.

ALASSIO, a seaport in the duchy of Genoa, in the Sardinian kingdom, with 6000 inhabitants, who equip several vessels annually to the coral fishery on the shores of the island of Sardinia.

ALASSONA, a town in European Turkey, with 3000 inhabitants. It is in the pashalic of Trikala, the ancient Thessaly. A great fair is held here.

ALATAMAHA, a large river of North America, which, rising in the Appalachian Mountains, runs south-east through the province of Georgia, and falls into the Atlantic Ocean, below the town of Frederica. It is formed by the junction of the Oakmutgee and Oconee, and is navigable for steamboats for 300 miles from its mouth.

ALATRIUM, now Alatri, a town in the Roman Campagna, six miles north of Frosinone, with considerable remains of its ancient fortifications, and other objects of antiquity. Pop. 8000.

ALAUDA, Lark, a numerous genus of birds. See Ornithology.

Alauda, was the name given by Cæsar to one of his transalpine legions about 55 years B.C., probably from the crest of their helmets resembling that on the head of the lark.—*Suet. Cæs.* 24.

ALAUTA or Alt, a considerable river of Turkey in Europe, which, after watering the north-east part of Transylvania and part of Wallachia, falls into the Danube almost opposite to Nicopolis.

ALAVA, a province in the north of Spain, one of those three usually denominated Provincias Vascongadas, or Basques, which enjoy privileges that distinguish them from the other dominions of the Spanish monarchy, and speak a language most remote from the Castilian, generally called by the natives Vascuence, and by other people the Basque. This province is of a triangular shape, bounded on the north by Guipúzcoa and Biscay, on the east by Navarre, on the south and south-west by Rioja, from which it is divided by the river Ebro, and on the west by the northern part of Old Castile. The extent of this province is 814 geographical square miles; and the population, by the census of 1849, amounted to 81,397 souls, giving a density of inhabitants somewhat exceeding the general average of Spain.

The surface of the province is very mountainous, and is abundantly clothed with woods and lofty trees. Its valleys are fertile. The soil yields more corn than the subsistence of its inhabitants requires, as well as flax, hemp, some oil, and a kind of wine called chacoli, which is drunk when new, and will not long retain its qualities. The mountains abound in iron-ore; and there were once extensive manufactories of iron goods, though they have of late decreased, owing to the destruction of the forests which supplied them with fuel; besides which, their productions are charged with heavy imposts on their introduction into Castile. The salt-works of Añana are among the largest in Spain, and yield a yearly average of 50,000 bushels, which is said, however, to be not more than one-eighth of what they are capable of producing. There are numerous weavers of coarse cloths and blankets over the whole province. Shoes and hats are manufactured; but these articles, like the ironware, have experienced a sensible declension of late years. The capital of the province is Vittoria, situated on the river Zadora, which empties itself into the Ebro. The other rivers are the Ayuda, which runs into the Zadora; and the Omecillo, which empties itself into the Ebro.

ALAY, signifying, in the Turkish language, "The Triumph," a ceremony which accompanies the assembling together the forces of that vast empire upon the breaking out of a war. It consists of the most insipid buffoonery, and is attended with acts of the most shocking barbarity.

ALAYOR, a Spanish town, in the island of Minorca, with a trade in linen, brandy, flour, wine, &c. Pop. 4722.

ALB, or ALBE, in the *Romish Church*, a vestment of white linen hanging down to the feet, and answering to the surplice of the English clergy. In the ancient church it was usual with those newly baptized to wear an alb, or white vestment; and hence the Sunday after Easter was called *dominica in albis*, on account of the albs worn by the baptized on Easter-day.

ALB is also the name of a Turkish coin, otherwise called *asper*.

ALBA, a province in the duchy of Piedmont, in the continental Sardinian dominions. It is a fine plain of 366 square miles, or 234,240 acres, producing abundant harvests of corn, wine, fruits, oil, and truffles, besides the best silk. The cattle are not numerous. There are no mines, but quarries of marble, slate, and rock-salt. The inhabitants amount to 150,000, living in two cities and 75 towns and villages. There is scarcely any demand for labour, but that which agriculture requires.

ALBA, a city of Italy, capital of the province of the same name, in Piedmont. It is situated on the river Tanaro, between Asti and Cherasco; is the seat of a bishop, and contains, besides the cathedral, six churches and seven religious establishments for the two sexes of ecclesiastics. Pop. 8286. Long. 8. 3. E. Lat. 44. 36. N.

ALBA DE TORMES, a district in the east of the province of Salamanca in Spain, with an agricultural population of 14,162.

Its chief town of the same name gave their title to the Dukes of Alva. The remains of their once magnificent castle stand on an eminence near the town, overlooking the plain of the Tormes. Pop. 2176. Here the French, under Kellermann, defeated the Spaniards, Nov. 26. 1809.

*ALBA Firma*, or *Album*, in our old customs, denoted rent paid in silver, and not in corn, which was called *black mail*.

*ALBA Longa*, in *Ancient Geography*, a colony from Lavinium, in Latium, fifteen miles south-east from Rome, established by Ascanius, the son of Æneas, at the foot of the Mons Albanus. It was called *Alba*, from a white sow found by Æneas, which farrowed thirty white pigs on that spot; which circumstance was interpreted to portend the building of a city there in thirty years after. (Propertius.) The epithet *Longa* was added on account of its length. It was the royal residence till the building of Rome, as was foretold by Anchises, (Virgil); was destroyed by Tullius Hostilius, all but the fane or temple; and the inhabitants were transplanted to Rome. (Strabo.)

*ALBA Terra*, one of the numerous names for the philosopher's stone.

ALBACETE, one of the new provinces of Spain, in the north-west of the ancient province of Murcia. The extent of the actual province is small; Pop. 19,000; but the judicial *audiencia* of Albacete embraces Murcia, Ciudad Real, and Cuenca, including a population of nearly one million.

Its chief town of the same name is a place of great traffic from its central situation, and its importance as the seat of the high court of appeal. From the extent and celebrity of its steel-manufactures, it has been called the *Sheffield* of Spain, but the designation is but comparatively applicable. An important article of export is saffron, which the province produces in great abundance. Pop. of the town 13,143.

ALBAHURIM, *figura sexdecim laterum*, a figure of great importance, according to astrological physicians, who built their prognosties on it.

ALBAN, ST, is said to have been the first person who suffered martyrdom for Christianity in Britain; he is therefore usually styled the protomartyr of this island. He was born at Verulam, and flourished towards the end of the third century. In his youth he took a journey to Rome in company with Amphibalus, a monk of Caerleon, and served seven years as a soldier under the emperor Diocletian. On his return home he settled at Verulam, and, through the example and instructions of Amphibalus, renounced the errors of Paganism, in which he had been educated, and became a convert to the Christian religion. It is generally agreed that Alban suffered martyrdom during the great persecution under the reign of Diocletian; but authors differ as to the year when it happened. Bede and others fix it in 286; some refer it to the year 296; but Usher reckons it amongst the events of 303. Between 400 and 500 years after St Alban's death, Offa, King of the Mercians, built a large and stately monastery to his memory; and the town of St Albans, in Hertfordshire, takes its name from our protomartyr.

ALBANENSES, in *Church History*, the same with Albigenses. See ALBIGENSES.

ALBANI, in *Roman Antiquity*, a college of the *Salii*, or priests of Mars; so called from Mount Albanus, the place of their residence.

ALBANI, *Cardinal Gian Francesco*, was elected Pope in November 1700, as the successor of Innocent XII. After his election, he hesitated about accepting the high office; but after some days ascended the chair of St Peter by the title of Clement XI. Whatever were his reasons for hesitation, he became one of the most active and zealous pontiffs in supporting the prerogatives and pretensions of the Holy See; which embroiled him with Victor Amadeus of Savoy, with Naples, and with Austria. But his most noted interference was in the religious dissensions in France; when by his bull entitled "Vineam Domini," he confirmed the edict of his predecessors against the Jansenists; but the issuing of his celebrated bull "Unigenitus," in 1713, set the kingdom of France in a flame. In this he condemned as heretical 101 propositions in Quesnel's *Reflections Morales sur le Nouveau Testament*, in which that author had maintained various opinions of St Augustin and the older fathers, which favoured the Jansenist doctrines on Grace and Free Will.

After a severe struggle and keen debates, Le Tellier, the Jesuit confessor of Louis XIV., persuaded his master to receive the bull; and it was at length registered by the Parliament of Paris; but these questions had for several years estranged France from the Holy See.

Another affair which troubled this pope was the disputes concerning the Jesuit missionaries in China, who had risen high in the consideration of the Imperial government, and seemed too independent of the court of Rome. Clement sent as his legate Cardinal Tournon in 1702; but he died at Macao, and his successor, Father Mezzbarba, was but coldly received at Pekin, and soon after ordered to quit China, at the instigation, as it was alleged, of the Jesuits; a source of deep mortification to this aspiring pontiff.

Clement warmly espoused the cause of the exiled house of Stuart, and furnished the son of James II. with money for his ill-advised attempt on Britain in 1715. After the failure of that expedition, he offered the prince an asylum at Urbine, where, as the Chevalier de St George, he had from the Pope a pension of 30,000 scudi; and, on his marriage with Clementina, daughter of the heroic John Sobieski, gave him a palace at Rome for his residence. This Pope died in March 1721.

Clement was a scholar, and wrote an excellent Latin style. His Homilies have been translated into Italian by Cescimbeni.

ALBANI, or ALBANO, *Francesco*, a celebrated Italian painter, was born in Bologna in 1578, and died in 1660. His father was a silk-merchant, and intended to bring up his son to the same occupation; but the young Albani was already, at the age of 12, filled with so strong an inclination for painting, that on the death of his father, he devoted himself entirely to art. His first master was Denys Calvert, with whom Guido Reni was at the same time a pupil. He was soon left by Calvert entirely to the care of Guido, and contracted with him a close friendship. He followed Guido to the school of the Caracci; but after this, owing to mutual rivalry, their friendship began gradually to cool. They kept up for a long time a keen competition, and their mutual emulation called forth some of their best productions. Notwithstanding this rivalry, they still spoke of each other with the highest esteem. Albani, after having greatly improved himself in the school of the Caracci, went to Rome, where he opened an academy and resided for many years. Here he painted, after the designs of Ann. Caracci, the whole of the frescoes in the chapel of St Diego in the church of San Giacomo degli Spagnuoli, besides numerous other pictures. On the death of his wife, he returned to Bologna, where he married a second time, and resided till his death in the enjoyment of much domestic happiness and general esteem.

Albani was naturally of a happy and amiable disposition, and his paintings breathe the same soft and joyous spirit. "In point of original invention," says Lanzi, "he is superior to Domenichino, perhaps to any other of the school; and in his representation of female forms, according to Mengs, he has no equal. By some he is denominated the Anacreon of painting. Like that poet, with his short odes, so Albani, from his small paintings, acquired great reputation; and as the one sings Venus and the Loves, and maids and boys, so does the artist hold up to the eye the same delicate and graceful subjects. Nature, indeed, formed, the perusal of the poets inclined, and fortune encouraged his genius for this kind of painting; and possessing a consort and twelve children, all of surprising beauty, he was, at the same time, blest with the finest models for the pursuit of his studies. He had a villa most delightfully situated, which farther presented him with a variety of objects enabling him to represent the beautiful rural views so familiar to his eye. Passeri greatly extols his talent in this branch, remarking that where others, being desirous of suiting figures to the landscape, or its various objects to one another, most frequently alter their natural colour, he invariably preserves the green of his trees, the clearness of his waters, and the serenity of the air, under the most lovely aspect, and contrives to unite them with the most enchanting power of harmony." The most of his works are at Bologna. Among the most celebrated of his pictures are those of the *Four Elements;* those of *Diana and Venus* in the Florentine gallery; the *Toilet of Venus*, in the Louvre; *Venus landing at Cythera*, in the Ghigi palace at Rome, &c. Among the best of his sacred subjects are a *St Sebastian* and an *Assumption of the Virgin*, both in the church of St Sebastian at Rome.

ALBANIA, a country of considerable extent, which, though frequently ruled by turbulent and nearly independent chiefs, ranks as one of the provinces of the Turkish empire. It extends from the thirty-ninth to the forty-third degree of north latitude, for the space of about 250 miles, along the Mediterranean and the Gulf of Venice. The extent inland nowhere exceeds 100 miles, and is in the southern part not more than 30. The chain of Pindus, called now the mountains of Sagori, of Metzovo, and of Suli, separate it by an ill-defined line from Macedonia and Thessaly. The Turks divided it into pashalics, of which the principal were those of Scutari, Ochrida, Vallona, and Butrinto; but these distinctions, amid late revolutions, have been in a great measure obliterated. The divisions chiefly recognised are those formed by the varieties of the native tribes. Colonel Leake, who is considered one of the best-informed authorities on this head, divides them into the Ngege, or Ghegides, whose principal towns are Dulcigno, Scutari, and Durazzo; the Toske or Toskides, who occupy Berat and Elbasan; the Liape, a poor and predatory race, who inhabit the mountains between the Toske and Delvino; and the Tsami, who inhabit the most southerly district, and whose principal towns are Suli and Paramithia. In 1838, it was divided by the Turks into six sanjaks, besides a number of smaller divisions.

Albania nearly coincides with the ancient Epirus, but comprising part of Macedonia, Illyria, and Chaonia. This country was then, as now, distinguished by the rude valour of its inhabitants. Its remote situation, and the want of union among its tribes, generally prevented it from acting any conspicuous part in Grecian politics. The only remarkable exception occurs in the reign of Pyrrhus II., who was justly ranked with the greatest captains of antiquity. After his death the country was again split into a number of petty states, which were unable to resist the united strength of Macedon; and to that kingdom Epirus continued subject, till both were alike subdued by the Roman arms.

It was during the time of the Greek empire that the name of Albania was first given to this district. During the decline of the empire the Albanians gradually rose to distinction, and at last to independence. Their valour enabled them to maintain their ground against the Bulgarians, who had occupied all the neighbouring districts of Greece. Nor were they less successful against the Turks, a more formidable enemy. Under the command of the celebrated George Castriot, commonly called Scanderbeg, they baffled all the efforts of Mahomet II. the conqueror of Constantinople. That powerful monarch entered Albania only to experience a succession of defeats, and was at length compelled to acknowledge its independence by a formal treaty. On the death of Scanderbeg, the Turks redoubled their efforts against Albania, which was at length reduced to a state of nominal subjection. The siege of Scutari, in 1478, formed the termination of this memorable struggle. The subjection, however, was always imperfect; revolts were frequent, and the inhabitants of the mountainous districts still preserved their independence. It was by the motives of pay and plunder, rather than by compulsion, that these hardy soldiers were allured into the Turkish ranks. In proportion as the Ottoman empire declined in vigour, its hold of Albania became less firm; and the vigorous and enterprising genius of Ali Pasha again converted this dependency into what might almost be called a separate kingdom.

Ali was born at Tepellene, a small town in the interior of Albania. His father held the rank of a pasha of two tails, but was not possessed of any extensive power; and he died when Ali was only fifteen. In a district so turbulent, and filled with warlike and hostile leaders, the young chief was necessarily placed in a very critical situation. He was himself accustomed to boast, that he began his fortune with sixty paras and a musket; and an Albanian who attended a late traveller (Mr Hobhouse) declared, that he remembered to have seen Ali with his jacket out at elbows. Ali was ere long driven from Tepellene, his native place, and was abandoned by almost all his followers. A plan was next formed for his destruction, by the inhabitants of Gardiki, a neighbouring town; and for this purpose they surrounded, in the night time, a village where he had taken refuge. Ali escaped through a garden, but his mother and sister fell into the hands of the Gardikiotes, and were treated with every species of indignity; wrongs for which he afterwards took a dreadful vengeance. His address and activity enabled him gradually to repair his fortunes. He insinuated himself into the favour of Coul Pasha, then the principal chief of Albania, whose daughter he at length married. Having thus been enabled to collect some followers, he succeeded in surprising Yanina, the capital, and in prevailing upon the Porte to recognise him as pasha of that important district. From this time he took the lead among the Albanian chiefs; employing sometimes force, sometimes money, and sometimes treachery, to increase his authority, and add to the extent of his dominions.

The most formidable adversaries with whom Ali had to contend were the Suliotes, a people placed in the southern extremity of Albania. They inhabit an almost inaccessible range of mountains, beneath whose gloomy shade winds a river, which Dr Holland conjectures, on very plausible grounds, to be the Acheron of the ancients. (*Travels in the Ionian Isles and Albania.*) The strength of their native bulwarks, their passion for war, and contempt of death, made them the terror of Albania, which they frequently invaded; while no foreign power had ever ventured to scale the tremendous barriers by which they were guarded. Ali at length succeeded, partly by force and partly by bribery, in gaining the passes which led into their country; and the whole nation, after a furious resistance, was reduced to subjection, and partly extirpated.

In 1811 and 1812 Ali attacked and defeated the pashas of Berat and Delvino; by which means he gained possession of some of the finest parts of Albania, and a population of between 200,000 and 300,000 souls. Tepellene, his native place, now fell into his power; and now also it was that he obtained the means of inflicting signal vengeance on Gardiki. With his accustomed duplicity he pretended a complete oblivion of all grounds of resentment, until he had surrounded and inclosed the city with his troops; when upwards of 700 of those of the inhabitants who were supposed to have been most deeply involved in the ancient guilt, were dragged into a large khan near the city, and bound together with cords. On a signal given by Ali, the Albanian soldiery, who were stationed on the walls of the khan, began a discharge of musketry, which continued until the destruction of the whole 700 was completed.

The dominions of Ali were not confined within the limits of Albania; he extended his sway over the mountainous district of Macedonia, nearly the whole of Thessaly, and great part of Livadia. He was kept in check by Ismael Bey, who possessed an authority nearly as independent over the plains of Macedonia. In Albania, his power was almost absolute; and while little regard was paid to the imperial firman, a letter with the signature of Ali commanded implicit obedience. The Albanians were enthusiastically attached to him; they viewed him as a native sovereign; they admired the energy of his character, and, when they heard of any other chief, commonly remarked, "he has not a head like Ali."

The natives estimated Ali's military force as high as 50,000, 60,000, or even 100,000 men. This could only apply to the case of a general levy *en masse*, in the event of invasion. It does not appear that Ali ever brought into the field a greater disposable force than 15,000. His standing army was supposed to be about 10,000, of whom 4000 or 5000 were stationed round his capital Yanina. The amount of his revenues was still more uncertain. They arose from the following sources:—1. A land-tax, amounting generally to about 10 per cent. of the produce; 2. a tax on cities and towns, levied in the form of requisition; 3. the customs, which he raised to six per cent.; 4. the inheritance of all who died without male heirs.

Ali's figure was corpulent and unwieldy, his neck short, his stature about five feet nine inches. The expression of his countenance was striking and majestic; and his features gave no indications of those terrible qualities by which he was characterised. His abilities were certainly of no mean order. He displayed that union of deep thought and contrivance, with prompt and decisive action, which indicate a mind equally formed for politics and for war. He was remarkable for his address, both in gaining friends, and in lulling asleep the suspicions of his bitterest enemies. But, if his abilities were of a superior order, his moral qualities were of a kind which rendered him an object of fear and detestation. His cruelty rather resembled that of an Indian savage than of even the least civilised European. Impaling and roasting alive were among the common punishments reserved for those who had unhappily offended him. The fierceness of his cruelty was only exceeded by the depth of his dissimulation. It was impossible for the most skilful observer to conjecture, from his outward deportment, the real sentiments with which he regarded any individual. The only observable difference consisted in a peculiar kindness of manner towards those unfortunates whose cruel doom he had silently and unrelentingly sealed.

Ali's ordinary residence was near Yanina, in an immense building which combines the characters of a palace and a fortress. The outer courts were irregularly crowded with Albanian soldiers, and with persons of all descriptions, who attended upon him, or had petitions to present. Each petitioner in approaching, knelt and kissed his garment. He exercised in person the whole judicial authority, and his decisions, though necessarily given too promptly, are, however, said to have been guided by an apparent wish of arriving at the truth, and of doing justice. He rose at six in the morning, and, with the exception of an hour at dinner, and an hour at supper, spent the whole day in business. His habits at table were extremely temperate, though he was not so strict a Mussulman as to decline the use of wine. His harem contained 390 females of various descriptions. It formed an edifice entirely distinct from the rest of the seraglio, and is said to have been furnished in a style of the most gorgeous magnificence; but no European ever found admission into it.

Although the government of Ali was completely despotical, yet, viewed comparatively, it appears to have been better for Albania than the terrible anarchy to which it was formerly exposed.

The progress of this enterprising chief was viewed by the Porte with jealousy and alarm, though it was found prudent to maintain an outward good understanding with him, by investing him with the government of the provinces which he had subdued. The Sultan having in vain attempted to induce Ali to repair to Constantinople, with the secret intention of despatching him, at length sent against him Pacho Bey, a former adherent of Ali, but afterwards one of his bitterest opponents. A recent and daring attempt, by two hired agents of Ali, to assassinate this person, furnished sufficient ground for placing Ali under the ban of the empire. He soon found himself deserted by the tribes in whom he had trusted, and Pacho Bey reached Yanina without firing a gun. The ferocious Ali ordered the capital to be given up to indiscriminate plunder by his bandit followers, and retreated to an impregnable castle in the midst of the lake, where be bade defiance to his enemies; who, after an ineffectual blockade, were obliged to retreat. Mahmoud, highly dissatisfied with the result of these operations, invested Chourschid, Pasha of the Morea, with the supreme command. Having assembled all the forces of the surrounding pashalics, he again hemmed in Ali within the precincts of his castle. The tower into which Ali had retired with his wives and treasures being closely beset, he surrendered to Chourschid, under a solemn promise that his life should be spared, and that he should have an honourable retreat; but scarcely had the agreement been concluded when a firman arrived from the Porte decreeing his immediate death.

In the grand insurrection of Greece, the Albanians, accustomed to view with disdain the Ottoman yoke, showed a considerable disposition to make common cause with the Greeks; and their co-operation would have almost insured success. But the Greeks, imprudently and unhappily, could not divest themselves of the feelings of enmity cherished during the long series of wars which Ali had waged against them. At the siege of Tripolizza overtures were made to them by a corps of 3000 Albanians, who formed part of the garrison; but the Greeks, having succeeded in entering the place, began a dreadful and indiscriminate massacre, in which the Albanians were equally involved. At the siege of Arta, although the capture was much facilitated by the coming over of a corps of Albanians, the Greeks treated them extremely ill. The Albanian nation was thus forcibly thrown into the arms of the Porte, to which it has since continued nominally subject.

The inhabitants of Albania are estimated at 800,000, of which a considerable proportion are Turks and Greeks; but the basis of the population consists of the original race, called Arnauts. This remarkable people differ completely from every other included within the limits of the Turkish empire. Their conversion to Mahometan tenets has been very imperfect, and chiefly induced by political motives. In every family the males usually go to the mosque, the females to church; and some members of a family are seen in the most amicable manner eating from the same table, and even from the same plate, meats forbidden to the others. With the Turks, accordingly, infidel and Albanian are terms nearly synonymous. Ali did not appear to make religion a ground of any the slightest distinction between the different classes of his subjects.

The native Albanian is of a middle stature; his face is oval, with high cheek-bones; his neck long, his chest full and broad. His air is erect and majestic to a degree which never fails to strike the traveller. He holds in utter contempt that dissimulation which is characteristic of the Greek, and piques himself upon giving utterance to every sentiment without the smallest reserve. Equally remote from the grave and sluggish deportment of the Turk, he is gay, lively, and active. Averse, however, to regular industry, his whole delight is in arms and plunder. He goes constantly armed; and there are few Albanians who, in the prime of their life, have not belonged to some of the numerous bands of robbers who infest the mountains of their native country, of Thessaly, and of Macedonia. This profession carries with it no disgrace: it is common for the Albanian to mention circumstances which occurred "when he was a robber." In proportion as the trade of robbing becomes overstocked, part of those engaged in it seek employment in the service of the sultan, and of the different pashas throughout the Turkish empire; by all of whom the Albanians are regarded as the most valuable of their troops.

An Albanian military force, according to the description of Dr Holland, cannot so properly be called an army, as a tumultuous assemblage of armed men. There is no regular distribution into corps; nor is much regard paid to the authority of any officer, with the single exception of the pasha himself. Yet such is their activity and intrepidity, that they have sometimes proved formidable to the best-disciplined European armies. The main strength of the Turkish infantry in the Russian campaigns consisted of Albanians.

This fierce and haughty race display a greater degree of contempt for the female sex than is usual even among the most barbarous nations. The females are literally regarded as inferior animals, and treated as such; but in the country districts they are not confined or veiled, as is customary in Mahometan countries.

The dress of the Albanian consists of a cotton shirt, a jacket, a mantle, sandals, and a red cap; to which is added a large *capote*, or great coat, as a shelter from the weather. Every part except the shirt consists of woollen. As they have usually one suit, which they wear day and night, it soon exhibits a dreadful spectacle of dirt and vermin, and at length literally falls to pieces. The dress of the females is more various, and often fantastical. A singular custom prevails among the girls, of stringing together the pieces of money which they have collected for their portion, and wearing them upon their heads. Some of them have their hair hanging down in braids to a great length, loaded with this species of ornament.

Yanina, the present capital, is beautifully situated on the banks of a small lake, inclosed within a circuit of lofty mountains. The houses in general are not externally either splendid or elegant; and they are built in the most irregular manner, with scarcely any approach to the form of streets. The intermixture, however, of gardens and trees gives to the city a fine appearance from a distance; particularly when combined with the magnificent background which everywhere crowns the landscape. There is a considerable number of Greeks at Yanina, who display an active and intelligent character, and cultivate with ardour the different branches of science and literature. The total number of inhabitants is estimated at upwards of 36,000.

The commerce of Albania is chiefly carried on through Arta, a small city situated on a gulf of the same name, in the most southern district of the country. The principal merchants, however, are Greeks residing at Yanina, among whom a very active commercial spirit appears to prevail. The mercantile houses of this city have often branches in other countries, particularly Germany and Russia; and several of them suffered considerably by the conflagration of Moscow. Under the continental system of Napoleon, Malta became the great channel for the trade of Albania, and, notwithstanding the subsequent political changes, probably retains it to a certain extent. The exports consist almost entirely of unmanufactured produce. Notwithstanding its mountainous character, the fertility of its plains affords a surplus of grain, of which a considerable quantity is sent to Italy, the Ionian Isles, Malta, and other places. Wool is exported chiefly unmanufactured, but partly also wrought into coarse cloth. Other important articles of export are, oil, tobacco of good quality, cotton and cotton yarn, chiefly from Thessaly. Some cargoes of wood for building and fire are annually sent to Malta. The chief imports consist of woollen cloths, used for winter coverings. For this purpose the preference is given to a coarser and cheaper species than any that is usually manufactured in Great Britain. This is supplied from Germany. Albania imports also guns, gunpowder, hardware, coffee, and sugar. On the 8th of October, an annual fair is opened in the neighbourhood of Yanina, and continues for fourteen days, when the imported articles are exchanged for native commodities, which then pour in from every quarter.

The reader will find much interesting information in regard to this country, and its late ruler, in the *Travels* of Mr Hobhouse and of Dr Holland. The latter resided for some time at Ali's court, where, in quality of physician, he enjoyed the privilege of a familiar intercourse with that extraordinary personage; and in the pages of Colonel Leake, we have still later notices of this country. (H. M.)

ALBANIA, a country of Asia, bounded on the west by Iberia; on the east by the Caspian Sea; on the north by Sarmatia; on the south by Armenia and the river Cyrus, now Kur, which, springing from the Moschian Mountains that separate Colchis from Armenia, falls into the Caspian Sea within a small distance from the southern borders of this country. The whole country, formerly called *Albania*, now goes under the names of *Daghistan*, *Schirwan*, and *Leghistan*, and is extremely fruitful and pleasant. The ancient historians take notice of the Albanian men as tall, strong-bodied, and, generally speaking, of a very graceful appearance; far excelling all other nations in comeliness as well as stature. Modern travellers extol the beauty of the women. The Albanians were anciently an independent and pretty powerful people; but we find no mention made of their kings till the reign of Alexander the Great, to whom the king of Albania is said to have presented a dog of extraordinary fierceness and size. It does not appear that the Albanians were ever conquered by the Romans, even when their power was at the greatest height; though, when they ventured to engage in war with that powerful empire, they were always defeated, as might naturally be expected.

ALBANO, a city near the lake of the same name, in the Campagna di Roma, in the Papal territories. It is much admired for the picturesque scenery around it. It is well built, and the Roman aqueduct and other monuments of antiquity are in tolerable preservation. The city contains a cathedral, four monasteries, a nunnery, and 5600 inhabitants. Long. 12. 43. 47. E. Lat. 41. 48. 50. N.

ALBANO, *Lake of*, about thirteen miles S.E. from Rome, is of a beautiful oval form, surrounded with high wooded banks, and about seven miles in circumference. It has long been a favourite object to the painter and the traveller; and on a cliff overhanging the lake is Castel Gandolfo, the only summer residence of the sovereign pontiffs, to which they retire during the unwholesome season at Rome. It has evidently been the crater of an extinct volcano. In the fourth century of ancient Rome, during the siege of Veii, the rise of the waters of this lake was so extraordinary, that the oracle of Delphi was consulted, and it gave no hope of success against Veii, while the Alban lake was allowed thus to swell. This prompted the Romans to drain the lake by an emissory or tunnel cut through the rock, a mile and a half in length, 4 feet wide, and 6 high, which is still perfect. As the nature of the *peperino* rock is crumbling, the cut is carefully cased with solid masonry. Its upper end is about the level of the ordinary surface of the lake, which is 920 feet above the level of the sea. Ten years after this work was finished, Veii succumbed to her hated rival.

ALBANO is also a town in the kingdom of Naples, remarkable for the fertility of the surrounding territory, and for the nobility of the inhabitants.

ALBANS, ST, a market-town of Hertfordshire, stands on the north side of the Ver, on the opposite side to the Roman city of Verulamia. It is chiefly remarkable for its immense Abbey church, the longest ecclesiastical structure in Great Britain. It was founded by the king of Mercia on his conversion to Christianity in the year 790; but the present building contains specimens of every style of English architecture. In the older portions, we find heavy circular arches, devoid of all ornament, springing from rude square piers, and sometimes large arches, divided by two interior arches, that rest on a low circular pier. This style is by some termed Saxon; but our best antiquaries now consider it as only early Norman. Some of the piers are clustered, showing a much later kind of architecture. This church is 556 feet long, by 174 feet in breadth at the transepts. The tower which surmounts it is only 150 feet in height; but from being on a moderate hill in a flat country, is visible from a great distance. The vast quantity of Roman bricks used in this structure is very striking; these were derived from the remains of the Roman Verulamia, which were extensively destroyed by the 8th and 9th abbots of St Albans, Ealdred and Eadmer, who rebuilt the church, and whose researches, according to Camden, were rewarded by the discovery in the ruins of great treasures of gold and silver, coins, and ancient MSS. Among the latter was said to be the famous *Book of St Albans*, the life of the saint in British, afterwards translated by a monk into Latin. The church contained, it is said, the bones of St Alban, but certainly those of Offa, and of the good Duke Humphrey of Gloucester, whose tomb was discovered in the last century. His bones show him to have been tall and vigorous. The town is divided into three parishes, St Albans, St Michaels, and St Peters. In St Michael's church, a small structure within the precincts of the ancient Verulam, is the tomb of the illustrious Lord Bacon; and in St Peter's church were deposited the bodies of the nobles who fell in the two battles of St Albans, in the civil wars of the two Roses. St Albans is twenty miles from London, in Lat. 51. 46. Long. 0. 21. W. The population in 1851 was 7000; and the number of inhabited houses 1361. It has hitherto returned two members to parliament; but in consequence of the gross corruption practised in electing the members, it is believed that it will shortly be deprived of that privilege, if not altogether disfranchised.

ALBANUS MONS, in *Ancient Geography*, now called *Mont Albano*, a mountain 14 miles from Rome, near the site of Alba Longa. It rises about 2000 feet above the surface of the lake.

ALBANY, the capital of the state of New York in North America, on the western bank of the river Hudson, about 145 miles above the city of New York. Placed on one of the noblest rivers of that part of America, and backed by a rich country, it has every natural requisite for commercial importance. These natural advantages have been increased by canals connecting it with Lakes Erie and Champlain; while a tissue of railways unites it with Boston and the valley of the Mohawk. It contains many handsome buildings, and valuable institutions of various kinds. Of its public buildings, the principal are the capitol, a handsome stone edifice 115 feet in length by 90 in width, with richly furnished apartments for the Senate and Assembly, &c.; the city hall, a superb building of white marble, surmounted with a large gilded dome; the exchange, &c. On 17th August 1848, a dreadful fire broke out which consumed one-eighth of the city. Its population in 1850 amounted to 50,771. Lat. 42. 39. N. Long. 73. 32. W.

ALBANY, a port and trading station of the Hudson's Bay Company, on the south-western shore of that sea, in Lat. 52. 20. N. Long. 82. 20. W.

ALBANY, a district in the eastern part of the British colony of the Cape of Good Hope, with an area of 2000 square miles, and a population of about 12,000. See GOOD HOPE, CAPE OF.

ALBARRACIN, a judicial district of the province of Teruel, in Spain. Pop. about 20,000. The country is cold, mountainous, and barren, but produces iron, and wool of a very fine quality.

Albarracin, *Sta. Maria de*, the chief town of the above district, on the banks of the Guadalaviar. It is the see of a bishop; and was once a place of great strength and importance, but its old fortifications are for the most part in ruins, and its population scarcely amounts to 2000.

ALBARIUM Opus, in *Antiquity*, the incrustation or covering of the interior of houses with white plaster, plain or ornamental. This is otherwise called *opus album*. It differed from *Tectorium*, which is a common name given to all roofing or ceiling, including even that formed of lime and sand, or lime and marble.

ALBATEGNI, an Arabic prince of Batan, in Mesopotamia, and a celebrated astronomer, who lived about the year 880, as appears by his observations. He is also called *Muhammed ben Geber Albatani, Mahomet the son of Geber*, and *Muhamedes Aractensis*. He made astronomical observations at Antioch, and at Racah or Aracta, a town of Chaldea. He is highly spoken of by Dr Halley, as a man of great genius, and an excellent observer. He received the title of the *Arabian Ptolemy*.

Instead of the tables of Ptolemy, which were imperfect, he computed new ones: these were adapted to the meridian of Aracta or Racah, and were long used as the best among the Arabs. He also composed in Arabic a work under the title of *The Science of the Stars*, comprising all parts of astronomy, according to his own observations and those of Ptolemy. This work was translated into Latin by Plato of Tibur, and published at Nuremberg in 1537, with some additions and demonstrations of Regiomontanus. It was reprinted at Bologna in 1645, with this author's notes. Dr Halley detected many faults in these additions. (*Philosophical Transactions* for 1693, No. 204.) In this work Albategni gives the motion of the sun's apogee since Ptolemy's time, as well as the motion of the stars, which he makes one degree in 70 years. He makes the longitude of the first star of Aries to be 18° 2′, and the obliquity of the ecliptic 23° 35′. Upon Albategni's observations were founded the Alphonsine tables of the moon's motion.

ALBATI Equi, an appellation given to such horses, in the games of the ancient circus, as wore white furniture.

ALBATROSS. See Ornithology, *Index*.

ALBAYDA, the name of a district, town, and river, in the province of Valencia in Spain. The district contains about 23,000 inhabitants, is extremely fertile and richly cultivated, and produces a great abundance of wine. Population of the town, 3130.

ALBAZIN, a town of Greater Tartary, with a strong castle. It is situated upon the river Amur or Yamour, and belongs to the Russians. Long. 103. 30. E. Lat. 54. N.

ALBEMARLE. See Aumale.

Albemarle, a county of Virginia, 700 square miles in extent, and in 1850 containing 25,684 inhabitants.

Albemarle Sound, an arm of the sea, 60 miles long and 10 wide, on the coast of N. Carolina.

ALBENGA, a seaport town of Italy, about 45 miles S.W. of Genoa. It is the see of a bishop, and is a very ancient, handsome town, but not well peopled, on account of the insalubrity of the air. It is seated in a well-cultivated and beautiful plain; and the suburbs are surrounded with olive-trees. Pop. 4735. Long. 8. 13. E. Lat. 44. 4. N.

ALBERIQUE, a district and town in the south of the province of Valencia, in Spain. Population of district about 16,000, of the town 3000. The chief products are silk, rice, and fruit.

ALBERONI, Julius, the son of a poor gardener in the suburbs of Placentia, born in 1664, who, by his great abilities and good fortune, rose from this low origin to the employment of first minister of state at the court of Spain, and to the dignity of cardinal. He roused that kingdom out of the lethargy it had sunk into for a century past, awakened the attention and raised the astonishment of all Europe by his projects, one of which was to set the Pretender on the throne of Great Britain. He was at length deprived of his employment, and banished to Rome. He died in 1752 at the advanced age of 87. His *Testament Politique*, collected from his memoirs and letters, was published at Lausanne in 1753.

ALBERT, a name borne by a large number of German princes, both temporal and spiritual, the more important of whom will be referred to under the several countries to which they belonged.

Albert, Margrave of Brandenburg, and the last grand master of the Teutonic order, laid aside the habit of his order, embraced Lutheranism, and concluded a peace at Cracow 1525, by which he was acknowledged duke of the east part of Prussia (formerly called for that reason *Ducal Prussia*), but to be held as a fief of Poland, and to descend to his male heirs. He was born in 1490; married in 1527 Dorothea, a princess of Denmark, and died in 1568. See Prussia.

ALBERTI, Leon Battista, one of the most distinguished men of his age, was descended of the noble and ancient family of the Alberti of Florence, where most probably he was born, about the year 1404. Having received from his father an excellent education, at twenty years of age he produced a Latin comedy entitled *Philodoxius*, which, from its classic style, was generally believed to be the work of an ancient poet; and indeed, by a mistake, it was afterwards edited and published as such by the younger Aldus. Alberti was originally of a powerful frame, and excelled in feats of strength and agility; but his constitution was irreparably injured by a severe illness in early life. The energy of his mind, however, suffered no diminution; and he pursued his studies with extraordinary ardour. He is generally regarded as one of the restorers of the ancient style of architecture, and has been called by some writers the Florentine Vitruvius. He was much employed by Pope Nicolas V. in his buildings; and specimens of his skill are to be seen at Rome, Florence, Mantua, and Rimini. He was also distinguished as a mathematician, a poet, and a philosopher. His writings in the various departments of science are numerous: his treatises on sculpture and painting, in particular, are highly esteemed; but his most celebrated work is the treatise on architecture, *De Re Ædificatorid*, which has been translated into Italian, French, and English. A splendid edition of this work in English and Italian, by Leoni, was published at London in 1726, in 3 vols. folio. This most accomplished man appears to have possessed an amiable and generous disposition, and was greatly respected and esteemed by his contemporaries. He died at Florence in his 85th year; and it is supposed that his remains were laid in the family sepulchre of the Alberti, which is still shown in that city. His life has been written by Poretti.

ALBERTUS MAGNUS (*Albert the Great*), one of the most celebrated philosophers and theologians of the middle ages, was born of the family of the Counts of Bollstädt, at Lauingen in Suabia. The date of his birth, according to the most probable calculation, is in 1193. He began his studies at Padua; where he became acquainted with Jordanus the General of the Dominicans, by whose influence he was led in 1222 to enter that order. After going through the regular course of philosophy and theology, he taught successively at Ratisbon, Strasburg, Friburg in Brisgau, Hildesheim, and Cologne. At the latter place, which became his favourite residence, he numbered among his pupils two future saints, Thomas of Cantimprato, and the "angelic" Aquinas. Aquinas followed him, when in 1245 he repaired to Paris for the purpose of obtaining the degree of doctor [*magister*]. During the requisite term of three years spent in public lecturing, Albert's instructions drew so large a concourse of scholars that he was obliged, in the ancient fashion, to teach in the open air. The name of the place *Maubert* (a contraction of *magister* or *magnus*, and *Aubert*), and that of the neighbouring *Rue de Maître-Albert*, still preserve the record of these Aristotelic hours.

On his return to Cologne he was made regent of the school of the Dominicans; and in 1254 he was elected Provincial of his order, the duties of which office he discharged with unwearied zeal, visiting on foot all the bounds of his extensive jurisdiction. During this residence at Cologne, he is said to have fabricated the famous speaking automaton, which, together with his scientific acquirement sand alchemistical pursuits, gained him the reputation of a magician. This curious machine is said to have so provoked the pious horror of the "angelic doctor" by its diabolical jargon, that he broke it in pieces with his staff. In 1255, Albert was called to Rome to defend the privileges of his order against the University of Paris; a mission which he fulfilled with partial success; leaving its completion to his friend Aquinas. At Rome he discharged the office of reader to the Pope, lecturing on the Gospel of John and the Epistles. In 1260 he was made Bishop of Ratisbon; but the troublesome duties of this office suited ill with his retired and studious habits, and after three years he resigned it. He retired once more to Cologne, where he continued to teach till within a few years of his death. During this period he was frequently delegated with episcopal authority; and on one occasion he travelled at the request of Urban IV. through Germany and Bohemia, preaching the crusade. He died in 1280 at the advanced age of 87; and was buried in the choir of the Dominican church at Cologne. His tomb, which had the fame of working miracles, was opened in 1483, in presence of the general of the Dominicans, and his bones taken out to be distributed as relics.

Albert is chiefly remarkable as having been beyond question the most learned man of his age, and as the first who gave its decided direction to the general tendency of speculative intelligence towards the system of Aristotle. Without according to him the possession of profound or original genius, we may well sympathise in the admiration that bestowed on him the title of *Great;* did we only consider the fact, in connection with the time in which he lived, that his writings, ranging over the domains of natural history, metaphysics, and theology, and containing a body of knowledge, however imperfect or unmethodical, yet marvellous in its universality, occupy no less than 21 folio volumes. They were published at Lyons in 1651, edited, under superior authority, by Pierre Jammy, a Dominican monk. A detailed list of Albert's works, the genuineness of many of which it is impossible to determine, is to be found in the *Scriptor. Ord. Predicat.* of Quétif and Echard, vol. i. p. 171.

His disciples were distinguished by the name of *Albertists.*

ALBESIA, in *Antiquity*, a kind of shields, otherwise called *Decumana.*

ALBI or ALBY, an arrondissement in the south-west of France, in the department of the Tarn, comprehending an extent of 558 square miles, or 357,276 acres. It is divided into eight cantons and 92 communes, and in 1846 contained 91,232 inhabitants.

ALBI, a city in the above arrondissement, the capital of the Albigeois. It is built on the river Tarn, 35 miles N.E. of Toulouse. The cathedral is dedicated to St Cecilia, and has one of the finest choirs in the kingdom. Here is a very valuable silver shrine, of exquisite mosaic work: it contains the relics of St Clair, the first bishop of the city. The chapel of that saint is magnificent, and adorned with paintings. La Lice is a fine promenade without the city, distinguished by a terrace above a deep mall, which serves instead of a fosse, and bordered with two rows of very fine trees. At one end is the convent of the Dominicans. The archbishop's palace is a very beautiful edifice. The river washes its walls, and serves both for ornament and defence. Pop. in 1846, 12,452. Long. 2. 9. E. Lat. 43. 56. N.

ALBIGEOIS, L', an ancient territory of France, in Upper Languedoc, about twenty-seven miles in length, and twenty in breadth, abounding in sheep, corn, wood, grapes, saffron, and plums. There is a considerable trade in dried prunes, grapes, a coarse sort of cloth, and wine of Gaillac. These wines are the only sort in this district that are fit for exportation: they are carried down to Bourdeaux, and generally sold to the British. There are likewise several coal-mines.

ALBIGENSES, in *Church History*, a sect or party of reformers, about Toulouse and Albigeois, in Languedoc, who sprung up in the 12th century, and distinguished themselves by their opposition to the discipline and ceremonies of the Romish church.

The name is supposed to have been derived, either from there being great numbers of them in the diocese of Albi, or because they were condemned by a council held in that city. It does not indeed appear that they were known by this name before the time of that council. They were also called *Albiani, Albigesei, Albii*, and *Albanenses*, though some distinguish these last from them. Other names given to them are *Cathari, Abelardists, Berengarians, Bulgarians*, &c.; some on account of the qualities they assumed; others from that of the country from whence it is pretended they were derived; and others on account of persons of note who adopted their cause, as Peter de Brius, Arnold of Brescia, Abelard, Henry, &c. Berengarius, if not Wycliffe himself, is by some ranked in the number. The *Albigenses* are frequently confounded with the *Waldenses;* from whom, however, they differ in many respects, both as being prior to them in point of time, as having their origin in a different country, and as being charged with different heresies, particularly Manicheism, with which the *Waldenses* are not charged. From that imputation, however, several Protestant writers have vindicated them. Dr Allix shows that a great number of *Manichees* did spread over the western countries from Bulgaria, and settled in Italy, Languedoc, and other places, where there were also *Albigenses;* by which means, being both under the imputation of *heresy*, they came, either by ignorance or malice, to be confounded, and called by the same common name, though in reality entirely different.

Grave errors were imputed to them by their malicious opponents: such as that they admitted two Christs; one evil, who appeared on earth; the other good who has not yet appeared: that they denied the resurrection of the body, and maintained human souls to be demons imprisoned in our bodies, by way of punishment for their sins: that they condemned all the sacraments of the church, rejected baptism as useless, held the eucharist in abhorrence, excluded the use of confessions and penance, maintained marriage unlawful, laughed at purgatory, prayers for the dead, images, crucifixes, &c. There were likewise said to be two classes of them, the Perfect and the Believers. The Perfect boasted of their living in continence, of eating neither flesh, eggs, nor cheese. The Believers lived like other men, and were even loose in their morals; but they were persuaded they should be saved by the faith of the perfect, and that none were damned who received imposition of hands from them. But from these charges also they are generally acquitted by Protestants, who consider them as the pious inventions of the Romish church, which accounts it no sin, but rather meritorious by any means to blacken heretics.

However this be, the Albigenses grew so formidable, that the Catholics agreed upon a holy league or crusade against them. They were at first supported by Raymond Count of Toulouse. Pope Innocent III., desirous to suppress them, sent legates into their country, who even inflicted capital punishment on pertinacious heretics. These legates were known by the name of Inquisitors. On the murder of one of these, the pope proclaimed a crusade against the Albigenses, and their supporter Raymond VI., Count of Toulouse. The French barons took the field under Simon de Montfort (Earl of Leicester) in 1209; and Raymond found it his interest to side with them. Soon after, however, finding himself plundered by the crusaders, he proclaimed war against them, and was joined by his relation the king of Aragon, who lost his life in the first battle. The defeat of his army was followed by the surrender of the city of Toulouse, and the conquest of the greater part of Languedoc and Provence. The war was attended with circumstances of the greatest atrocity: at the massacre of Beziers, Arnald the pope's legate, on being asked how the heretics and the orthodox were to be distinguished, replied—" Slay all, and God will find his own." Montfort was killed at the siege of Toulouse in 1218, and Raymond died four years afterwards. Their sons renewed the war; but at last the Count of Toulouse was compelled to make peace in 1229. From this time the Albigenses gradually dwindled, till the time of the Reformation, when such of them as were left fell in with the Vaudois, and became conformable to the doctrine of Zuinglius and the discipline of Geneva.—*Mosheim's Eccles. Hist; General Hist. of Languedoc*, Paris, 1730.

ALBIGENSES is also a name sometimes given to the followers of Peter Vaud or Waldo. See VALDENSES.

ALBINI, in *Antiquity*, the workmen employed in what was called *opus albarium.* They made a different profession from the *dealbatores* or *whiteners.*

ALBINOS, the name by which the Portuguese call the white Moors, who are looked upon by the negroes as monsters. At a distance they might be taken for Europeans; but on a nearer view, their white colour appears like that of persons affected with leprosy.

In Saussure's *Voyages dans les Alpes* is the following account of the two boys at Chamouni, who have been called *Albinos*:—" The elder, who was at the end of the year 1785 about twenty or twenty-one years of age, had a dull look, with lips somewhat thick, but nothing else in his features to distinguish him from other people. The other, who is two years younger, is rather a more agreeable figure; he is gay and sprightly, and seems not to want wit. But their eyes are not blue; the iris is of a very distinct rose colour: the pupil, too, when viewed in the light, seems decidedly red, which seems to demonstrate that the interior membranes are deprived of the uvea, and of that black mucous matter that should line them. Their hair, their eyebrows, and eye-lashes, the down upon their skin, were all during their infancy of the most perfect milk-white colour, and very fine; but their hair is now of a reddish cast, and has grown pretty strong. Their sight, too, is somewhat strengthened, though they exaggerate to strangers their aversion for the light, and half shut the eye-lids, to give themselves a more extraordinary appearance; but those who, like me, have seen them in their infancy, before they were tutored to this deceit, and when too few people came to Chamouni to make this affectation profitable to them, can attest that then they were not very much offended with the light of day. At that time they were so little desirous of exciting the curiosity of strangers, that they hid themselves to avoid such; and it was necessary to do a sort of violence to them before they could be prevailed on to allow themselves to be inspected. It is also well known at Chamouni, that when they were of a proper age they were unable to tend the cattle like the other children at the same age; and that one of their uncles maintained them out of charity, at a time of life when others were capable of gaining a subsistence by their labour.

" I am therefore of opinion, that we may consider these two lads to be albinos; for if they have not the thick lips and flat noses of the white negroes, it is because they are albinos of Europe, not of Africa. This infirmity affects the eyes, the complexion, and the colour of the hair; it even diminishes the strength, but does not alter the conformation of the features. Besides, there are certainly in this malady various degrees—some may have less strength, and be less able to endure the light; but these circumstances in those of Chamouni are marked with characters sufficiently strong to entitle them to the unhappy advantage of being classed with that variety of the human species denominated albinos.

" I at first imagined that this disease might be referred to a particular sort of organic debility; that a relaxation of the lymphatic vessels within the eye might suffer the globules of the blood to enter too abundantly into the iris, the uvea, and even into the retina, which might occasion the redness of the iris and of the pupil. The same debility seemed also to account for the intolerance of the light, and for the whiteness of the hair.

" But a learned physiologist, M. Blumenbach, professor in the university of Göttingen, who has made many profound observations on the organs of sight, and has considered with great attention the albinos of Chamouni, attributes their infirmity to a different cause.

" The study of comparative anatomy has furnished him with frequent opportunities of observing this phenomenon; he has found it in brutes, in white dogs, and in owls; he says it is generally to be seen in the warm-blooded animals, but that he has never met with it in those with cold blood.

" From his observations, he is of opinion that the redness of the iris, and of the other internal parts of the eye, as well as the extreme sensibility that accompanies this redness, is owing to the total privation of that brown or blackish mucus, which, about the fifth week after conception, covers all the interior parts of the eye in its sound state. He observes that Simon Pontius, in his treatise *de Coloribus Oculorum*, long ago remarked, that in blue eyes the interior membranes were less abundantly provided with this black mucus, and were therefore more sensible to the action of light. This sensibility of blue eyes agrees very well, says M. Blumenbach, with northern people, during their long twilight; while, on the contrary, the deep black in the eyes of negroes enables them to support the splendour of the sunbeams in the torrid zone.

" As to the connection between this red colour of their eyes and the whiteness of the skin and hair, the same learned physiologist says, that it is owing to a similarity of structure, *consensus ex similitudine fabricæ.* He asserts that this black mucus is formed only in the delicate cellular substance, which has numerous bloodvessels contiguous to it, but contains no fat, like the inside of the eye, the skin of negroes, the spotted palate of several domestic animals, &c. And, lastly, he says that the colour of the hair generally corresponds with that of the iris—*Gazette Litt. de Gottingue*, Oct. 1784.

" At the very time that M. Blumenbach was reading this memoir to the Royal Society of Göttingen, M. Buzzi, surgeon to the hospital at Milan, an élève of the celebrated anatomist Moscati, published in the *Opuscoli Scelti de Milan*, 1784, tom. vii. p. 11, a very interesting memoir, in which he demonstrates by dissection what Blumenbach had only supposed.

" A peasant of about thirty years of age died in the hospital of Milan of a pulmonary disorder. His body being exposed to view, was exceedingly remarkable for the uncommon whiteness of the skin, of the hair of the beard, and of all the other covered parts of the body. M. Buzzi, who had long desired an opportunity of dissecting such a subject, immediately seized upon this. He found the iris of the eyes perfectly white, and the pupil of a rose colour. The eyes were dissected with the greatest possible care, and were found entirely destitute of that black membrane which anatomists call the *uvea;* it was not to be seen either behind the iris or under the retina. Within the eye there was only found the choroid coat, extremely thin, and tinged of a pale red colour, by vessels covered with discoloured blood. What was more extraordinary, the skin, when detached from different parts of the body, seemed almost entirely divested of the *rete mucosum;* maceration did not discover the least vestige of this, not even in the wrinkles of the abdomen, where it is most abundant and most visible.

"M. Buzzi likewise accounts for the whiteness of the skin and of the hair, from the absence of the *rete mucosum*, which, according to him, gives the colour to the cuticle, and to the hairs that are scattered over it. Among other proofs of this opinion, he alleges a well-known fact, that if the skin of the blackest horse be accidentally destroyed in any part of the body, the hairs that afterwards grow on that part are always white, because the *rete mucosum* which tinges those hairs are never regenerated with the skin.

"The proximate cause of the whiteness of albinos, and the colour of their eyes, seems therefore pretty evidently to depend on the absence of the *rete mucosum;* but what is the remote cause?

"M. Buzzi relates a singular fact, which seems to throw some light on this subject.

"A woman of Milan, called Calcagni, had seven sons. The two eldest had brown hair and black eyes; the three next had white hair, white skins, and red eyes; the two last resembled the two eldest. It is said that this woman, during the three pregnancies that produced the albinos, had a continual and immoderate appetite for milk, which she took in great quantities; but that, when she was with child of the other four children, she had no such desire. It is not, however, ascertained that this preternatural appetite was not itself the effect of a certain heat, or internal disease which destroyed the *rete mucosum* in the children before they were born.

"The albinos of Chamouni are also the offspring of parents with dark skins and black eyes. They have three sisters by the same father and mother, who are also brunettes. One of them that I saw had the eyes of a dark brown, and the hair almost black. They are said, however, to be all afflicted with a weakness of sight. When the lads are married, it will be curious to observe how the eyes of their children will be formed. The experiment would be particularly decisive if they were married to women like themselves. But this faulty conformation seems to be more rare among women than among men; for the four of Milan, the two of Chamouni, the one described by Maupertuis, the other by Helvetius, and almost all the instances of these singular productions, have been of our sex. It is known, however, that there are races of men and women affected with this disease, and that these races perpetuate themselves in Guinea, in Java, at Panama, &c.

"Upon the whole, this degeneration does not seem to be owing to the air of the mountains; for though I have traversed the greatest part of the Alps, and the other mountains of Europe, these are the only individuals of that kind that I ever met with."

Very perfect albinos, exactly answering to those described by Saussure, occur in our own island. A Welsh family in which every alternate child was an albino, is described by Dr Traill of Liverpool, in *Nicholson's Journal*, vol. xix. p. 81; and several other instances have since occurred in Britain.

ALBINOVANUS, C. Pedo, a Latin poet, whom Ovid calls *sidereus Pedo, the starry*, on account of the loftiness of his style. There is now nothing of his extant except three elegies, of doubtful genuineness, and a fragment in Seneca.

ALBINUS or Albus, the name of a noble Roman family, the head of the gens Postumia. It produced many consuls and distinguished men. The first of the name, surnamed Regillensis, commanded, according to Livy, as dictator, in the great battle of the Lake Regillus; but Niebuhr considers the name to have been derived merely from the place of his residence.

Albinus, *Bernhard Siegfred*, a celebrated physician and anatomist, was born of an illustrious family at Frankfort-on-the-Oder in 1697. His father was then professor of the practice of medicine in the university of Frankfort; but in the year 1702 he repaired to Leyden, being nominated professor of anatomy and surgery in that university. Here his son had an opportunity of studying under Boërhaave and other eminent masters, who, from the singular abilities which he then displayed, had no difficulty in prognosticating his future eminence. But while he was distinguished in every branch of literature, his attention was particularly turned to anatomy and surgery. His peculiar attachment to these branches of knowledge gained him the intimate friendship of Ruysch and Rau, who at that time flourished in Leyden; and the latter, so justly celebrated as a lithotomist, is said to have seldom performed a capital operation without inviting him to be present. Having finished his studies at Leyden, he went to Paris, where he attended the lectures of Du Verney, Vaillant, and other celebrated professors. But he had scarcely spent a year there when he was invited by the curators of the university of Leyden to be a lecturer on anatomy and surgery at that place. Though contrary to his own inclination, he complied with their request, and upon that occasion was created doctor of physic without any examination. Soon after, upon the death of his father, he was appointed to succeed him as professor of anatomy; and upon being admitted into that office on the 9th of November 1721, he delivered an oration *De vera via ad fabricæ humani corporis cognitionem ducente*, which was heard with universal approbation. In the capacity of a professor, he not only bestowed the greatest attention upon the instruction of the youth intrusted to his care, but on the improvement of the medical art. With this view he published many important discoveries of his own; and, by elegant editions, turned the attentions of physicians to works of merit which might otherwise have been neglected. By these means his fame was soon extended over Europe; and the societies of London, Petersburg, and Haarlem cheerfully received him as an associate. In 1745 he was appointed professor of the practice of medicine at Leyden, and was succeeded in the anatomical chair by his brother, Frid. Bern. Albinus. He was twice rector of the university, and as often he refused that high honour when it was voluntarily offered him. At length, worn out by long service and intense study, he died on the 9th of September 1770, in the 74th year of his age.

Albinus, *Clodius*, a native of Africa, was a distinguished military commander in the reigns of Marcus Aurelius, Commodus, and Pertinax. On the death of Pertinax he was proclaimed emperor by the legions in Britain and Gaul, but was defeated and slain by his formidable competitor Severus, in a battle near Lyons, A.D. 197.

ALBION, the ancient name of Britain. See Britain.

Albion, *New*, a name given by Sir Francis Drake to California on the north-west coast of America, which he discovered and took possession of in the year 1578. Captain Cook visited this coast in 1778, and landed in a place situate in Long. 235. 20. E. Lat. 44. 33. N. In the year 1792 it was again visited by Captain Vancouver, who was employed in surveying the western coast of North America. The name is now applied to that part of the coast which lies between 43° and 48° N. Lat.

ALBIREO, in *Astronomy*, a star of the third or fourth magnitude, in the constellation Cygnus.

ALBIS, in *Ancient Geography*, now the Elbe, which divided Ancient Germany in the middle, and was the boundary of this country, so far as it was known to the Romans. All beyond they owned to be uncertain, no Roman except Drusus, Tiberius, and D. Ahenobarbus having penetrated so far as the Elbe.

ALBITE, a species of felspar, called also CLEAVLANDITE. See MINERALOGY.

ALBOGALERUS, in *Roman Antiquity*, a white cap worn by the *flamen Dialis*, on the top of which was an ornament of olive branches.

ALBOIN, King of the Lombards. See LOMBARDS.

AL BORAK, amongst the Mahometan writers, the beast on which Mahomet rode in his journeys to heaven. The Arab commentators give many fables concerning this extraordinary mode of conveyance. It is represented as of an intermediate shape and size between an ass and a mule. A place, it seems, was secured for it in Paradise, at the intercession of Mahomet; which, however, was in some measure extorted from the prophet, by Al Borak's refusing to let him mount when the angel Gabriel was come to conduct him.

ALBORAN, a small and barren rocky islet in the Mediterranean sea, 66 miles S.S.W. of Almeria in Spain, Lat. 35. 58. N., Long. 3. 1. W.

ALBOX, a town of Spain, in the province of Almeria. It is well-built and healthy, and contains 7425 inhabitants. Principal manufactures, oil, flour, pottery, woollen and linen stuffs. The latter give employment to about 400 looms chiefly worked by women.

ALBRECHTSBERGER, JOHANN GEORGE, a musician, born at Kloster-Neuburg, Vienna, in 1729. He was a very learned contrapuntist, and became court organist at Vienna, was a member of the Academy, and had the honour of being the instructor of Beethoven. He died in 1809. Twenty-seven of his numerous compositions have been printed. His excellent *Guide to Composition, with Examples*, was first published at Leipsic, in 1790; and a collection of his writings on harmony, in 3 vols., appeared at Vienna in 1826.

ALBRIC, ALBRICIUS, or ALFRICUS, a learned British physician and philosopher, who flourished at London about the end of the eleventh century, or, according to others, in the beginning of the thirteenth. The following works of his are cited by Bale: [*Script. Illustr. Magn. Brit.*]—1. *De Deorum Imaginibus;* 2. *De Ratione Veneni;* 3. *Virtutes Antiquorum;* 4. *Canones Speculativi.* The first alone has been published, and is to be found in the *Mythographi Latini*, Amsterdam, 1681.

ALBUERA, a small village of Spain, in the province of Estremadura, 12 miles S.S.E. of Badajos. It has been rendered celebrated by a victory gained there on the 16th of May 1811, by the English, Portuguese, and Spaniards, under Marshal Beresford, over the French army, commanded by Marshal Soult.

ALBUFEIRA, a Portuguese town, on a bay in the province of Algarve, containing 2665 inhabitants. Its harbour is capable of containing large ships, and is well defended by a castle and battery. Lat. 37. 7. N. Long. 7. 19. W.

ALBUFERA DE VALENCIA, a lake seven miles south of Valencia, in Spain, about twelve miles in length and four in breadth. It has an opening to the sea, and abounds with fish and waterfowl. The banks are inhabited by fishermen. On the days of St Martin and St Catalina, the public have the freedom of fishing and shooting on the lake, which on these occasions is covered with hundreds of boats.

ALBUM, in *Antiquity*, a kind of white tablet or register, wherein the names of certain magistrates, public transactions, &c., were entered. Of these there were various sorts; as the *album decurionum, album senatorum, album judicum, album prætoris, &c.*

The high priest entered the chief transactions of each year into an *album*, or tablet, which was hung up in his house for the public use.

ALBUM is also used, in later times, to denote a kind of tablet, or pocket-book, for containing autographs, sketches, and original compositions.

ALBUMAZAR, a celebrated Arabian astronomer of the ninth century, born at Balkh, in Khorassan. He had reached the age of 47 before he entered on the studies to which he owes his fame. His principal works are *An Introduction to Astronomy*, and the *Book of Conjunction*, both published in a Latin translation at Augsburg, in 1489, and again at Venice in 1515; and a work *On the Revolution of the Years* is also attributed to him.

ALBUMEN, a substance found both in animal and vegetable matters, and in great abundance in the white of eggs. It coagulates by heat, and becomes insoluble in water after that process. See CHEMISTRY.

ALBUQUERQUE, a town of Spain, in a district of the same name, in the province of Estremadura, on an eminence, nine miles from the frontiers of Portugal. It is defended by an almost impregnable fortress, built on a high mountain. It was taken by the allies of Charles, king of Spain, in 1705, but was restored to the Crown in 1715. It has some trade in woollen and linen manufactures, and exports cattle and fruits. Long. 7. 0. W. Lat. 38. 52. N. Pop. 6787.

ALBUQUERQUE, *Alfonso*, the celebrated commander who laid the foundations of the Portuguese power in India, was born at Melinda, in Africa, in 1452. He died in 1515, at the mouth of the Persian Gulf. See PORTUGAL.—*Historia de Barros; Lafiteau, Conquêtes des Portugais.*

ALBURN, the English name of a compound colour, being a mixture of white and red, or reddish brown. Skinner derives the word, in this sense, from the Latin *albus*, and the Italian *bruno*, brown.

ALBURNUM, the soft white substance which in trees is found between the *liber* or inner bark and the wood, and in process of time acquiring solidity becomes itself the wood. From its colour and comparative softness, it has been styled by some writers the fat of trees, *adeps arborum.* Its popular name is sap-wood.

ALCÆUS, one of the great lyric poets of Greece, was a native of Mitylene, in Lesbos, aud flourished about the year 600 B.C. From the fragments of his poems which have come down to us, we learn that his life was greatly mixed up with the political disputes and internal feuds of his native city. He sided with the nobles, and took an active part against the tyrants, who at that time set themselves up in Mitylene. He was obliged, in consequence, to quit his native country, and spend the rest of his life in exile. The date of his death is unknown. His poems, which were composed in the Æolian dialect, were collected afterwards, and apparently divided into ten books. The subjects, as we can still see from the fragments, were of the most varied kind: some of his poems were hymns to the gods; others were of a martial or political character; others again breathed an ardent love of liberty and hatred of the tyrants; and lastly, some were of an erotic kind, and appear to have been particularly remarkable for the fervour of the passion they described. Horace looks upon Alcæus as his great model, and has, in one passage (*Od.* ii. 13. 26. *et seq.*), given a fine picture of the poetical powers of the Æolian bard. The care which Alcæus bestowed upon the construction of his verses was probably the reason why one kind of metre, the Alcaic, was named after him. Not one of his compositions has come down to us entire, but a complete collection of all the extant fragments may be found in Bergk's "*Poetae Lyrici Græci*," Lipsiae, 1852, 8vo. (L. S.)

ALCÆUS, an Athenian comic poet, or rather a writer of what is termed mixed comedy. He left ten pieces, one of which, *Pasiphaë*, he produced when he contended with Aristophanes, in the year B.C. 388.

ALCÆUS, of Messene, the author of 22 Epigrams in the Greek Anthology. He was contemporary with Philip III., king of Macedon, whom he did not spare in his Epigrams, and who replied to one of them in another, containing a broad hint of a dreadful retaliation if he should fall into his hands.

ALCAICS, in *Ancient Poetry*, a name given to several kinds of verse, from Alcæus, their alleged inventor.

The first kind consists of five feet, viz. a spondee or iambic, an iambic, a long syllable, a dactyle, another dactyle. Such are the following lines of Horace:

*Omnes | eo|dem | cogimur, | omnium*
*Versa|tur ur|na | serius, | ocius,*
*Sors exitura.*

The second kind consists of two dactyles and two trochees; as,

*Exili|um imposi|tura | cymbæ.*

Besides these two, which are called *dactylic Alcaïcs*, there is another, simply styled *Alcaïc*, consisting of an epitrite, a choriambus, another choriambus, and a bacchius. The following is of this species:

*Cur timet fla|vum Tiberim | tangere, cur | olivum?*

*ALCAIC Ode*, a kind of manly ode, composed of several strophes, each consisting of four verses; the first two of which are always alcaïcs of the first kind; the third verse is an iambic dimeter hypercatalectic, or consisting of four feet and a long syllable; and the fourth verse is an alcaïc of the second kind. The following strophe is of this species, which Horace calls "*minaces Alcæi camenæ.*"

*Non possidentem multa vocaveris*
*Recte beatum; rectius occupat*
*Nomen beati, qui deorum*
*Muneribus sapienter uti,* &c.

ALCAID, ALCAYDE, or ALCALDE, in the polity of the Moors, Spaniards, and Portuguese, a magistrate or officer of justice, answering nearly to the French provost and the British justice of peace. The alcaid among the Moors is vested with supreme jurisdiction, both in civil and criminal cases. Alcalde is still the title of the *mayors* of Spanish towns.

ALCALA DE GUADAIRA, a town of Spain, in Andalucia, upon the river Guadaira, with 7000 inhabitants, chiefly engaged in agriculture and the making of bread. It has abundance of springs, from which water is conveyed to Seville by an aqueduct. Long. 5. 47. W. Lat. 37. 15. N.

ALCALA *de Henares*, a city of Spain, on the river Henares, in the province of New Castile. It was formerly celebrated for its university, which has latterly been transferred to Madrid. This university was founded by Cardinal Ximenes, and it was here that the famous edition of the Holy Bible, known as the *Complutensian Polyglot*, was prepared. Alcala contains 5153 inhabitants, and has a military school for the artillery and engineer corps. Among many distinguished men to whom it had the honour of giving birth are, the poet Figueroa, the naturalist Bustamente de la Cámara, the historian Solis, and last and greatest of all, Cervantes.

ALCALA *de los Gazules*, a town of Seville in Spain, 27 miles N.W. of Cadiz, in a picturesque mountainous district. It has about 6000 inhabitants, chiefly engaged in agriculture.

ALCALA *la Real*, a city of Andalucia in Spain, 18 miles S.W. of Jaen. It stands between two mountain ridges, at an elevation of about 3000 feet above the sea. It has a fine abbey, two parish churches, and two convents, and a population chiefly agricultural, of about 7000. Alonso de Alcala, a celebrated physician and jurist of the sixteenth century, was born here. In 1810 the Spaniards were defeated here by the French.

ALCALY, or ALCALI, or ALKALI. See CHEMISTRY, *Index*.

ALCAMENES (Ἀλκαμένης), a famous Athenian sculptor, a pupil of Phidias, who is celebrated for his skill in art by Cicero, Pliny, Pausanias, Lucian, &c. He appears as one of the great triumvirate of Greek sculptors, Phidias, Alcamenes, and Polycletus. He competed with his master in a statue of Minerva. It would appear that in this attempt his style was exquisite in finish, but that he failed in the spirit of his work, when compared to that of his mighty master. His statue of Venus Urania, that adorned her temple at Athens, was reckoned his masterpiece. He flourished about 430 years B. C.

ALCAMO, a city of Sicily, on the river Freddo or St Bartholomew, in the intendancy of Trapani. It is a parliamentary city, in a district of peculiar fertility, which produces some of the best wines of the island. It contains a very strong castle, many churches and monasteries, and 13,000 inhabitants. Near to it are remains of the ancient Segesta, with its temple and theatre in good preservation; and near the sea are some celebrated warm baths.

ALCANIZ, a Spanish town upon the Guadaloupe, in the province of Teruel, with a fine town-house, a college, three parish churches, six monasteries, one hospital, and 5100 inhabitants. The surrounding country is wild, but rich in olives, mulberry trees, and alum.

ALCANNA, or ALKANNA, in *Commerce*, a powder prepared from the leaves of the Egyptian privet, in which the people of Cairo drive a considerable trade. It is much used by the Turkish women, to give a golden colour to their nails and hair. In dyeing, it gives a yellow colour when steeped with common water, and a red when infused in vinegar. There is also an oil extracted from the berries of alcanna, which is sometimes used in medicine.

ALCANTARA, the *Interamnium* of the Romans, a town of Estremadura in Spain, on the left bank of the Tagus, with 4273 inhabitants. Alcantara (*Arabice*, Al Kantrah, *i.e.* the bridge), derived its name from the magnificent Roman bridge which spanned the Tagus at this point; and which was erected, according to the inscription, in A.D. 104, at the joint expense of the several towns therein mentioned, in honour of the Emperor Trajan, who was a native of Spain. This noble monument of antiquity was injured by the English, and afterwards, with gratuitous barbarism, blown up by the French general Victor, during the campaign of 1809. It was repaired with timber in 1818, and again burnt in 1836 to prevent the passage of the Carlist troops. Lat. 39. 41. N. Long. 6. 44. W.

*Knights of ALCANTARA*, one of the five military orders of Spain, which took its name from the above-mentioned city. They make a very considerable figure in the history of the expeditions against the Moors. The knights of Alcantara make the same vows as those of Calatrava, and are only distinguished from them by this, that the cross fleur-de-lis, which they bear over a large white cloak, is of a green colour. They possess 37 commanderies. By the terms of the surrender of Alcantara to this order, it was stipulated that there should be a confraternity between the two orders, with the same practices and observances in both; and that the order of Alcantara should be subject to be visited by the grand master of Calatrava. But the former soon released themselves from this engagement, on pretence that their grand master had not been called to the election of that of Calatrava, as had been likewise stipulated in the articles. After the expulsion of the Moors, and the taking of Granada, the sovereignty of the order of Alcantara and that of Calatrava was settled in the crown of Castile by Ferdinand and Isabella. In 1540 the knights of Alcantara sued for leave to marry, which was granted them.

ALCARAZ, a small city of La Mancha, in Spain, now in the province of Albacete. The judicial district of the same name contains 28,000 inhabitants. It is a very mountainous region, interspersed with fertile valleys. The principal mountain chain is the Sierra de Alcaraz, a prolongation of the Sierra Morena. The city stands near the river Guardamena, and has the remains of a once strong castle, and of a magnificent Roman aqueduct. It is mentioned by Ptolemy under the name of *Urcesa*, converted by the Arabs into Al Karrasch. Pop. 7325.

ALCAUDETE, a town of Andalucia, in Spain, in the province of Jaen, in a fertile territory, producing wine, oil, corn, and abundance of fruits. It has a castle, two parish churches, four monasteries, and 6499 inhabitants.

ALCAVALA was a duty imposed in Spain and its colonies on all transfers of property, whether public or private. It was originally imposed in 1341, as an *ad valorem* tax of 10, increased afterwards to 14, per cent., charged on all commodities, whether raw or manufactured, as often as they were sold or exchanged, being always rated according to their selling price. The levying of this tax required a multitude of revenue officers sufficient to guard the transportation of goods not only from one province to another, but from one shop to another. It subjected not only the dealers in some sort of goods, but those in all sorts, every farmer, every manufacturer, every merchant and shopkeeper, to the continual visits and examination of the tax-gatherers. This monstrous impost was permitted to ruin the industry and commerce of the greater part of the kingdom down to the invasion of Napoleon. Catalonia and Aragon purchased from Philip V. an exemption from the alcavala, and from another pernicious tax called the *milliones* (duties on butcher-meat, and other articles of provisions), by the substitution of a tax on the rents of lands and houses, and on profits, and the wages of labour. Extremely onerous as this latter tax was, Catalonia and Aragon were in a comparatively flourishing state, in consequence of their exemption from the oppressive alcavala.—M'Culloch *on Taxation*.

ALCAZAR DE SAN JUAN, a Spanish town in a district of the same name, in the province of Ciudad Real, and diocese of Toledo. It contains 7540 inhabitants. It has manufactures of soap, saltpetre, and gunpowder. This is the *Alce* of the Romans, taken by T. Sempronius Gracchus after a victory over the Celtiberians, B.C. 180.—*Livy*, xl. 48, 49.

ALCAZAR DO SAL, a town of Portugal, in Estremadura, with a castle said to be impregnable. It is fortified both by art and nature, being built on the top of a rock exceedingly steep on all sides. The salt produced here, whence the town takes its name, is of remarkable whiteness. The fields produce large quantities of rushes, of which mats are made, which are transported out of the kingdom. Pop. 4000. Long. 9. 10. W. Lat. 38. 18. N.

ALCAZAR KEBIR, a city of Barbary, seated about two leagues from Larache, in Asga, a province of the kingdom of Fez. It was of great note, and the seat of the governor of this part of the kingdom. It was built by Jacob Almanzor, king of Fez, about the year 1180, and designed for a magazine and place of rendezvous for the great preparations he was making to enter Granada in Spain, and to make good the footing which Joseph Almanzor had got some time before. It is said his father first invaded Spain with 300,000 men, most of whom he was obliged to bring back to Africa to quell a rebellion that had broken out in Marocco. This done, he returned to Spain again with an army, as is said, of 200,000 horse and 300,000 foot. The city is now fallen greatly to decay, so that of fifteen mosques, two only are used, probably in consequence of the bad situation of the town; for it stands so low, that it is excessively hot in summer, and in winter almost overflowed with water. Population about 5000. Near this city there is a high ridge of mountains running towards Tetuan, whose inhabitants were never brought entirely under subjection. Not far from this is the river Elmahassen, famous for the battle fought between Don Sebastian, king of Portugal, and the Moors, in which the Portuguese were defeated, and their king slain. Long. 12. 35. W. Lat. 35. 15. N.

ALCAZAR, *Luis de*, a learned Spanish Jesuit, born at Seville in 1554. His ingenuity was chiefly directed to the interpretation of the Apocalypse, on which subject he wrote various treatises. He was greatly beloved in his native city, where he died in 1613.

ALCEDO, the genus *Kingfisher*, in Ornithology.

ALCEDO, *Antonio de*, a Spanish geographer of the West Indies, whose work printed, in 5 vols. 4to, in 1786-9, was suppressed by the government. It was translated into English in 1812-15 by Mr G. A. Thompson; but is now entirely superseded.

ALCESTER, a parish and market town in the county of Warwick, 13 miles W.S.W. of Warwick, with 2027 inhabitants, who manufacture needles and fish-hooks. It was the ancient *Alauna*.

ALCESTIS, the daughter of Pelias, and wife of Admetus king of Pheræ in Thessaly, who consented to die in place of her husband, and was afterwards restored to life by Hercules. This beautiful instance of female devotion forms the subject of one of the best plays of Euripides.

ALCHADEB, a Spanish rabbi, who flourished about the end of the 15th century. He was celebrated as an astronomer, but his works, with one exception, exist only in MS.

ALCHEMY, a word of equally doubtful origin with the science which it denotes. The prefix *al* suggests an Arabic source, and the word has accordingly been explained as signifying *the chemistry*, with reference to the "great projection," as the terminating and highest result of the science.

It is impossible now to connect the *hermetic art* of the Egyptians, and the traces of alchemy in the later history of Rome, with its first historical development in the middle ages, beginning in the eighth century with the Arabian Gebir. From the Arabians it passed into Europe; and the period from the eleventh to the sixteenth century inclusive constitutes the proper reign of alchemy. During this period it numbered among its adepts the great names of Roger Bacon, Albertus Magnus, Aquinas, Raymond Lully, Arnauld of Villa Nova, Basil Valentine, and Paracelsus. From these, the genuine and highest type of alchemists, we must take our estimate of the art, and not from the baser class of visionaries and impostors with whom the name has too long been universally associated. These men, then, will be found to have been in reality laborious experimental chemists, and their belief in the particular doctrines of alchemy to have been the very natural offspring of the contact of high speculative intellect, in a dark and enthusiastic age, with the wonders of a science pregnant above all others in marvels and in mystery. That these men contributed little to our real knowledge of nature, even if true, might well be accounted for, by the fact that the trammels of spiritual authority still fettered the human mind, and that the jealous guardianship of superstition too faithfully bounded the inquiries of a bold curiosity. Modern science, however, stands indebted in no small degree to the alchemy of the middle ages.

The peculiar objects of the enthusiastic and patient pursuit of the alchemist were, 1*st*, the *alkahest*, or universal solvent, an element to which modern chemistry has made a kind of approximation. 2*d*, the transmutation of metals, an idea under different forms, which will be found to pervade the whole course of chemical inquiry. "The improvements," says Sir Humphry Davy, "taking place in the methods of examining bodies, are constantly changing the opinions of chemists with respect to their nature; and there is no reason to suppose that any real indestructible principle has yet been discovered. Matter may ultimately be found to be the same in essence, differing only in the arrangement of its particles; or two or three simple substances may produce all the varieties of compound bodies." The possibility of the realisation of this idea still remains, however, to be demonstrated. 3*d*, The *elixir vitæ*, or universal medicine, for the cure of all diseases, and the indefinite prolongation of human life, an idea which, we may remark, has not been peculiar to the alchemists, having substantially been held by Bacon and Descartes. For fuller historical particulars see CHEMISTRY, *History*.

ALCIATI, ANDREA, an eminent Italian jurist, who was born near Milan, in 1492, and died in 1550. He mixed much of polite learning in the explication of the laws, and happily drove out the barbarity of language which till then had reigned in the lectures and writings of lawyers: for which Thuanus highly praises him. He published a great many law-books, and some notes upon Tacitus. His *Emblems* have been much admired, and translated into French, Italian, and Spanish. His *History of Milan* appeared after his death.

ALCIBIADES, the celebrated Athenian general, son of Clinias and Deinomache, was born at Athens about the year 450 B.C. Of high birth, princely fortune, and surpassing personal beauty, he was eminently distinguished for the brilliancy and versatility of his talents; but his youth was disgraced by debauchery and excess, from which his friend Socrates strove in vain to reclaim him. Mutual services had cemented their friendship; Socrates having rescued him from death at the battle of Potidæa, as he afterwards saved the life of Socrates at that of Delium. On the death of Cleon, in 422, he became one of the leaders in the Athenian commonwealth, and the head of the war party, in opposition to Nicias. He warmly advocated the Sicilian expedition, of which he was chosen a joint commander with Nicias and Lamachus. Shortly after his arrival there, he was recalled to Athens, to stand his trial respecting the mysterious mutilation of the Hermes busts, with which act of impiety he was charged as a ringleader previously to his departure; but contriving to escape from the state vessel that was conveying him, he proceeded to Sparta, where he acted as the avowed enemy of his country. Sentence of death was passed upon him at Athens, and his property confiscated. The machinations of Agis II. obliged him to leave Sparta; and taking refuge with Tissaphernes, he induced that commander to desert the Spartans, and declare himself in favour of the Athenians, who thereupon recalled Alcibiades from exile. Before he returned, however, the Athenians under his command gained the victories of Cynossema, Abydos, and Cyzicus, and took possession of Chalcedon and Byzantium; after which, in 407, he entered Athens in triumph, and was appointed commander of all the land and sea forces. But the year following he was superseded, in consequence of the defeat of his fleet at Notium, occasioned by the rashness of his lieutenant Antiochus, and he retired into voluntary exile to his fortified domain at Bisanthe. Before the fatal battle of Ægos-Potamos, he gave an ineffectual warning to the Athenian leaders. After the fall of Athens, he was banished and took refuge with Pharnabazus, and was about to proceed to the court of Artaxerxes, when assassins, hired either by the Spartans or by the brothers of a lady whom he had seduced, fired his house in the night; and in attempting to escape, he was slain with darts, in the forty-sixth year of his age, B.C. 404. He left a son, of his own name, by his wife Hipparete.

ALCIDAMAS, a Greek rhetorician, who gave instructions in eloquence at Athens, where he resided between the years B.C. 432 and 411. His chief works are lost; but there are two orations extant that pass under his name.—See Reiske's *Oratores Græci*; and Bekker's *Oratores Attici*.

ALCIDES, a name of Amphitryon, son of Alcæus, and more especially of Hercules the grandson of Alcæus.

ALCINOUS, a Platonic philosopher of uncertain date, author of a work entitled Ἐπιτομὴ τῶν Πλάτωνος δογμάτων, which has been translated into English by Stanley in his History of Philosophy. The best edition of the Greek original is that by Fisher, Lips. 1783, 8vo.

ALCINOUS, a mythical king of the Phæacians, in the island of Scheria or Drepane, which it would be difficult to identify with any modern island, was son of Nausithous, and grandson of Neptune and Peribœa. This king has been immortalised in the Odyssey. He received Ulysses with much civility, when a storm had cast him on his coast. His people loved pleasure and good cheer, yet were skilful seamen; and Alcinous is described as a good prince.

ALCIPHRON, the most eminent of the Greek epistolary writers, was probably a contemporary of Lucian. His letters, of which 116 have been published, are written in the purest Attic dialect: the imaginary authors of them are country people, fisherwomen, courtesans, and parasites; who express their sentiments and opinions on familiar subjects in refined and elegant language, yet without any very apparent inconsistency. The new Attic comedy being the principal source from which Alciphron derived his information, these letters are valuable as delineating the private life of the Athenians at that period. The best editions are by Bergler, Lips. 1715, and Wagner, Lips. 1798.

ALCIRA, the ancient *Sucro*, a Spanish town upon an island in the river Júcar, in the province of Valencia. It is surrounded with walls, and has two parish churches, six monasteries, one hospital, four poorhouses, and 13,000 inhabitants. Its principal productions are silk, rice, and oranges, which are exported to Seville, France, and England.

ALCMÆON, a philosopher of Crotona, who lived about 550 B.C. He is said to have been a pupil of Pythagoras, and according to some he was the first who dissected the human body. His writings are lost, but his opinions may be gathered from Stobæus, Plutarch, and Galen.

ALCMAER, a city of the United Provinces, in North Holland, seated about four miles from the sea, 15 from Haarlem, and 18 from Amsterdam. The streets and houses are extremely neat and regular, and the public buildings very beautiful. The church of St Lawrence is a fine Gothic building of the fifteenth century, with a beautiful porch. Alcmaer has a court of primary jurisdiction, a college, a theatre, &c. In 1850 the number of inhabitants was 10,148.

ALCMAN, sometimes also called ALCMAEON, one of the most ancient, and, in the opinion of the Alexandrian critics, the most distinguished among the lyric poets of Greece. According to one account he was by birth a Lydian, while others state that he was a native of Sparta, where, at any rate, he lived from a very early age. The time at which he flourished is uncertain, though it is generally assumed that it was the period between the years 620 and 640 B.C. Alcman may in some respects be regarded as the father of lyric poetry among the Greeks, and it was probably for this reason that the Alexandrian critics put him at the head of their lyric canon. His poems, which seem to have formed a collection of six books, are known to us only from a number of small fragments. Many of them were of an erotic character, but others of them were hymns, and *scolia*. All were written in the vigorous broad dialect of the Dorians. The best collection of these fragments was published by F. G. Welcker, Giesen, 1815, 4to; they are also contained in Bergk's "*Poetæ Lyrici Græci*," 1852, 8vo. (L. S.)

ALCMANIAN, an ancient lyric kind of verse, consisting of two dactyles and two trochees: as,—

*Virgini|bus pue|risque|canto.*

It derived its name from the poet above mentioned.

ALCMENA, the daughter of Electryon, king of Mycenæ, and wife of Amphitryon. She was the mother of Hercules by Zeus, who assumed the likeness of her husband during his absence; and at the same birth she bore Iphicles by Amphitryon.

ALCOBAZA, a town of Portugal, to the north of Lisbon, in the province of Estremadura, at the confluence of the two rivers Alcoa and Baza. It is celebrated for its monastery, one of the richest and most splendid establishments in the kingdom. It contains 295 houses and 2000 inhabitants.

ALCOCK, JOHN, doctor of laws, and bishop of Ely in the reign of Henry VII., was born at Beverley in Yorkshire, and educated at Cambridge. He was first made dean of Westminster, and afterwards appointed master of the rolls. In 1471 he was consecrated bishop of Rochester; in 1476 he was translated to the see of Worcester; and in 1486 to that of Ely, in the room of Dr John Morton, preferred to the see of Canterbury. He was a prelate of great learning and piety, and so highly esteemed by King Henry, that he appointed him lord-president of Wales, and afterwards lord-chancellor of England. Alcock founded a school at Kingston-upon-Hull, and built the spacious hall belonging to the episcopal palace at Ely. He was also the founder of Jesus College in Cambridge, for a master, six fellows, and as many scholars. This house was formerly a nunnery, dedicated to St Radigund; and Godwin says that the building being greatly decayed, and the revenues reduced almost to nothing, the nuns had all forsaken it, except two; whereupon Bishop Alcock procured a grant from the crown, and converted it into a college. But Camden and others tell us, that the nuns of that house were so notorious for their incontinence, that King Henry VII. and Pope Julius II. consented to its dissolution: Bale accordingly calls this nunnery *spiritualium meretricum cœnobium*, a community of spiritual harlots. Bishop Alcock wrote several pieces, among which are the following:—1. Mons Perfectionis; 2. In Psalmos Pœnitentiales; 3. Homiliæ Vulgares; 4. Meditationes Piæ. He died October 1. 1500, and was buried in the chapel built by himself in Ely cathedral.

ALCOENTRE, a town of Portugal, in the province of Estremadura. It is within the lines of Torres Vedras, and was occupied by the allied troops as cantonments during the important period when those lines were the barrier that secured the safety of the peninsula.

ALCOHOL, or ALKOHOL, in *Chemistry*, spirits of wine highly rectified. It is also used for any highly rectified spirit. *Absolute* alcohol has been obtained of a specific gravity, 794·2. See MATERIA MEDICA.

ALCOHOLIZATION, the process of rectifying any spirit.

ALCOR, the name of a small star adjoining to the large bright one in the middle of the tail of *Ursa major*. The word is Arabic. It is a proverb among the Arabians, applied to one who pretends to see small things, but overlooks much greater: *Thou canst see Alcor, and yet not see the full moon.*

ALCORA, a town of Valencia in Spain, celebrated for its delft and porcelain manufactory. Pop. 6000.

ALCORAN, or AL-KORAN, the scripture or bible of the Mahometans. The word is compounded of the Arabic particle *al*, and *koran*, derived from the verb *karaa*, to read. It therefore properly signifies *the reading*, or rather *that which ought to be read.* By this name the Mahometans denote not only the entire book or volume of the Koran, but also any particular chapter or section of it; just as the Jews call either the whole Scripture, or any part of it, by the name of *Kara* or *Mikra*, words of the same origin and import.

Besides this peculiar name, the Koran is also honoured with several appellations common to other books of Scripture: as *al Farkan*, from the verb *foraka*, to divide or distinguish; not, as the Mahometan doctors say, because those books are divided into chapters or sections, or distinguish between good and evil, but in like manner as the Jews use the word *Perek* or *Pirka*, from the same root, to denote a section or portion of Scripture. It is also called *al Moshaf*, the volume, and *al Kitah*, the book, by way of eminence, which answers to the *Biblia* of the Greeks; and *al Dhikr*, the admonition, which name is also given to the Pentateuch and Gospel.

The Koran is divided into 114 larger portions of very unequal length, which we call *chapters*, but the Arabians *sowar*, in the singular *sura*, a word rarely used on any other occasion, and properly signifying a row, order, or a regular series; as a course of bricks in a building, or a rank of soldiers in an army; and is the same in use and import with the Sura or Tora of the Jews, who also call the fifty-three sections of the Pentateuch *Sedarim*, a word of the same signification.

These chapters are not distinguished in the manuscript copies by their numerical order, but by particular titles, which are taken sometimes from a particular matter treated of, or person mentioned therein; but usually from the first word of note, exactly in the same manner as the Jews have named their *Sedarim;* though the word from which some chapters are denominated be very far distant, towards the middle, or perhaps the end of the chapter; which seems ridiculous. But the occasion of this appears to have been, that the verse or passage wherein such word occurs was, in point of time, revealed and committed to writing before the other verses of the same chapter which precede it in order; and the title being given to the chapter before it was completed, or the passages reduced to their present order, the verse from whence such title was taken did not always happen to begin the chapter. Some chapters have two or more titles, occasioned by the difference of the copies.

Some of the chapters having been revealed at Mecca, and others at Medina, the noting of this difference makes a part of the title; but the reader will observe that several of the chapters are said to have been revealed partly at Mecca and partly at Medina; and as to others, it is yet a dispute among the commentators to which of the two places they belong.

Every chapter is subdivided into smaller portions, of very unequal length also, which we customarily call *verses;* but the Arabic word is *ayat*, the same with the Hebrew *ototh*, and signifies *signs* or *wonders:* such as are the secrets of God, his attributes, works, judgments, and ordinances, delivered in those verses; many of which have their particular titles also, imposed in the same manner as those of the chapters.

Besides these unequal divisions of chapter and verse, the Mahometans have also divided their Koran into sixteen equal portions, which they call *Ahzab*, in the singular *Hizb*, each divided into four equal parts; which is also an imitation of the Jews, who have an ancient division of their Mishna into sixty portions called *Massictoth.* But the Koran is more usually divided into thirty sections only, named *Ajza*, from the singular *Joz*, each of twice the length of the former, and in like manner subdivided into four parts. These divisions are for the use of the readers of the Koran in the royal temples, or in the adjoining chapels, where the emperors and great men are interred. There are thirty of these readers belonging to every chapel, and each reads his section every day; so that the whole Koran is read over once a day.

Next after the title, at the head of every chapter, except only the ninth, is prefixed the following solemn form, by the Mahometans called the *Bismallah*, IN THE NAME OF THE MOST MERCIFUL GOD; which form they constantly place at the beginning of all their books and writings in general, as a peculiar mark or distinguishing characteristic of their religion, it being counted a sort of impiety to omit it. The Jews, for the same purpose, make use of the form, *In the name of the LORD*, or *In the name of the great GOD;* and the eastern Christians that of *In the name of the Father, and of the Son, and of the Holy Ghost.* But Mahomet probably took this form, as he did many other things, from the Persian Magi, who used to begin their books in these words, *Benam Yezdan bakshaishgher dadar;* that is, *In the name of the most merciful just GOD.*

There are twenty-nine chapters of the Koran which have this peculiarity, that they begin with certain letters of the alphabet, some with a single one, others with more. These letters the Mahometans believe to be the peculiar marks of the Koran, and to conceal several profound mysteries, the certain understanding of which, the most intelligent confess, has not been communicated to any mortal, their prophet only excepted. Notwithstanding which, some will take the liberty of guessing at their meaning by that species of Cabala called by the Jews *Notarikon*, and suppose the letters to stand for as many words, expressing the names and attributes of God, his works, ordinances, and decrees; and therefore these mysterious letters, as well as the verses themselves, seem in the Koran to be called *signs.* Others explain the intent of these letters from their nature or organ, or else from their value in numbers, according to another species of the Jewish Cabala, called *Gematria;* the uncertainty of which conjectures sufficiently appears from their disagreement. Thus, for example, five chapters, one of which is the second, begin with these letters, A. L. M. which some imagine to stand for *Allah latiff magid, GOD is gracious and to be glorified;* or, *Ana li minni*, i. e. *to me and from me*, viz. belongs all perfection, and proceeds all good; or else for *Ano Allah alam, I am the most wise GOD*, taking the first letter to mark the beginning of the first word, the second the middle of the second word, and the third the last of the third word; or for *Allah, Gabriel Mohammed*, the author, revealer, and preacher of the Koran. Others say, that as the letter A belongs to the lower part of the throat, the first of the organs of speech; L to the palate, the middle organ; and M to the lips, which are the last organ; so these letters signify that God is the beginning, middle, and end, or ought to be praised in the beginning, middle, and end, of all our words and actions: or, as the total value of those three letters, in numbers, is seventy-one, they signify, that, in the space of so many years, the religion preached in the Koran should be fully established. The conjecture of a learned Christian is at least as certain as any of the former, who supposes those letters were set there by the amanuensis, for *Amar li Mohamed*, i. e. *at the command of Mohammed*, as the five letters prefixed to the nineteenth chapter seem to be there written by a Jewish scribe, for *Coh yaas, Thus he commanded.*

The Koran is universally allowed to be written with the utmost elegance and purity of language, in the dialect of the tribe of Koreish, the most noble and polite of all the Arabians, but with some mixture, though very rarely, of other dialects. It is confessedly the standard of the Arabic tongue, and, as the more orthodox believe and are taught by the book itself, inimitable by any human pen (though some sectaries have been of another opinion); and therefore insisted on as a permanent miracle, greater than that of raising the dead, and alone sufficient to convince the world of its divine original.

And to this miracle did Mahomet himself chiefly appeal for the confirmation of his mission, publicly challenging the most eloquent men in Arabia, which was at that time stocked with thousands whose sole study and ambition it was to excel in elegance of style and composition, to produce even a single chapter that might be compared with it.[1]

To the pomp and harmony of expression some ascribe all the force and effect of the Koran, which they consider as a sort of music, equally fitted with other species of that art to ravish and amaze. In this Mahomet succeeded so well, and so strangely captivated the minds of his audience, that several of his opponents thought it the effect of witchcraft and enchantment, as he himself complains. Others have attributed the effect of the Koran to the frequent mention of rewards and punishments,—heaven and hell occurring almost in every page. Some suppose that the sensual pleasures of paradise, so frequently set before the imaginations of the readers of the Koran, were what chiefly bewitched them; though, with regard to these, there is a great dispute whether they are to be understood literally or spiritually. Several have even allegorized the whole book.

The general design of the Koran was to unite the professors of the three different religions then followed in the populous country of Arabia (who for the most part lived promiscuously, and wandered without guides, the far greater number being idolaters, and the rest Jews and Christians mostly of erroneous and heterodox belief) in the knowledge and worship of one God, under the sanction of certain laws, and the outward signs of ceremonies partly of ancient and partly of novel institution, enforced by the consideration o rewards and punishments both temporal and eternal, and to bring them all to the obedience of Mahomet, as the prophet and ambassador of God, who, after the repeated admonitions, promises, and threats of former ages, was at last to establish and propagate God's religion on earth, and to be acknowledged chief pontiff in spiritual matters, as well as supreme prince in temporal.

The great doctrine, then, of the Koran is the unity of God, to restore which point, Mahomet pretended, was the chief end of his mission; it being laid down by him as a fundamental truth, that there never was, nor ever can be, more than one true orthodox religion. For, though the particular laws or ceremonies are only temporary, and subject to alteration, according to the divine directions, yet the sub-

[1] As the composition and arrangement of words, however, admit of infinite varieties, it can never be absolutely said that any one is the best possible. In fact, Hamzah Benahmed wrote a book against the Koran with at least equal elegance; and Moselema another, which even surpassed it, and occasioned a defection of a great part of the Mussulmans. (*Jour. de Sçav.* tom. xiii. p. 280. *Œuv. de Sçav.* Nov. 1708, p. 404.)

stance of it being eternal truth, is not liable to change, but continues immutably the same. And he taught, that whenever this religion became neglected, or corrupted in essentials, God had the goodness to re-inform and re-admonish mankind thereof, by several prophets, of whom Moses and Jesus were the most distinguished, till the appearance of Mahomet, who is their seal, and after whom no other is to be expected. The more effectually to engage the people to hearken to him, great part of the Koran is employed in relating examples of dreadful punishments formerly inflicted by God on those who rejected and abused his messengers. Several of these stories, or some circumstances of them, are taken from the Old and New Testaments, but many more from the apocryphal books and traditions of the Jews and Christians of those ages, and are set up in the Koran as truths in opposition to the Scriptures, which the Jews and Christians are charged with having altered. But in fact few or none of the relations or circumstances in the Koran were invented by Mahomet, as is generally supposed, it being easy to trace the greater part of them much higher, as the rest might be, were more of those books extant, and were it worth while to make the inquiry.

The rest of the Koran is taken up in prescribing necessary laws and directions, frequent admonitions to moral and divine virtues, the worship and reverence of the Supreme Being, and resignation to his will. One of their most learned commentators distinguishes the contents of the Koran into *allegorical* and *literal*. Under the former are comprehended all the obscure, parabolical, and enigmatical passages, with such as are repealed or abrogated; under the latter, such as are clear and in full force.

The most excellent moral in the whole Koran, interpreters say, is that in the chapter *Al Alraf*, viz. "Show mercy, do good to all, and dispute not with the ignorant;" or, as Mr Sale renders it, "Use indulgence, command that which is just, and withdraw far from the ignorant." Mahomet, according to the authors of the *Keschaf*, having begged of the angel Gabriel a more ample explication of this passage, received it in the following terms:—"Seek him who turns thee out, give to him who takes from thee, pardon him who injures thee; for God will have you plant in your souls the roots of his chief perfections." It is easy to see that this commentary is copied from the Gospel. In reality, the necessity of forgiving enemies, though frequently inculcated in the Koran, is of a later date among the Mahometans than among the Christians; among those latter, than among the heathens; and to be traced originally to the Jews. (See Exodus xxiii. 4, 5.) But it matters not so much who had it first, as who observes it best. The caliph Hassan, son of Ali, being at table, a slave unfortunately let fall a dish of meat, reeking hot, which scalded him severely. The slave fell on his knees, rehearsing these words of the Koran:—"Paradise is for those who restrain their anger." "I am not angry with thee," answered the caliph. "And for those who forgive offences against them," continues the slave. "I forgive thee thine," replies the caliph. "But, above all, for those who return good for evil," adds the slave. "I set thee at liberty," rejoined the caliph; "and I give thee ten dinars."

There are also a great number of occasional passages in the Koran, relating only to particular emergencies. For in the piecemeal method of receiving his revelation, Mahomet had this advantage, that whenever he happened to be particularly perplexed with any thing, he had a certain resource in some new morsel of revelation. It was an admirable contrivance of his to bring down the whole Koran at once only to the lowest heaven, not to earth; since, had the whole been published at once, innumerable objections would have been made, which it would have been impossible for him to solve; but as he received it by parcels, as God saw fit they should be published for the conversion and instruction of the people, he had a sure way to answer all emergencies, and to extricate himself with honour from any difficulty which might occur.

It is the general and orthodox belief among the Mahometans that the Koran is of divine original; nay, that it is eternal and uncreated, remaining, as some express it, in the very essence of God; that the first transcript has been from everlasting by God's throne, written on a table of vast size, called the *preserved table*, in which are also recorded the divine decrees, past and future; that a copy from this table, in one volume, on paper, was, by the ministry of the angel Gabriel, sent down to the lowest heaven, in the month of Ramadan, on the night of *power;* from whence Gabriel revealed it to Mahomet by parcels, some at Mecca, and some at Medina, at different times, during the space of 23 years, as the exigency of affairs required; giving him, however, the consolation to show him the whole (which, they say, was bound in silk, and adorned with gold and precious stones of paradise) once a-year; but that in the last year of his life he had the favour to see it twice. They say that few chapters were delivered entire, the greater part being revealed piecemeal, and written down from time to time by the prophet's amanuensis in such a part of such and such a chapter till they were completed, according to the directions of the angel. The first parcel that was revealed is generally agreed to have been the first five verses of the 46th chapter.

After the new-revealed passages had been from the prophet's mouth taken down in writing by his scribe, they were published to his followers, several of whom took copies for their private use, but the far greater number got them by heart. The originals, when returned, were put promiscuously into a chest, observing no order of time; for which reason it is uncertain when many passages were revealed.

When Mahomet died, he left his revelations in the same disorder, and not digested into the method, such as it is, in which we now find them. This was the work of his successor, Abu Bekr, who, considering that a great number of passages were committed to the memory of Mahomet's followers, many of whom were slain in the wars, ordered the whole to be collected, not only from the palm-leaves and skins on which they had been written, and which were kept between two boards or covers, but also from the mouths of such as had learned them by heart; and this transcript, when completed, he committed to the custody of Hassa, the daughter of Omar, one of the prophet's widows.

From this relation it is generally imagined that Abu Bekr was really the compiler of the Koran, though, for aught that appears to the contrary, Mahomet left the chapters complete as we now have them, excepting such passages as his successor might add or correct from those who had committed them to memory; what Abu Bekr did else being perhaps no more than to range the chapters in their present order, which he seems to have done without any regard to time, having generally placed the longest first.

However, in the 30th year of the Hegira, Othman being then caliph, and observing the great disagreement in the copies of the Koran in the several provinces of the empire, —those of Irak, for example, following the reading of Abu Musa al Ashari, and the Syrians that of Makdad Ebn Aswad, —he, by the advice of the *companions*, ordered a great number of copies to be transcribed from that of Abu Bekr, in Hassa's care, under the inspection of Zeid Ebn Thabet, Abd'allah Ebn Zobair, Said Ebn al As, and Abd'alrahman Ebn al Hareth the Makhzumite; whom he directed, that wherever they disagreed about any word, they should write it in the dialect of the Koreish, in which it was at first delivered. These copies, when made, were dispersed in the several provinces of the empire, and the old ones burnt and suppressed. Though many things in Hassa's copy were corrected by the above-mentioned revisers, yet some few various readings still occur.

"The most prominent feature of the Koran, that point of excellence in which the partiality of its admirers has ever delighted to view it, is the sublime notion it generally impresses of the nature and attributes of God. If its author had really derived these just conceptions from the inspiration of that Being whom they attempt to describe, they would not have been surrounded, as they now are on every side, with error and absurdity. But it might easily be proved, that whatever it justly defines of the Divine attributes, was borrowed from our Holy Scriptures; which even from its first promulgation, but especially from the completion of the New Testament, has extended the views and enlightened the understandings of mankind; and thus furnished them with arms which have too often, though ineffectually, been turned against itself by its ungenerous enemies.

"In this instance particularly, the copy is far below the great original, both in the propriety of its images and the force of its descriptions. Our Holy Scriptures are the only compositions that can enable the dim sight of mortality to penetrate into the invisible world, and to behold a glimpse of the Divine perfections. Accordingly, when they would represent to us the happiness of heaven, they describe it, not by any thing minute and particular, but by something general and great,—something that, without descending to any determinate object, may at once, by its beauty and immensity excite our wishes and elevate our affections. Though in the prophetical and evangelical writings the joys that shall attend us in a future state are often mentioned with ardent admiration, they are expressed rather by allusion than similitude, rather by indefinite and figurative terms than by any thing fixed and determinate. 'Eye hath not seen, nor ear heard, neither have entered into the heart of man, the things which God hath prepared for them that love him.' (1 Cor. ii. 9.) What a reverence and astonishment does this passage excite in every hearer of taste and piety! What energy, and at the same time what simplicity, in the expression! How sublime, and at the same time how obscure, is the imagery!

"Different was the conduct of Mahomet in his descriptions of heaven and of paradise. Unassisted by the necessary influence of virtuous intentions and divine inspiration, he was neither desirous, nor indeed able, to exalt the minds of men to sublime conceptions or to rational expectations. By attempting to explain what is inconceivable, to describe what is ineffable, and to materialize what in itself is spiritual, he absurdly and impiously aimed to sensualize the purity of the Divine essence. Thus he fabricated a system of incoherence, a religion of depravity, totally repugnant indeed to the nature of that Being who, as he pretended, was its object; but therefore more likely to accord with the appetites and conceptions of a corrupt and sensual age.

"That we may not appear to exalt our Scriptures thus far above the Koran by an unreasonable preference, we shall produce a part of the second chapter of the latter, which is deservedly admired by the Mahometans, who wear it engraved on their ornaments, and recite it in their prayers. 'God! there is no God but he; the living, the self-susbisting: neither slumber nor sleep seizeth on him: to him belongeth whatsoever is in heaven and on earth. Who is he that can intercede with him but through his good pleasure? He knoweth that which is past, and that which is to come. His throne is extended over heaven and earth, and the preservation of both is to him no burden. He is the high, the mighty.'" (*Sale's Kor.* ii. p. 30, 4to edit.)

ALCORAN is also figuratively applied to certain other books full of impieties and impostures. In this sense we meet with the Alcoran of the Cordeliers, which once made a great noise; wherein St Francis is extravagantly magnified, and put on a level with Jesus Christ. The Alcoran of the Cordeliers is properly an extract of a very scarce book, entitled *The Conformity of the Life of the seraphic father St Francis with the Life of Christ*, published in 1510, 4to; and again at Bologna in folio. Erasmus Albertus, being by the elector of Brandenburg appointed to visit a monastery of Franciscans, found this book; and being struck with the extreme folly and absurdity of it, collected a number of curiosities out of it, and published them under the title of the *Alcoran* of the Franciscans, with a preface by Martin Luther.

ALCOY, one of the most thriving manufacturing cities of Spain, on an elevated site near the river of the same name, in the province of Alicante, and 24 miles north of the town of that name. It manufactures an annual average of 23,000 pieces of cloth, and 200,000 reams of paper. Pop. about 20,000.

ALCUIN, in Latin *Albinus*, surnamed *Flaccus*, an eminent ecclesiastic, and the reviver of learning in the eighth century. He was born, it is supposed, in Yorkshire, about 735. He was educated at York, under the direction of Archbishop Egbert, as we learn from his own letters, in which he frequently calls that great prelate his beloved master, and the clergy of York the companions of his youthful studies. As he survived Bede about 70 years, it is hardly possible that he could have received any part of his education under him, as some writers of literary history have affirmed; and it is worthy of observation, that he never calls that great man his master, though he speaks of him with the highest veneration. It is not well known to what preferments he had attained in the church before he left England, though some say he was abbot of Canterbury. He was sent to Rome by Eanbald, the successor of Ethelbert, and in returning, at Parma he met Charlemagne, who, as Alcuin had already visited the French court, was no stranger to his extraordinary merit. The emperor contracted so great an esteem and friendship for him, that he earnestly solicited, and at length prevailed upon him, to settle in his court and become his preceptor in the sciences. Alcuin accordingly instructed that great prince in rhetoric, logic, mathematics, and divinity, which rendered him one of his greatest favourities. He particularly distinguished himself by his writings in defence of the orthodox faith against the heresiarch Felix D'Urgel; and on more than one occasion was employed in important missions between Charlemagne and Offa king of Mercia. "France," says one of our best writers of literary history, "is indebted to Alcuin for all the polite learning it boasted of in that and the following ages. The universities of Paris, Tours, Fulden, Soissons, and many others, owe to him their origin and increase, those of which he was not the superior and founder being at least enlightened by his doctrine and example, and enriched by the benefits he procured for them from Charlemagne." After Alcuin had spent many years in the most intimate familiarity with the greatest prince of his age, he at length, with great difficulty, obtained leave to retire from court to his abbey of St Martin, at Tours; where he reremained till his death, A.D. 804. In his retirement he kept up a constant correspondence with Charlemagne, from which it appears that both were animated with the most ardent love to learning and religion, and constantly employed in contriving and executing the noblest designs for their advancement. Alcuin composed many treatises on a great variety of subjects, in a style much superior in purity and elegance to that of the generality of writers in the age in which he flourished. His works were collected and published by Du Chesne, in one volume folio, Paris, 1617: a better edition is that of Froben, 2 vols. folio, Ratisbon, 1777. They consist of, 1. Tracts upon Scripture; 2. Tracts upon doctrine, discipline, and morality; 3. Historical treatises, letters, and poems. It is not improbable that Alcuin was the writer of the famous *Caroline Books.*

ALCYONIA, a family of marine animal bodies of the order of Zoophytes, included in the *polypifera.* They are distinct from sponges, but are allied to them. See ZOOLOGY.

ALCYONIUM STAGNUM, in *Ancient Geography,* a lake in the territory of Corinth, whose depth was unfathomable, and in vain attempted to be discovered by Nero. Through this lake Bacchus is said to have descended to hell to bring back Semele. (Pausanias.)

ALCYONIUS, PETER, a learned Italian, born in 1487. He was, for a considerable time, corrector of the press to Aldus Manutius, and afterwards Professor of Greek at Florence. His treatise on banishment entitled *Medices Legatus, sive de Exsilio,* written in imitation of the style of Cicero, brought upon him, though unjustly, the charge of plagiarism. Paulus Manutius, who bore him no goodwill, was the author of this insinuation, and says that Alcyonius made away with the only existing MS. of Cicero's Treatise *De Gloria,* to save detection; but the accusation has been satisfactorily refuted. Alcyonius composed two excellent orations on the taking of Rome, representing very strongly the injustice of Charles V. and the barbarity of his soldiers. There is also an oration ascribed to him, on the knights who died at the siege of Rhodes.

ALDBOROUGH, a small town in the wapentake of Claro, in the West Riding of Yorkshire. It is on the river Ure, and is supposed to be the ancient *Isurium Brigantium.* Near it are some remains of a druidical temple. It formerly returned two members to parliament, but has been disfranchised. Population of parish in 1851, 2438.

ALDEBARAN, in *Astronomy,* a star of the first magnitude, called in English the *bull's eye,* as making the eye of the constellation Taurus. Its longitude is 6. 32. 9. of Gemini, and its latitude 5. 29. 40. south.

ALDEBURGH, a market-town in the hundred of Plomesgate, in the county of Suffolk, chiefly inhabited by fishermen, and now much frequented as a bathing place. It formerly returned two members to parliament, but was disfranchised by the Act of Reform. The poet Crabbe was born here. Population of parish in 1851, 1627.

ALDEGREVER, HEINRICH, an eminent engraver of Westphalia, a pupil of Albert Durer, whom he imitated closely. His works are very numerous, chiefly from his own designs; so that he is considered also as a painter. His works date from 1522 to 1562.

ALDER, *Betula alnus.* The wood of this tree, which thrives in moist soils, is used on account of its durability, when of considerable dimensions, for piles, mill-work, pumps, and sluices. On account of its variegated colour it is occasionally used in turnery; but one of its most important uses is the excellent charcoal it affords for gunpowder. The bark is astringent, and is used in preparing leather; and the plant has also been used as a dye.

ALDERHOLM, an island of Sweden, formed by the three arms of a river running through Gefle, a town of Nordland, in Sweden, 80 miles north from Stockholm. Here is a wharf, a repository for planks and deals, two packing-houses, a large custom-house for taking toll of the ships, an arsenal for cannon, and a granary. Lat. 60. 40. N.

ALDERMAN, a word derived from the Anglo-Saxon *ealdorman,* compounded of the comparative degree of the word *eald* (old), and *man.* The term implies the possession of an office of rank or dignity. Earls and governors of provinces and other persons of distinction received this title among the Anglo-Saxons. Thus we meet with the titles of *aldermannus totius Angliæ, aldermannus regis, comitatis, civitatis, burgi, castelli, hundredi sive wapentachii, et novemdecimorum.* According to Spelman, the *aldermannus totius Angliæ* seems to have been the same officer who was afterwards styled *capitalis justiciarius Angliæ,* or chief justice of England; the *aldermannus regis* seems to have been an occasional magistrate, answering to our justice of assize; and the *aldermannus comitatus,* a magistrate who held a middle rank between what was afterwards called the *earl* and the *sheriff:* he sat at the trial of causes with the bishop; the latter proceeding according to ecclesiastical law, and the former declaring and expounding the common law of the land.

In modern times aldermen are office-bearers in the municipal corporations of England and Wales, and Ireland. Before the passing of the Municipal Corporations Act, their functions varied according to the charters of the different burghs. By the statute 5th and 6th Will. IV. c. 76, and 3d and 4th Vict. c. 118, the aldermen are elected by the councillors from among themselves (in Ireland, by the burgesses), for six years, one-half going out every three years. The number of councillors in each borough varies from 12 to 48, according to its magnitude. One-fourth of the municipal council consists of aldermen, and three-fourths of councillors. In the municipal corporations of Scotland there is no such title as alderman, the office-bearers of corresponding rank there being termed bailies.

The corporation of London was not included in the Burgh Reform Act; and the antiquated system remains there in full force. The court of aldermen consists of twenty-six, including the lord-mayor; the twenty-five aldermen are elected for life by the freemen of the different wards; when one dies or resigns a wardmote is called, who return two persons, one of whom the Court of Aldermen elect to supply the vacancy. The city is divided into twenty-six wards; twenty-four of these send up one alderman each; the other two between them choose a twenty-fifth; the twenty-sixth serves for the independent borough of Southwark, and is appointed by the other aldermen, who generally select the senior from among themselves when a vacancy occurs.

The lord-mayor is elected from such of the aldermen as have served the office of sheriff; from these the Common-hall, which consists of the freemen of the various wards, elect two; and the aldermen select one of these for the mayoralty.

The Court of Aldermen act as magistrates for the city of London, and also possess authority of a judicial nature in the affairs of the corporation. They are constituent members of the Court of Common Council, which is the legislative body of the corporation; but the other members of the Common Council, which consists of 264 members, are elected annually by the freemen.

ALDERNEY, an island in the English channel, subject to the crown of Great Britain. It is about eight miles in compass, and is separated from Cape la Hogue, in Normandy, by a narrow strait, called the *Race of Alderney,* which is a very dangerous passage in stormy weather, when the two currents meet; otherwise it is safe, and has depth of water for the largest ships. Through this strait the French fleet made their escape after their defeat at La Hogue in 1692. It is a healthful island, is fruitful both in corn and pasture, and is remarkable for its fine breed of cows. The town, of the same name, is the seat of the population, amounting in 1851 to 3333. It has but one harbour, called *Crabby,* which is at a good distance from the town, and is only fit for small vessels. To the west lies the range of rocks called the *Caskets,* so dangerous to mariners. Long. 2. 7. W. Lat. 49. 45. N. The extension of the sea-wall of the break-water was commenced in 1850; to be completed in eight years, at the estimated cost of L.620,000.

ALDHELM, or Adelm, St, bishop of Shireburn, in the time of the Saxon Heptarchy. He is said to have been the son of Kenred, brother to Ina, king of the West Saxons; but in the opinion of William of Malmesbury, his father was no more than a distant relation to the king. Having received the first part of his education in the school of one Maldulph, a learned Scot, he travelled into France and Italy for his improvement. On his return home he studied some time under Adrian, abbot of St Augustin's, in Canterbury, the most learned professor of the sciences who had ever been in England. The fame of his learning soon spread, not only in England, but in foreign countries. Learned men sent him their writings for his criticism; among others, Prince Arcivil, a son of the king of Scotland, who sent his compositions to Aldhelm, "entreating him to give them the last polish by rubbing off their Scotch rust." He was the first Englishman who wrote in the Latin language, both in prose and verse; and composed a book for the instruction of his countrymen in the prosody of that language. Bede says that Aldhelm "was a man of universal erudition, having an elegant style, and being wonderfully well acquainted with books, both on philosophical and religious subjects." In fact, considering the cloud of ignorance by which he was surrounded, and the great difficulty of acquiring knowledge without proper instruction, Aldhelm was a very extraordinary man. From one of his letters to Hedda, bishop of Winchester, concerning the nature of his studies whilst at Canterbury, he appears to have been indefatigably determined to acquire every species of learning in his power. For a copy of this curious epistle, see Henry's *History*, vol. ii. p. 320. King Alfred the Great declared that Aldhelm was the best of all the Saxon poets; and that a favourite song, which was universally sung in his time, near 200 years after its author's death, was of his composition. He was a musician as well as a poet, and made his own songs the medium of instruction and refinement to his barbarous countrymen. After having governed the monastery of Malmesbury, of which he was the founder, about thirty years, he was made bishop of Shireburn, where he died A.D. 709.—He wrote, 1. De octo Vitiis principalibus. This treatise is extant in the *Bibliotheca Patrum* of Canisius. 2. Ænigmatum versus mille. This, with several others of his poems, was published by Martin Delrio at Mentz, 1701, 8vo. 3. A book addressed to a certain king of Northumberland, named Alfrid, on various subjects. 4. De Vita Monachorum. 5. De Laude Sanctorum. 7. De Arithmetica. 7. De Astrologia. 8. A book against the mistake of the Britons concerning the celebration of Easter; printed by Sonius, 1576. 9. De Laude Virginitatis; manuscript, in Bennet College, Cambridge; published among Bede's *Opuscula*. Besides these, he wrote many sonnets, epistles, and homilies in the Saxon language.

ALDINE. See Manutius, Aldus.

ALDPORT, an ancient name for Manchester.

ALDRED, abbot of Tavistock, was promoted to the bishopric of Worcester in the year 1046. He had great influence over Edward the Confessor, and procured his reconciliation to Sweyn, the son of Earl Godwin, who had revolted against him. He also restored the union and friendship between King Edward and Griffith, king of Wales. In the year 1050, he went to Jerusalem, which no archbishop or bishop of England had ever done before. On his return to England, he was sent in the year 1054 as ambassador to the emperor Henry II. He staid a whole year in Germany, and was very honourably entertained by Herman, archbishop of Cologne, from whom he learned much relating to ecclesiastical discipline, of which he made use on his return to his own diocese. On the death of Kinsius, archbishop of York, 1060, Aldred was elected in his stead, and was permitted to retain the see of Worcester with the archbishopric of York, as some of his predecessors had done. He was afterwards, however, deprived of it by the pope.

On the death of Edward the Confessor in 1066, Aldred was to have placed the crown on the head of Harold, but before the ceremony could take place, the battle of Hastings intervened. He officiated at the coronation of William the Conqueror, and gained great favour with that monarch, over whose imperious spirit he seems to have exercised a remarkable influence. At the end of a year, however, he broke his allegiance, by escaping into Scotland with Edgar Atheling. He died in September 1069, broken-hearted, according to William of Malmesbury, by the tyranny of the Conqueror. Stubbs, again, ascribes his death to grief at the invasion of the Danes.

ALDRICH, Dr Henry, an eminent English divine and philosopher, born at London in 1647, was educated at Westminster school under the famous Dr Busby, and admitted of Christ-church College, Oxford. He had a great share in the controversy with the Papists in the reign of James II.; and Bishop Burnet ranks him among those who examined all the points of Popery with a solidity of judgment, clearness of argument, depth of learning, and vivacity of writing, far beyond any who had before that time written in our language. He rendered himself so conspicuous, that at the Revolution, when Massey the Popish dean of Christ-church fled, his deanery was conferred on him. In this station he behaved in an exemplary manner, and that fabric owes much of its beauty to his ingenuity. He published, besides some other pieces, a System of Logic, still in use as a text-book in Oxford; and the revising of Clarendon's History of the Rebellion was intrusted to him and Bishop Sprat. Besides his preferments above mentioned, Dr Aldrich was also rector of Wem, in Shropshire. He was chosen prolocutor of the convocation in 1702. He died at Christ-church on the 14th of December 1710. Sir John Hawkins has favoured the public with several particulars relative to Dr Aldrich's skill in music. He composed many services for the church, which are well known; as are also his anthems, nearly twenty in number. He adapted, with great skill and judgment, English words to many of the notes of Palestrina, Carissimi, Victoria, and other Italian composers for the church, some of which are frequently sung in our cathedrals as anthems. By his happy talent of naturalizing the compositions of the old Italian masters, and accommodating them to an English ear, he increased the stores of his own church.

Dr Aldrich is of some note as a Latin poet. In the *Musæ Anglicanæ* we find two elegant copies of verses by him; one on the accession of King William III., and the other on the death of the Duke of Gloucester. Sir John Hawkins has preserved a humorous translation by him of the well-known English ballad,

> A soldier and a sailor,
> A tinker and a tailor, &c.

The following epigram, entitled "Causæ Bibendi," is likewise ascribed to Dr Aldrich:—

> *Sic bene quid memini, Causæ sunt quinque bibendi;*
> *Hospitis Adventus, præsens Sitis, atque futura,*
> *Aut Vini Bonitas, aut quælibet altera Causa.*

The epigram has been thus translated:—

> If on my theme I rightly think,
> There are five reasons why men drink;
> Good wine, a friend, because I'm dry,
> Or lest I should be by and by,
> Or any other reason why.

The translation is not equal to the original. It is evident from the verses cited and referred to, that Dr Aldrich was of a very cheerful and pleasant turn of mind. Having never been married, he appropriated his income to works of hospitality and beneficence, and the encouragement of learning. His modesty and humility prevented him from prefixing his name to the learned tracts which he published during his life. He was buried in the cathedral, according to his own wish, without any memorial.

Aldrich, *Robert*, bishop of Carlisle, was born at Burnham, in Buckinghamshire, about the year 1493, and educated at Eton school, from whence, in 1507, he was elected scholar of King's College, Cambridge, where he took his degree in arts, and was afterwards proctor of the university. In 1525 he was appointed master of Eton school, then became fellow of that college, and finally provost. In 1529 he went to Oxford, where he took his degree of B.D., and in the following year that of D.D. In 1531 he was made archdeacon of Colchester, in 1534 canon of Windsor, and the same year registrar of the order of the Garter. He was consecrated bishop of Carlisle in the year 1537, and died at Horncastle in Lincolnshire in 1556. He wrote, 1. Epistola ad Gul. Hormannum, in Latin verse, printed in Horman's *Antibossicon*, Lond. 1521, of which book Pitts erroneously makes Aldrich the author; 2. Epigrammata varia; 3. Latin verses, and another epistle to Horman, prefixed to the *Vulgaria Puerorum* of that author, Lond. 1519, 4to; 4. Answers to certain queries concerning the abuses of the mass, and the receiving of the sacrament.

ALDROVANDUS, Ulysses, professor of philosophy and physic at Bologna, was born there in 1522. He was a most curious inquirer into natural history, and travelled into the most distant countries on purpose to inform himself of their natural productions. Minerals, metals, plants, and animals, were the objects of his curious researches; but he applied himself chiefly to birds, and was at a great expense to have figures of them drawn from the life. Aubert le Mire says that he gave a certain painter, famous in that art, a yearly salary of 200 crowns, for 30 years and upwards; and that he employed, at his own expense, Lorenzo Bennino and Cornelius Swintus, as well as the famous engraver Christopher Coriolanus. These expenses ruined his fortune, and at length reduced him to the utmost necessity; and it is said that he died blind in an hospital at Bologna, at the age of 85. Mr Bayle observes, that antiquity does not furnish us with an instance of a design so extensive and so laborious as that of Aldrovandus, with regard to natural history; that Pliny has treated of more kinds of subjects, but only touches lightly on them, saying but a little upon any thing, whereas Aldrovandus has collected all he could meet with. His compilation, or that compiled upon his plan, consists of 13 volumes in folio, several of which were printed after his death. He himself published his Ornithology, or History of Birds, in three folio volumes, in 1599; and his seven books of Insects, which make another volume of the same size. The volume of Serpents, three of Quadrupeds, one of Fishes, that of exsanguious Animals, the History of Monsters, with the Supplement to that of Animals, the Treatise of Metals, and the Dendrology, or History of Trees, were published at several times after the death of Aldrovandus, by the care of different persons. He himself is the sole author only of the first six volumes of this work, the rest having been finished and compiled by others upon his plan. In this extensive plan he not only relates what he has read in naturalists, but remarks also what historians have written, legislators ordained, and poets feigned. He explains also the different uses which may be made of the things he treats of, in common life, in medicine, architecture, and other arts; in short, he speaks of morality, proverbs, devices, riddles, hieroglyphics, and many other things which relate to his subject.

ALDSTON-MOOR, a market-town of the Ward of Leath, in the county of Cumberland. It is on the banks of the Tyne, in a picturesque district, abounding in mines of lead, which produce also some silver and copper. The market is held on Saturday. Pop. in 1851, 2005.

ALE, a fermented liquor obtained from an infusion of malt, and differing from beer chiefly in having a less proportion of hops. This liquor, the natural substitute of wine in such countries as could not produce the grape, is said to have originally been made in Egypt, the first planted kingdom, on the dispersion from the East, that was supposed unable to produce grapes. The natives of Spain, the inhabitants of France, and the aborigines of Britain, all used an infusion of barley for their ordinary liquor; and it was called by the various names of *Cœlia* and *Ceria* in the first country, *Cerevisia* in the second, and *Curmi* in the last; all literally importing only *the strong water*.

"All the several nations," says Pliny, "who inhabit the west of Europe, have a liquor with which they intoxicate themselves, made of corn and water. The manner of making this liquor is sometimes different in Gaul, Spain, and other countries, and is called by many various names; but its nature and properties are everywhere the same. The people of Spain, in particular, brew the liquor so well that it will keep good a long time. So exquisite is the cunning of mankind in gratifying their vicious appetites, that they have thus invented a method to make water itself intoxicate." The method in which the ancient Britons and other Celtic nations made their ale is thus described by Isidorus and Orosius:—"The grain is steeped in water, and made to germinate, by which its spirits are excited and set at liberty; it is then dried and ground; after which it is infused in a certain quantity of water; which, being fermented, becomes a pleasant, warming, strengthening, and intoxicating liquor." This ale was most commonly made of barley, but sometimes of wheat, oats, and millet.

Anciently the Welsh and Scots had also two kinds of ale, called *common ale* and *spiced ale;* and their value was thus ascertained by law: "If a farmer had no mead, he shall pay two casks of spiced ale, or four casks of common ale, for one cask of mead." By this law a cask of spiced ale, nine palms in height and eighteen palms in diameter, was valued at a sum of money equal in value to L.7, 10s. of our present money; and a cask of common ale of the same dimensions at a sum equal to L.3, 15s. This is a sufficient proof that even common ale at that period was an article of luxury among the Welsh, which could only be obtained by the great and opulent. Wine seems to have been quite unknown even to the kings of Wales at that period, as it is not so much as once mentioned in their laws; though Giraldus Cambrensis, who flourished about a century after the Conquest, informs us that there was a vineyard in his time at Maenarper, near Pembroke, in South Wales.

Ale was the favourite liquor of the Anglo-Saxons and Danes, as it had been of their ancestors the ancient Germans. Before their conversion to Christianity, they believed that drinking large and frequent draughts of ale was one of the chief felicities which those heroes enjoyed who were admitted into the hall of Odin. Scotland has long been celebrated for the manufacture of ale. The quantity brewed in Edinburgh and Leith for the year ending 10th October 1852, is estimated at 259,982 barrels. For further details see Brewing, Scotland, Edinburgh, &c.

*Ale, Medicated*, that wherein medicinal herbs have been infused or added during the fermentation.

*Ale-Conner*, an officer in London, who inspects the measures used in public houses. There are four ale-conners, who are all chosen by the liverymen in common-hall on Midsummer-day.

*Ale-Silver*, a tax paid annually to the lord-mayor of London by all who sell ale within the city.

ALEA, in *Roman Antiquity*, denotes in general all manner of games of chance, but, in a more restricted sense, was used for a particular game played with dice and tables, not unlike our backgammon.

ALEANDRO, Geromino, cardinal and archbishop of Brindisi, was born in 1480, and distinguished himself by his fiery zeal against the Reformation. Being sent into Germany as the pope's nuncio in 1519, he acted as occasion served, in the character both of ambassador and doctor, and opposed Luther in the diet of Worms with bitter vehemence. His violent conduct alienated him from Erasmus, who had been his early friend. He published several works, and died at Rome in 1542.

Aleandro, *Geromino*, grand-nephew of the former, a jurist, antiquarian, and poet, was born at Motta, near Friuli, in 1574. He was long employed as secretary to Cardinal Ottavio Bandini, and afterwards to Cardinal Barberini, in whose service he died, at Rome, in 1629. He was one of the first members of the Academy of Humourists, wrote a learned treatise in Italian on the device of the society, and displayed his genius on many different subjects. Barberini gave him a magnificent funeral at the Academy of Humourists.

ALECTO, one of the Furies, daughter of Acheron and Night, or, as others would have it, of Pluto and Proserpine.

ALECTORIA, a stone said to be formed in the gall-bladder of old cocks, to which the ancients ascribe many fabulous virtues. This is otherwise called *Alectorius lapis*, sometimes *Alectorolithos*, in English the *cock-stone*. The more modern naturalists hold the *alectorius lapis* to be originally swallowed down, not generated in, the stomach and gizzards of cocks and capons. It is known that many of the fowl kind make a practice of swallowing pebbles, which are supposed to be of service in the business of trituration and digestion.

ALECTOROMANTIA, in *Antiquity*, a species of divination performed by means of a cock. This is otherwise called *Alectryomancy*, of which there appear to have been different species. But that most spoken of by authors was in the following manner: a circle was described on the ground, and divided into twenty-four equal portions; in each of these spaces was written one of the letters of the alphabet, and on each of the letters was laid a grain of wheat; after which, a cock being turned loose in the circle, particular notice was taken of the grains picked up by the cock, because the letters under them, being formed into a word, made the answer desired. It was thus, according to Zonaras, that Libanius and Jamblicus sought who should succeed the emperor Valens; and the cock eating the grains answering to the spaces ΘΕΟΔ, several whose names began with those letters, as Theodotus, Theodistes, Theodulus, &c. were put to death; which, however, did not hinder the succession of Theodosius. But the story, however current, is but ill supported: it has been called in question by some, and refuted by others, from the silence of Marcellinus, Socrates, and other historians of that time.

A-LEE, in the sea-language, a term used when the wind, crossing or flanking the line of a ship's course, presses upon the masts and sails so as to make her incline to what is then called the lee-side. When the helm is moved over to this side, it is said to be *a-lee* or *hard a-lee*.

ALEGAR, acetic acid, produced by fermenting ale, as vinegar is produced from wine.

ALEIUS Campus, from ἄλη, wandering, in *Ancient Geography*, a plain in Cilicia, on this side of the river Pyramus, near the mountain Chimæra. It derived the name from Bellerophon's wandering and perishing there, after being thrown off Pegasus.

ALEMAN, Louis, archbishop of Arles, and cardinal of St Cecilia, was born in 1390, and died in 1452. He presided, along with Cardinal Julian, in the council of Basil, which deposed Eugenius IV. and elected the antipope Felix V. He is much commended by Æneas Sylvius, as a man extremely well formed for presiding in such assemblies,—firm and vigorous, illustrious by his virtue, learned, and of an admirable memory in recapitulating all that the orators and disputants had said. At the request of the canons and Celestine monks of Avignon, and the solicitation of the cardinal of Clermont, legate *a latere* of Clement VII., he was beatified by the pope in the year 1527.

Aleman, *Mateo*, a remarkable Spanish writer, born at Sevilla, about the middle of the sixteenth century; best known to us by his racy and amusing *Adventures of Guzman Alfarache*, published in 1599; a work highly esteemed for the purity and elegance of its Castilian style, though the delineations are often coarse and indelicate. This and several succeeding works of the same kind, under the feigned adventures of rogues and vagabonds, cover a sly satire on the corruption of Spanish manners in the time of Philip II. It was from this, and the novel of Espinèl, entitled *The Life of Squire Mareos Olregon*, that Le Sage borrowed many of the characters and adventures in his admirable *Gil Blas*. Aleman also wrote a *Life of St Antonio de Padona;* and having visited Mexico, he there published an *Ortografia Castellanà* in 1609, which has obtained some reputation. He died in the reign of Philip III.

ALEMANNI, a large German tribe on the Upper Rhine, where they are first mentioned by Dion Cassius in the reign of the Emperor Caracalla, who gained, in A.D. 213, a victory over them on the banks of the Maine, and thence assumed the surname *Alemannicus*. The origin of this tribe, and the country from which they came, are unknown; but we have a distinct statement, which is apparently confirmed by the very name of the people, that they had flocked together from all parts, and were a mixed race. They proved most formidable enemies to the Romans as well as to the Gauls, their western neighbours, who to this day apply the name Alemanni (Allemands) to all the Germans indiscriminately, though the Alemanni, properly so called, occupied only the country between the Maine and the Danube. In the reign of Aurelian, A.D. 270, they attempted to invade Italy, but were repulsed. After the death of that emperor, however, they renewed their attacks by invading Gaul, and ravaging the country at different times. Several undertakings against them were of little avail, until in A.D. 357 the Emperor Julian completely defeated them in the neighbourhood of Strasburg, where all their forces were assembled under seven chiefs. This and other defeats, however, did not break the power of the Alemanni, who being pressed on by other barbarians in the north were forced to advance southward and westward to conquer new countries for themselves. Hence, after the middle of the 5th century, we find them established not only in the country now called Suabia, but also in a part of Switzerland and in Alsace. In these countries the Alemanni have maintained themselves ever since; and the greater part of the modern Suabians and the northern Swiss are descendants of that ancient race. (L. S.)

ALEMBERT, Jean le Rond d', an eminent French philosopher, was born at Paris in 1717. He derived the name of Jean le Rond from that of the church near which, after his birth, he was exposed as a foundling. His father, informed of this circumstance, listened to the voice of nature and duty, took measures for the proper education of his child, and for his future subsistence in a state of ease and independence.

He received his first education in the College of the Four

D'Alembert.

Nations, among the Jansenists, where he gave early marks of capacity and genius. In the first year of his philosophical studies he composed a Commentary on the Epistle of St Paul to the Romans. The Jansenists considered this production as an omen that portended to the party of Port-Royal a restoration to some part of their ancient splendour, and hoped to find one day in M. d'Alembert a second Pascal. To render this resemblance more complete, they engaged their rising pupil in the study of the mathematics; but they soon perceived that his growing attachment to this science was likely to disappoint the hopes they had formed with respect to his future destination: they therefore endeavoured to divert him from this line; but their endeavours were fruitless.

On his leaving college, he found himself alone and unconnected with the world; and sought an asylum in the house of his nurse. He comforted himself with the hope that his fortune, though not ample, would better the condition and subsistence of that family, which was the only one that he could consider as his own. Here, therefore, he took up his residence, resolving to apply himself entirely to the study of geometry; and here he lived, during the space of forty years, with the greatest simplicity, discovering the augmentation of his means only by increasing displays of his beneficence, concealing his growing reputation and celebrity from these honest people, and making their plain and uncouth manners the subject of good-natured pleasantry and philosophical observation. His good nurse perceived his ardent activity, heard him mentioned as the writer of many books, but never took it into her head that he was a great man, and rather beheld him with a kind of compassion. "*You will never*," said she to him one day, "*be any thing but a philosopher—and what is a philosopher?—a fool, who toils and plagues himself during his life, that people may talk of him when* HE IS NO MORE."

As M. d'Alembert's fortune did not far exceed the demands of necessity, his friends advised him to think of a profession that might enable him to augment it. He accordingly turned his views to the law, and took his degrees in that profession; but soon abandoned this plan, and applied to the study of medicine. Geometry, however, was always drawing him back to his former pursuits; and after many ineffectual efforts to resist its attractions, he renounced all views of a lucrative profession, and give himself over entirely to mathematics and poverty.

In the year 1741 he was admitted member of the Academy of Sciences; for which distinguished literary promotion, at such an early age, he had prepared the way by correcting the errors of a celebrated work,[1] which was deemed *classical* in France in the line of geometry. He afterwards set himself to examine, with deep attention and assiduity, what must be the motion of a body which passes from one fluid into another more dense, in a direction not perpendicular to the surface separating the two fluids. Every one knows the phenomenon which happens in this case, and which amuses children under the denomination of *Ducks and Drakes;* but M. d'Alembert was the first who explained it in a satisfactory and philosophical manner.

[1] The *Analyse Démontrée* of F. Beniau.

Two years after his election to a place in the Academy he published his treatise on *Dynamics.* The new principle developed in this treatise consisted in establishing equality at each instant between the changes that the motion of a body has undergone, and the forces or powers which have been employed to produce them; or, to express the thing otherwise, in separating into *two parts* the action of the moving powers, and considered the *one* as producing alone the motion of the body in the second instant, and the *other* as employed to destroy that which it had in the first.

So early as the year 1744, M. d'Alembert had applied this principle to the theory of the equilibrium and the motion of fluids; and all the problems before solved by geometricians became in some measure its corollaries. The discovery of this new principle was followed by that of a new calculus, the first trials of which were published in a *Discourse on the General Theory of the Winds,* to which the prize-medal was adjudged by the Academy of Berlin in the year 1746, and which was a new and brilliant addition to the fame of M. d'Alembert.

He availed himself of the favourable circumstance of the king of Prussia having just terminated a glorious campaign by an honourable peace, and in allusion to this, dedicated his work to that prince in the three following Latin verses:—

*Hæc ego de ventis, dum ventorum ocyor alis*
*Palantes agit Austriacos Fredericus, et orbi,*
*Insignis lauro, ramum prætendit olivæ.*

Swifter than wind, while of the winds I write,
The foes of conquering Frederick speed their flight;
While laurel o'er the hero's temple bends,
To the tir'd world the olive branch he sends.

This flattering dedication procured the philosopher a polite letter from Frederick, and a place among his literary friends.

In the year 1747 D'Alembert applied his new calculus of Partial Differences to the problem of vibrating chords, the solution of which, as well as the theory of the oscillation of the air and the propagation of sound, had been given but incompletely by the geometricians who preceded him, and these his masters or his rivals.

In the year 1749 he furnished a method of applying his principles to the motion of any body of a given figure; and he solved the problem of the precession of the equinoxes, determined its *quantity,* and explained the phenomenon of the nutation of the terrestrial axis, discovered by Dr Bradley.

In 1752 M. d'Alembert published a treatise on the *Resistance of Fluids,* to which he gave the modest title of an *Essay,* but which contains a multitude of original ideas and new observations. About the same time he published, in the Memoirs of the Academy of Berlin, *Researches concerning the Integral Calculus,* which is greatly indebted to him for the rapid progress it has made in the present century.

While the studies of M. d'Alembert were confined to geometry, he was little known or celebrated in his native country. His connections were limited to a small society of select friends: he had never seen any man in high office except Marquis d'Argenson. Satisfied with an income which furnished him with the necessaries of life, he did not aspire after opulence or honours; nor had they been hitherto bestowed upon him, as it is easier to confer them on those who solicit them, than to look out for men who deserve them. His cheerful conversation, his smart and lively sallies, a happy knack at telling a story, a singular mixture of malice of speech with goodness of heart, and of delicacy of wit with simplicity of manners, rendered him a pleasing and interesting companion; and his company, consequently, was much sought after in the fashionable circles. His reputation at length made its way to the throne, and rendered him the object of royal attention and beneficence. He received also a pension from government, which he owed to the friendship of M. d'Argenson.

The tranquillity of M. d'Alembert was abated when his fame grew more extensive, and when it was known beyond the circle of his friends, that a fine and enlightened taste for literature and philosophy accompanied his mathematical genius. Our author's eulogist ascribes to envy, detraction, and to other motives equally ungenerous, all the disapprobation, opposition, and censure that M. d'Alembert met with on account of the publication of the famous Encyclopedical

Dictionary of Arts and Sciences, in conjunction with Diderot. None surely will refuse the well-deserved tribute of applause to the eminent displays of genius, judgment, and true literary taste, with which M. d'Alembert has enriched the great work now mentioned. Among others, the Preliminary Discourse which he has affixed to it, concerning the rise, progress, connections, and affinities of all the branches of human knowledge, is perhaps one of the first productions of which the philosophy of the present age can boast, and will be regarded as a striking specimen of just arrangement and sound criticism, and also as a model of accurate thinking and elegant writing.

Some time after this D'Alembert published his *Philosophical, Historical, and Philological Miscellanies.* These were followed by the *Memoirs of Christina, Queen of Sweden*, in which M. d'Alembert showed that he was acquainted with the natural rights of mankind, and was bold enough to assert them. His *Essay on the Intercourse of Men of Letters with Persons high in Rank and Office* wounded the former to the quick, as it exposed to the eyes of the public the ignominy of those servile chains which they feared to shake off or were proud to wear. A lady of the court hearing one day the author accused of having exaggerated the despotism of the great, and the submission they require, answered slyly, *If he had consulted me, I would have told him still more of the matter.*

M. d'Alembert gave very elegant specimens of his literary abilities in his translations of some select pieces of Tacitus. But these occupations did not divert him from his mathematical studies; for about the same time he enriched the *Encyclopédie* with a multitude of excellent articles in that line, and composed his *Researches on several important points of the System of the World*, in which he carried to a higher degree of perfection the solution of the problem of the perturbations of the planets, that had several years before been presented to the Academy.

In 1759 he published his *Elements of Philosophy;* a work extolled as remarkable for its precision and perspicuity; in which, however, are some tenets, relative both to metaphysics and moral science, that are far from being admissible.

The resentment that was kindled, and the disputes that followed it, by the article *Geneva*, inserted in the *Encyclopédie*, are well known. M. d'Alembert did not leave this field of controversy with flying colours. Voltaire was an auxiliary in the contest; but as, in point of candour and decency, he had no reputation to lose, and as he weakened the blow of his enemies by throwing both them and the spectators into fits of laughter, the issue of the war gave him little uneasiness. It fell more heavily on D'Alembert, and exposed him, even at home, to much contradiction and opposition.

It was on this occasion that the late king of Prussia offered him an honourable asylum at his court, and the place of president of his academy; and was not offended at his refusal of these distinctions, but cultivated an intimate friendship with him during the rest of his life. He had refused, some time before this, a proposal made by the empress of Russia to intrust him with the education of the grand duke; a proposal accompanied with all the flattering offers that could tempt a man ambitious of titles or desirous of making an ample fortune; but the objects of his ambition were tranquillity and study.

In the year 1765 he published his *Dissertation on the Destruction of the Jesuits.* This piece drew upon him a swarm of adversaries, who confirm the merit and credit of his work by their manner of attacking it.

Besides the works already mentioned, he published nine volumes of memoirs and treatises under the title of *Opuscules*, in which he has solved a multitude of problems relative to astronomy, mathematics, and natural philosophy; of which our panegyrist gives a particular account, more especially of those which exhibit new subjects, or new methods of investigation.

He published also *Elements of Music*, and rendered at length the system of Rameau intelligible; but he did not think the mathematical theory of the sonorous body sufficient to account for the rules of that art. He was always fond of music; which, on the one hand, is connected with the most subtile and learned researches of rational mechanics; while, on the other, its power over the senses and the soul exhibits to philosophers phenomena no less singular, and still more inexplicable.

In the year 1772 he was chosen secretary to the French Academy. He formed, soon after this preferment, the design of writing the lives of all the deceased academicians from 1700 to 1772; and in the space of three years he executed this design, by composing 70 *éloges.*

M. d'Alembert died on the 29th of October 1783. There were many amiable lines of candour, modesty, disinterestedness, and beneficence, in his moral character; which are described, with a diffusive detail, in his *éloge*, by M. Condorcet, *Hist. de l'Acad. Royale des Sciences*, 1783.

The scientific works of D'Alembert have never been published in a collected form; the best edition of his literary works is that of 1821 in 5 vols. 8vo, which contains his correspondence with Voltaire and Frederick the Great.

ALEMBIC, a chemical vessel, usually made of glass or copper, formerly used for distillation. The bottom part, which contained the subject for distillation, is called, from its shape, the *cucurbit;* the upper part, which receives and condenses the steam, is called the *head*, the beak of which is fitted into the neck of a receiver. Retorts, and the common *worm still*, are now more generally employed.

ALEMBROTH, in the writings of the alchemists, a word used for a sort of fixed alkaline salt, which had the power of the famous alkahest, in dissolving bodies, and promoting the separation of metals from their ores. It is also used for a compound of corrosive mercury and sal ammoniac.

ALENCON, an arrondissement in the department of the Orne, in the N.W. of France, comprehending an extent of 416 square miles, or 266,240 English acres. It is divided into six cantons, with 72,418 inhabitants. The capital on the river Sarthe bears the same name. It is well built, and contains a cathedral, a church of the 8th century, a court-house, and a theatre. It was the ancient seat of the counts and dukes of Alençon. Its manufactures include tanning, spinning, bleaching, printing calicoes, and lace-making. Pop. 13,533.

ALENIO, Gulioi, a Jesuit missionary, born at Brescia, in 1582. He travelled into the East, and arrived at Macao in 1610. From thence he travelled through the Chinese empire, where he continued to propagate the Christian religion for 36 years. He was the first who planted the faith in the province of Xansi, and he built several churches in the province of Fokien. He died in 1649, leaving behind him several works in the Chinese language.

ALENQUER a fortified town of Portuguese Estremadura, 26 miles N.N.E. of Lisbon, with extensive manufacture of paper, and 3200 inhabitants.

ALENTEJO, one of the provinces into which the kingdom of Portugal is divided, deriving its name from its situation on the banks of the Tagus, in the Portuguese language Tejo. On the north it is bounded by the Portuguese Estremadura and Beira; on the east by Spanish Estremadura and Andalucia; on the south by Algarve; and on the west by the Atlantic Ocean, except in that part where the district or Setubal, which is a port of Portuguese Estremadura, in-

Aleppo. terposes between it and the sea. Its extent is 883 square leagues, and in 1841 the number of its inhabitants was 277,590. It is the largest province in the kingdom. Its surface is very unequal: towards Spanish Estremadura the soil is moderately fruitful, but towards Algarve the country is covered with extensive forests of oak, cork, holm, and other trees, especially on the northern sides of the Sierras de Monchique and Caldeiraon. The climate is considered unhealthy, especially in the summer months, when the waters, which are abundant, become stagnant. The province produces abundance of cattle; it yields more wheat than it consumes, and in part supplies Lisbon with that necessary. It grows sufficient wine for its own consumption, but is deficient in oil, which is occasionally supplied from Spanish Estremadura and Andalucia. The natural boundary, on the side of Spain, is the river Guadiana; but the territory of Olivenza, extending over 110 square leagues, on the eastern side of that river, has, ever since the thirteenth century, been a part of Portugal; and the possession of it has been and still is an object of greater jealousy to the two nations, than its value to either will justify. The only rivers of this province which empty themselves into the ocean are the Tagus and the Odemira: the latter enters it near Villa Nova de Milfontes, and is navigable five leagues from its mouth to the town of its own name. The other streams run, some to the Guadiana, and the others to the Tagus. As this province presents a frontier to Spain, it is most abundantly provided with fortified places, which, if in a good state and well garrisoned, would become formidable auxiliaries in either offensive or defensive warfare; but in the late invasion by the armies of France, they were found to be of little practical benefit. This province is between Lat. 37. 20. and 39. 34. N.

ALEPPO, or Halab, a town of Syria, the capital of a pashalic, of which the limits are not exactly defined, is situated in the vast plain which extends from the Orontes to the Euphrates, and which towards the south terminates in the desert. It is built on eight hills or eminences, and is intersected by the Koeick, which in winter swells into a large stream, overflowing its bridges, and the neighbouring gardens which cover its banks. This river terminates 18 miles beyond Aleppo, in a morass which is haunted by wild boars and pelicans. The city itself is above 3½ miles in circumference, and is surrounded by an ancient strong stone-wall 40 feet high. Including the suburbs, the city is about 7 or 8 miles in compass. The wall is flanked by frequent towers; but the ditch is partly filled up with rubbish or occupied by kitchen-gardens, and the city being commanded by the adjacent heights, is entirely indefensible. The town has seven gates, all known by different names. On one of the hills on which the city is built, and on its north-east corner, is a castle seated on a mount. This mount is of a conic form 200 feet high, and seems in a great measure to be raised with the earth thrown up out of a deep broad ditch which surrounds it. The castle is entered from the south by a bridge of seven lofty narrow arches thrown over the ditch, on which are two gates fortified by turrets, and two more still higher on the hill. Aleppo ranked among the cities of the Ottoman empire, next after Constantinople, Cairo, and Damascus; but was nearly destroyed by the terrible earthquakes of 1822 and 1830. It is gradually recovering from these disasters.

Formerly its commerce placed it in the first rank among the cities of Asia, and it was the grand emporium of Syria, Arabia, Mesopotamia, and Armenia. It is still the emporium of northern Syria, and has extensive commercial relations with Diarbekr, and the upper parts of Anatolia, with Merdin, Mosul, and Baghdad. Since 1832 several British merchants have established houses at Aleppo. The principal manufacture of the city consists of various kinds of cloths, which have been long famous throughout the East, and which are still produced to a considerable amount. Some are woven with gold and silver thread; others with silk and cotton, both flowered and striped; while some consist of striped cotton only. These stuffs employ about 4000 looms. There are besides numerous soap, dyeing, and print works. The chief attractions of Aleppo are its gardens, which extend continuously about 12 miles to the south-east of the city, They are watered by the Koikh, and produce abundance of fruit and culinary vegetables; but their most celebrated product is the pistachio-nut, which is regularly cultivated. The city is supplied with water by an ancient aqueduct, which conveys it from a distance of eight miles.

The air of Aleppo is dry and piercing, but at the same time salubrious for all who are not troubled with asthmatic complaints. The city, however, and the environs, are subject to a singular endemic disorder, which is called the ringworm or pimple of Aleppo: it is in fact a pimple which is at first inflammatory, and at length becomes an ulcer of the size of the nail. The usual duration of this ulcer is one year: it commonly fixes on the face, and leaves a scar, which disfigures almost all the inhabitants. No reason is assigned for this malady; but M. Volney suspects it proceeds from the quality of the water, as it is likewise frequent in the neighbouring villages, in some parts of Diarbekr, and even in certain districts near Damascus, where the soil and the water have the same appearances. But the plague is a more destructive malady, a visitation of which is anticipated by the inhabitants every ten years. Its ravages are most deadly, owing to the blind fatalism of the Turks, who cannot be persuaded to take any precautions against the progress of this dreadful disease. In the plague which immediately preceded the year 1797, about 60,000 inhabitants were swept off. Aleppo is of great antiquity, and is supposed to occupy the site of the ancient Berœa. It was overwhelmed by the flood of Saracen invasion in 638, when it was taken from the emperor Heraclius. In 1260 it was taken possession of and wasted by the Tartars, and in 1401 by Tamerlane, who defeated the Syrians, when it was given up to pillage. The adjacent country is fertile, and yields grain of all sorts, with which the city is plentifully supplied. All the fruits of Europe, as well as those of the East, are cultivated in gardens. Its galls, the produce of *Quercus infectoria*, are highly valued. Aleppo is 70 miles east of Scanderoon, on the seacoast, and 234 north of Damascus. Long. 37. 12. E. Lat. 36. 12. N.

Aleppo once contained 150,000 inhabitants. Colonel Chesney computes them now at 100,000; of whom 66,500 are Turks, 19,000 Greeks, 5000 Maronites, 3000 Armenians, 2000 Syrians of a mixed race, and 4500 Jews. The Christians enjoy not only the most perfect toleration, but have some envied privileges. Their exemption from the Conscription excited in 1850 the indignant jealousy of the Mahometans, and occasioned tumults in which some blood was shed, and property to the amount, it is said, of L.1,000,000 sterling destroyed. The houses amount to 40,000; but the aspect of the town, once the fairest and cleanest of Turkish cities, has been much damaged by the great earthquakes of 1822 and 1830, and by the erection of an irregular suburb, originally intended only for a temporary shelter.

Ales. ALES, Alexander, a celebrated divine of the rigid school of Augsburg, was born at Edinburgh on the 23d April 1500. He soon made considerable progress in school divinity, and entered the lists very early against Luther, this being then the grand field wherein all authors, young and old, used to display their abilities. Soon after he had a share in the dispute which Patrick Hamilton maintained against the ecclesiastics, in favour of the new faith he had imbibed at Marburg. He endeavoured to bring him back to the Catholic religion; but this he could not effect, and even began him-

Alessandri || Alessandria.

self to doubt about his own religion, being much affected by the discourse of Hamilton, and still more by the constancy he showed at the stake. Beginning thus to waver, he was himself persecuted with so much violence, that he was obliged to retire into Germany, where he became at length a perfect convert to the Protestant religion. The change of religion in England after the marriage of Henry VIII. with Anne Boleyn, induced Ales to go to London in 1535. He was highly esteemed by Cranmer, Latimer, and Thomas Cromwell, who were at that time in high favour with the king. Upon the fall of these favourites he was obliged to return to Germany, where the elector of Brandenburg appointed him professor of divinity at Frankfort on the Oder in 1540. Having offended the court of Brandenburg by publicly maintaining the right and duty of the civil magistrate to punish fornication, he underwent a public rebuke from the University of Wittenberg. He left Frankfort in disgust, and returned to Leipsic, where he was chosen professor of divinity, and died in March 1565. He wrote various commentaries on the Scriptures, besides many controversial works against the Roman Catholics.

ALESSANDRI, Alessandro, in Latin, *Alexander ab Alexandro*, a Neapolitan lawyer, of great learning, who flourished toward the end of the 15th and beginning of the 16th century. He followed the profession of the law, first at Naples, afterwards at Rome: but he devoted all the time he could spare to the study of polite literature; and at length he entirely left the bar, that he might lead a more easy and agreeable life with the Muses. The particulars of his life are to gathered from his work entitled *Dies Geniales.* We are there informed that he lodged at Rome, in a house that was haunted; and he relates many surprising particulars about the ghost. He says also, that when he was very young, he went to the lectures of Philelphus, who explained at Rome the Tusculan Questions of Cicero. He was there also when Nicholas Perot and Domitius Calderinus read their lectures upon Martial. He is supposed to have died about the year 1523, aged 62, and was buried in the monastery of the Olivets. Tiraquca wrote a learned commentary upon his work, which was printed at Lyons in 1587, and reprinted at Leyden in 1673, with the notes of Dennis Godfrey, Christopher Colerus, and Nicholas Mercerus.

ALESSANDRIA, a city of Italy, in the Sardinian dominions, situated on the right bank of the Tanaro, capital of the province of the same name. It is the see of a bishop, and, besides the cathedral, contains 12 churches, 2 collegiate churches, with 17 monasteries and nunneries. It has many fine public and private buildings. It was strongly fortified, and in the several successive hostilities in Italy has been attacked and defended with great fury. It has not yet recovered the effects of the obstinate defence of the French against the allies in 1799. Two great fairs are held here, when the city becomes a mart resorted to by merchants from all parts of Italy. It is in Long. 8. 40. E. Lat. 44. 57. N. Pop. 40,000.

Alessandria, a province of the duchy of Piedmont, in the dominions of the king of Sardinia, bounded on the north by Casale, on the east by Mortara, Boghera, and Tortona, on the south-east by Genoa, on the south-west by Aqui, and on the west by Asti. The extent is 343 square miles, or 219,520 acres. It comprehends two cities, 29 towns and villages, and 12 hamlets. The country is a plain, with few elevations, and very fruitful; but suffers from a deficiency of water, though the Po and the Tanaro, with some other rivers, pass through it. The chief productions are wheat, maize, wine, and silk; but besides these, wood, madder, hemp, flax, and fruit, are raised in abundance. The population is very dense, amounting to 117,870 persons, mostly employed in agriculture, which is conducted on the system of garden cultivation.

Alessi || Aleutian Islands.

ALESSI, Galeazzo, an eminent Italian architect, born at Perugia in the beginning of the 16th century. He studied at Rome, where he became intimate with Michael Angelo and the other great men who adorned that period. The Strada Nuova at Genoa, and various works at Bologna, Milan, and Naples, bear testimony to his skill.

ALET, a town of France, in the department of the Aude and district of Limoux, at the foot of the Pyrenees. It is remarkable for its baths, and for the grains of gold and silver found in the stream which runs from the Pyrenean mountains, at the foot of which it stands. It is seated on the river Aude, 15 miles south of Carcassone, and 37 south-west of Narbonne. Long. 2. 15. E. Lat. 42. 59. N.

ALEUROMANCY, the same with what was otherwise called *alphitomantia*, and *crithomantia*, an ancient kind of divination performed by means of meal or flour.

ALEUTIAN, Aleutic, or Aleutsky Islands, so called from the Russian word *aleut*, signifying a bold rock, is the name given by the Russian discoverers to a chain of small islands situated in the Northern Pacific Ocean, and extending in an easterly direction between the peninsula of Kamtschatka, in Asiatic Russia, to the promontory of Alaska, in North America. According to the practice of the most recent Russian geographers, we have comprehended the whole of this archipelago under one general name, although it has been sometimes divided into three several groups; those nearest to the eastern coast of Kamtschatka being properly called Aleutian, the central group the Andreanofskie or Andrenovian, and those nearest to the American promontory the Fox Islands. The Russian geographers usually separate Behring's and Copper Island which are at the western extremity of this chain, from the other parts of it, included by them under the general name of Aleutian Islands; but as there seems no good reason for this exception, it certainly would be better to comprehend the whole under one general denomination.

Progress of Discovery.

The first voyage of discovery in this remote and dangerous archipelago was projected by Peter the Great, whose enterprising mind appears to have been strongly excited by the question, then much agitated, relative to the distance between the Asiatic and American continents; the solution of which seemed to be facilitated by the recent conquest of Kamtschatka. A short time previous to the death of that monarch, which took place in 1725, he drew up instructions, with his own hand, for the conduct of an expedition, which was to be intrusted to the command of an officer named Behring, who had already made several voyages in the sea of Kamtschatka by order of the crown. In 1728 Behring set sail from the mouth of the Kamtschatka River, and coasted the eastern shores of Siberia, as far to the northward as Lat. 67. 18., but made no discovery of the opposite continent. In 1729 he again set sail, for the purpose of prosecuting the same enterprise, but with no better success. A third voyage was undertaken by order of the Empress Anna in 1741, and Behring was again selected as chief of the expedition, another vessel being intrusted to the command of Tschirikoff. This enterprise proved more fortunate, and led the way to all the subsequent important discoveries of the Russians in those seas; although the immediate results of the voyage, upon the whole, were not deemed commensurate with the time and expense employed in fitting out the expedition. The principal object of the undertaking, however, appears to have been accomplished. Tschirikoff discovered the coast of America in the 56th degree of latitude; and Behring, who was separated from his companion in a storm, saw it in Lat. 58. 28. On his voyage back to Kamtschatka, Behring's ship was driven on the island which now bears his name, where he soon afterwards died.

In the year 1768 Captain Krenitzin and Lieutenant Le-

Aleutian Islands.

vashef sailed from the mouth of the Kamtschatka River by order of the Empress Catherine, to examine the chain of the Aleutian Islands. This commission they accordingly executed very carefully, having surveyed the whole of this archipelago, from Behring's Island to the promontory of Alaska; and, after spending the winter among the Fox Islands, they returned to Kamtschatka in the autumn of 1769.

During his third and last voyage, in the year 1778, Captain Cook surveyed the eastern portion of this archipelago, accurately determined the positions of some of the most remarkable islands, and corrected many errors of former navigators.

In the year 1785 a fresh expedition was set on foot by the Russian government, the command of which was intrusted to Captain Billings, an English naval officer in the Russian service, who had accompanied Captain Cook in his last celebrated voyage to the Pacific Ocean. This expedition appears to have been suggested by Mr Coxe, who was at that time at St Petersburg, and whose *Account of the Russian Discoveries between Asia and America* had already attracted the attention of the Russian government. During this voyage, which was not completed until the year 1796, Captains Billings and Sarytschef explored the whole chain of the Aleutian Islands, particularly that part of it which had been visited by Captain Cook, and some parts of the adjacent western coast of America. Ample details of the conduct of this expedition have been published in the narratives of Martin Sauer, who officiated as secretary to Captain Billings, and of Admiral Sarytschef.

With the view of ascertaining the practicability of supplying the Russian settlements in N. America and the adjacent isles by sea, instead of the tedious route by Ochotsk, Captain Krusenstern, an experienced Russian naval officer, who had served for a long period in the British navy, suggested the plan of an expedition from Cronstadt, round Cape Horn, to the Aleutian Islands and the north-west coast of America. This plan was approved of by Count Romanzof, the minister of commerce, and Admiral Mordwinof, minister of the marine, and obtained the sanction of his Imperial Majesty. Two vessels, the Nadeshda and the Neva, under the command of Captain Krusenstern, the original author of the plan, and Captain Lisiansky sailed in company from Cronstadt, in the month of August 1803, and proceeded to the Brazils, from whence they sailed round Cape Horn to the Sandwich Islands. Here they separated, the Nadeshda being ordered on a distinct mission to Japan and China, while Captain Lisiansky, in the Neva, proceeded to Kadyak and the American settlements. Of this voyage very full and interesting accounts have been published by Captains Krusenstern and Lisiansky, and by Dr Langsdorff, who accompanied the expedition in the quality of physician.

By far the most important and best explored portion of this archipelago is the most easterly group, called by the Russians *Lyssie Ostrova*, or the Fox Islands. Of these islands the most considerable are, Umnak, Unalashka or Oonalashka, and Unimak, the last of which is separated by a narrow strait from the promontory of Alaska. Beyond these, to the north-east, lies the large island of Kadyak or Kodiak, which is generally included among the group called Schumagin's Islands.

The whole of the islands composing this chain are bare and mountainous; their coasts are rocky and surrounded by breakers, which renders the navigation of those seas exceedingly dangerous. The land rises immediately from the coasts to steep bald mountains, gradually ascending higher behind each other, and assuming the appearance of chains of mountains, running parallel to the length of the island. Springs take their rise at the bottom of the mountains, and either flow in broad and rapid streams into the neighbouring sea, or, collecting in the rocky vales and glens, form ample lakes, which send off their superfluous waters by natural canals into the adjacent bays. These islands bear evident marks of volcanic formation, and several of them have still active volcanoes, which continually emit smoke, and sometimes flames.

Island of Unalashka.

Unalashka, one of the largest of the Fox Islands, was visited by Captain Cook during his last voyage, and seems to merit particular notice. This island stretches from north-east to south-west and is from 70 to 80 versts in length, but of very unequal breadth. On the north and north-east sides there are many bays and creeks, in some of which are very secure harbours for vessels. A part of the south-west shore consists of very high, steep, inaccessible cliffs, and another part has remained hitherto wholly unexplored. The whole island consists of a mass of rocks, covered only with a very thin coat of earth; the hills are of very unequal height, and are intersected by irregular valleys, the soil of which is commonly argillaceous, or an earth which appears washed down from the hills. In the lower valleys there is great abundance of grass, which would furnish very good food for cattle; indeed, Captain Cook was of opinion that cattle might subsist at Unalashka all the year round without being housed; and the soil, in many places, appeared capable of producing grain, roots, and vegetables. But the Russian traders and the natives seem satisfied with what nature brings forth. No wood grows on this and the neighbouring islands; only low bushes, and shrubs of dwarf birch, willow, and alder. For all the timber used for the purposes of building, &c. they are indebted to the sea, which wafts it to their shores from the adjacent continent of America. The inhabitants are rather low in stature, but plump and well-shaped, with short necks, swarthy chubby faces, black eyes, small beards, and long, straight, black hair, which the men wear loose behind and cut before, but the women tie up in a bunch.

Occupations.

The principal occupations of the Aleutians are fishing and hunting, and preparing the implements necessary for both.

Their *baidars*, *baidarkas*, or boats, resemble the canoes of other savages. They consist of a skeleton of wood over which is stretched a leather covering made of seal-skins. The boats of the Unalashkans are much superior in point of beauty to those of any of the other islands: some of them appear so transparent that one might trace the formation of the inside, and the manner in which the rower sits. In their form they are long and narrow, and commonly hold only one person.

Population and government.

The population of Unalashka and the neighbouring islands appears to have been considerable, amounting to several thousands. In 1790 Sarytcheff reckoned it at 1300. According to the most recent accounts, it does not appear to amount to more than 300. This rapid depopulation is ascribed partly to the practice of sending the best hunters to a distance, to chace the large sea-otters, few of them ever returning to their families; and partly to the state of oppression under which the natives live, and the change which has taken place in their modes of living. Captain Cook seems to consider the natives of these islands as originally of the same extraction with the Greenlanders and Esquimaux. When first discovered by the Russians they were under the government of *Toigons*, or chiefs, who, however, possessed little superior distinction or dignity, and had no revenue. At present they are all subject to the government of the Russian settlers. Population of the whole group is now estimated at 8000.

Russian settlements and commerce.

Throughout the whole of the Aleutian Islands, on the island of Kadyak, and the western coast of America, the Russians have formed settlements, for the purpose of hunting and collecting furs, with which they carry on a lucrative commerce, particularly with the Chinese. The most

Alexander. valuable fur is that of the sea-otter; an animal which has now become rare on these islands, in consequence of the extreme eagerness with which they have been hunted and killed. Besides the sea-otter, there are numbers of foxes, especially on the Fox Islands, which from that circumstance derive their name. The black foxes found on these islands are not so valuable as those of Siberia. The Arctic or ice fox, called also the rock fox, and the blue fox, from the natural colour of the fur, which is of a bluish-gray, is very common.

ALEXANDER THE GREAT. See MACEDONIA.

ALEXANDER of Aphrodisias, the most celebrated of the Greek commentators on Aristotle, and styled by way of pre-eminence, ὁ ἐξηγητής, *the expositor*. He was a native of Aphrodisias, in Caria, and flourished between the 2d and 3d centuries. His first and principal work, *On Fate*, written in opposition to the stoical doctrine of necessity, was dedicated to Severus and his son Caracalla. It has been edited by Orelli, Zurich, 1824. His other works, which are very voluminous, consist chiefly of commentaries on treatises of Aristotle. They were greatly esteemed among the Arabians, who translated many of them. A list of his works, with an account of his life, will be found in the *Bibl. Arab. Hisp. Escur.* of Casiri, vol. i. p. 243.

ALEXANDER of Hales, *Alexander Halensis*, surnamed *the irrefragable Doctor*, a celebrated English theologian of the thirteenth century. Like most of the scholars of his time, he studied at Paris, where he took his degree of Doctor, and publicly taught philosophy and theology. Among his numerous disciples were the famous Bonaventura, Aquinas, and Duns Scotus. His great work is the system of theology known as his *Summa*, being a commentary on the *Sentences* of Peter Lombard, composed by the express orders of Pope Innocent IV., and approved after being submitted to the examination of 70 doctors, as a system of instruction for all the schools of Christendom. Of the private history of this famous man little is known. He died in 1245, and was buried in the convent of the Cordeliers at Paris, where he had spent the 23 last years of his life.

ALEXANDER of Tralles. See TRALLIANUS.

ALEXANDER, surnamed BALAS, a personage who figures in the history of the Maccabees and in Josephus. He professed to be the natural son of Antiochus Epiphanes, and as such, out of opposition to Demetrius Soter, he was recognised as king of Syria by the king of Egypt, by the Romans, and eventually by Jonathan Maccabæus, on the part of the Jews. Demetrius was not long after slain in battle, and Balas obtained possession of the kingdom; but abandoning himself to voluptuousness and debauchery, he soon rendered his reign odious. This encouraged Demetrius Nicator, the eldest son of Demetrius Soter, to claim his father's crown. Alexander took the field against him, but was defeated in a pitched battle, and fled with 500 cavalry to Abæ in Arabia, and sought refuge with the emir Zabdieh, who murdered his confiding guest in the fifth year of his reign over Syria. (1 Macc. xi. 13–18; Joseph. *Antiq.* xiii. 4.)

ALEXANDER JANNÆUS, second king of Judea of the Asmolæan family, but who disgraced the blood of the heroic Maccabees by most barbarous cruelties. He succeeded his brother Aristobulus in 104 B.C., and died in 81 B.C.—*Josephus, Ant. Jud.* xiii.

ALEXANDER SEVERUS, a Roman emperor who reigned from A.D. 222 till A.D. 235. He was born about A.D. 205, in Phœnicia, being the son of Julia Mammæa, by her husband Gessius Marcianus, a Syrian, or, according to others, by Caracalla. When his cousin Elagabalus was raised to the imperial throne, he accompanied him to Rome, where after some time he was adopted by his cousin, and elevated to the rank of Cæsar. On his adoption by Elagabalus he received the name Alexander (he had before been called Bassianus), to which subsequently that of Severus was added. As the young Cæsar refused to take part in the brutal amusements of the emperor, he drew upon himself hatred and persecution, which were only increased by the circumstance that he was a favourite with the soldiers. This gave rise to more than one outbreak among the prætorians, who in March 222, murdered Elagabalus and raised Alexander Severus to the throne. The senate and people readily acquiesced in this decision of the prætorian guards, and conferred upon the new emperor the highest titles and honours. He had been carefully educated by his mother and Mæsa his grandmother, who had procured for him the ablest instructors of the time. While on the throne he was guided by the counsels of these two ladies, and was ever ready to listen to the advice of men of wisdom and experience, among whom we find the illustrious lawyers Ulpian and Paullus. It was on the suggestion of his mother that Alexander excluded women from the senate, and formed a privy-council of sixteen of the wisest and most virtuous senators, of which Ulpian became the president. Notwithstanding her jealousy and some disposition to cruelty, Mammæa exercised a most salutary influence over the emperor and the affairs of the empire. Alexander himself was not wanting either in ability or in zeal: he devoted the greater part of the day to public business; and in his leisure hours refreshed himself by the study of Virgil, Horace, Plato, and Cicero. He did away with the superstitious abominations which had been introduced at Rome by his predecessor, but at the same time appears to have had a peculiar religion of his own, for we are informed that in the chapel of his palace (the Lararium) he paid divine honours to Abraham, Orpheus, Apollonius of Tyana, and Jesus Christ, of all of whom images were set up there. His reign is indeed praised on account of his great mildness, but at the same time he always allowed the law to take its course unimpeded, and endeavoured by all means to check the immorality which pervaded all classes. His attempts, however, to reform the legions and prætorians were unsuccessful; and as the latter regarded the wise Ulpian as the author of the measures adopted by the emperor, they mutinied and compelled Alexander to give up that most faithful friend and adviser to be murdered before his own eyes, in A.D. 228. In the mean time commotions had taken place in Asia, where the empire of the Parthians and the kingdom of the Arsacidæ had been overturned by the Persians. The conquerors, under their king Artaxerxes, even marched across the frontiers of the Roman empire, in consequence of which Alexander was obliged, in A.D. 232, to undertake an expedition against the Persians. According to some accounts he was successful, while according to others the whole undertaking was not carried out in a very creditable manner. It is certain, however, that the Persians after this time for some years abstained from making inroads into the Roman dominion. On his return from Asia, Alexander found that the northern barbarians were threatening the frontier in another part. He accordingly hastened to the Rhine. While he was there encamped in a place called Sicila, the soldiers, instigated by their commander Maximinus, murdered both him and his mother, and proclaimed the Thracian Maximinus his successor, A.D. 235. Compare Gibbon, chap. vi.; Niebuhr, *Lect. on Rom. Hist.* iii. p. 273, fol. (L. S.)

Alexander.

Alexander V., raised to the papal see in 1409, was born in the island of Candia, of parents so poor that he begged from door to door. He is praised by historians for the purity of his morals. He died at Bologna aged 70, after a pontificate of about ten months.

Alexander VI., *Pope*, Rodrigo Lenzuoli, was born of a noble Spanish family at Valencia, in 1429, and assumed the name of Borgia, on the elevation of his maternal uncle, Calixtus III., to the chair of St Peter, who made Rodrigo a cardinal at the age of 25. His private life had always been a disgrace to his ecclesiastical profession; and before his election to the papacy, he had four natural children by Vanozza, his Roman mistress, who long possessed the chief place in his affections. That he was a man of talent has never been denied; but his open profligacy and contempt for decency even after he became pope, were such that his reign is compared by Gibbon to that of Tiberius in ancient Rome. While cardinal, he was employed in several important negotiations, during which he contrived to amass great wealth, and to lay the foundations of the future power of his family. On his return from one of these embassies to Spain and Portugal, he was shipwrecked, and was one of the few survivors of a catastrophe in which 180 persons perished; among whom were three bishops, and many other men of rank and learning. His wealth, unscrupulously used, enabled him to attain the papacy in 1492, on the demise of Innocent III.

We shall not dwell on the impurities and crimes that stained the court of Alexander, which the concurrent testimony of Italian writers, represent as flagitious in the highest degree; but give his character in the words of Guicciardini. "In Alexander VI. were singular degrees of prudence and sagacity, a sound understanding, a wonderful power of persuasion, and an incredible vigilance and dexterity in all he undertook. But these qualities were more than counterbalanced by his vices. In his manners he was most shameless; wholly divested of sincerity, of decency, and of truth; without fidelity, without religion; in his avarice immoderate; in his ambition insatiable; in his cruelty more than barbarous; with a passionate desire of elevating his numerous children by whatever means this could be accomplished." His pontificate was the signal for the recommencement of those troubles and jealousies among the Italian potentates that had slumbered for some time, and which paved the way for a succession of foreign oppressions under which that fine country long groaned, commencing with the unprincipled irruption of the French King Charles VIII. "No sooner," says Roscoe, "was the new pontiff firmly seated in the chair of St Peter, than those jealousies, intrigues, and disputes among the potentates of Italy which had for some time ceased to agitate that country, began again to revive, and prepared the way not only for a long series of bloodshed and misery, but for events which overturned in a great degree the political fabric of Italy, and materially affected the rest of Europe." The pontificate of Alexander VI. must be considered, from the intrigues and crimes of him and his family, as disastrous and disgraceful to Italy. His violence and misrule for a while interrupted the progress of reviving literature, which had begun to spread from Italy as a centre over Europe.

The audacious villanies, however, of the pontiff's son Cæsar Borgia, throw those of the father into the shade. The equivocal character of his only daughter Lucrezia, has found a chivalrous defender in the elegant historian of the Medici. (See *Appendix I. Life of Leo. X.*) Lucrezia was first married to Gio. Sforza, lord of Pesaro, but divorced from him by her father, who soon after united her to Alfonso of Aragon, a natural son of Alfonso II. of Naples; but two years afterwards her unfortunate husband was assassinated before the great door of the church of St Peter, as is alleged with probability by the instrumentality of her brother Cæsar, who is alleged also to have murdered his own brother Giovanni in the streets of Rome. In the following year, 1501, she was finally married to Alfonso d'Este, the son of the reigning Duke of Ferrara. From this time, whatever may have been her previous character, Lucrezia became the ornament of the court of Ferrara, the patroness of learning, and was entrusted by her husband with the principal administration of his affairs during his military expeditions, in which she acquitted herself with ability and dignity.

After a life of profligacy and crime, in which he had cut off the principal members of the Colonna, Orsini, and Savelli families, the noblest of the Roman nobility, and had concentrated wealth on his own family, Alexander died Aug. 18. 1503, in the 74th year of his age, by poison prepared by himself for the destruction of the cardinal of Corneto. (T.S.T.)

Alexander VII., *Pope*. See Chigi.

Alexander, *St*, whom St Irenæus reckons the fifth bishop of Rome, succeeded St Everistus in the year 109, and died in the year 119. There is no account of his life, and the epistles attributed to him are supposititious.

Alexander I., king of Scotland, youngest son of Malcolm Canmore, succeeded his elder brother Edgar in 1107. His kingdom was turbulent; but he contrived by energy and valour to overcome all opposition. His most formidable competitor was Angus, grandson of Lulach, son of Macbeth's queen; but the dangerous insurrection was put down by the vigour of Alexander. He was no less determined in resisting all attempts on the independence of his crown by foreign princes. He died childless at Stirling in 1124, and was succeeded by his brother, David I. See Scotland.

Alexander II., king of Scotland, succeeded his father William in 1213, at 16 years of age. He made an expedition into England, to oppose the tyranny of King John, who returned the visit, and was offered battle by Alexander, but refused it. He took the city of Carlisle from Henry III., which was afterwards exchanged for Berwick. Alexander died in 1249, in the 51st year of his age and 35th of his reign, and left for his successor his son,

Alexander III., who was crowned king of Scotland in 1249. The Comyns, a powerful family, took arms against him, and, taking him prisoner, confined him at Stirling; but he was afterwards released by his subjects. He first married the daughter of Henry III., king of England; and next the daughter of the Count de Dreux; but was at length killed by a fall from his horse, on the 10th of April 1290, after having reigned 42, or, according to others, 37 years.

Alexander, *Noel*, an indefatigable writer of the 17th century, born at Rouen, in Normandy, 1639. After finishing his studies at Rouen, he entered into the order of Dominican friars, and was professed there in 1655. Soon after he went to Paris, to go through a course of philosophy and divinity in the great convent, where he distinguished himself so greatly, that he was appointed professor of philosophy there, which office he held for twelve years. M. Colbert showed him many marks of his esteem; and being determined to omit nothing to perfect the education of his son, afterwards archbishop of Rouen, he formed an assembly of the most learned persons, whose conferences upon ecclesiastical history might be of advantage to him. Father Alexander was invited to this assembly, where he exerted himself with so much genius and ability, that he gained the particular friendship of young Colbert, who showed him the utmost regard as long as he lived. These conferences gave rise to Alexander's design of writing an ecclesiastical history; for being desired to reduce what was material in these conferences to writing, he did it with so much accuracy, Alexander. that the learned men who composed this assembly advised him to undertake a complete body of church history. This he executed with great assiduity, collecting and digesting the materials himself, and writing even the tables with his own hand. He at last completed his work in 1686. Towards the latter part of his life he was afflicted with the loss of his sight; a misfortune which he bore with great patience and resignation. He died in 1724, in the 86th year of his age.

ALEXANDER, *William*, earl of Stirling, an eminent Scottish statesman and poet in the reigns of James VI. and Charles I., who, after travelling with the Duke of Argyll as his tutor or companion, wrote a poetical work, with the view of alleviating the sorrows of unsuccessful love, under the title of *Aurora*. He then removed to the court of James VI., where he cultivated poetry upon the plan of the Greek and Roman tragedians. In 1607 he published some dramatic performances, entitled *Monarchic Tragedies* dedicated to King James. After this, he is said to have written *A Supplement* to complete the third part of Sir Philip Sidney's *Arcadia*. He also wrote a poetical piece, entitled *A Parænesis to the Prince;* and in 1614 he published his last poem, *Doomsday*, or *the Great Day of Judgment*. His poetical works were published by himself, in a folio volume, under the title of *Recreations with the Muses*. He was made gentleman-usher to Prince Charles, and master of the requests; was knighted; and obtained a grant of Nova Scotia, where he projected the settlement of a colony, but afterwards sold it to the French. In 1626 he was made secretary of state for Scotland, was created first viscount and then earl of Stirling, and died in 1640.

ALEXANDER, *Paulovich*, emperor of Russia, was born on 28th December 1777. He was the son of Paul, afterwards emperor, by Maria, daughter of Prince Eugene of Würtemberg. His early education was conducted under his excellent mother, and afterwards was carefully directed by his grandmother, the Empress Catherine II., who confided its general superintendence to Laharpe, of whom Alexander ever afterwards retained a grateful recollection. The death of Catherine, in 1796, made room for the accession of her son Paul, whose wild eccentricities were so extravagant and prejudicial to his country, that they ended in his assassination in 1801; and Alexander was immediately placed on the Russian throne.

The policy of the young emperor was indicated by his concluding a peace with Britain, against which his father had declared war; and after the recommencement of hostilities between us and France in 1803, Alexander joined Austria and Sweden in a coalition with Great Britain against the pretensions of France in 1805. This war was very disastrous to the allies. The armies of Austria were totally defeated in a succession of battles between the 6th and 13th of October of that year; and the combined Austrian and Russian armies, under the two emperors, were defeated by Napoleon in the great battle of Austerlitz on the 2d of December. Austria concluded a separate treaty of peace, and Alexander led the remains of his army into his own dominions. Britain thus left single-handed to contend with the increased power of France, was probably saved from the worst consequences of the contest, by the annihilation of the combined navies of France and Spain, in the battle of Trafalgar, on 21st of October, on the very day on which General Mack surrendered a fine Austrian army of 36,000 men at Ulm to Napoleon.

Prussia, which had injudiciously stood neutral while France was humbling Austria and Russia, rashly engaged in hostilities with Napoleon in 1806, while her allies, the Russians, were still beyond the Vistula; but the defeats at Auerstadt and Jena laid Prussia prostrate; and in the succeeding year, the battles of Eylau and Friedland, in which the Russians were fairly beaten, led to the dismemberment of Prussia, and the treaty of Tilsit with Russia. A few days after the last battle, Alexander and Napoleon met on a raft anchored in the river Niemen, and agreed to the articles of a treaty which was signed at Tilsit, on July 7. Napoleon gained so on Alexander, as to obtain his consent to a secret article of the treaty, by which Alexander was not only to withdraw from his connection with Britain, but to become her enemy; and he declared war against her on the 26th of October. Alexander.

For nearly five years, Alexander appeared attached to the alliance of France; but the privations of his subjects by the interruption of the commerce with England, and the intolerable load of Napoleon's "Continental System," at length induced him to return to his old alliance, and to declare war against France on March 19. 1812. On the 24th April, he left St Petersburg, to join his armies on the west frontier of Lithuania. Napoleon assembled the most numerous and magnificent army that had ever been brought together in modern times, augmented by the unwilling levies of Prussia and Austria, and entered Russia on the 25th of June 1812. The first encounter was at Borodino, where there was a well-contested action, in which each army suffered the loss of 25,000 men. Kutusoff made a skilful retreat; and as the French advanced, they found a deserted wasted country to the confines of Moscow, which Napoleon entered on the 14th September; but in a few hours the city was in flames, supplies of every kind intercepted, and the approach of winter compelled Napoleon to leave its smoking ruins. The enterprising generals, Kutusoff, Wittzenstein, and Tschichagoff, hung on his retreat like thunderclouds; and the destruction of his gallant army at the passage of the Berizina, and the firmness of Alexander through the mighty contest, gave the first blow to Napoleon's colossal power, which had well nigh annihilated the independence of Continental Europe.

In 1813, the advancing Russians were successively joined by the forces of Prussia, Austria, and Sweden. Alexander continued with the allied armies, and he was especially present in the battles of Dresden and Leipsic. The extraordinary military genius of Napoleon had made wonderful exertions to repair his losses in the early part of 1814; but the victories of Wellington in Spain, and his advance into the heart of France, favoured the progress of the allies; and on March 30. 1814, 150,000 men of the allied armies took possession of Paris, which was entered next day by Alexander and the king of Prussia.

After the deposition of Napoleon, the allied sovereigns visited England. By the treaty of Vienna, Alexander was acknowledged king of Poland; but before the Congress of Vienna had separated, Napoleon had escaped from Elba, and was enthusiastically received at Paris. The two eastern emperors and the king of Prussia remained together, until the battle of Waterloo gave peace to Europe.

On the advance of the British and Prussians to Paris, the three allied sovereigns again made their entry into Paris, where they concluded, on September 26, that treaty which has been miscalled *the Holy Alliance*.

After that period, Alexander was chiefly occupied in the internal administration of his vast dominions, which certainly advanced in every kind of improvement during the twenty-five years of his reign, more than under any of his predecessors from the time of Peter I. The gradual abolition of the feudal servitude of the peasantry, begun by the most enlightened of his predecessors, was continued under Alexander. Education, agriculture, manufactures, commerce, were also greatly extended; while literature and the fine arts were liberally encouraged. His disposition has been represented by his subjects as mild and merciful; yet his influence in the affairs of Europe was not exerted in the cause of public liberty. But this could hardly be expected from the autocrat of an unmitigated despotism in his own territories. He will, however, bear a very favourable comparison with any Russian sovereign, or even with his European contemporary princes.

Early in the winter of 1825, he left St Petersburg for the last time on a tour of inspection of his southern provinces. About the middle of November, he was attacked by a violent intermittent fever, which is endemical in those countries; and when he reached Taganrog, on the Gulf of Azof, he was alarmingly ill from reiterated accessions of the disease, which carried him off on December 1. 1825. In foreign countries his death has been attributed to poison; but this is refuted by the history of his disease, and is very improbable, from his great popularity with his countrymen. He was married in 1793, to Louisa Maria Augusta, princess of Baden, but left no issue, and was succeeded by his second brother Nicolas, the present emperor. (T. S. T.)

ALEXANDRETTA. See SCANDEROON.

ALEXANDRIA, called ISKANDERIA by the Turks, an ancient city of Lower Egypt, and for a long time its capital. This city was built by Alexander the Great, soon after the overthrow of Tyre, about 333 years before Christ. It is situated on the Mediterranean, twelve miles west of that mouth of the Nile anciently called *Canopicum*, and lies in Long. 29. 54. E. Lat. 31. 10. N.

Alexander is said to have been induced to build this city on account of its affording a fine port, and being advantageously situated for trade. It realised his expectations; for it soon became the emporium, not only for merchandise, but also for all the arts and sciences of the Greeks. Alexandria, according to Strabo, was 30 stadia in length from east to west, and 7 or 8 stadia in breadth where narrowest. The circumference was about 70 stadia, or 9 miles; but Pliny, including no doubt the suburbs, reckons the circumference 15 miles. Lake Mareotis bathed its walls on the south, and the Mediterranean on the north. It was intersected lengthwise by straight parallel streets. This direction left a free passage to the northern wind, which alone conveys coolness and salubrity into Egypt. A street of 100 feet wide began at the gate of the sea, and terminated at the gate of Canopus. It was decorated with magnificent houses, temples, and public buildings. In its extensive range, the eye wandered with admiration over the marble, the porphyry, and the obelisks, which were destined at some future day to embellish Rome and Constantinople. The great street, the handsomest in the world, was intersected by another of the same breadth. From the middle of this place were to be seen at once vessels arriving under full sail from the north and from the south.

An artificial mole, called the *Heptastadium*, nearly a mile in length, stretched from the continent to the isle of Pharos, and divided the great harbour into two. That which is to the northward preserved its name. A dike drawn from the island to the rock on which the watch-tower was built, secured it from the westerly winds. The other was called *Eunostos*, or the Safe Return. The former is called at present the new, the latter the old harbour: they were connected with each other by two breaks in the mole, crossed by two bridges, which could be raised at pleasure. The palace, which advanced beyond the promontory of *Lochias*, extended as far as the dike, and occupied more than a quarter of the city. Each of the Ptolemies added to its magnificence. It contained within its inclosure, the museum, an asylum for learned men, groves, and buildings worthy of royal majesty, and a temple where the body of Alexander was deposited in a golden coffin. Ptolemy Soter II. violated this monument, carried off the golden coffin, and put a glass one in its place. In the great harbour was the little island of Anti-Rhodes, where stood a theatre and a royal place of residence. Within the harbour of Eunostos was a smaller one called *Kibotos*, dug by the hand of man, which communicated with Lake Mareotis by a canal. Between this canal and the palace was the grand temple of Serapis, while that of Neptune stood near the great market place. Alexandria extended likewise along the northern banks of the lake. Its eastern part presented to view the gymnasium, with its porticoes of more than 600 feet long, supported by several rows of marble pillars. Without the gate of Canopus was a spacious circus for the chariot races. Beyond that the suburb of Nicopolis ran along the sea-shore, and seemed a second Alexandria. A superb amphitheatre was built there, with a race-ground, for the celebration of the quinquennalia.

Such is the description of Alexandria left us by the ancients, and above all by Strabo.

The architect employed by Alexander in this undertaking was the celebrated Dinocrates, who had acquired so much reputation by rebuilding the temple of Diana at Ephesus. The city was first rendered populous by Ptolemy Soter, the son of Lagus, one of Alexander's captains, who, after the death of the Macedonian monarch, being appointed governor of Egypt, soon assumed the title of king, and took up his residence at Alexandria, about 304 years before Christ.

In the 30th year of Ptolemy's reign he took his son Ptolemy Philadelphus as his partner in the empire; and by this prince the city of Alexandria was much embellished. In the first year of his reign the famous watch-tower of Pharos was finished. It had been begun several years before by his father; and, when finished, was looked upon as one of the wonders of the world. The same year, the islet of Pharos itself, originally seven furlongs distant from the peninsula, was joined to it by a causeway. This was the work of Dexiphanes, who completed it at the same time that his son put the last hand to the tower. The tower was a large square structure of white marble, on the top of which fires were kept constantly burning for the direction of sailors. The building cost 800 talents; which, if Attic, amounted to L.155,000; if Alexandrian, to L.248,000. This is reckoning the Attic talent at 60, and the Alexandrian at 96 minæ, and each mina equal to L.3, 4s. 7d.

The architect employed in this famous structure is said to have fallen upon the following contrivance to usurp the whole glory to himself. Being ordered to engrave upon it the following inscription,—"King PTOLEMY to the Gods the Saviours, for the benefit of Sailors,"—instead of the king's name he substituted his own, and then filling up the hollow of the marble with mortar, wrote upon it the above-mentioned inscription. In process of time, the mortar being worn off, the following inscription appeared: "SOSTRATUS the CNIDIAN, the son of DEXIPHANES, to the Gods the Saviours, for the benefit of Sailors."

This year also was remarkable for the bringing of the image of Serapis from Pontus to Alexandria. It was set up in one of the suburbs of the city, called *Rhacotis*, where a temple was afterwards erected to his honour, suitable to the greatness of that stately metropolis, and called, from the god worshipped there, *Serapeion*. This structure, according to Ammianus Marcellinus, surpassed in beauty and magnificence all others in the world, except the Capitol at Rome. Within the verge of this temple was the famous Alexandrian library. It was founded by Ptolemy Soter, for the use of an academy he instituted in this city; and, by continual additions by his successors, became at last the finest library in the world, containing no fewer than 700,000 volumes. The method followed in collecting books for this library was to seize all those which were brought into Egypt by Greeks or other foreigners. The books were transcribed in the museum by persons appointed for that purpose: the copies were then delivered to the proprietors, and the originals laid up in the library. Ptolemy Euergetes, having borrowed from the Athenians the works of Sophocles, Euripides, and Æschylus, returned them only the copies, which he caused to be transcribed in as beautiful a manner as possible; presenting them at the same time with fifteen talents (equal to L.2906, 5s., reckoning by the smaller talent) for the exchange.

As the museum was at first in that quarter of the city called *Brucheion*, near the royal palace, the library was placed there likewise; but when it came to contain 400,000 volumes, another library, within the Serapeion, was erected by way of supplement to it, and on that account called the *daughter* of the former. In this second library 300,000 volumes in process of time were deposited; making in all 700,000. In the war carried on by Julius Cæsar against the inhabitants of this city, the library in the Brucheion, with all its contents, was reduced to ashes. The library in the Serapeion, however, still remained; and here Cleopatra deposited 200,000 volumes of the Pergamencan library, which Mark Antony presented to her. These, and others added from time to time, rendered the new library at Alexandria more numerous and considerable than the former; but when the temple of Serapis was demolished under the archiepiscopate of Theophilus A.D. 389, the valuable library was pillaged or destroyed, and twenty years afterwards the empty shelves excited the regret and indignation of every intelligent spectator. Afterwards the church and seat of the patriarchs may have been enriched with considerable collections of books, consisting chiefly of theological controversy, but the library no longer contained the 400,000 or 700,000 volumes collected by the curiosity and magnificence of the Ptolemies. For 293 years Alexandria was the capital of the kingdom of the Ptolemies.

This city, as we have already observed, soon became extremely populous, and was embellished both by its own princes and the Romans; but, like most other noted cities of antiquity, it has been the seat of terrible massacres. About 141 years before Christ it was almost totally depopulated by Ptolemy Physcon. That barbarous monster, without the least provocation, gave free liberty to his guards to plunder his metropolis, and murder the inhabitants at their pleasure. The cruelties practised on this occasion cannot be expressed, and the few who escaped were so terrified that they fled into other countries. Upon this, Physcon, that he might not reign over empty houses, invited strangers from the neighbouring countries; by whom the city was repeopled, and soon recovered its former splendour. On this occasion many learned men, having been obliged to fly, proved the means of reviving learning in Greece, Asia Minor, and the islands of the Archipelago, and other places where it was almost totally lost.

The new inhabitants were not treated with much more kindness by Physcon than the old ones had been; for, on their complaining of his tyrannical behaviour, he resolved on a general massacre of the young men. Accordingly, when they were one day assembled in the gymnasium, or place of public exercise, he ordered it to be set on fire; so that they all perished, either in the flames, or by the swords of the tyrant's mercenaries, whom he had posted at all the avenues.

Though Julius Cæsar was obliged to carry on a war for some time against this city, it seems not to have suffered much damage, except the burning of the library already mentioned. Before Cæsar left Alexandria, in acknowledgment of the assistance he had received from the Jews he confirmed all their privileges there, and even engraved his decree on a pillar of brass. This, however, did not prevent the massacre of 50,000 of them in this city, about the year of Christ 67.

The city of Alexandria seems to have fallen into decay soon after this, and to have forfeited many of its ancient privileges, though for what offence is not known; but when Hadrian visited Egypt, about the year 122, it was almost totally ruined. He repaired both the public and private buildings, not only restoring the inhabitants to their ancient privileges, but heaping new favours upon them; for which they returned him their solemn thanks, and conferred upon him what honours they could while he was present; though as soon as he was gone they published the most bitter lampoons against him.

The fickle and satirical humour of the Alexandrians was highly offensive to Hadrian, though he visited it with no punishment. Caracalla, however, did not let it pass so easily. That tyrant, when he visited their city in the year 215, having become the subject of their foolish satires, ordered a general massacre by his numerous troops, who were dispersed all over the city. The inhuman order being given, all were murdered, without distinction of age or sex; so that in one night's time the whole city floated in blood, and every house was filled with carcasses. The monster who occasioned this had retired during the night to the temple of Serapis, to implore the protection of that deity; and, not yet satiated with slaughter, commanded the massacre to be continued all the next day; so that very few of the inhabitants remained. As if even this had not been sufficient, he stripped the city of all its ancient privileges; suppressed the academy; ordered all strangers who lived there to depart; and that the few who remained might not have the satisfaction of seeing one another, he cut off all communication of one street with another, by walls built for that purpose, and guarded by troops.

Notwithstanding this terrible disaster, Alexandria soon recovered its former splendour after the death of Caracalla. It was long esteemed the first city in the world, next to Rome; and we may judge of its magnificence, and the multitude of people contained in it, from the account of Diodorus Siculus, who relates that in his time (B.C. 44) Alexandria had on its rolls 300,000 free inhabitants. Mannert, a learned German writer, thinks the slaves must have been at least equally numerous; and thus the city, in its flourishing periods, had contained not less than 600,000 inhabitants. According to Eutychius, it was on the 22d December A.D. 640, that Amrou, Omar's general, took it by storm after a siege of 14 months, and with the loss of 23,000 men. Heraclius, then emperor of Constantinople, did not send a single ship to its assistance. This prince affords an example very rare in history: he had displayed some vigour in the beginning of his reign, and then suffered himself to be lulled into idleness and effeminacy. Awakened suddenly from his lethargy by the noise of the conquests of Chosroes, that scourge of the East, he put himself at the head of his armies, distinguished himself as a great captain from his very first campaign, laid waste Persia for seven years, and returned to his capital covered with laurels: he then became a theologian on the throne, lost all his energy, and amused himself the rest of his life with disputing upon monotheism, whilst the Arabs were robbing him of the finest provinces of the empire. Deaf to the cries of the unfortunate inhabitants of Alexandria, as he had been to those of the people of Jerusalem, who defended themselves for two years, he left them a sacrifice to the rising fortune of the indefatigable Amrou. All their intrepid youth perished with their arms in their hands.

The victor, astonished at his conquest, wrote to the caliph, "I have taken the city of the west. It is of an immense extent. I cannot describe to you how many wonders it contains. There are 4000 palaces, 4000 baths, 12,000 dealers in fresh oil, 12,000 gardeners, 40,000 Jews who pay tribute, 400 theatres or places of amusement."

At this time, according to the Arabian historians, Alexandria consisted of three cities, viz. *Menna*, or the port, which includes Pharos and the neighbouring parts; *Alexandria*, properly so called, where the modern Alexandria now stands; and *Nekita*, probably the Necropolis of Josephus and Strabo.

The following story relating to the destruction of the famous library is told by Abulfaragius, whose account, however, is utterly irreconcileable with the silence of all historians of the period.—See Gibbon, *Decline and Fall, &c.* c. 51.

At that time John, surnamed *the Grammarian*, a famous Peripatetic philosopher, being in the city, and in high favour with Amrou Ebn al Aas, the Saracen general, begged of him the royal library. Amrou replied that it was not in his power to grant such a request; but that he would write to the caliph on that head, since, without knowing his pleasure, he dared not to dispose of a single book. He accordingly wrote to Omar, who was then caliph, acquainting him with the request of his friend; to which he is said to have replied, That if those books contained the same doctrine with the Koran, they could be of no use, since the Koran contained all necessary truths; but if they contained anything contrary to that book, they ought not to be suffered; and, therefore, whatever their contents were, he ordered them to be destroyed. Pursuant to this order, they were distributed among the public baths, where, for the space of six months, they served to supply the fires of those places, of which there was an incredible number in Alexandria. See Amrou.

After the city was taken, Amrou thought proper to pursue the Greeks who had fled farther up the country; and therefore marched out of Alexandria, leaving but a very slender garrison in the place. The Greeks, who had before fled on board their ships, being apprised of this, returned on a sudden, surprised the town, and put all the Arabs they met with to the sword; but Amrou, receiving advice of what had happened, suddenly returned, and drove them out of it with great slaughter; after which the Greeks were so intimidated, that he had nothing further to fear from them.—A few years after, however, Amrou being deprived of his government by the caliph Othman, the Egyptians were so much displeased with his dismission that they showed a tendency to revolt. Constantine, the Greek emperor, having received intelligence of their disaffection, determined on the reduction of Alexandria. For this purpose he sent the eunuch Manuel, his general, with a powerful army, to retake that place; which, by the assistance of the Greeks in the city, who kept a secret correspondence with the imperial forces while at sea, and joined them as soon as they had made a descent, he effected with inconsiderable loss. The caliph, now perceiving his mistake, immediately restored Amrou to his former dignity. This step was very agreeable to the natives, who, having had experience of the military skill and bravery of this renowned general, and apprehending that they should be called to an account by the Greeks for their former perfidious conduct, had petitioned Othman to send him again into Egypt.—Upon Amrou's arrival, therefore, at Alexandria, the Copts or natives, with the traitor Al-Mokawkas (who had formerly betrayed to Amrou the fortress of Mesr) at their head, not only joined him, but supplied him with all kinds of provisions, exciting him to attack the Greeks without delay. This he did; and after a most obstinate struggle, which lasted several days, drove them into the town, where, for some time, they defended themselves with great bravery, and repelled the utmost efforts of the besiegers. This so exasperated Amrou that he swore, if God enabled him to conquer the Greeks, he would throw down the walls of the city, and make it as easy of access as the house of a prostitute. Nor did he fail to execute his threat; for, having taken the town by storm, he quite dismantled it, entirely demolishing the walls and fortifications. The lives of the citizens, however, were spared, at least as far as lay in the general's power; but many of them were put to the sword by the soldiers on their first entrance. In one quarter particularly, Amrou found them butchering the Alexandrians with unrelenting barbarity; to which, however, by his seasonable interposition, he put a stop, and on that spot erected a mosque, which he called the *mosque of mercy*.

From this time Alexandria never recovered its former splendour. It continued under the dominion of the caliphs till the year 924, when it was taken by the Magrebians, two years after its great church had been destroyed by fire. This church was called by the Arabs *Al Kaisaria* or *Cæsarea*, and had formerly been a pagan temple, erected in honour of Saturn by Cleopatra.

The city was soon after abandoned by the Magrebians; but in 928 they again made themselves masters of it. Their fleet being afterwards defeated by that of the caliph, Abul Kâsem the Magrebian general retired from Alexandria, leaving there only a garrison of 300 men; of which Thamaâl, the caliph's admiral, being apprised, he in a few days appeared before the town, and carried off the remainder of the inhabitants to an island of the Nile called Aboukir. This was done to prevent Abul Kâsem from meeting with any entertainment at Alexandria, in case he should think proper to return. According to Eutychius, above 200,000 of the miserable inhabitants perished this year.

What contributed to raise Alexandria to the extraordinary height of splendour it enjoyed for a long time, was its being the centre of commerce between the eastern and western parts of the world. It was with the view of becoming master of this lucrative trade that Alexander built this city, after having extirpated the Tyrians, who formerly engrossed all the traffic of the East. Of the immense riches which that trade afforded, we may form an idea from considering that the Romans accounted it a point of policy to oppress the Egyptians, especially the Alexandrians. Extravagant accounts have been given of the wealth of Alexandria; but according to Strabo, the revenue of all Egypt under the last and most indolent of the Ptolemies, amounted only to 12,500 talents, or about two millions and a half of our money. This was afterwards considerably increased by the more exact economy of the Romans, and the increase of the trade of Ethiopia and India.

Though the revolutions which happened in the government of Egypt after it fell into the hands of the Mahometans frequently affected this city to a very great degree, yet still the excellence of its port, and the innumerable conveniences resulting from the East India trade to the possessors of Egypt, preserved it from total destruction, even when in the hands of the most barbarous nations. Thus, in the 13th century, when the European nations began to acquire a taste for the elegancies of life, the old mart of Alexandria began to revive; and the port, though far from recovering its former magnificence, grew once more famous by becoming the centre of commerce: but having fallen under the dominion of the Turks, and the passage round the Cape of Good Hope being discovered by the Portuguese in 1497, a fatal blow was given to the Alexandrian commerce, and the city thenceforward rapidly declined.

Alexandria, *Modern*, is built upon a neck of land between the two ports. That to the westward, the ancient *Eunostos*, now *the old port*, is by far the best. It stretches from the town westward to Marabout, nearly six miles, is about a mile and a half wide, and has three entrances. The first, or that nearest the city, has seventeen feet of water, and is about two miles south-west from the large building situated a little to the westward of the town, called the palace. The entrance, however, is difficult. The eastern side of the second or middle entrance is marked by buoys, which lie about two miles and three quarters south-west from the palace: it is about a quarter of a mile wide, and has, where shallowest, twenty-seven feet of water. The third or western entrance, which is the best, has its western boundary about three eighths of a mile from the east end of Marabout Island, is about half a mile wide, and has at its shallowest part from twenty-five to twenty-seven feet of water. The new or Asiatic harbour is on the eastern side of the town. The space for anchorage in it is very limited; and being exposed to the north winds, with a foul and rocky bottom, the cables of vessels soon chafe and part, by which serious accidents sometimes happen, from the violent collision of the vessels thus driven from their moorings.

The country around Alexandria is entirely destitute of water. That necessary is supplied from the Nile by the kalidj, a canal of 12 leagues, which conveys it every year at the time of the inundation. It fills the vaults or reservoirs dug under the ancient city; and this provision serves till the next year. It is evident, therefore, that were a foreign power to take possession, the canal would be shut, and all supplies of water cut off. It is this canal alone which connects Alexandria with Egypt; for, from its situation without the Delta, and the nature of the soil, it really belongs to the deserts of Africa. Its environs on the western and southern side are sandy, flat, and sterile, without trees or houses; on the eastern side the country is broken and undulating, and adorned in the vicinity of the town with well-cultivated gardens. The famous tower of Pharos has long since been demolished, and a castle, called Pharillon, built in its place. The causeway which joined the island to the continent is broken down, and its place supplied by a strong bridge of several arches.

Some parts of the Saracenic walls of the city are yet standing, and present a fine specimen of ancient masonry. They were flanked with large towers, about 200 paces distant from each other, with small towers in the middle. Below were some extensive casemates, which might serve for galleries to walk in. In the lower part of one of the towers was a large square hall, the roof of which was supported by thick columns of Thebaic syenite. Above were several rooms, over which were platforms more than 20 paces square. The ancient reservoirs, vaulted with so much art, which extend under the whole town, remain almost entire at the end of 2000 years.

Of Cæsar's palace there remain only a few porphyry pillars, and the front, which is almost entire, and very beautiful. The palace of Cleopatra was built upon the walls facing the port, with a gallery on the outside, supported by several fine columns. Not far from this palace are two obelisks, vulgarly called Cleopatra's Needles. They are of Thebaic stone, and covered with hieroglyphics. One is overturned, defaced, and lying under the sand; the other is on its plinth. These two obelisks, each of which is a single stone, measured 70 feet high, by 7 feet 7 inches at the base. Denon, who went to Egypt along with the French army in 1798, supposed that these columns decorated the entrance of the palace of the Ptolemies, the ruins of which still exist at no great distance from the place of the obelisks. Towards the gate of Rosetta are five columns of marble, on the place formerly occupied by the porticoes of the gymnasium. The rest of the colonnade, the design of which was discoverable 150 years ago by Maillet, has since been destroyed by the barbarism of the Turks.

But what most engages the attention of travellers is the pillar of Pompey, as it is commonly called, situated at a quarter of a league from the southern gate. It is composed of red granite. The capital, which is Corinthian, with palm leaves, and not indented, is nine feet high. The shaft and the upper member of the base are of one piece of nearly 90 feet long and 9 in diameter. The base is a square of about 15 feet on each side. This block of marble, 60 feet in circumference, rests on two layers of stone bound together with lead; which, however, has not prevented the Arabs from forcing out several of them, to search for an imaginary treasure. The whole column is 98 feet 9 inches high; 29 feet 8 inches in circumference; and the diameter at the top of the capital measures 16 feet 6 inches. It is perfectly polished, and only a little shivered on the eastern side. Nothing can equal the majesty of this monument: seen from a distance, it overtops the town, and serves as a signal for vessels. On a nearer approach, it produces an astonishment mixed with awe. One can never be tired with admiring this beautiful column, the length of the shaft, or the extraordinary simplicity of the pedestal. This last has been somewhat damaged by the instruments of travellers, who are curious to possess a relic of this antiquity. The column was considered inaccessible, till it was scaled about half a century ago by the wild frolic of a party of English sailors, who conceived the project of emptying a bowel of punch on the top of this celebrated monument. Dexterously availing themselves of the movements of a paper kite, they succeeded in fastening a rope to the summit, by which they ascended, and performed this great achievement. They discovered a foot and ankle, the only remnant of a gigantic statue which had originally adorned it. It was ascended by Captain W. H. Smyth, R.N. in 1822, for the purpose of ascertaining, by a series of angles taken from its summit, whether, as he had imagined, it had been erected as a mark at the north end of the degree of the meridian measured by Eratosthenes. At that time it was ascended by many persons; and Mr Madden mentions an English lady who breakfasted and wrote a letter from this elevated position. At the base, on the west side of the pedestal, some English officers found a Greek inscription, from which it would appear to have been erected in the time, and to the honour, of the emperor Diocletian; although the monolithic shaft appears of far greater antiquity.

The island of the Pharos, called by the Arabs, Rondahel-Tyn, or the Garden of Fig-trees, lies in a N.E. and S.W. direction, to the N. of the city, and consists of a dry saline soil, and dazzling white calcareous rocks, bordered with reefs, especially on the S.W. side. At its north-eastern extremity is situate the castle, a large and lofty square building, which, previous to 1842 was surmounted by a lighthouse in the form of a minaret, a substitute for the ancient magnificent structure, which stood on a rock in the eastern harbour. The castle has been strongly fortified, and occupies a small island joined to the larger one by a dike, constructed in part of ancient granite columns laid crosswise. A new lighthouse was erected in 1842, on the most westerly point of the island. It has a fixed light, 180 feet above the level of the sea, which in clear weather is visible at a distance of nearly 20 miles. The high coasts of the island shelter the old harbour from the violent winds that blow between N.W. and N.E. At its south-western extremity, called Ras-el-Tyn, or Fig-tree point, there is a naval hospital, capable of holding 300 beds, with spacious, lofty, and well-aired apartments. The foundations of the ancient Pharos are to be seen in a calm day below water.

On the south-west side of the city, at a mile's distance, are situate the catacombs, the ancient burial-place of Alexandria; a remarkable object, although they cannot be compared to those of the ancient Thebes. The Baron de Tott, in describing these, observes "that Nature not having furnished this part of Egypt with a ridge of rocks, like that which runs parallel with the Nile above Delta, the ancient inhabitants of Alexandria could only have an imitation by

Alexandria.

digging into a bed of solid rock; and thus they formed a *Necropolis*, or City of the Dead. The excavation is from 30 to 40 feet wide, 200 long, and 25 deep, and is terminated by gentle declivities at each end. The two sides, cut perpendicularly, contain several openings, about 10 or 12 feet in width and height, hollowed horizontally; and which form, by their different branches, subterranean streets. One of these, which curiosity has disencumbered from the ruins and sands that render the entrance of others difficult or impossible, contains no mummies, but only the places they occupied. The order in which they were ranged is still to be seen. Niches, 20 inches square, sunk six feet horizontally, narrowed at the bottom, and separated from each other by partitions in the rock seven or eight inches thick, divided into checkers the two walls of this subterranean vault. It is natural to suppose, from this disposition, that each mummy was introduced with the feet foremost into the cell intended for its reception; and that new streets were opened, in proportion as these dead inhabitants of Necropolis increased." This observation, he adds, which throws a light on the catacombs of Memphis, may perhaps likewise explain the vast size and multitude, as well as the different elevations, of the pyramids in Upper and Lower Egypt.

About seventy paces from Pompey's pillar is the canal of the Nile, which was dug by the ancient Egyptians, to convey the water of the Nile to Alexandria, and fill the cisterns under the city. This canal had ceased altogether to be navigable, till Mahommed Ali spent immense labour and cost in restoring it. The work was begun in 1819, and completed within a year, at a melancholy sacrifice of human life. Unfortunately, the Italian engineers whom he employed were entirely destitute of the skill necessary to conduct so great and arduous an undertaking. They took no measures to protect the canal against the fresh influx of mud from the Nile, so that it was soon choked up, and still requires frequent cleaning out. It now forms the regular line of communication between Alexandria and the Nile for the overland passage to India. The distance between Alexandria and Atfeh, where passengers embark on the Nile, is 48 English miles.

Alexandria, in modern times, until its complete fortification by Mahommed Ali, has never ranked as a place of strength. Accordingly, when attacked by Bonaparte in 1798, it surrendered almost without a blow. The French were very industrious in forming the place, if not into a regular fortress, yet into a very strong entrenched position. They appear to have succeeded. In 1801 Sir Ralph Abercromby undertook his memorable expedition. On the 13th and 21st March he gained, in the plain before Alexandria, two successive victories, of which the last was most complete and signal, though purchased by the life of the distinguished commander. Yet it was still not considered possible to carry Alexandria, unless by regular siege; the conclusion of which, on the 2d September, was accompanied by a general convention for the evacuation of Egypt by the French armies.

In 1807 a British force under the command of General Frazer landed and took possession of Alexandria without resistance; but being repulsed in two successive attempts upon Rosetta, they finally evacuated it on the 23d September of the same year.

It has recently begun to recover some degree of prosperity, from its being an important station on the overland route to India, by which the distance is shortened more than a half, and rendered comparatively safe and expeditious. Steamers from England, Marseilles, Trieste, and Constantinople sail regularly to and from Alexandria; and the goods, mails, and passengers which they convey, pass by the Mahmoodëeh canal and the Nile, through Cairo and the desert, to and from Suez, which communicates with India by the Red Sea steamers. The consequence has been a rapid increase of population, and enlargement of the town. In the Turkish quarter, however, the streets are still narrow and irregular, and the greater part of the houses very humble and poor. In the Frank or European quarter, the houses are clean and whitewashed, generally elegant and well-built, in wide, airy streets, and it contains a large new square, where are found the principal hotels and most of the consulates. The houses are built of brick or of stone, dug from the ruins of the ancient city. In the environs there are a number of handsome villas, with well-inclosed gardens. Its exports are chiefly corn, cotton, flax, wool, rice, opium, senna, and other African products; and its imports are cotton, woollen, and silk goods, hardware, iron, machinery, coals, &c. In the year 1847, 2019 vessels of the united burden of 409,516 tons entered its port; of which 465 vessels, of 136,499 tons, were British; and in 1849, 1651 vessels, of which 336 were British. In 1843 the value of its imports was L.1,005,412, and of its exports, L.1,321,268. It has a new palace, a custom-house, and two theatres; a naval arsenal, a marine hospital, a dry dock, a military and a naval school, several mosques, synagogues, and Christian churches; and since 1840 a Protestant church. Its population amounts to about 60,000 exclusive of the military, and is of a very mixed character, consisting of Turks, Copts, Armenians, Greeks, Syrians, Jews, and Europeans.

Alexandria is about forty leagues north-west of Cairo. A railway is at present (1853) in the course of construction between these two places. Long. 30. 10. E. Lat. 31. 12. N.

Alexandria, a city of Virginia, in N. America, capital of the county of the same name, and lately in the district of Columbia. It is beautifully situated on the right bank of the river Potomac, six miles south of Washington. It is neat and well-built, has a good harbour, and a considerable trade in flour. The Chesapeake and Ohio Canal begins here, which must tend to increase the prosperity of the town. In 1850 the population amounted to 8795; and that of the county to 10,216.

Alexandria, a city of Russia, capital of the circle of that name in the province of Cherson. It is situated on the river Inguletz, and contains 270 houses and 1200 inhabitants. Great quantities of maize are grown in the neighbourhood; and the sheep are of the broad-tailed kind, like those of the Cape of Good Hope. Long. 33. 3. E. Lat. 48. 22. N.

Alexandria, in *Ancient Geography*, a city of Arachosia, called also *Alexandropolis*, on the river Arachotus (Stephanus, Isidorus Characenus).—Another *Alexandria* in Gedrosia, built by Leonnatus by order of Alexander (Pliny).—A third *Alexandria* in Aria, situated at the lake Arias (Ptolemy); but, according to Pliny, built by Alexander on the river Arius.—A fourth in Bactriana (Pliny).—A fifth *Alexandria*, an inland town of Caramania (Pliny, Ptolemy, Ammian).—A sixth *Alexandria*, or *Alexandropolis*, in Sogdiana (Isidorus Characenus).—A seventh in India, at the confluence of the Acesines and Indus (Arrian).—An eighth, called also *Alexandretta*, near the Sinus Issicus, on the confines of Syria and Cilicia, now *Scanderoon*, the port town to Aleppo.—A ninth *Alexandria* of Margiana, which being demolished by the barbarians, was rebuilt by Antiochus the son of Seleucus, and called *Antiochia* of Syria (Pliny); watered by the river Margus, which is divided into several channels, for the purpose of watering the country which was called *Zotale*. The city was seventy stadia in circuit, according to Pliny; who adds, that after the defeat of Crassus, the captives were conveyed to this place by Orodes, the king of the Parthians.—A tenth, of the Oxiana, built on the Oxus by Alexander, on the confines of Bactria (Pliny).—An eleventh, built by Alexander at the foot of Mount Paropamisus, which was called *Caucasus* (Pliny, Arrian).—A twelfth *Alexandria* in Troas, called also *Troas* and *Antigonia* (Pliny).—A thirteenth on the Jaxartes, the boundary of Alexander's victories towards Scythia, and the last that he built on that side.

ALEXANDRIAN MS., *Codex Alexandrinus*, the appellation given to a manuscript of the Sacred Scriptures of the Old and New Testaments now in the British Museum. This venerable Greek MS. was presented to our Charles I., through the hands of his ambassador to the Porte, Sir Thomas Rowe, by Cyrillus Lucaris, patriarch of Constantinople, in 1628. The donor had then recently brought it from Alexandria, whence its name. It remained in the royal library of our sovereigns, until transferred to the Museum in 1753. It is contained in four small folio volumes, written on vellum in double columns; the first three containing the Old Testament, the last the New Testament. The *Old*, however, is more perfect than the *New*: for the beginning of the Gospel of St Matthew is lost, the MS. commencing with the 6th verse of chapter xxv. There are several *lacunæ* in the Gospel of St John, as vi. 50, viii. 52; and a still larger one in 2d Epistle to Corinthians, from chap. iv. 13. to xii. 6. (See Woide's *Prolegomena*.) Occasionally too, single letters have disappeared, from the operations of the bookbinder. The characters are *uncial*, well rounded, and carefully written. There are no interspaces dividing words, no aspirates, nor accents, few contractions; and no instances of *Stichometry*, or division into lines to be read without pauses, an improvement introduced by *Euthalius*, about the year 462; from which last circumstance Woide and many other critics believe this MS. to be at least older than that period. An Arabic inscription on the reverse of the leaf containing a list of the books of both Testaments, states that it was written by the martyred Thekla. Whether this be true or not, the manuscript bears marks of an Egyptian origin, from Egyptian orthography, the confusion of vowels with nearly similar sounds, and Alexandrian forms of inflection of some tenses, as of the 2d Aorist. That the MS. is very ancient is undoubted, though able critics are divided whether it ought to be referred to the early part of the fourth or beginning of the sixth century; but it seems most probably written before the middle of the fifth. Besides the books of the Old Testament which we regard as *canonical*, it contains the Apocryphal books, with the exception of the story of Susannah, and of Bel and the Dragon; but it contains the 3d and 4th books of Maccabees. These books are somewhat differently arranged from that of our version, or of the Vulgate of St Jerome. The psalms are divided into 151, with 15 hymns. As an introduction to them, the MS. contains the Epistle of Athanasius to Marcellinus, contained in 1277 lines; with the hypothesis of Eusebius on the Psalms. These three volumes, with very valuable prolegomena and notes, have been printed in *fac-simile* of the MS. at the expense of the British Museum, by the Rev. H. H. Baber, lately librarian to that institution. Half of the third volume is occupied with Baber's most valuable notes. The *fac-simile* of the New Testament published by Woide, in 1786, contains very excellent prolegomena and critical remarks on the MS., the general accuracy of which are admitted, though his deductions as to the age of the transcript have been much canvassed. This publication renders a collation of the MS. of the New Testament unnecessary; and his volume is now considered as completing this important work. In the 4th volume of the MS. we have the books of the New Testament in nearly the order usually adopted; except that the Epistle of Paul to the Hebrews immediately follows 2d Thessalonians; and that the Epistle of James, the two of Peter, the three of John, and that of Jude, are included under the *Catholicæ* placed between the Acts and the Epistles of Paul. The MS. contains also the whole of the 1st and part of the 2d Epistle of Clement to the Corinthians, which follow the Apocalypse, and are succeeded by the 8 Psalms of Solomon. We may remark that the well-known verses about the *three witnesses* in the 5th chapter of the 1st Epistle of St John, are not in this MS., nor indeed in almost any of the very ancient Codices; whence its genuineness is doubted by most critics. See Burnet's *Travels, Letter I.*

To those who desire a more minute account of the Alexandrian manuscript, we must refer them to the prolegomena and notes of Baber and Woide, while we shall add the table of contents of the four volumes (as given in the first volume), with the corresponding designations in the English Bible.

Tom. I.

| | |
|---|---|
| *Γενεσις Κοσμου* | Genesis. |
| *'Εξοδος 'Αιγοπτου* | Exodus. |
| *Λευιτικὸν* | Leviticus. |
| *'Αριθμοι* | Numbers. |
| *Δευτερονόμια* | Deuteronomy. |
| *'Ιησούς Ναυῆ* | Joshua, son of Nun. |
| *Κριται* | Judges. |
| *Ρυθ* | Ruth. |
| *Βασιλεῶν ά* | Samuel I. or Kings I. |
| *Βασιλεῶν β'* | Samuel II. or Kings II. |
| *Βασιλεῶν γ'* | Kings I. or Kings III. |
| *Βασιλεῶν δ'* | Kings II. or Kings IV. |
| *Παραλειπομένα ά* | Chronicles I. |
| *Παραλειπομένα β'* | Chronicles II. |

Tom. II.

*Προφῆται ις* (16 Prophets).

| | |
|---|---|
| *'Ωσηε* | Hosea. |
| *'Αμὼς* | Amos. |
| *Μιχαίας* | Micah. |
| *'Ιωηλ* | Joel. |
| *'Αβδαιου* | Obadiah. |
| *'Ιωνας* | Jonah. |
| *Ναουμ* | Nahum. |
| *'Αμβακουμ* | Habakkuk. |
| *Σοφονὶας* | Zephaniah. |
| *'Αγγαιος* | Haggai. |
| *Ζαχαραιας* | Zachariah. |
| *Μαλαχιας* | Malachi. |
| *'Ησαιας* | Isaiah. |
| *'Ιερεμιας* | Jeremiah. |
| *Θρηνηματα* | Lamentations. |
| *'Ιεζεκιηλ* | Ezekiel. |
| *Δανιελ* | Daniel. |
| *'Εσθηρ* | Esther. |
| *Τωβιτ* | Tobit. |
| *'Ιυδειθ* | Judith. |
| *'Εσζρας ά* | Esdras I. |
| *Εσζρας β'* | Esdras II., including *Νεεμια*, and part of the canonical Book of Ezra. |
| *Μακκαβιων ά* | Maccabees I. |
| *Μακκαβιων β'* | Maccabees II. |
| *Μακκαβιων γ'* | Maccabees III. |
| *Μακκαβιων δ'* | Maccabees IV. |

Tom. III.

| | |
|---|---|
| *'Αθανασιου 'Επιστολη* | Epistle of Athanasius to Marcellinus on the Psalms. |
| *'Ευσεβιου 'Υποθεσις* | Hypothesis of Eusebius on the Psalms. |
| *Ψαλτεριον μετ' 'Αδων* | Psalms 151, Hymns 15. |

Alexandrian School.

| | |
|---|---|
| Ἰωβ | Job. |
| Παροιμιαι | Proverbs. |
| Ἐκκλησιαστης | Ecclesiastes. |
| Ἀσματα Ἀσματων | Canticles. |
| Σοφια ἡ Παναρητος | Wisdom prayed for, or Wisdom of Solomon. |
| Σοφια Ἰησου υἱου Ζιραχ | Ecclesiasticus, or Wisdom of Jesus, son of Sirach. |

*Notæ* H. H. Baber fill 264 pages, or about half this volume.

Tom. IV.

| | |
|---|---|
| Ἐυαγγελιων κατα Ματθαιον | Matthew. |
| Ἐυαγγελιων κατα Μαρκον | Mark. |
| Ἐυαγγελιων κατα Λουκαν | Luke. |
| Ἐυαγγελιων κατα Ἰωαννην | John. |
| Πραξις Ἀποστολων | Acts of the Apostles. |
| Ἐπιστολαι Καθολικαι ζ' | Seven Catholic Epistles, comprehending those of James, 2 of Peter, 3 of John, and 1 of Jude. |
| Ἐπιστολαι Παυλου ιδ' | Fourteen Epistles of Paul. |
| Ἀποκαλυψις Ἰωαννου | Revelation of John. |
| Κλημεντος Ἐπιστολη α' | 1st Epistle of Clement to the Corinthians. |
| Κλημεντος Ἐπιστολη β' | 2d Epistle of Clement to the Corinthians. |
| Ψαλμοι Σολομοντος η' | Eight Psalms of Solomon. |

(T. S. T.)

Alexandrian School. At the time when Greece, by a series of disasters, was deprived of her ancient independence, the glorious era of her poetry was already past; and that intellectual pre-eminence which she had enjoyed for so long a period, was now to find a powerful rival in the city of Alexandria, which, under the Græco-Egyptian dynasty of the Lagidæ, was destined to attain a high celebrity as the seat of letters. At the end of the fourth century before Christ, Ptolemy Soter drew around him at Alexandria many philosophers and men of letters from different parts of Greece; and the work thus commenced by the son of Lagus, was continued after him by Ptolemy Philadelphus, and Ptolemy Euergetes, in succession. Ptolemy Soter, animated with a laudable ambition, founded the *Museum*, a vast establishment in connection with the royal residence, and thither the learned of all countries were welcomed. That every facility might be afforded them for cultivating the several branches of science and literature, this prince collected from all parts of the world the most celebrated literary productions, and thus laid the foundation of that famous library, which excited the admiration of the ancients, and of which the destruction has given rise to so many contradictory reports. The office of librarian was first held by Demetrius Phalereus. The library and museum, with its theatre for lectures and public assemblies, were connected with the palace by long colonnades of marble, and magnificently adorned by obelisks, sphinxes, and other trophies from the Pharaonic cities. The museum was provided with private apartments for the accommodation of the members, and contained a great saloon in which they took their repasts in common. To this establishment was attached a botanic garden enriched with tropical flora; and also a menagerie of the rarest animals. The museum was governed by a president who was nominated by the Ptolemies, and afterwards by the Cæsars. An exterior peristyle or corridor was devoted to exercise and ambulatory lectures. Ptolemy Philadelphus instituted, in honour of Apollo, those literary contests called *Ludi Musarum et Apollinis*, at which public prizes were adjudged to the successful competitors. This prince also made very considerable additions to the library, of which an account has already been given. See Alexandria.

Alexandria and its school appear to have soon recovered from the disasters of civil war; for in the second century of our era the learned assembled there in great numbers; and a new school of philosophy arose, which, from the third down to the close of the fifth century, attempted to supply the human intellect with a standing ground between the scepticism that followed the decline of Grecian philosophy on the one hand, and the rapidly spreading, and finally victorious, influence of Christianity on the other. The term "Alexandrian School" is applied in a loose sense to the whole body of eminent men who, in all the departments of knowledge, conferred lustre on the capital of the Ptolemies; but as a characteristic designation, it is more strictly confined to that particular section of its philosophers known as the Neo-Platonists. This philosophy, as the name implies, was a new development of Platonism, in a form and combination suited to the exigency of the time, and is specially remarkable as an advance from the more purely rational point of view of the Greeks towards the sphere of religious ideas—as a transition stage between the grossness of pagan superstition, and the spiritual reign of Christianity. Setting out from the higher doctrines of Plato, which formed at once its starting point and its unifying centre, it sought by a broad electicism to harmonize, 1*st*, All philosophy; 2*d*, All religion. Its first step was the reconciliation, in a higher unity, of Platonism and Aristotelianism; it next set itself to harmonise all the old religious beliefs, by bringing in the mysticism of the East to interpret their higher meaning; and thus it presented the new and peculiar phenomenon of Grecian dialectics applied to oriental theosophy, of philosophy and religion for the first time in alliance. To Christianity its relation was one of direct hostility; while at the same time, it approached it on the side of its higher mysteries, and represented itself as possessed of all that was true in the new religion. Neo-Platonism and Christianity (so far at least as the Alexandrian theology is concerned) exercised on each other a mutually modifying influence.

The first beginning of this remarkable electicism dates with the Jew Philo in the first century; but it does not appear as a distinct and influential movement till the opening of the school of Ammonius Saccas (A.D. 193), followed by the more decided and comprehensive development of Neo-Platonism by his disciple Plotinus (A.D. 200-270). In the next generation it was represented by Porphyry and Iamblichus; somewhat later by Hierocles; and it finally attained its culmination with Proclus (A.D. 412-485), in whose person the philosophy of Alexandria, and of the Old World, became extinct. Neo-Platonism thus presents three periods or stages of development: its metaphysics are chiefly represented by Plotinus; its logic and theosophy by Porphyry and Iamblichus; and the systematic combination of its parts gave employment to the genius of Proclus.

For a more particular account of their doctrines, see Ammonius, Plotinus, &c.

But Alexandria was not distinguished alone by its philosophical school. At the same period also arose those new systems of cosmography which prepared the way for the geography of the moderns, and gave a fresh impulse to research and discovery. Under the infamous Caracalla the museum was suppressed, and from A.D. 257 to 267, pestilence, conflagrations, and civil wars, gave a blow to this seat of learning, from which it recovered with difficulty. The library, however, still subsisted, and continued to augment, until fanaticism completed its ruin. In 391 a bloody struggle took place between the Pagans and the Christians, the priests on either side fomenting the division; and during this contest the magnificent Serapeion was terribly devastated.

Whether any part of the library was preserved cannot now be ascertained, but in the sixth century Alexandria became famous for its medical school, and doubtless a new library must have been formed. The story of its destruction by the command of Omar has been already mentioned.

The system of instruction pursued at Alexandria must not be confounded with the modern, nor yet with the ancient academical course, for the promulgation of a systematic doctrine, or a positive science. There was not at any given period a regular school for the teaching of fixed general principles. The views of the Greeks differed from those of the Christian philosophers as well as from those of the Jews. Nor were mental philosophy and letters the sole objects of study with the Alexandrians; they also engaged in the natural and exact sciences, in philology, medicine, and anatomy. The latter science, indeed, may be said to have been created by them, notwithstanding that the dissection of the human body was repugnant to the religious prejudices of the Greeks. In short, at this school every branch of knowledge was represented, and some of its learned men may truly be styled encyclopædists, whose studies embraced the whole circle of the sciences, and who drew their information from the literature of all countries. If the productions of Greece chiefly occupied the shelves of the library, it is certain that native works, and the written documents of other countries, existed in great numbers at Alexandria. These works were sometimes translated into the Greek tongue; as, for example, the version of the Hebrew Scriptures known as the Septuagint. Alexandria, in its earlier period, was almost exclusively a school of grammar and criticism, to which sciences the learned devoted themselves with unwearied assiduity. Hence the Alexandrians soon became the arbiters of the Greek language; and by devoting their labours to the writings of the ancients, they became the restorers of learning, producing correct editions of their works, often accompanied with learned commentaries of great value, though occasionally they are chargeable with prolixity and excessive refinement. The name of Aristarchus of Samothrace is proverbial in literary criticism; and in the same category must be placed Zenodotus of Ephesus, Eratosthenes of Cyrene the celebrated geometer and astronomer, Aristophanes of Byzantium, Crates of Mallos, Dionysius of Thrace, Apollonius the sophist, Didymus, and Zoilus. In the same department must also be noticed the learned dictionaries and laborious lucubrations of Harpocration, of Julius Pollux, Hephæstion, Hesychius, and Ammonius. The studies of these men comprehended not only grammar, but likewise criticism, the science of the scholiast, the drama, metrical verse, and archæology. Though occasionally heavy, their erudition was real and profound; and to this class of men we are indebted for elaborate editions of Thucydides, Plato, Aristotle, and other ancient classics. Admirably fitted as they were for the task, they omitted nothing that could serve to elucidate the ancient text. The natural result, however, of this incessant application to the study of the ancients, was to limit the original productions of the Alexandrians. With the exceptions of the curious chronicles of Manetho, and the Chronographia of Eratosthenes (of which works the fragments which remain have acquired deep interest by the hieroglyphical discoveries of Young and Champollion), the Alexandrians have bequeathed to us no valuable work on Egyptian history; their researches being chiefly directed to the traditional histories of the several Greek states, and the obscure question of their origin. In poetry they devoted themselves rather to the niceties of style and artifices of combination than to the nobler part of that art. With those works of unapproachable excellence ever before their eyes, they laboured to become original inventors, and in default of genius, they fell into exaggeration and affectation. It would be erroneous, however, to include in this censure all the poets of the Alexandrian school, or to ascribe an equal degree of merit to the names of Apollonius Rhodius, Lycophron, Aratus, Nicander, Euphorion, Callimachus, Theocritus, Philetas, Phanocles, Scymnus, and Dionysius. Besides these poets, Alexandria possessed a *Pleiad* of seven tragedians, famous in their day; but there appears to be little reason to regret the loss of their works.

The natural sciences were cultivated at Alexandria with great success. Herophilus and Erasistratus were distinguished anatomists: Demosthenes Philalethes wrote the first work on diseases of the eye: Zopyrus and Cratevas were the improvers of pharmacy, especially of that branch known as rhizotomy: and here also Asclepiades, Soranus, and the celebrated Galen, received instruction in the healing art. But yet greater was its fame as a mathematical school. Among its scholars were Euclid, the father of scientific geometry; Apollonius of Perga, whose work on the conic sections still exists; Nicomachus, the first scientific arithmetician; and it is well known that at Alexandria were made those improvements in the theory of the calendar which were afterwards adopted into the Julian calendar. Here also Claudius Ptolemy (whose system of geography and astronomy was followed until the time of Copernicus) composed his *Magna Syntaxis*, Aratus his *Phænomena*, Menelaus his *Sphærica*; and to these must be added the names of Eratosthenes, Hipparchus, and Aristyllus. The studies of some of these philosophers embraced every variety of human learning. Their knowledge was frequently profound on subjects of the most opposite nature,—as, for example, we find Eratosthenes celebrated not only as a geometer and astronomer, but also as a geographer, philosopher, historian, and grammarian; and the *Deipnosophistæ* of Athenæus is an inexhaustible mine of learning on subjects the most widely diversified, in philology, poetry, history, and archæology. Among the interpreters of Sacred Writ were the (Hellenizing) Jews, Aristobulus and Philo, while the Christian school of Theology flourished under the successive care of Pantænus, Clement, and Origen. At a later period, the Christian school of Alexandria was adorned by the talents of Athanasius, Gregory of Nazianzen, Julius Africanus, Hesychius, Cyril, Synesius, and a host of others.—*Essai Historique sur l'Ecole d'Alexandrie, par M. Jacob Matter*, Paris, 1820, 2 vols. 8vo.

ALEXANDRIAN, or *Alexandrine*, in *Poetry*, a kind of verse consisting of 12, or of 12 and 13 syllables alternately; so called from a poem on the life of Alexander, written in this kind of verse by a French poet of the 12th century. Alexandrines are sometimes used by most nations of Europe, but chiefly by the French, whose tragedies are generally composed of Alexandrines. A well known example of an Alexandrian verse is given in Pope's *Essay on Criticism*:—

> A needless Alexandrine ends the song,
> That like a wounded snake drags its slow length along.

ALEXICACUS, the *averter of evil*, an epithet of Jupiter, Apollo, and Neptune.

ALEXIN, a circle of the province of Tula, in Russia in Europe, to the south of Moscow and east of Kaluga. It is a level district, watered by the river Oka and its tributary streams, of moderate fertility, and abundantly supplied with wood. It comprehends one city and 74 parishes, containing 241 villages and about 90,000 inhabitants. The capital of the circle, of the same name, is built on the river Oka, has four churches, with 2000 inhabitants, some of whom manufacture hats and soap. It is in Long. 36. 30. E. and Lat. 54. 42. N.

ALEXIS, an ancient comic poet, born about B.C. 390 at Thurii in Magna Græcia, the uncle and instructor of

Menander. He lived 106 years, and wrote 245 plays, the fragments extant bearing testimony to their wit and elegance. They were frequently translated by the Latin comic writers. —See Meineke, *Fragm. Com.* vol. 1.

ALEXIS, a Piedmontese (whose real name, according to Haller, was Hieronimo Rosello), the reputed author of the *Book of Secrets*. It was printed at Basil in 1536, in 8vo, and translated from Italian into Latin by Wecher. It has also been translated into most European languages; and in an abridged form was long a popular book. There is a preface to the piece, wherein Alexis informs us that he was born of a noble family; that he had from his most early years applied himself to study; that he had learned many languages; that having an extreme curiosity to be acquainted with the secrets of nature, he had collected as much as he could during his travels for 57 years; that he piqued himself upon not communicating his secrets to any person; but that when he was 82 years of age, having seen a poor man who had died of a sickness which might have been cured had he communicated his secret to the surgeon who took care of him, he was touched with such a remorse of conscience, that he lived almost like a hermit; and it was in this solitude that he arranged his secrets in such order as to make them fit to be published.

ALEXIS, or *Alexei Michailowitz*, Czar of Russia, the second sovereign of the house of Romanoff, father of Peter I., was one of the most eminent princes of that country. He was born at Moscow in 1630, and died in 1674. See RUSSIA.

ALEXIUS I., the nephew of Isaac Comnenus, the first Byzantine emperor of the family of which Alexius was the most distinguished member. In early life he signalised himself in arms against the enemies of his country; but the mean jealousies of the ministers of the emperor Nicolas III., surnamed Botaniates, drove him to take up arms against a sovereign whose throne he had thrice gallantly defended against powerful insurgent leaders; and he ascended the throne of Constantinople in 1081. His character has been too partially drawn by the pen of his favourite daughter Anna Comnena, who has, however, justly remarked that the disorders of the times were both the misfortune and glory of Alexius, and that he paid the penalty of the judgments of heaven on the vices of his predecessors. In his reign the conquering Turks extended their desolating career from Persia to the Hellespont; on the north the empire was pressed upon by the hordes of barbarians from the Danube; on the west it was assailed by the daring valour of the Normans; while Europe precipitated itself on Asia through the route of Constantinople, in the madness of the first crusade. Amid these storms Alexius steered the reeling vessel of the state with a dexterous and courageous hand, though his policy was by the Latins ascribed to cowardice or treachery. His was undoubtedly a very difficult game, which it required no common ability to bring to a safe conclusion; and he had the policy to derive solid advantages from the wild valour of the crusaders. Yet Alexius outlived the love of his subjects, and their patience was well-nigh exhausted in the latter part of his long reign. The noble families were irritated by the profusion of his numerous relations; the people by his severity and exactions; while the clergy murmured at his unscrupulous application of the wealth of the church to the defence of the state, though they applauded his defence of religion by his eloquence, his pen, and his sword. Alexius died on the 15th of August 1118. (T. S. T.)

ALEYN, CHARLES, an English poet in the reign of Charles I. He published two poems, entitled *The Battailes of Cressy and Poictiers*, and several other pieces and translations. He succeeded his father as clerk of the ordnance, and was commissary-general of the artillery to the king at the battle of Edgehill. He died in 1640.

ALFAQUES, a seaport in the province of Catalonia, in Spain. It is on a peninsula formed by the river Ebro, near its mouth. The government has expended vast sums on its improvement, but without correspondent success, chiefly owing to the insalubrity of the situation.

ALFAQUES, among the Moors, the name generally used for their clergy, or those who teach the Mahometan religion; in opposition to the Morabites, who answer to monks among Christians.

ALFARABIUS, a celebrated eastern philosopher of the tenth century, was born at Farab, now called Othrar, a city of Asia Minor. The date of his birth is unknown. He studied for some time at Baghdad, then the chief seat of learning; and afterwards travelled, in order to form an acquaintance with the learned of other countries.

A great revolution of sentiment in regard to letters had taken place, in the preceding century, among the followers of Mahomet. Under the caliphs of the house of Abbas, men of learning were raised to a degree of favour and consequence which has never been enjoyed by that class, under the sovereigns of any other country, in any age of the world. Every little court, too, had its circle of men of letters, who were always admitted to the society of the prince, and for the most part liberally supported by his bounty. Thus, when Alfarabius, after he had finished his travels, settled at Damascus, he was received with open arms by its sovereign, who bestowed upon him a pension, which he continued to enjoy till his death, in the year 950.

But to gain the notice of princes, or to acquire wealth, formed none of the aims of this philosopher. He is said to have led a very retired and ascetic life, rather contemning than seeking after the good things of the world. "He constantly slept, even during winter, upon straw; his countenance was always sorrowful, and he found no consolation in anything but philosophy." (Enfield's *History of Philosophy*, b. v. c. 1.) His works were numerous, and very various in their subjects: his speculations seem, indeed, from the list of his writings, to have embraced the whole circle of the sciences. He is particularly deserving of notice, as having been perhaps the first compiler of an *Encyclopædia*. Such is the title of one of his works, of which there is a copy in manuscript in the library of the Escurial. It contains, according to the brief notice of it given in Casiri's valuable account of the Arabic manuscripts in that collection, a clear and comprehensive definition and compendium of all the arts and sciences; and it appears to have been regarded in the East as the most valuable of Alfarabius's compositions. It would have been agreeable to the lovers of literary history to have possessed some more detailed view of the extent, plan, and contents of an Encyclopædia written by an Arabian so many centuries before any work of that description was thought of in Europe.

Next to this in estimation appears to have been his treatise on *Music*, in which he is said to have applied the principles of physics to correct the errors of musical theorists, and to regulate the construction of musical instruments. (*Biog. Universelle*, tom. i.) Casiri gives a complete list of his writings, but it is too long to be copied in this place. (See *Bibl. Arabico-Hispana Escurialensis*, tom. i.) Some of his pieces were published in Latin at Paris in 1633, under the title of *Opuscula Varia* Alfarabii.

ALFARO, a town of Spain, at the confluence of the Alhama, with the Ebro, in the province of Logroño. It is surrounded with walls, and has four gates, one church, and four monasteries. It manufactures cloth, saltpetre, brandy, &c. Pop. 6450.

ALFERGAN, or ALFRAGAN, an Arabian astronomer, who lived under the reign of the caliph Almamoun, and who, on account of his skill in calculation, was surnamed *the Cal-*

*culator.* He wrote an *Introduction to Astronomy*, which contains little that is original, being chiefly compiled from the *Almagest* of Ptolemy. He was also the author of a treatise on *Dials*, and of an account of the construction and use of the *Astrolabe.* These two pieces still remain in manuscript; but there have been three different Latin translations of his astronomical work published. The first, by Joannes Hispalensis, appeared at Ferrara in 1493, and was afterwards reprinted at Nuremberg in 1537, with a preface by Melanchthon. The second, by John Christman, was published at Frankfort in 1590. The third, and the best, by Golius, professor of mathematics and oriental languages at Leyden, was published at Amsterdam in 1669, with the Arabic text, and notes by the translator, which are extremely curious: but these notes extend no farther than the ninth chapter, as the author did not live to complete this part of his undertaking. The work itself contains thirty short chapters.

ALFET, an ancient ordeal, in which the accused person plunged his arm up to the elbow into a caldron of boiling water.

ALFIERI, Vittorio, chiefly celebrated as the author who raised the Italian tragic drama from its previous state of degradation, was born on the 17th January 1749, at the town of Asti, in Piedmont. He lost his father in early infancy; but he continued to reside with his mother, who married a second time, till his tenth year, when he was placed at the academy of Turin. After he had passed a twelvemonth at the academy, he went on a short visit to a relation who dwelt at Coni; and during his stay there he made his first poetical attempt, in a sonnet chiefly borrowed from lines in Ariosto and Metastasio, the only poets he had at that time read. When thirteen years of age, he was induced to commence the study of civil and canonical law; but the attempt only served to disgust him with every species of application, and to increase his relish for the perusal of French romances.

By the death of his uncle, who had hitherto taken some charge of his education and conduct, he was left, at the age of fourteen, to enjoy without control his vast paternal inheritance, augmented by the recent accession of his uncle's fortune. He now began to attend the riding-school, where he acquired that rage for horses and equestrian exercise which continued to be one of his strongest passions till the close of his existence.

After some time spent in alternate fits of extravagant dissipation and ill-directed study, he was seized with a desire of travelling; and having obtained permission from the king, he departed, in 1766, under the care of an English preceptor. Restless and unquiet, he posted with the utmost rapidity through the towns of Italy; and his improvement was such as was to be expected from his mode of travelling and his previous habits. Dissatisfied with himself, he felt as little relish for spectacles or entertainments as for literature; and was as little amused by the gaiety of a carnival at Naples, as he was impressed by the remains of antiquity at Rome, or the exhibitions of modern art at Florence and Bologna. This indifference and insensibility did not, however, arise from defect of talent or the natural powers of taste, but from the want of some serious passion, or some ennobling or praiseworthy pursuit. Hoping to find in foreign countries some relief from the tedium and *ennui* with which he was oppressed, and being anxious to become acquainted with the French theatre, he proceeded to Paris; but his feelings were only those of disgust or indifference for the dramas which he saw represented in that capital. He seems, indeed, to have been completely dissatisfied with every thing he witnessed in France, and contracted a dislike to its people, which his intercourse in future years rather contributed to augment than diminish. In Holland he became deeply enamoured of a married lady, who returned his attachment, but who was soon obliged to accompany her husband to Switzerland. Alfieri whose feelings were of the most impetuous description, was in despair at this separation, and returned to his own country in the utmost anguish and despondency of mind. While under this depression of spirits, he was induced to seek alleviation from works of literature; and the perusal of Plutarch's Lives, which he read with profound emotion, inspired him with an enthusiastic passion for freedom and independence. Under the influence of this rage for liberty he recommenced his travels; and his only gratification, in the absence of freedom among the Continental states, appears to have been derived from contemplating the wild and sterile regions of the north of Sweden, where gloomy forests, lakes, and precipices, conspired to excite those sublime and melancholy ideas which were congenial to his disposition. Human manners and human institutions he seems invariably to have surveyed with an eye of passion or prejudice, instead of viewing them with the calmness of a philosopher, who meditates how they may be rectified, or what lessons may be drawn from them. In every country his soul felt as if confined by the bonds of society: he everywhere panted for something more free in governments, more elevated in sentiment, more devoted in love, and more perfect in friendship. In search of this ideal world he posted through various countries, more with the rapidity of a courier than of one who travels for amusement or instruction. During a journey to London, he engaged in an intrigue with a married lady of high rank; and having been detected, the publicity of a rencounter with the injured husband, and of a divorce, which followed, united to the knowledge he now acquired of the abandoned character of the woman to whom he was ardently attached, rendered it expedient and desirable for him to quit England. He then visited Spain and Portugal, where he became acquainted with the Abbé Caluso, who remained through life the most attached and estimable friend he ever possessed. In 1772 Alfieri returned to Turin, where he again became enamoured of a lady, whom he loved with his usual ardour, and who seems to have been as undeserving of a sincere attachment as those he had hitherto adored. In the course of a long attendance on his mistress, during a malady with which she was afflicted, he one day wrote a dialogue, or scene of a drama, which he left at this lady's house. About a year after, on a difference taking place between them, this piece was returned to him. Having then retouched and extended it to five acts, it was performed at Turin in 1775, under the title of *Cleopatra*, whose amours had always been a favourite subject with Italian dramatists.

From this moment Alfieri was seized with an immeasurable thirst of theatrical fame, and the remainder of his life was devoted to its attainment. His first two tragedies, *Filippo* and *Polinice*, were originally written in French prose; and when he came to versify them in Italian, he found that, from his Lombard origin, and long intercourse with foreigners, he expressed himself with feebleness and inaccuracy. Accordingly, with the view of improving his Italian style, he went to Tuscany, and, during an alternate residence at Florence and Sienna, he completed his *Filippo* and *Polinice*, and conceived the plan of various other dramas. While thus employed, he became acquainted with the countess of Albany, who then resided with her husband at Florence. For her he formed an attachment which, if less violent than his former loves, appears to have been more permanent. With this motive to remain at Florence, he could not endure the chains by which his vast possessions bound him to Piedmont. He therefore resigned his whole property to his sister, the Countess Cumiana, reserving an annuity which scarcely amounted to a half of his original revenues. At this period the Countess of Albany, urged by the ill treatment she received from her husband, sought refuge in Rome, where she at length received permission from the pope to live apart from her tormentor. Alfieri followed the countess to that capital, where he completed fourteen tragedies, four of which were now for the first time printed at Sienna.

At length, however, it was thought proper that, by leaving Rome, he should remove the aspersions which had been thrown on the object of his affections. During the year 1783 he therefore travelled through different states of Italy, and published six additional tragedies. The interests of his love and literary glory had not diminished his rage for horses, which seems to have been at least the third passion of his soul. He came to England solely for the purpose of purchasing a number of these animals, which he carried with him to Italy. On his return he learned that the Countess of Albany had gone to Colmar in Alsace, where he joined her, and resided with her under the same roof during the rest of his life. They chiefly passed their time between Alsace and Paris, but at length took up their abode entirely in that metropolis. While here, Alfieri made arrangements with Didot for an edition of his tragedies; but was soon after forced to quit Paris by the storms of the Revolution. He recrossed the Alps with the countess, and finally settled at Florence. The last ten years of his life, which he spent in that city, seem to have been the happiest of his existence. During that long period his tranquillity was only interrupted by the entrance of the revolutionary armies into Florence in 1799. Though an enemy of kings, the aristocratic feelings of Alfieri rendered him also a decided foe to the principles and leaders of the French Revolution; and he rejected, with the utmost contempt, those advances which were made with a view to bring him over to their cause. The concluding years of his life were laudably employed in the study of the Greek literature, and in perfecting a series of comedies. His assiduous labour on this subject, which he pursued with his characteristic impetuosity, exhausted his strength, and brought on a malady, for which he would not adopt the prescriptions of his physicians, but obstinately persisted in employing remedies of his own. Under this regimen his disorder rapidly increased, and at length terminated his life on the 8th October 1803, in the fifty-fifth year of his age.

The character of Alfieri may be best appreciated from the portrait which he has drawn of himself in his own *Memoirs of his Life.* He was evidently of an irritable, impetuous, and almost ungovernable temper. Pride, which seems to have been a ruling sentiment, may account for many apparent inconsistencies of his character. While it made him abhor kings, because superior to himself, it led him to detest those republicans who, by too near an approach, contaminated aristocratic dignity; and it induced him, while yet undistinguished himself, and panting for literary fame, to decline a proffered introduction to Metastasio and Rousseau. But as all his bad qualities were greatly softened by the cultivation of literature, it may be presumed that a better education, and an earlier employment of his faculties, would have rendered him a much more amiable character. His application to study gradually tranquillized his temper and softened his manners, leaving him at the same time in perfect possession of those good qualities which he had inherited from nature,—a warm and disinterested attachment to his family and friends, united to a generosity, vigour, and elevation of character, which rendered him not unworthy to embody in his dramas the actions and sentiments of Grecian heroes.

To these dramas Alfieri is chiefly indebted for the high reputation to which he has attained. Before his time the Italian language, so harmonious in the *Sonnets* of Petrarch, and so energetic in the *Commedia* of Dante, had been invariably languid and prosaic in dramatic dialogue. The pedantic and inanimate tragedies of the sixteenth century were followed, during the iron age of Italian literature, by dramas, of which extravagance in the sentiments and improbability in the action were the chief characteristics. The prodigious success of the *Merope* of Maffei, which appeared in the commencement of the last century, may be attributed more to a comparison with such productions, than to intrinsic merit. In this degradation of tragic taste, the appearance of the tragedies of Alfieri was perhaps the most important literary event that had occurred in Italy during the eighteenth century. On these tragedies it is difficult to pronounce a judgment, as the taste and system of the author underwent considerable change and modification during the intervals which elapsed between the three periods of their publication. An excessive harshness of style, an asperity of sentiment, and total want of poetical ornament, are the characteristics of his first four tragedies, *Filippo, Polinice, Antigone*, and *Virginia.* These faults were in some measure corrected in the six tragedies which he gave to the world some years after, and in those which he published along with *Saul*, the drama which enjoyed the greatest success of all his productions; a popularity which may be partly attributed to the severe and unadorned manner of Alfieri being well adapted to the patriarchal simplicity of the age in which the scene of the tragedy is placed. But though there be a considerable difference in his dramas, there are certain observations applicable to them all. None of the plots are of his own invention. They are founded either on mythological fable or history; most of them had been previously treated by the Greek dramatists, or by Seneca. *Rosmunda*, the only one which could be supposed of his own contrivance, and which is certainly the least happy effusion of his genius, is partly founded on the eighteenth novel of the third part of Bandello, and partly on Prevost's *Mémoires d'un Homme de Qualité.* But whatever subjects he chooses, his dramas are always formed on the Grecian model, and breathe a freedom and independence worthy of an Athenian poet. Indeed, his *Agide* and *Bruto* may rather be considered oratorical declamations and dialogues on liberty, than tragedies. The unities of time and place are not so scrupulously observed in his as in the ancient dramas; but he has rigidly adhered to a unity of action and interest. He occupies his scene with one great action and one ruling passion, and removes from it every accessary event or feeling. In this excessive zeal for the observance of unity, he seems to have forgotton that its charm consists in producing a common relation between multiplied feelings, and not in the bare exhibition of one, divested of those various accompaniments which give harmony to the whole. Consistently with that austere and simple manner which he considered the chief excellence of dramatic composition, he excluded from his scene all *coups de théâtre*, all philosophical reflections, and that highly ornamented versification which had been so assiduously cultivated by his predecessors. In his anxiety, however, to avoid all superfluous ornament, he has stripped his dramas of the embellishments of imagination; and for the harmony and flow of poetical language he has substituted, even in his best performances, a style which, though correct and pure, is generally harsh, elaborate, and abrupt; often strained into unnatural energy, or condensed into factitious conciseness. The chief excellence of Alfieri consists in powerful delineation of dramatic character. In his *Filippo* he has represented, almost with the masterly touches of Tacitus, the sombre character, the dark mysterious counsels, the *suspensa semper et obscura verba*, of the modern Tiberius. In *Polinice*, the characters of the rival brothers are beautifully contrasted; in *Maria Stuarda*, that unfortunate queen is represented unsuspicious, impatient of contradiction, and violent in her attachments. In *Mirra*, the character of *Ciniro* is perfect as a father and king, and *Ceeri* is a model of the virtues of a wife and mother. In the representation of that species of mental alienation where the judgment has perished, but traces of character still remain, he is peculiarly happy. The insanity of Saul is skilfully managed; and the horrid joy of Orestes in killing Ægisthus rises finely and naturally to madness, in finding that, at the same time, he had inadvertently slain his mother.

Whatever may be the merits or defects of Alfieri, he may be considered as the founder of a new school in the Italian drama. His country hailed him as her sole tragic poet; and his successors in the same path of literature have regarded his bold, austere, and rapid manner, as the genuine model of tragic composition.

Besides his tragedies, Alfieri published during his life many sonnets, five odes on American independence, and the poem of *Etruria*, founded on the assassination of Alexander I. duke of Florence. Of his prose works the most distinguished for animation and eloquence is the *Panegyrie on Trajan*, composed in a transport of indignation at the supposed feebleness of Pliny's eulogium. The two books entitled *La Tirannide* and the *Essays on Literature and Government*, are remarkable for elegance and vigour of style, but are too evidently imitations of the manner of Machiavel. His *Antigallican*, which was written at the same time with his *Defence of Louis XVI.*, comprehends an historical and satirical view of the French Revolution. The posthumous works of Alfieri consist of satires, six political comedies, and the *Memoirs of his Life*—a work which will always be read with interest, in spite of the cold and languid gravity with which he delineates the most interesting adventures and the strongest passions of his agitated life.—See *Mem. di. Vit. Alfieri;* Sismondi *de la Lit. du Midi de l'Europe;* Walker's *Memoir on Italian Tragedy; Giorn. de Pisa.* tom. lviii. (J. C. D.)

ALFORD, a town in Lincolnshire, 24 miles N.N.E. of Boston. It has a free grammar school, founded in 1576, with fellowships in Magdalen College, Cambridge: and some breweries, tanneries, and rope-works. In the vicinity is the medicinal spring called Holy Well, discovered in 1670. Pop. in 1851, 2262.

Alford, *Michael*, an English Jesuit, whose real name was Griffiths, was born at London in 1587. This work entitled *Annales Ecclesiastiei et Civiles Britannorum, Saxonum et Anglorum*, is valuable to the student of early English history.

ALFRED, or Ælfred, the Great, king of England, was the fifth and youngest son of Æthelwolf, king of the West Saxons, and was born at Wantage, in Berkshire, in 849 He distinguished himself during the reign of his brother Ethelred in several engagements against the Danes, and upon his death succeeded to the crown, in the year 871, and the 22d of his age. On his accession to the throne he found himself involved in a dangerous war with the Danes, and placed in circumstances fitted to call forth all the great qualities by which he was distinguished. The Danes had already penetrated into the heart of his kingdom; and before he had been a month upon the throne, he was obliged to take the field against those formidable enemies. After many battles gained on both sides, he was at length reduced to the greatest distress, and was entirely abandoned by his subjects. In this situation Alfred, laying aside the useless insignia of royalty, took shelter in the house of one of his own herdsmen. He afterwards retired to Æthelingey, in Somersetshire, the modern Athelney, where he built a fort for the security of himself and family, and his few faithful followers. When he had been about a year in this retreat, having been informed that some of his subjects had routed a great army of the Danes, killed their chief, and taken their magical standard, he issued his letters, giving notice where he was, and inviting his nobility to come and consult with him. Before they came to a final determination, Alfred, putting on the habit of a harper, went into the enemy's camp, where, without suspicion, he was everywhere admitted, and introduced to play before their chief. Having thus acquired an exact knowledge of their situation, he returned in great secrecy to his nobility, whom he ordered to their respective homes, there to draw together each man as great a force as he could; appointing a day for a general rendezvous at the forest of *Selwood* in Wiltshire. This affair was transacted so secretly and expeditiously, that the king, at the head of his army, was close upon the Danes before they had the least intelligence of his design. Alfred, taking advantage of their surprise and terror, fell upon them, and totally defeated them at Æthendune, now Eddington. Those who escaped fled to a neighbouring castle, where they were soon besieged, and obliged to surrender at discretion. Alfred granted them better terms than they had reason to expect. He agreed to give up the whole kingdom of the East Angles to such as would embrace the Christian religion, on condition that they would oblige the rest of their countrymen to quit the island, and, as much as was in their power, prevent the landing of any more foreigners. For the performance of this treaty he took hostages; and when, in pursuance of the stipulation, Godrun the Danish chief came, with thirty of his chief officers, to be baptized, Alfred answered for him at the font, and gave him the name of *Æthelstane;* and certain laws were drawn up betwixt the king and Godrun for the regulation and government of the Danes settled in England. In 884 a fresh swarm of Danes landed in Kent and laid siege to Rochester; but the king coming to the relief of that city, they were obliged to abandon their design. Alfred had now great success, which was chiefly owing to his fleet, an advantage of his own creating. Having secured the sea-coasts, he fortified the rest of the kingdom with castles and walled towns; and he besieged and recovered from the Danes the city of London, which he resolved to repair, and to keep as a frontier.

After some years' respite, Alfred was again called into the field; for a body of Danes, being worsted in the west of France, came with a fleet of 250 sail on the coast of Kent, and having landed, fixed themselves at Appuldre. Shortly after, another fleet of eighty vessels coming up the Thames, the men landed, and built a fort at Milton. Before Alfred marched against the enemy, he obliged the Danes settled in Northumberland and Essex to give him hostages for their good behaviour. He then moved towards the invaders, and pitched his camp between their armies, to prevent their junction. A great body, however, moved off to Essex, and crossing the river, came to Farnham in Surrey, where they were defeated by the king's forces. Meanwhile the Danes settled in Northumberland, in breach of treaty, and notwithstanding the hostages given, equipped two fleets, and after plundering the northern and southern coasts, sailed to Exeter and besieged it. The king, as soon as he received the intelligence, marched against them; but before he reached Exeter they had got possession of it. He kept them, however, blocked up on all sides, and reduced them at last to such extremities that they were obliged to eat their horses, and were even ready to devour each other. Being at length rendered desperate, they made a general sally on the besiegers; but were defeated, though with great loss on the king's side. The remainder of this body of Danes fled into Essex, to the fort they had built there, and to their ships. Before Alfred had time to recruit himself, Laf, another Danish leader, came with a great army out of Northumberland, and ravaged all before him, marching on to the city of Werheal in the west (supposed to be Chester), where they remained the rest of the year. The year following they invaded North Wales; and after having plundered and destroyed every thing, they divided, one body returning to Northumberland, another into the territories of the East Angles, from whence they proceeded to Essex, and took possession of a small island called *Meresig*. Here they did not long remain; for having separated, some sailed up the river Thames, and others up the Lea road, where, drawing up their ships, they built a fort not far from London, which proved a great check upon the citizens, who went in a body and attacked it, but were repulsed with great loss. At harvest-time the king himself was obliged to encamp with a body of troops in the neighbourhood of the city, in order to cover the reapers from the excursions of the Danes. As he was one day riding by the side of the river Lea, after some observations he began to think that the Danish ships might be laid quite dry. This he attempted; and having succeeded, the Danes were forced to desert their fort and ships, and march away to the banks of the Severn, where they built a fort, and wintered at a place called *Quatbrig*.[1] Such of the Danish ships as could be got off, the Londoners carried into their own road; the rest they burned and destroyed.

Alfred enjoyed a profound peace during the last three years of his reign, which he chiefly employed in establishing and regulating his government, for the security of himself and his successors, as well as the ease and benefit of his subjects in general. After a troubled reign of 28 years, he died on the 28th of October A.D. 900, and was buried at Winchester, in Hyde Abbey. A monument of porphyry was erected over his tomb.

All our historians agree in characterising him as perhaps the wisest, best, and greatest king that ever reigned in England; and it is also generally allowed, that he not only digested several particular laws still in existence, but that he laid the first foundation of our present constitution. There is great reason to believe that we are indebted to this prince for trial by jury; and the Doomsday Book, which is preserved in the Exchequer, is thought to be no more than another edition of Alfred's book of Winchester, which contained a survey of the kingdom. It is said also that he was the first who divided the kingdom into shires. What is ascribed to him is not a bare division of the country, but the settling of a new form of judicature; for after having divided his dominions into shires, he subdivided each shire into three parts, called *trythings*. There are some remains of these ancient divisions in the ridings of Yorkshire, the laths of Kent, and the three parts of Lincolnshire. Each trything was divided into *hundreds* or *wapentakes;* and these again into *tythings* or dwellings of ten householders. Each of these householders stood engaged to the king as a pledge for the good behaviour of his family, and all the ten were mutually pledges for each other; so that if any one of the tythings was suspected of an offence, if the head boroughs or chiefs of the tythings would not be security for him, he was imprisoned; and, if he made his escape, the tything and hundred were fined to the king. Each shire was under the government of an *earl*, under whom was the *rieve*, his deputy, since, from his office, called *shire-rieve*, or sheriff. And so effectual were these regulations, that it is said he caused bracelets of gold to be hung up in the highways, as a challenge to robbers; and that they remained untouched.

In private life Alfred was singularly amiable; of so equal a temper, that he never suffered either sadness or unbecoming gaiety to disturb his mind; but appeared always of a calm yet cheerful disposition, familiar to his friends, just even to his enemies, kind and tender to all. He was a remarkable economist of his time; and Asser has given us an account of the method he took for dividing and keeping an account of it. He caused six wax-candles to be made, each of 12 inches long, and of as many ounces weight; on the candles the inches were regularly marked, and having found that one of them burned just four hours, he committed them to the care of the keepers of his chapel, who from time to time gave him notice how the hours went.

This prince, we are told, was 12 years of age before a master could be procured in the western kingdom to teach him the alphabet; such was the state of learning when Alfred began to reign. He had felt the misery of ignorance, and determined even to rival his contemporary Charlemagne in the encouragement of literature. He is supposed to have appointed persons to read lectures at Oxford, and is thence considered as the founder of that university. By other suitable measures and by his general encouragement of learning and abilities, he did everything in his power to diffuse knowledge throughout his dominions. Nor was this end promoted more by his countenance and encouragement than by his own example and his writings; for notwithstanding the lateness of his education he had acquired extraordinary erudition; and, had he not been illustrious as a king, he would have been famous as an author. His works are, 1. *Breviarium quoddam collectum ex Legibus Trojanorum*, &c. lib. i.; a Breviary collected out of the Laws of the Trojans, Greeks, Britons, Saxons, and Danes. Leland saw this book in the Saxon tongue, at Christ Church, in Hampshire. 2. *Visi-Saxonum Leges*, lib. i. Pitts tells us that it is in Bennet College library, at Cambridge. 3. *Institutu quædam*, lib. i. This is mentioned by Pitts, and seems to be the second capitulation with Godrun. 4. *Contra Judices Iniquos*, lib. i. 5. *Acta Magistratuum suorum*, lib. i. This is supposed to be the Book of Judgments mentioned by Horne, and was in all probability a kind of Reports intended for the use of succeeding ages. 6. *Regum Fortunæ variæ*, lib. i. 7. *Dicta Sapientum*, lib. i. 8. *Parabolæ et Sales*, lib. i. 9. *Collectiones Chronicorum*. 10. *Epistolæ ad Wulfsigium Episcopum*, lib. i. 11. *Manuale Meditationum*. Besides those original works, he translated many authors from the Latin, &c., into the Saxon language, viz., 1. Bede's History of England. 2. Paulus Orosius's History of the Pagans. 3. St Gregory's Pastoral, &c. The first of these, with his prefaces to the others, together with his laws, were printed at Cambridge, 1644. His laws are likewise inserted in Spelman's Councils. 4. Boethius's Consolations of Philosophy. Dr Plot tells us King Alfred translated it at Woodstock, as he found in a MS. in the Cotton Library. 5. Æsop's Fables; which he is said to have translated from the Greek both into Latin and Saxon. 6. The Psalms of David. This was the last work the king attempted, and was unfinished at the time of his death. It was, however, completed by another hand, and published at London in 1640, in quarto, by Sir John Spelman. Several others are mentioned by Malmsbury, and the old history of Ely asserts that he translated the Old and New Testaments.

ALFRETON, a small town in Derbyshire, 13 miles from Derby. The inhabitants are chiefly engaged in the manufacture of earthenware and stockings. In the vicinity are ironworks and collieries.

ALGÆ. See Cryptogamia.

ALGAIOLA, a small seaport town in the island of Corsica, fortified with walls and bastions. It was almost destroyed

[1] The king's contrivance is thought to have produced the meadow between Hertford and Bow; for at Hertford was the Danish fort, and from thence they made frequent excursions on the inhabitants of London. Authors are not agreed as to the method the king pursued in laying dry the Danish ships. Dugdale supposes that he did it by straightening the channels; but Henry of Huntingdon alleges that he cut several canals, which exhausted its water.

by the malcontents in 1731, but has since been repaired. Long. 8. 52. E. Lat. 42. 37. N.

ALGARDI, Alessandro, a painter and excellent sculptor of Bologna, was born, according to some accounts, in 1602; and died in 1654. His best sculptures are in St Peter's at Rome, and in his native city.

ALGAROTH, in *Chemistry*, is a white oxide of antimony, which is obtained by washing the butter or chloride with pure water.

ALGAROTTI, Francesco, *Count*, was born at Venice in 1712. Led by curiosity, as well as a desire of improvement, he travelled early into foreign countries; and in 1733 visited Paris. Here he composed his Newtonian Philosophy for the Ladies, as Fontenelle had done his Cartesian Astronomy, in the work entitled The Plurality of Worlds. He was much honoured by Frederick the Great, who, when crowned at Königsberg in 1740, created Algarotti a count of Prussia. He died at Pisa the 23d of May 1764, and ordered his own mausoleum, with this inscription, *Hic jacet Algarottus, sed non omnis.* He is allowed to have been a very great connoisseur in painting, sculpture, and architecture; and he contributed much to the reformation of the Italian opera. His works, which are numerous, and upon a variety of subjects, abound with vivacity, elegance, and wit. They were printed at Leghorn in 1764, in 6 vols. 12mo.

ALGARVE, a province of Portugal, the most southern of the kingdom. It is divided from the Spanish province of Andalucia by the river Guadiana. On the north it is bounded by the province of Alentejo, and on the south and west by the Atlantic Ocean. It is one of the smallest divisions of Portugal, and very thinly peopled; its extent being 232 square leagues, and the number of inhabitants 130,329. On the northern part, towards Alentejo, the Sierras de Caldeyraron and Monchique rise to a great height. The roads are very bad, the soil unfruitful, and the inhabitants few in those districts. Numerous flocks of goats are bred, and some other cattle are pastured. The country on the coast is more fruitful, and produces abundant harvests of grapes, figs, oranges, lemons, olives, and almonds, considerable quantities of which are shipped from the seaport to the different countries in the north of Europe. Very little wheat or other corn is grown in this province, but the inhabitants draw their principal supply from the adjoining provinces of Spain. On the coasts the people derive their subsistence in a great measure from the fisheries; and both the tunny and sardines are caught in very considerable quantities. The rivers are of short course, running from north to south, and at their mouths vessels may enter at high tide; but the harbours on the whole coast are bad, though near Tavira, the principal city, some islands afford shelter, and allow of good anchorage for large vessels behind them. The whole of the foreign trade from the various ports in Algarve is carried on by the vessels of other countries, as there are scarcely any other than fishing boats owned by the inhabitants of the ports. The name Algarve is derived from an Arabic word which signifies westward. The province is designated by the name of kingdom, and gives one of the titles to the Portuguese monarch. This province contains 4 cities, 14 towns, 63 villages, 71 parishes, and 25,503 houses. It is situated between Lat. 36. 56. and 37. 30. N.

ALGAZEL. See Alghazzali.

ALGAZI, the name of several learned rabbis. *Chajim Algazi*, who lived about the beginning of the seventeenth century, wrote a book entitled *Neshiboth Mishpat*, or *The Paths of Judgment*, printed at Constantinople in 1669. *Samuel-ben-Isaac Algazi* was a native of Candia, and lived about the middle of the sixteenth century. His principal work was a chronology, *Toledoth Adam*, or *the Generations of Adam*, printed at Venice in 1587. *Solomon-ben-Abraham Algazi* was a native of the Levant, and died in 1683. He was for some time chief rabbi at Mentz, and wrote a large number of works on the Talmud.

# ALGEBRA.

## INTRODUCTION.

ALGEBRA is a branch of the mathematics, which has for its object whatever can be expressed by number, either exactly or by approximation.

In this respect, and also in its employing arbitrary signs to denote the things of which it treats, it agrees with arithmetic. The analogy between the two sciences induced Sir Isaac Newton to denominate it *Universal Arithmetic;* but by the application of algebra to geometry, the science has acquired a new character and new powers, which render this appellation too limited, and not sufficiently descriptive of its nature. In its present state it is nearly alike related to arithmetic and geometry. In its application to both sciences, the reasoning is carried on by general symbols: its true character consists in this, that the results of its operations do not exhibit the individual values of the quantities which are the subject of investigation, such as we obtain in arithmetical calculations or geometrical constructions. They only indicate the operations, whether arithmetical or geometrical, which ought to be performed on the given quantities, to obtain the value of the quantities sought.

It has been a question much agitated, at what period and in what country was algebra invented? Who were the earliest writers on the subject? What was the progress of its improvement? And lastly, by what means, and at what period, was the science diffused over Europe?

It was a common opinion in the 17th century, that the ancient Greek mathematicians must have possessed an analysis of the nature of modern algebra, by which they discovered the theorems and solutions of the problems which we so much admire in their writings; but that they carefully concealed their instruments of investigation, and gave only the results, with synthetic demonstrations.

This opinion is, however, now exploded. A more intimate acquaintance with the writings of the ancient geometers has shown that they had an analysis, but that it was purely geometrical, and essentially different from our algebra.

Although there be no reason to suppose that the great geometers of antiquity derived any aid in their discoveries from the algebraic analysis, yet we find, that at a considerably later period it was known to a certain extent among the Greeks.

About the middle of the 4th century of the Christian era, a period when the mathematical sciences were on the decline, and their cultivators, instead of producing original works of genius, contented themselves with commentaries on the works of their more illustrious predecessors, there was a valuable addition made to the fabric of ancient learning.

This was the treatise of Diophantus on arithmetic, which originally consisted of thirteen books, but of which only the first six, and an incomplete book on polygonal numbers, supposed to be the thirteenth, have descended to our times.

This precious fragment does not exhibit any thing like a complete treatise on algebra. It rather is an application of its doctrines to a peculiar class of arithmetical questions, which belong to what is now called the indeterminate analysis.

Diophantus may have been the inventor of the Greek algebra, but it is more likely that its principles were not unknown before his time; and that, taking the science in the state he found it as the basis of his labours, he enriched it with new applications. The elegant solutions of Diophantus show that he possessed great address in the particular branch of which he treated, and that he was able to resolve determinate equations of the second degree. Probably this was the greatest extent to which the science had been carried among the Greeks. Indeed, in no country did it pass this limit, until it had been transplanted into Italy on the revival of learning.

The celebrated Hypatia, the daughter of Theon, composed a commentary on the work of Diophantus. This, however, is now lost, as well as a similar labour of this illustrious and ill-fated lady on the Conics of Apollonius. It is commonly known that she fell a sacrifice to the fury of a fanatical mob about the beginning of the 5th century.

About the middle of the 16th century, the work of Diophantus, written in the Greek language, was discovered at Rome in the Vatican library, where probably it had been carried from Greece when the Turks possessed themselves of Constantinople. A Latin translation, without the original text, was given to the world by Xylander in 1575; and a more complete translation, by Bachet de Mezeriac (one of the oldest members of the French academy), accompanied by a commentary, appeared in 1621. Bachet was eminently skilful in the indeterminate analysis, and therefore well qualified for the work he had undertaken; but the text of Diophantus was so much injured, that he was frequently obliged to divine the meaning of the author, or supply the deficiency. At a later period, the celebrated French mathematician Fermat, in addition to the commentary of Bachet, added notes of his own on the writings of the Greek algebraist. These are extremely valuable, on account of Fermat's profound knowledge of this particular branch of analysis. This edition, the best which exists, appeared in 1670.

Although the revival of the writings of Diophantus was an important event in the history of the mathematics, yet it was not from them that algebra became first known in Europe. This important invention, as well as the numeral characters and decimal arithmetic, was received from the Arabians. That ingenious people fully appreciated the value of the sciences; for at a period when all Europe was enveloped in the darkness of ignorance, they preserved from extinction the lamp of knowledge. They carefully collected the writings of the Greek mathematicians; they translated them into their language, and illustrated them with commentaries. It was through the medium of the Arabic tongue that the elements of Euclid were first introduced into Europe; and a part of the writings of Apollonius are only known at the present day by a translation from the Arabic, the Greek original being probably irrecoverably lost. The Arabians ascribe the invention of their algebra to one of their mathematicians, Mahommed-Ben-Musa, or Moses, called also Mahommed of Buziana, who flourished about the middle of the 9th century, in the reign of the Caliph Almamon.

It is certain that this person composed a treatise on this subject, because an Italian translation was known at one time to have existed in Europe, although it be now lost. Fortunately, however, a copy of the Arabic original is preserved in the Bodleian Library at Oxford, bearing a date of transcription corresponding to the year 1342. The title-page identifies its author with the ancient Arabian. A marginal note concurs in this testimony, and farther declares the work to be the first treatise composed on algebra among the faithful; and the preface, besides indicating the author, intimates that he was encouraged by Almamon, commander of the faithful, to compile a compendious treatise of calculation by algebra.

The circumstance of this treatise professing to be only a compilation, and, moreover, the first Arabian work of the kind, has led to an opinion that it was collected from books in some other language. As the author was intimately acquainted with the astronomy and computations of the Hindoos, he may have derived his knowledge of algebra from the same quarter. Hence we may conclude, with some probability, that the Arabian algebra was originally derived from India.

The algebraic analysis having been once introduced among the Arabians, it was cultivated by their own writers. One of these, Mahommed Abulwafa, who flourished in the last forty years of the 10th century, composed commentaries on the writers who had preceded him. He also translated the writings of Diophantus. Probably this was the first translation that was made of the Greek algebraist into the Arabian tongue.

It is remarkable, that although the mathematical sciences were received with avidity, and sedulously cultivated during a long period, by the Arabians, yet in their hands they received hardly any improvement. It might have been expected that an acquaintance with the writings of Diophantus would have produced some change in their algebra. This, however, did not happen: their algebra continued nearly in the same state, from their earliest writer on the subject, to one of their latest, Behaudin, who lived between the years 953 and 1031.

Writers on the history of algebra were long under a mistake as to the time and manner of its introduction into Europe. It has now, however, been ascertained that the science was brought into Italy by Leonardo, a merchant of Pisa. This ingenious man resided in his youth in Barbary, and there learned the Indian method of accounting by the nine numeral characters. Commercial affairs led him to travel into Egypt, Syria, Greece, and Sicily, where we may suppose he made himself acquainted with every thing known respecting numbers. The Indian mode of computation appeared to him to be by far the best. He accordingly studied it carefully; and, with this knowledge, and some additions of his own, and also taking some things from Euclid's Geometry, he composed a treatise on arithmetic. At that period algebra was regarded only as a part of arithmetic. It was indeed the sublime doctrine of that science; and under this view the two branches were handled in Leonardo's treatise, which was originally written in 1202, and again brought forward under a revised form in 1228. When it is considered that this work was composed two centuries before the invention of printing, and that the subject was not such as generally to interest mankind, we need not wonder that it was but little known; hence it has always remained in manuscript, as well as some others by the same author. Indeed it was not known to exist from an early period until the middle of the last century, when it was discovered in the Magliabecchian library at Florence.

The extent of Leonardo's knowledge was pretty much the same as that of the preceding Arabian writers. He could resolve equations of the first and second degree, and he was particularly skilful in the Diophantine analysis. He was well acquainted with geometry, and he employed its doctrines in demonstrating his algebraic rules. Like the Arabian writers, his reasoning was expressed in words at length; a mode highly unfavourable to the progress of the art. The use of symbols, and the method of combining them so as to convey to the mind at a single glance a long process of reasoning, was an invention considerably later than Leonardo's time.

Considerable attention was given to the cultivation of algebra between the time of Leonardo and the invention of printing. It was publicly taught by professors. Treatises were composed on the subject; and two works of the oriental algebraists were translated from the Arabian language into Italian. One was entitled *the Rule of Algebra*, and the other was the oldest of all the Arabian treatises, that of Mahommed-Ben-Musa of Corasan.

The earliest printed book on algebra was composed by Lucas Paciolus, or Lucas de Burgo, a minorite friar. It was first printed in 1494, and again in 1523. The title is *Summa de Arithmetica, Geometria, Proportioni, et Proportionalita*.

This is a very complete treatise on arithmetic, algebra, and geometry, for the time in which it appeared. The author followed close on the steps of Leonardo; and, indeed, it is from this work that one of his lost treatises has been restored.

Lucas de Burgo's work is interesting, inasmuch as it shows the state of algebra in Europe about the year 1500: probably the state of the science was nearly the same in Arabia and Africa, from which it had been received.

The power of algebra as an instrument of research is in a very great degree derived from its notation, by which all the quantities under consideration are kept constantly in view; but in respect of convenience and brevity of expression, the algebraic analysis in the days of Lucas de Burgo was very imperfect: the only symbols employed were a few abbreviations of the words or names which occurred in the processes of calculation, a kind of short-hand, which formed a very imperfect substitute for that compactness of expression which has been attained by the modern notation.

The application of algebra was also at this period very limited; it was confined almost entirely to the resolution of certain questions of no great interest about numbers. No idea was then entertained of that extensive application which it has received in modern times.

The knowledge which the early algebraists had of their science was also circumscribed; it extended only to the resolution of equations of the first and second degree; and they divided the last into cases, each of which was resolved by its own particular rule. The important analytical fact, that the resolution of all the cases of a problem may be comprehended in a single formula, which may be obtained from the solution of one of its cases, merely by a change of the signs, was not then known: indeed it was long before this principle was fully comprehended. Dr Halley expresses surprise, that a formula in optics which he had found, should by a mere change of the signs give the focus of both converging and diverging rays, whether reflected or refracted by convex or concave specula or lenses; and Molyneux speaks of the universality of Halley's formula as something that resembled magic.

The rules of algebra may be investigated by its own principles, without any aid from geometry; and although in some cases the two sciences may serve to illustrate the doctrines of each other, there is now not the least necessity in the more elementary parts to call in the aid of the latter to the former. It was otherwise in former times. Lucas de Burgo found it to be convenient, after the example of Leonardo, to employ geometrical constructions to prove the truth of his rules for resolving quadratic equations, the nature of which he did not completely comprehend; and he was induced by the imperfect nature of his notation to express his rules in Latin verses, which will not now be read with the satisfaction we receive from the perusal of the well-known poem, "the Loves of the Triangles."

As it was in Italy that algebra became first known in Europe, so it was there that it received its earliest improvements. The science had been nearly stationary from the days of Leonardo to the time of Paciolus, a period of three centuries; but the invention of printing soon excited a spirit of improvement in all the mathematical sciences. Hitherto an imperfect theory of quadratic equations was all the extent to which it had been carried. At last this boundary was passed, and about the year 1505 a particular case of equations of the third degree was resolved by Scipio Ferreus, a professor of mathematics in Bononia. This was an important step, because it showed that the difficulty of resolving equations of the higher orders, at least in the case of the third degree, was not insurmountable, and a new field was opened for discovery. It was then the practice among the cultivators of algebra, when they advanced a step, to conceal it carefully from their contemporaries, and to challenge them to resolve arithmetical questions, so framed as to require for their solution a knowledge of their own new-found rules. In this spirit did Ferreus make a secret of his discovery: he communicated it, however, to a favourite scholar, a Venetian named Florido. About the year 1535 this person, having taken up his residence at Venice, challenged Tartalea of Brescia, a man of great ingenuity, to a trial of skill in the resolution of problems by algebra. Florido framed his questions so as to require for their solution a knowledge of the rule which he had learned from his preceptor Ferreus; but Tartalea had, five years before this time, advanced farther than Ferreus, and was more than a match for Florido. He therefore accepted the challenge, and a day was appointed when each was to propose to the other thirty questions. Before the time came, Tartalea had resumed the study of cubic equations, and had discovered the solution of two cases in addition to two which he knew before. Florido's questions were such as could be resolved by the single rule of Ferreus; while, on the contrary, those of Tartalea could only be resolved by one or other of three rules, which he himself had found, but which could not be resolved by the remaining rule, which was also that known to Florido. The issue of the contest is easily anticipated; Tartalea resolved all his adversary's questions in two hours, without receiving one answer from him in return.

The celebrated Cardan was a contemporary of Tartalea. This remarkable person was a professor of mathematics at Milan, and a physician. He had studied algebra with great assiduity, and had nearly finished the printing of a book on arithmetic, algebra, and geometry; but being desirous of enriching his work with the discoveries of Tartalea, which at that period must have been the object of considerable attention among literary men in Italy, he endeavoured to draw from him a disclosure of his rules. Tartalea resisted for a time Cardan's entreaties. At last, overcome by his importunity, and his offer to swear on the holy Evangelists, and by the honour of a gentleman, never to publish them, and on his promising on the faith of a Christian to commit them to cypher, so that even after his death they would be unintelligible to any one, he ventured with much hesitation to reveal to him his practical rules, which were expressed by some very bad Italian verses, themselves in no small degree enigmatical. He reserved, however, the demonstrations. Cardan was not long in discovering the reason of the rules, and he even greatly improved them, so as to make them in a manner his own. From the imperfect essays of Tartalea, he deduced an ingenious and systematic method of resolving all cubic equations whatsoever; but with a remarkable disregard for the principles of honour, and the oath he had taken, he published, in 1545, Tartalea's discoveries, combined with his own, as a supplement to a treatise on arithmetic and algebra, which he had published six years before. This work is remarkable for being the second printed book on algebra known to have existed.

In the following year Tartalea also published a work on algebra, which he dedicated to Henry VIII. king of England.

It is to be regretted that in many instances the authors of important discoveries have been overlooked, while the honours due to them have been transferred to others having only secondary pretensions. The formulæ for the resolution of cubic equations are now called Cardan's rules, notwithstanding the prior claim of Tartalea. It must be confessed, however, that he evinced considerable selfishness in concealing his discovery; and although Cardan cannot be absolved from the charge of bad faith, yet it must be recollected that by his improvements in what Tartalea communicated to him, he made the discovery in some measure his own; and he had moreover the high merit of being the first to publish this important improvement in algebra to the world.

The next step in the progress of algebra was the discovery of a method of resolving equations of the fourth order. An Italian algebraist had proposed a question which could not be resolved by the newly invented rules, because it produced a biquadratic equation. Some supposed that it could not be at all resolved; but Cardan was of a different opinion: he had a pupil named Lewis Ferrari, a young man of great genius, and an ardent student in the algebraic analysis: to him Cardan committed the solution of this difficult question, and he was not disappointed. Ferrari not only resolved the question, but he also found a general method of resolving equations of the fourth degree, by making them depend on the solution of equations of the third degree.

This was another great improvement; and although the precise nature of an equation was not then fully understood, nor was it indeed until half a century later, yet, in the general resolution of equations, a point of progress was then reached which the utmost efforts of modern analyses have never been able to pass.

There was another Italian mathematician of that period who contributed somewhat to the improvement of algebra. This was Bombelli. He published a valuable work on the subject in 1572, in which he brought into one view what had been done by his predecessors. He explained the nature of the *irreducible case* of cubic equations, which had greatly perplexed Cardan, who could not resolve it by his rule; he showed that the rule would apply sometimes to particular examples, and that all equations of this case admitted of a real solution; and he made the important remark, that the algebraic problem to be resolved in this case corresponds to the ancient problem of the trisection of an angle.

There were two German mathematicians contemporary with Cardan and Tartalea, viz. Stifelius and Scheubelius. Their writings appeared about the middle of the 16th century, before they knew what had been done by the Italians. Their improvements were chiefly in the notation. Stifelius, in particular, introduced for the first time the characters which indicate addition and subtraction, and the symbol for the square root.

The first treatise on algebra in the English language was written by Robert Recorde, teacher of mathematics and practitioner in physic at Cambridge. At this period it was common for physicians to unite with the healing art the studies of mathematics, astrology, alchemy, and chemistry. This custom was derived from the Moors, who were equally celebrated for their skill in medicine and calculation. In Spain, where algebra was early known, the title of physician and algebraist were nearly synonymous. Accordingly, in the romance of Don Quixotte, when the bachelor Samson Carasco was grievously wounded in his rencounter with the knight, an *algebrista* was called in to heal his bruises.

Recorde published a treatise on arithmetic, which was dedicated to Edward VI.; and another on algebra, with this title, "The Whetstone of Wit," &c. Here, for the first time, the modern sign for equality was introduced.

By such gradual steps did algebra advance in improvement from its first introduction by Leonardo, each succeeding writer making some change for the better; but with the exception of Tartalea, Cardan, and Ferrari, hardly any one rose to the rank of an inventor. At length came Vieta, to whom this branch of mathematical learning, as well as others, is highly indebted. His improvements in algebra were very considerable; and some of his inventions, although not then fully developed, have yet been the germs of later discoveries. He was the first that employed general characters to represent known as well as unknown quantities. Simple as this step may appear, it has yet led to important consequences. He must also be regarded as the first that applied algebra to the improvement of geometry. The older algebraists had indeed resolved geometrical problems, but each solution was particular; whereas Vieta, by introducing general symbols, produced general formulæ, which were applicable to all problems of the same kind, without the trouble of going over the same process of analysis for each.

This happy application of algebra to geometry has produced great improvements: it led Vieta to the doctrine of angular sections, one of the most important of his discoveries, which is now expanded into the arithmetic or calculus of sines. He also improved the theory of algebraic equations, and he was the first that gave a general method of resolving them by approximation. As he lived between the years 1540 and 1603, his writings belong to the latter period of the 16th century. He printed them at his own expense, and liberally bestowed them on men of science.

The Flemish mathematician Albert Girard was one of the improvers of algebra. He extended the theory of equations somewhat farther than Vieta, but he did not completely unfold their composition; he was the first that showed the use of the negative sign in the resolution of geometrical problems, and he also first spoke of *imaginary* quantities, a subject not yet completely cleared up; and he inferred by induction that every equation has precisely as many roots as there are units in the number that expresses its degree. His algebra appeared in 1629.

The next great improver of algebra was Thomas Harriot, an Englishman. As an inventor he has been the boast of this country. The French mathematicians have accused the British of giving discoveries to him which were really due to Vieta. It is probable that some of these may be justly claimed for both, because each may have made the discovery for himself, without knowing what had been done by the other. Harriot's principal discovery, and indeed the most important ever made in algebra, was, that every equation may be regarded as formed by the product of as many simple equations as there are units in the number expressing its order. This important doctrine, now familiar to every student of algebra, was yet slowly developed: it was quite within the reach of Vieta, who unfolded it in part, but left its complete discovery to Harriot.

We have seen the very inartificial form in which algebra first appeared in Europe. The improvements of almost 400 years had not given its notation that compactness and elegance of which it is susceptible. Harriot made several changes in the notation, and added some new signs: he thus gave to algebra greater symmetry of form. Indeed, as it came from his hands, it differed but little from its state at the present time.

Oughtreed, another early English algebraist, was a contemporary with Harriot, but lived long after him. He wrote a treatise on the subject, which was long taught in the universities.

In tracing the history of algebra, we have seen, that in the form under which it was received from the Arabs, it was hardly distinguishable as a peculiar mode of reasoning, because of the want of a suitable notation; and that, poor in its resources, its applicability was limited to the resolution of a small number of uninteresting numeral questions. We have followed it through different stages of improvement, and we are now arrived at a period when it was to acquire additional power as an instrument of analysis, and to admit of new and more extended applications. Vieta saw the great advantage that might be derived from the application of algebra to geometry. The essay he made in his theory of angular sections, and the rich mine of discovery thus opened, proved the importance of his labours. He did not fully explore it, but it has seldom happened that one man began and completed a discovery. He had, however, an able and illustrious successor in Descartes, who, employing in the study of algebra that high power of intellect with which he was endowed, not only improved it as an abstract science, but, more especially by its application to geometry, he laid the foundation of the great discoveries which have since so much engaged mathematicians, and made the last two centuries ever memorable in the history of the progress of the human mind.

Descartes's grand improvement was the application of algebra to the doctrine of curve lines. As in geography we refer every place on the earth's surface to the equator, and to a determinate meridian, so he referred every point of a curve to some line given by position. For example, in a circle, every point in the circumference might be referred to the diameter. The perpendicular from any point in the curve, and the distance of that perpendicular from the centre or from the extremity of a diameter, were lines which, although varying with every change of position in the point from which the perpendicular was drawn, yet had a determinate relation to each other, which was the same for all points in the curve, which depended on its nature, and which, therefore, served as a characteristic to distinguish it from all other curves.

The relations of lines drawn in this way could be readily expressed in algebraic symbols; and the combination of these constituted what is called the *equation* of the curve. This might serve as its definition; and from the equation by the processes of algebra, all the properties of the curve could be investigated.

Descartes's geometry (or, as it might have been named, the application of algebra to geometry) appeared first in 1637. This was six years after the publication of Harriot's discoveries, which was a posthumous work. Descartes availed himself of some of Harriot's views, particularly the manner of generating an equation without acknowledgement; and on this account Dr Wallis, in his algebra, has reflected with considerable severity on the French algebraist.

This spirit has engendered a corresponding eagerness in the French mathematicians to defend him. Montucla, in his history of the mathematics, has evinced a strong national prejudice in his favour; and, as usually happens, in order to exalt him, he hardly does justice to Harriot, the idol of his adversaries.

In treating of the claims of algebra and geometry to be considered as kindred sciences, a question arises, why was this relation not sooner perceived and appreciated? The sciences of geometry and algebra have each had a distinct origin. The former is the more ancient, and no doubt for this reason, that its principles are less removed from the ordinary affairs of men. The subjects of geometry, extension, and figure are continually presented to attention; and the elements of the science are to a certain extent employed in the most ordinary arts of life. We cannot sufficiently admire the ingenuity with which the natural geometry of the early times had been wrought up into a system more than two thousand years ago; but when we consider that its assistance was wanted in the partition of land, in the erection of houses and temples, and numberless other cases, we need not wonder at the early progress of the science among such an ingenious people as the ancient Greeks.

Algebra, however, is a more refined speculation. Its first object was number; but the properties of number are more recondite than those of extension and figure.

In geometry, the objects of our attention are the very figures themselves; but in algebra, the subjects of our reasonings are represented by symbols, which have no resemblance to the things they represent; hence it is not wonderful that algebra should have a later origin, and that it should have been slower in its progress towards perfection.

Notwithstanding the different origin of geometry and algebra, and their long-continued separate existence, like some chemical substances of different natures, they have a strong affinity; and, when united, their new properties are entirely different from those which belong to each apart. By their union, a new science was created, and new instruments of invention furnished, vastly more powerful than any possessed by the sciences apart.

The new views which the labours of Vieta, Harriot, and Descartes opened in geometry and algebra were seized with avidity by the powerful minds of men eager in the pursuit of real knowledge. Accordingly, we find in the seventeenth century a whole host of writers on algebra, or algebra combined with geometry.

Our limits will not allow us to enter minutely into the claims which each has on the gratitude of posterity. Indeed, in pure algebra the new inventions were not so conspicuous as the discoveries made by its applications to geometry, and the new theories which were suggested by their union. The refined speculations of Kepler concerning the solids formed by the revolutions of curvilinear figures, the Geometry of Indivisibles by Cavalerius, the Arithmetic of Infinites of Wallis, and, above all, the Method of Fluxions of Newton, and the Differential and Integral Calculus of Leibnitz, are fruits of the happy union. All these were agitated incessantly by their inventors and contemporaries; such men as Barrow, James Gregory, Wren, Cotes, Taylor, Halley, De Moivre, Maclaurin, Stirling, and others, in this country; and abroad by Roberval, Fermat, Huygens, the two Bernoullis, Herman, Pascal, and many others.

It is at this period, then, that our sketch of the history of algebra, at least in Europe, must terminate, because of the great number of writers who have in one way or other elucidated or improved different parts of the subject, either directly, or when treating of collateral theories.

We have been as copious as our limits would permit on the early history, because it presents the interesting spectacle of the progress of a science from an almost imperceptible beginning, until it has attained a magnitude too great to be fully grasped by the human mind.

### *Of the Indian Algebra.*

The attention of the learned has, within the last thirty years, been called to a branch of the history of algebra, in no small degree interesting; we mean the cultivation of the science to a considerable extent, and at a remote period, in India.

We are indebted, we believe, to Mr Reuben Burrow for some of the earliest notices which reached Europe on this very curious subject. His eagerness to illustrate the history of the mathematical sciences led him to collect oriental manuscripts, some of which, in the Persian language, with partial translations, were bequeathed to his friend Mr Dalby of the Royal Military College, who communicated them to such as took an interest in the subject, about the year 1800.

In the year 1813 Mr Edward Strachey published in this country a translation from the Persian of the Bija Ganita (or Vija Ganita), a Hindoo treatise on algebra; and in 1816 Dr John Taylor published at Bombay a translation of Lilawati (or Lilavati), from the Sanscrit original. This last is a treatise on arithmetic and geometry, and both are the production of an oriental algebraist, Bhascara Acharya. Lastly, in 1817 there came out a work entitled *Algebra, Arithmetic, and Mensuration, from the Sanscrit of Brahmegupta and Bhascara*, translated by Henry Thomas Colebrooke, Esq. This contains four different treatises, originally written in Sanscrit verse, viz. the *Vija Ganita* and *Lilavati* of Bhascara Acharya, and the *Ganitad'haya* and *Cuttacad'hyaya* of Brahmegupta. The first two form the preliminary portion of Bhascara's Course of Astronomy, entitled *Sidd'hanta Siromani*, and the last two are the twelfth and eighteenth chapters of a similar course of astronomy, entitled *Brahma-sidd'hanta.*

The time when Bhascara wrote is fixed with great precision, by his own testimony and other circumstances, to a date that answers to about the year 1150 of the Christian era. The works of Brahmegupta are extremely rare, and the age in which he lived is less certain. Mr Davis, an oriental scholar, who first gave the public a correct view of the astronomical computations of the Hindoos, is of opinion that he lived in the 7th century; and Dr William Hunter, another diligent inquirer into Indian science, assigns the year 628 of the Christian era as about the time he flourished. From various arguments, Mr Colebrooke concludes that the age of Brahmegupta was antecedent to the earliest dawn of the culture of the sciences among the Arabians, so that the Hindoos must have possessed algebra before it was known to that nation.

Brahmegupta's treatise is not, however, the earliest work known to have been written on this subject. Ganessa, a distinguished astronomer and mathematician, and the most eminent scholiast of Bhascara, quotes a passage from a much older writer, Arya-Bhatta, specifying algebra under the designation of *Vija*, and making separate mention of *Cuttaca*, a problem subservient to the resolution of indeterminate problems of the first degree. He is understood by another of Bhascara's commentators to be at the head of the older writers. They appear to have been able to resolve quadratic equations, by the process of completing the square; and hence Mr Colebrooke presumes that the treatise of Arya-Bhatta then extant extended to quadratic equations in the determinate analysis, and to indeterminate equations of the first degree, if not to those of the second likewise, as most probably it did.

Considering the proficiency of Arya-Bhatta in astronomical science, and adverting to the fact of his having written on algebra, and being placed at the head of algebraists when the commentators of extant treatises have occasion to mention the early and original writers on this branch of science, he may be regarded as the great improver of the analytic art in India, and likely to have been the person by whom it was carried to the pitch it was found to have attained among the Hindoos, and at which it was observed to be nearly stationary through the long lapse of ages which have since passed; the later additions being few and unessential in the writings of Brahmegupta, of Bhascara, and of Jnyanaraja, though they lived at intervals of centuries from each other.

The exact period when Arya-Bhatta lived cannot be determined with certainty; but Mr Colebrooke thinks it probable that this earliest of known Hindoo algebraists wrote as far back as the fifth century of the Christian era, and perhaps earlier. He was therefore nearly as ancient as the Grecian algebraist Diophantus, who is reckoned to have flourished in the time of the emperor Julian, or about A. D. 360. Supposing then the Hindoo and Greek algebraists to be nearly of the same antiquity, it must be conceded in favour of the former, that he was farthest advanced in the science, since he knew how to resolve equations containing several unknown quantities: now it does not appear that Diophantus could do this. He also had a general method for indeterminate equations, of at least the first degree, to a knowledge of which the Grecian algebraist had certainly not attained.

It appears from the Hindoo treatises on algebra, that they understood well the arithmetic of surd roots; that they were aware of the infinite quotient resulting from the division of finite quantity by cypher; that they knew the general resolution of equations of the second degree, and had touched on those of higher denomination, resolving them in particular cases, and in those in which the solution may be effected in the manner of quadratics; that they had found a general solution of indeterminate equations of the first degree, and a method for deriving a multitude of answers to problems of the second degree, when one solution was obtained by trials: now this is as near an approach to a general solution of such problems as was made until the time of Lagrange. The Hindoos had also attempted to solve indeterminate equations of higher orders, but, as might be expected, with very little success.

We have seen how long it was before algebra was applied to geometry in Europe: but the Hindoos not only applied algebra both to astronomy and geometry, but conversely applied geometry to the demonstration of algebraic rules; and indeed they cultivated algebra much more and with greater success than geometry, as appears by the low state of their knowledge of the one and the high pitch of their attainments in the other.

Mr Colebrooke has instituted a comparison between the Indian algebraist and Diophantus, and found reason to conclude, that in the whole science the latter is very far behind the former. He says, the points in which the

Hindoo algebra appears particularly distinguished from the Greek are, besides a better and more convenient algorithm, 1*st*, the management of equations of more than one unknown quantity; 2*d*, the resolution of equations of a higher order, in which, it they achieved little, they had at least the merit of the attempt, and anticipated a modern discovery in the resolution of biquadratics; 3*d*, general methods for the resolution of indeterminate problems of the first and second degrees, in which they went far indeed beyond Diophantus, and anticipated discoveries of modern algebraists; 4*th*, the application of algebra to astronomical investigations and geometrical demonstration, in which also they hit upon some matters which have been re-invented in modern times.

When we consider that algebra made little or no progress among the Arabians, a most ingenious people, and particularly devoted to the study of the sciences, and that centuries elapsed from its first introduction into Europe until it reached any considerable degree of perfection, we may reasonably conjecture, that it may have existed in one shape or other in India long before the time of Arya-Bhatta: indeed, from its close connection with their doctrines of astronomy, it may be supposed to have descended from a very remote period, along with that science. The late learned Professor Playfair took a great interest in this curious and interesting subject; and, adopting the opinion of Bailly, the eloquent author of the *Astronomie Indienne*, he with great ingenuity attempted to prove, in a *Memoir on the Astronomy of the Brahmins*, that the observations on which the Indian astronomy is founded were of great antiquity, indeed more than 3000 years before the Christian era. Again, in a later memoir, *On the Trigonometry of the Brahmins*, he endeavoured to establish, that the origin of the mathematical sciences in Hindostan must be referred to an equally remote period. The same judicious writer has further considered this most curious subject in a Review of Strachey's Translation of Bija Gannita (*Edinburgh Review*, No. 42), and again, in a Review of Colebrooke's work on the Indian algebra, to which we have so frequently adverted (*Edinburgh Review*, No. 57). This last article, published in 1817, may be supposed to contain the matured opinions of one of the most ardent, able, and we must say most candid, inquirers into the history of Hindoo mathematical science. There is here certainly an abatement of his first confidence in the opinions of Bailly on the Indian astronomy, and a corresponding caution in his own opinion as to the antiquity of the mathematical sciences. The very remote origin of the Indian astronomy had been strongly questioned by many in this country, and also on the Continent; particularly by Laplace, also by Delambre in his *Histoire de l'Astronomie Ancienne*, tome i. p. 400, &c., and again in *Histoire de l'Astronomie du Moyen Age, Discours Préliminaire*, p. 18, &c. where he speaks slightingly of their algebra; and in this country, Professor Leslie, in his very learned work on *The Philosophy of Arithmetic*, p. 225 and 226, calls the Lilavati " a very poor performance, containing merely a few scanty precepts couched in obscure memorial verses." We shall conclude this slight sketch of the history of Indian algebra with the last recorded sentiments of Professor Playfair on the mathematical science of India. " Among many subjects of wonder which the study of these ancient fragments cannot fail to suggest, it is not one of the least that algebra has existed in India, and has been cultivated for more than 1200 years, without any signal improvement, or the addition of any material discovery. The works of the ancient teachers of science have been commented on, elucidated, and explained with skill and learning; but no new methods have been invented, nor any new principle introduced. The method of resolving indeterminate problems, that constitute the highest merit of their analytical science, were known to Brahmegupta hardly less accurately than to Bhascara; and they appear to have been understood even by Arya-Bhatta, more ancient by several centuries than either. A long series of scholiasts display in their annotations great acuteness, intelligence, and judgment; but they never pass far beyond the line drawn by their predecessors, which probably seemed even to those learned and intelligent men as the barrier within which it was to be confined. In India, indeed, every thing seems equally insurmountable, and truth and error are equally assured of permanence in the stations they have once occupied. The politics, the laws, the religion, the science, and the manners, seem all nearly the same as at the remotest period to which history extends. Is it because the power which brought about a certain degree of civilisation, and advanced science to a certain height, has either ceased to act, or has met with such a resistance as it is barely able to overcome? or is it because the discoveries which the Hindoos are in possession of are an inheritance from some more inventive and more ancient people, of whom no memorial remains but some of their attainments in science?"

*Writers on Algebra, with the years in which they wrote or flourished.*

Diophantus, Arithmeticorum Libri sex, flourished, A.C. 360

*Writers on the History of Algebra.*

Wallis in his Algebra; Montucla in Histoire des Mathématiques; Bossuet, Histoire des Mathématiques; Cossali, Origine, Trasporto in Italia, Primi Progressi in Essa dell' Algebra, 2 vols. printed in 1797; Hutton in his Dictionary, and more diffusely in his Tracts, vol. ii.

For the titles of works on Algebra, consult Murhard, *Bibliotheca Mathematica;* and for memoirs on algebra, in Academical Collections, see Reuss, *Repertorium Commentationum*, tom. vii.

NOTATION AND EXPLANATION OF THE SIGNS.

1. In arithmetic there are ten characters, which being variously combined, according to certain rules, serve to denote all magnitudes whatever. But this method of expressing quantities, although of the greatest utility in every branch of the mathematics (for we must always have recourse to it in the different applications of that science to practical purposes), is yet found to be inadequate, taken by itself, to the more difficult cases of mathematical investigation; and it is therefore necessary, in many inquiries concerning the relations of magnitude, to have recourse to that more general mode of notation, and more extensive system of operations, which constitute the science of algebra.

In algebra quantities of every kind may be denoted by any characters whatever, but those commonly used are the letters of the alphabet; and as in every mathematical problem there are certain magnitudes given, in order to determine other magnitudes which are unknown, the first letters of the alphabet $a$, $b$, $c$, &c. are used to denote known quantities, while those to be found are represented by $v$, $x$, $y$, &c. the last letters of the alphabet.

2. The sign $+$ (*plus*) denotes that the quantity before which it is placed is to be added to some other quantity. Thus, $a+b$ denotes the sum of $a$ and $b$; $3+5$ denotes the sum of 3 and 5, or 8.

The sign $-$ (*minus*) signifies that the quantity before which it is placed is to be subtracted. Thus, $a-b$ denotes the excess of $a$ above $b$; $6-2$ is the excess of 6 above 2. or 4.

3. Quantities which have the sign $+$ prefixed to them are called *positive* or *affirmative;* and such as have the sign $-$ are called *negative.*

When quantities are considered abstractedly, the terms *positive* and *negative* can only mean that such quantities are to be added or subtracted; for as it is impossible to conceive a number less than 0, it follows, that a negative quantity by itself is unintelligible. But, in considering the affections of magnitude, it appears, that in many cases a certain opposition may exist in the nature of quantities. Thus, a person's property may be considered as a positive quantity, and his debts as a negative quantity. Again, any portion of a line drawn to the right hand may be considered as positive, while a portion of the same line, continued in the opposite direction, may be taken as negative.

When no sign is prefixed to a quantity, $+$ is always understood, or the quantity is to be considered as positive.

Quantities which have the same sign, either $+$ or $-$, are said to have like signs. Thus, $+a$ and $+b$ have like signs, but $+a$ and $-c$ have unlike signs.

4. A quantity which consists of one *term*, is said to be *simple;* but if it consist of several terms, connected by the signs $+$ or $-$, it is then said to be compound. Thus, $+a$ and $-c$ are simple quantities; and $b+c$, also $a+b-d$, are compound quantities.

5. To denote the product arising from the multiplication of quantities. If they be simple, they are either joined together, as if intended to form a word, or else the quantities are connected together, with the sign $\times$ interposed between every two of them. Thus, $ab$, or $a\times b$, denotes the product of $a$ and $b$; also $abc$, or $a\times b\times c$, denotes the product of $a$, $b$, and $c$: the latter method is used when the quantities to be multiplied are numbers. If some of the quantities to be multiplied be compound, each of them has a line drawn over it called a vinculum, and the sign $\times$ is interposed, as before. Thus, $a\times\overline{c+d}\times\overline{e-f}$ denotes that $a$ is to be considered as one quantity, the sum of $c$ and $d$ as a second, and the difference between $e$ and $f$ as a third; and that these three quantities are to be multiplied into one another. Instead of placing a line over such compound quantities as enter a product, it is now common among mathematical writers to inclose each of them between two parentheses, so that the last product may be otherwise expressed thus, $a(c+d)(e-f)$; or thus, $a\times(c+d)\times(e-f)$.

6. A number prefixed to a letter is called a *numerical co-efficient*, and denotes how often that quantity is to be taken. Thus, $3a$ signifies that $a$ is to be taken three times. When no number is prefixed, the co-efficient is understood to be unity.

7. The quotient arising from the division of one quantity by another is expressed by placing the *dividend* above a line, and the *divisor* below it. Thus, $\frac{12}{3}$ denotes the quotient arising from the division of 12 by 3, or 4; $\frac{b}{a}$ denotes the quotient arising from the division of $b$ by $a$. This expression of a quotient is also called a fraction.

8. The equality of two quantities is expressed by putting the sign $=$ between them. Thus, $a+b=c-d$ denotes that the sum of $a$ and $b$ is equal to the excess of $c$ above $d$.

9. Simple quantities, or the terms of compound quantities, are said to be *like*, which consist of the same letter or letters. Thus, $+ab$ and $-5ab$ are like quantities, but $+ab$ and $+abb$ are unlike.

There are some other characters, which will be explained when we have occasion to use them; and in what follows we shall suppose that the operations of common arithmetic are sufficiently understood; for algebra, being an extension of that science, ought not to be embarrassed by the demonstration of its elementary rules.

### Sect. I.—Fundamental Operations.

The primary operations in algebra are the same as in common arithmetic; namely, addition, subtraction, multiplication, and division; and from the various combinations of these four, all the others are derived.

#### Problem I.—*To Add Quantities.*

10. In addition there may be three cases: the quantities to be added may be like, and have like signs; or they may be like, and have unlike signs; or, lastly, they may be unlike.

*Case* 1. To add quantities which are like, and have like signs.

*Rule.* Add together the co-efficients of the quantities, prefix the common sign to the sum, and annex the letter or letters common to each term.

Examples.

$$\text{Add together}\left\{\begin{array}{r}+7a\\+3a\\+a\\+2a\end{array}\right.\qquad\text{Add together}\left\{\begin{array}{r}-2ax\\-ax\\-5ax\\-12ax\end{array}\right.$$

$$\text{Sum,}\quad +13a\qquad\qquad \text{Sum,}\quad -20ax$$

*Case* 2. To add quantities which are like, but have unlike signs.

*Rule.* Add the positive co-efficients into one sum, and the negative ones into another; then subtract the least of these sums from the greatest, prefix the sign of the greatest to the remainder, and annex the common letter or letters as before.

Examples.

$$\text{Add together}\left\{\begin{array}{r}+2ax\\-ax\\-3ax\\+9ax\end{array}\right.\qquad\text{Add together}\left\{\begin{array}{r}+6ab+7\\-4ab+9\\+ab-5\\+7ab-13\end{array}\right.$$

$$\begin{array}{lr}\text{Sum of the pos.} & +11ax\\ \text{Sum of the neg.} & -4ax\\ \hline \text{Sum required,} & +7ax\end{array}\qquad\begin{array}{lr}\text{Sum of the pos.} & +14ab+16\\ \text{Sum of the neg.} & -4ab-18\\ \hline \text{Sum required,} & +10ab-2\end{array}$$

$$\begin{array}{rrr}aa+2ax-xx & \quad & -4aab\\ -2aa+3ax-4xx & & +aab\\ 6aa-5ax+11xx & & +3aab\\ \hline \text{Sum,}\quad 5aa\quad 0\quad +6xx & & \text{Sum,}\quad 0\end{array}$$

*Case* 3. To add unlike quantities.

*Rule.* Put down the quantities, one after another, in any order, with their signs and co-efficients prefixed.

Examples.

$$\begin{array}{r}2a\\3b\\-4c\\ \hline \text{Sum,}\quad 2a+3b-4c\end{array}\qquad\begin{array}{r}ax+2ay\\bb-3bz\\ \hline \text{Sum,}\quad ax+2ay+bb-3bz\end{array}$$

#### Prob. II.—*To Subtract Quantities.*

11. *General Rule.* Change the signs of the quantities to be subtracted, or suppose them changed, and then add them to the other quantities, agreeably to the rules of addition.

EXAMPLES.

$$\begin{array}{lll} \text{From} & 5a-12b & \\ \text{Subtract} & 2a-\ \ 5b & \\ \hline \text{Remainder} & 3a-\ \ 7b & \end{array} \qquad \begin{array}{ll} \text{From} & 6x-\ \ 8y+3 \\ \text{Subtract} & 2x+\ \ 9y-2 \\ \hline \text{Remainder} & 4x-17y+5 \end{array}$$

$$\begin{array}{l} 5xy-2+\ 8x-\ y \\ 3xy-8-\ 8x-3y \\ \hline 2xy+6+16x+2y \end{array} \qquad \begin{array}{l} aa-ax-yy \\ bb-by+zz \\ \hline aa-ax-yy-bb+by-zz \end{array}$$

The reason of the rule for subtraction may be explained thus. Let it be required to subtract $2p-3q$ from $m+n$. If we subtract $2p$ from $m+n$, there will remain $m+n-2p$; but if we are to subtract $2p-3q$, which is less than $2p$, it is evident that the remainder will be greater by a quantity equal to $3q$; that is, the remainder will be $m+n-2p+3q$; hence the reason of the rule is evident.

PROB. III.—*To Multiply Quantities.*

12. *General Rule for the Signs.* If the quantities to be multiplied have like signs, the sign of the product is $+$; but if they have unlike signs, the sign of the product is $-$.

The examples of multiplication may be referred to two cases; the first is when both the quantities are simple, and the second when one or both of them are compound.

*Case* 1. To multiply simple quantities.

*Rule.* Find the sign of the product by the general rule, and annex to it the product of the numeral co-efficients; then set down all the letters, one after another, as in one word.

EXAMPLES.

$$1.\left\{\begin{array}{ll} \text{Multiply} & +a \\ \text{By} & +c \\ \hline \text{Product} & +ac \end{array}\right. \qquad 2.\left\{\begin{array}{r} +\ 5b \\ -\ 4a \\ \hline -20ab \end{array}\right. \qquad 3.\left\{\begin{array}{r} -\ 3ax \\ +\ 7ab \\ \hline -21aabx \end{array}\right.$$

$$4.\left\{\begin{array}{l} -2ab \\ -3cz \\ \hline +6abcz \end{array}\right.$$

*Case* 2. To multiply compound quantities.

*Rule.* Multiply every term of the multiplicand by all the terms of the multiplier, one after another, by the preceding rule, and collect their products into one sum, which will be the product required.

EXAMPLES.

$$\begin{array}{ll} \text{Multiply} & 4a-2b+c \\ \text{By} & 3a \\ \hline \text{Product} & 12aa-6ab+3ac \end{array} \qquad \begin{array}{l} 2x+y \\ x-2y \\ \hline 2xx+xy \\ \qquad\ -4xy-2yy \\ \hline 2xx-3xy-2yy \end{array}$$

$$\begin{array}{l} aa-ab+bb \\ a+b \\ \hline aaa-aab+abb \\ \quad +aab-abb+bbb \\ \hline aaa\quad *\quad *+bbb \end{array} \qquad \begin{array}{l} a-b+c \\ a+b-c \\ \hline aa-ab+ac \\ \quad +ab\quad -bb+bc \\ \qquad -ac\quad +bc-cc \\ \hline aa\quad *\quad *-bb+2bc-cc. \end{array}$$

The reason of the rules for the multiplication of quantities may be explained in the following manner:—Let it be required to multiply $a-b$ by $c-d$; because multiplication is a repeated addition of the multiplicand as often as the multiplier contains unity; therefore, $a-b$ is to be taken as often as there are units in $c-d$, and the sum will be the product required. Now, if $a-b$ be taken as often as there are units in $c$, the result will evidently exceed the product required, and that by a quantity equal to $a-b$, taken as often as there are units in $d$. But, from the nature of addition, $a-b$ taken as often as there are units in $c$, is $ca-cb$, and for the same reason, $a-b$ taken as often as there are units in $d$, is $da-db$; therefore, to obtain the product required, we must subtract $da-db$ from $ca-cb$; but from what has been shown in subtraction, the remainder will be $ca-cb-da+db$; therefore the product arising from the multiplication of $a-b$ by $c-d$ is $ca-cb-da+db$; hence, the reason of the general rule for the signs, as well as the other rules, is manifest.

When several quantities are multiplied together so as to constitute a product, each of them is called a *factor* of that product: thus $a$, $b$, and $c$ are factors of the product $abc$; also, $a+x$ and $b-x$ are factors of the product $(a+x)(b-x)$.

The products arising from the continual multiplication of the same quantity are called *powers* of that quantity, which is called the *root*. Thus $aa$, $aaa$, $aaaa$, &c. are powers of the root $a$. These powers are commonly expressed by placing above the root, towards the right hand, a figure, denoting how often the root is repeated. This figure serves to denominate the power, and is called its *index* or *exponent*. Thus, the quantity $a$ being considered as the root, or as the first power of $a$, we have $aa$ or $a^2$ for its second power, $aaa$ or $a^3$ for its third power, $aaaa$ or $a^4$ for its fourth power, and so on.

The second and third powers of a quantity are generally called its *square* and *cube*; and the fourth, fifth, and sixth powers are sometimes respectively called its *biquadrate*, *sursolid*, and *cubocube*.

By considering the notation of powers, and the rules for multiplication, it appears that powers of the same root are multiplied by adding their exponents. Thus $a \times a^3 = a^4$, also $x^3 \times x^4 = x^7$; and in general $a^m \times a^n = a^{m+n}$.

PROB. IV.—*To Divide Quantities.*

13. *General Rule for the Signs.* If the signs of the divisor and dividend be like, the sign of the quotient is $+$; but if they be unlike, the sign of the quotient is $-$.

This rule is easily derived from the general rule for the signs in multiplication, by considering that the quotient must be such a quantity as, when multiplied by the divisor, shall produce the dividend, with its proper sign.

The quotient arising from the division of one quantity by another may be expressed by placing the dividend above a line and the divisor below it (sect. 25); but it may also be often expressed in a more simple manner by the following rules.

*Case* 1. When the divisor is simple, and a factor of every term of the dividend.

*Rule.* Divide the co-efficient of each term of the dividend by the co-efficient of the divisor, and expunge out of each term the letter or letters in the divisor: the result is the quotient.

*Ex.* 1. Divide $12abc$ by $3ac$.

From the method of notation, the quotient may be expressed thus, $\frac{12abc}{3ac}$; but the same quotient, by the rule just given, is more simply expressed thus, $4b$.

*Ex.* 2. Divide $16a^3xy-28a^2xz^2+4a^2x^3$ by $4a^2x$.

The quotient is $4ay-7z^2+x^2$.

If the divisor and dividend be powers of the same quantity, the division will evidently be performed by subtracting the exponent of the divisor from that of the dividend. Thus $a^5$, divided by $a^3$, has for a quotient $a^{5-3}=a^2$.

*Case* 2. When the divisor is simple, but not a factor of the dividend.

*Rule.* The quotient is expressed by a fraction, of which the numerator is the dividend, and the denominator the divisor.

Thus the quotient of $3ab^2$, divided by $2mbc$, is the fraction $\frac{3ab^2}{2mbc}$.

It will sometimes happen that the quotient found thus may be reduced to a more simple form, as shall be explained when we come to treat of fractions.

*Case* 3. When the divisor is compound.

*Rule* 1. The terms of this dividend are to be arranged according to the powers of some one of its letters, and those of the divisor according to the powers of the same letter.

2. The first term of the dividend is to be divided by the first term of the divisor, observing the general rule for the signs; and this quotient, being set down for a part of the quotient wanted, is to be multiplied by the whole divisor, and the product subtracted from the dividend. If nothing remain, the division is finished; but if there be a remainder, it is to be taken for a new dividend.

3. The first term of the new dividend is next to be divided by the first term of the dividend, as before, and the quotient joined to the part already found, with its proper sign. The whole divisor is also to be multiplied by this part of the quotient, and the product subtracted from the new dividend; and thus the operation is to be carried on till there be no remainder, or till it appear that there will always be a remainder.

To illustrate this rule, let it be required to divide $8a^2+2ab-15b^2$ by $2a+3b$, the operation will stand thus:

$$\begin{array}{l}
2a+3b)8a^2+2ab-15b^2(4a-5b \\
\qquad\quad 8a^2+12ab \\
\hline
\qquad\qquad -10ab-15b^2 \\
\qquad\qquad -10ab-15b^2 \\
\hline
\end{array}$$

Here the terms of the divisor and dividend are arranged according to the powers of the quantity $a$. We now divide $8a^2$, the first term of the dividend, by $2a$ the first term of the divisor; and thus get $4a$ for the first term of the quotient. We next multiply the divisor by $4a$, and subtract the product $8a^2+12ab$ from the dividend; we get $-10ab-15b^2$ for a new dividend.

By proceeding in all respects as before, we find $-5b$ for the second term of the quotient, and no remainder: the operation is therefore finished, and the whole quotient is $4a-5b$.

The following examples will also serve to illustrate the manner of applying the rule.

Ex. 1.

$$\begin{array}{l}
3a-b)3a^3-12a^2-a^2b+10ab-2b^2(a^2-4a+2b \\
\qquad\quad 3a^3 \qquad\qquad -a^2b \\
\hline
\qquad\qquad -12a^2 \quad +10ab \\
\qquad\qquad -12a^2 \quad +\ 4ab \\
\hline
\qquad\qquad\qquad\quad +6ab-2b^2 \\
\qquad\qquad\qquad\quad +6ab-2b^2 \\
\hline
\end{array}$$

Ex. 2.

$$\begin{array}{l}
a+b)a^3+b^3(a^2-ab+b^2 \\
\qquad a^3+a^2b \\
\hline
\qquad\quad -a^2b+b^3 \\
\qquad\quad -a^2b-ab^2 \\
\hline
\qquad\qquad +ab^2+b^3 \\
\qquad\qquad +ab^2+b^3 \\
\hline
\end{array}$$

Ex. 3.

$$\begin{array}{l}
a^3-b^3)a^6-b^6(a^3+b^3 \\
\qquad\quad a^6-a^3b^3 \\
\hline
\qquad\qquad +a^3b^3-b^6 \\
\qquad\qquad +a^3b^3-b^6 \\
\hline
\end{array}$$

Ex. 4.

$$\begin{array}{l}
1-x)1 \qquad (1+x+x^2+, \&c. \\
\qquad 1-x \\
\hline
\qquad\quad +x \\
\qquad\quad +x-x^2 \\
\hline
\qquad\qquad +x^2 \\
\qquad\qquad +x^2-x^3 \\
\hline
\qquad\qquad\quad +x^3.
\end{array}$$

14. Sometimes, as in this last example, the quotient will never terminate: in such a case it may either be considered as an infinite series, the law according to which the terms are formed being in general sufficiently obvious; or the quotient may be completed as in arithmetical division, by annexing to it a fraction, the numerator of which is the remainder, and denominator the divisor. Thus the quotient in last example may stand thus:

$$1+x+x^2+\frac{x^3}{1-x}.$$

The reason of the rule for division is sufficiently manifest. For, in the course of the operation, all the terms of the quotient obtained by it are multiplied by all the terms of the divisor, and the products successively subtracted from the dividend, till nothing remain; that therefore must evidently be the true quotient.

## Sect. II.—Of Fractions.

15. In the operation of division, the divisor may be sometimes less than the dividend, or may not be contained in it an exact number of times: in either case the quotient is expressed by means of a fraction. There can be no difficulty, however, in estimating the magnitude of such a quotient; if, for example, it were the fraction $\frac{5}{7}$, we may consider it as denoting either that some unit is divided into 7 equal parts, and that 5 of these are taken, or that 5 times the same unit is divided into 7 equal parts, and one of them taken.

16. In any fraction the upper number, or the dividend, is called the *numerator*, and the lower number or divisor is called the *denominator*. Thus, in the fraction $\frac{a}{b}$, $a$ is the numerator, and $b$ the denominator.

17. If the numerator be less than the denominator, such a fraction is called a *proper* fraction; but if the numerator be either equal to, or greater than the denominator, it is called an *improper* fraction; and if a quantity be

made up of an integer and a fraction, it is called a *mixed* quantity. Thus, $\frac{a}{a+x}$ is a proper fraction; $\frac{a}{a}$, also $\frac{a+x}{a}$, are both improper fractions; and $b+\frac{x}{a}$ is a mixed quantity.

18. The *reciprocal* of a fraction is another fraction, having its numerator and denominator respectively equal to the denominator and numerator of the former.

Thus, $\frac{b}{a}$ is the reciprocal of the fraction $\frac{a}{b}$.

19. The following proposition is the foundation of the operations relating to fractions.

If the numerator and denominator of a fraction be either both multiplied or both divided by the same quantity, the value of that fraction is the same as before. For, let any fraction $\frac{b}{a}=c$; then, because $c$ is the quotient arising from the division of $b$ by $a$, it follows that $b=ac$; and multiplying both by any quantity $n$, we have $nb=nac$: let these equals be both divided by the same quantity $na$, and the quotients will be equal, that is, $\frac{nb}{na}=c=\frac{b}{a}$; hence the truth of the proposition is manifest.

From this proposition, it is obvious that a fraction may be very differently expressed, without changing its value, and that any integer may be reduced to the form of a fraction, by placing the product arising from its multiplication by any assumed quantity as the numerator, and the assumed quantity as the denominator of the fraction. It also appears that a fraction very complex in its form may often be reduced to another of the same value, but more simple, by finding a quantity which will divide both the numerator and denominator, without leaving a remainder. Such a common measure, or common divisor, may be either simple or compound; if it be simple, it is readily found by inspection, but if it be compound, it may be found as in the following problem.

20. Prob. I.—*To find the greatest common Measure of two Quantities.*

*Rule* 1. Range the quantities according to the power of some one of the letters, as taught in division, leaving out the simple divisors of each quantity.

2. Divide that quantity which is of most dimensions by the other one, and if there be a remainder, divide it by its greatest simple divisor; and then divide the last compound divisor by the resulting quantity, and if any thing yet remain, divide it also by its greatest simple divisor, and the last compound divisor by the resulting quantity. Proceed in this way till nothing remain, and the last divisor shall be the common measure required.

*Note.* It will sometimes be necessary to multiply the dividends by simple quantities in order to make the divisions succeed.

*Ex.* 1. Required the greatest common measure of the quantities $a^2x—x^3$ and $a^3—2a^2x+ax^2$. The simple divisor $x$ being taken out of the former of these quantities, and $a$ out of the latter, they are reduced to $a^2—x^2$, and $a^2—2ax+x^2$; and as the quantity $a$ rises to the same dimensions in both, we may take either of them as the first divisor: let us take that which consists of several terms, and the operation will stand thus:

$$
\begin{array}{l}
a^2—x^2)a^2—2ax+x^2(1 \\
\qquad\quad a^2—x^2 \\
\hline
\qquad\quad —2ax+2x^2 \text{ remainder,}
\end{array}
$$

which divided by $—2x$ is $a—x)a^2—x^2(a+x$

$$
\begin{array}{l}
a^2—ax \\
\hline
+ax—x^2 \\
+ax—x^2 \\
\hline
\quad * \quad *
\end{array}
$$

Hence it appears that $a—x$ is the greatest common measure required.

*Ex.* 2. Required the greatest common measure of $8a^2b^2—10ab^3+2b^4$, and $9a^4b—9a^3b^2+3a^2b^3—3ab^4$.

It is evident, from inspection, that $b$ is a simple divisor of both quantities; it will therefore be a factor of the common measure required. Let the simple divisors be now left out of each quantity, and they are reduced to $4a^2—5ab+b^2$ and $3a^3—3a^2b+ab^2—b^3$; but as the second of these is to be divided by the first, it must be multiplied by 4 to make the division succeed, and the operation will stand thus:

$$
\begin{array}{l}
4a^2—5ab+b^2)12a^3—12a^2b+4ab^2—4b^3(3a \\
\qquad\qquad\qquad 12a^3—15a^2b+3ab^2 \\
\hline
\qquad\qquad\qquad\qquad +3a^2b+ab^2—4b^3.
\end{array}
$$

This remainder is to be divided by $b$, and the new dividend multiplied by 3, to make the division again succeed, and the work will stand thus:

$$
\begin{array}{l}
3a^2+ab—4b^2)12a^2—15ab+3b^2(4 \\
\qquad\qquad\qquad 12a^2+4ab—16b^2 \\
\hline
\qquad\qquad\qquad —19ab+19b^2.
\end{array}
$$

This remainder is to be divided by $—19b$, which being done, and the last divisor taken as a dividend as before, the rest of the operation will be as follows:

$$
\begin{array}{l}
a—b)3a^2+ab—4b^2(3a+4b \\
\qquad 3a^2—3ab \\
\hline
\qquad +4ab—4b^2 \\
\qquad +4ab—4b^2 \\
\hline
\qquad\quad * \quad *
\end{array}
$$

from which it appears that the compound divisor sought is $a—b$, and remarking that the quantities proposed have also a simple divisor $b$, the greatest common measure which is required will be $b(a—b)$.

21. The reason of the rule given in this problem may be deduced from the following considerations.

1. If two quantities have a compound divisor common to both, and they be either multiplied or divided by any simple quantities, the results will each have the same compound divisor. Thus the quantities $p(a—x)$ and $q(a—x)$ have the common divisor $a—x$, and the quantities $n\,p(a—x)$, $r\,q(a—x)$ have each the very same divisor.

2. In the operation of division, whatever quantity measures both the divisor and dividend, the same will also measure the remainder. For let $x$ be such a quantity, then the divisor and dividend may be represented by $ax$ and $bx$; let $q$ be the quotient, and the remainder will evidently be $bx—qax$, which is evidently divisible by $x$.

3. Whatever quantity measures both the divisor and remainder, the same will also measure the dividend; for, let the divisor be $ax$, and the remainder $rx$, then $q$, denoting the quotient, the dividend will be $aqx+rx$, which, as well as the divisor and dividend, is divisible by $x$.

Let us apply these observations to the last example. From the first observation, the reason for leaving out the simple quantities in the course of the operation, as well as for multiplying by certain other quantities, to make the divisions succeed, is obvious; and from the second observation it appears, that whatever quantity measures $4a^2-5ab+b^2$, and $12a^3-12a^2b+4ab^2-4b^3$, the same must measure $3a^2b+ab^2-4b^3$, the first remainder, as also $-19ab+19ab^2$, the second remainder; but the only compound divisor which this last quantity can have is $a-b$, which is also found to be a divisor of $3a^2+ab-4b^2$, or of $3a^2b+ab^2-4b^3$. The first remainder, therefore, by the third observation, $a-b$, must also be a divisor of $12a^2-15ab+3b^2$, or of $4a^2-5ab+b^2$, the first divisor, and therefore also it must be a divisor of $12a^3-12a^2b+4ab^2-4b^3$, the first dividend; so that $a-b$ is the greatest common measure, as was required.

22. Prob. II.—*To Reduce a Fraction to its lowest Terms.*

*Rule.* Divide both numerator and denominator by their greatest common measure, which may be found by Prob. I.

*Ex.* 1. Reduce $\frac{56a^2bc}{24adc^2}$ to its lowest terms.

It appears from inspection, that the greatest common measure is $8ac$; and dividing both numerator and denominator by this quantity, we have $\frac{56a^2bc}{24adc^2}=\frac{7ab}{3dc}$.

*Ex.* 2. Reduce $\frac{a^2x-x^3}{a^3-2a^2x+ax^2}$ to its lowest terms.

We have already found in the first example of Prob. I. that the greatest common measure of the numerator and denominator is $a-x$; and dividing both by this quantity, we have $\frac{a^2x-x^3}{a^3-2a^2x+ax^2}=\frac{ax+x^2}{a^2-ax}$.

In like manner we find

$$\frac{9a^4b-9a^3b^2+3a^2b^3-3ab^4}{8a^2b^2-10ab^3+2b^4}=\frac{9a^3+3ab^2}{8ab-2b^2};$$

the common measure being $b(a-b)$, as was shown in Example 2. Problem I.

23. Prob. III.—*To Reduce a mixed Quantity to an improper Fraction.*

*Rule.* Multiply the integer by the denominator of the fraction, and to the product add the numerator; and the denominator being placed under this sum, the result will be the improper fraction required.

*Ex.* 1. Let $x+\frac{x^2}{a}$, and $x-\frac{a^2-x^2}{x}$ be reduced to improper fractions.

First, $x+\frac{x^2}{a}=\frac{ax+x^2}{a}$, the answer.

And $x-\frac{a^2-x^2}{x}=\frac{x^2-a^2+x^2}{x}=\frac{2x^2-a^2}{x}$, Ans.

*Ex.* 2. Reduce $a-x+\frac{x^2}{a+x}$ to an improper fraction.

$$a-x+\frac{x^2}{a+x}=\frac{(a+x)(a-x)+x^2}{a+x}=\frac{a^2}{a+x}, \text{ Ans.}$$

24. Prob. IV.—*To Reduce an improper Fraction to a whole or mixed Number.*

*Rule.* Divide the numerator by the denominator for the integral part, and place the remainder, if any, over the denominator, and it will be the mixed quantity required.

*Ex.* 1. Reduce $\frac{ax+a^2}{x}$ to a whole or mixed quantity.

$\frac{ax+a^2}{x}=a+\frac{a^2}{x}$, the answer required.

*Ex.* 2. Reduce $\frac{ax+2x^2}{a+x}$, also $\frac{x^2-y^2}{x-y}$, to whole or mixed quantities.

First $\frac{ax+2x^2}{a+x}=x+\frac{x^2}{a+x}$, the answer.

And $\frac{x^2-y^2}{x-y}=x+y$ a whole quantity, which is the answer.

25. Prob. V.—*To Reduce Fractions of different Denominators to others of the same value which shall have a common Denominator.*

*Rule.* Multiply each numerator separately into all the denominators except its own for the new numerators, and all the denominators together for the common denominator.

*Ex.* 1. Reduce $\frac{a}{b}, \frac{c}{d}$, and $\frac{e}{f}$, to fractions of equal value which have a common denominator.

$$\left.\begin{array}{l} a\times d\times f=adf \\ c\times b\times f=cbf \\ e\times b\times d=ebd \end{array}\right\} \text{New numerators.}$$

$b\times d\times f=bdf$ Common denominator.

Hence we find $\frac{a}{b}=\frac{adf}{bdf}, \frac{c}{d}=\frac{cbf}{bdf}$, and $\frac{e}{f}=\frac{ebd}{bdf}$, where the new fractions have a common denominator, as was required.

*Ex.* 2. Reduce $\frac{ax}{a-x}$ and $\frac{a^2-x^2}{a+x}$ to fractions of equal value, and having a common denominator.

$$\left.\begin{array}{l} ax(a+x)=a^2x+ax^2 \\ (a^2-x^2)(a-x)=a^3-a^2x-ax^2+x^3 \end{array}\right\} \text{New numerators.}$$

$a-x)(a+x)=a^2-x^2$, the common denominator.

Hence $\frac{ax}{a-x}=\frac{a^2x+ax^2}{a^2-x^2}$ and $\frac{a^2-x^2}{a+x}=\frac{a^3-a^2x-a^2x+x^3}{a^2-x^2}$.

26. Prob. VI.—*To Add or Subtract Fractions.*

*Rule.* Reduce the fractions to a common denominator, and add or subtract their numerators, and the sum or difference placed over the common denominator, is the sum or remainder required.

*Ex.* 1. Add together $\frac{a}{b}, \frac{c}{d}$, and $\frac{e}{f}$.

$$\frac{a}{b}=\frac{adf}{bdf}$$
$$\frac{c}{d}=\frac{bcf}{bdf}$$
$$\frac{e}{f}=\frac{bde}{bdf}$$

Hence $\frac{a}{b}+\frac{c}{d}+\frac{e}{f}=\frac{adf+bcf+bde}{bdf}$, the sum required.

*Ex.* 2. From $\frac{a+x}{a}$ subtract $\frac{a}{a+x}$.

$$\frac{a+x}{a}=\frac{a^2+2ax+x^2}{a^2+ax}$$
$$\frac{a}{a+x}=\frac{a^2}{a^2+ax}$$

Hence $\frac{a+x}{a}-\frac{a}{a+x}=\frac{2ax+x^2}{a^2+ax}$.

*Ex.* 3. Add together $\frac{x+2}{3}, \frac{x}{4}$, and $\frac{x-5}{2}$.

$$\frac{x+2}{3}+\frac{x}{4}+\frac{x-5}{2}=\frac{8x+16+6x+12x-60}{24}=$$

$\frac{13x-22}{12}$. If it be required to add or subtract mixed quantities, they may either be reduced to the form of fractions by prob. 3, and then added or subtracted, or else these operations may be performed first on the integer quantities, and afterwards on the fractions.

27. Prob. VII.—*To Multiply Fractions.*

*Rule.* Multiply the numerators of the fractions for the numerator of the product, and the denominators for the denominator of the product.

*Ex.* 1. Multiply $\frac{b}{a}$ by $\frac{d}{c}$.

$\frac{b}{a} \times \frac{d}{c} = \frac{bd}{ac}$, the product required.

*Ex.* 2. Multiply $\frac{a+b}{c}$ by $\frac{a-b}{d}$.

$\frac{a+b}{c} \times \frac{a-b}{d} = \frac{a^2-b^2}{cd}$, the product.

If it be required to multiply an integer by a fraction, the integer may be considered as having unity for a denominator. Thus, $(a+x) \times \frac{3d}{c} = \frac{a+x}{1} \times \frac{3d}{c} = \frac{3ad+3dx}{c}$.

Mixed quantities may be multiplied after being reduced to the form of fractions by prob. 3. Thus, $\left(b+\frac{bx}{a}\right) \times \frac{a}{x} = \frac{ab+bx}{a} \times \frac{a}{x} = \frac{a^2b+abx}{ax} = \frac{ab+bx}{x}$.

The reason of the rule for multiplication may be explained thus. If $\frac{a}{b}$ is to be multiplied by $c$, the product will evidently be $\frac{ac}{b}$; but if it is only to be multiplied by $\frac{c}{d}$, the former product must be divided by $d$, and it becomes $\frac{ac}{bd}$, which is the product required. Or let $\frac{a}{b} = m$, and $\frac{c}{d} = n$, then $a = bm$ and $c = dn$ and $ac = bdmn$; hence, $mn$ or $\frac{a}{b} \times \frac{c}{d} = \frac{ac}{bd}$.

28. Prob. VIII.—*To Divide Fractions.*

*Rule.* Multiply the denominator of the divisor by the numerator of the dividend for the numerator of the quotient. Then multiply the numerator of the divisor by the denominator of the dividend for the denominator of the quotient.

Or, multiply the dividend by the reciprocal of the divisor, the product will be the quotient required.

*Ex.* 1. Divide $\frac{a}{b}$ by $\frac{c}{d}$.

$\frac{c}{d}\Big)\frac{a}{b}\Big(\frac{ad}{bc}$ the quotient required, or $\frac{a}{b} \times \frac{d}{c} = \frac{ad}{bc}$ as before.

*Ex.* 2. Divide $\frac{a^2+ab}{2x}$ by $\frac{3a^2}{a-b}$.

$\frac{3a^2}{a-b}\Big)\frac{a^2+ab}{2x}\Big(\frac{a^3-ab^2}{6a^2x} = \frac{a^2-b^2}{6ax}$, the quotient.

If either the divisor or dividend be an integer quantity, it may be represented as a fraction, by placing unity for a denominator; or if it be a mixed quantity, it may be reduced to a fraction by prob. 3, and the operation of division performed agreeably to the rule.

The reason of the rule for division may be explained thus: Let it be required to divide $\frac{c}{d}$ by $\frac{a}{b}$. If $\frac{c}{d}$ is to be divided by $a$, the quotient is $\frac{c}{ad}$; but if it is to be divided by $\frac{a}{b}$, then the last quotient must be multiplied by $b$; thus we have $\frac{cb}{ad}$ for the quotient required. Or let $\frac{a}{b} = m$, and $\frac{c}{d} = n$, then $a = bm$ and $c = dn$; also $ad = bdm$ and $bc = bdn$; therefore $\frac{bdn}{bdm} = \frac{n}{m} = \frac{bc}{ad}$.

Sect. III.—Involution and Evolution.

29. In treating of multiplication, we have observed, that when a quantity is multiplied by itself any number of times, the product is called a *power* of that quantity, while the quantity itself, from which the powers are formed, is called the *root* (sect. 12). Thus, $a$, $a^2$, and $a^3$, are the first, second, and third powers of the root $a$; and in like manner $\frac{1}{a}$, $\frac{1}{a^2}$, and $\frac{1}{a^3}$, denote the same powers of the root $\frac{1}{a}$.

But before considering more particularly what relates to powers and roots, it will be proper to observe, that the quantities $\frac{1}{a}$, $\frac{1}{a^2}$, $\frac{1}{a^3}$, &c. admit of being expressed under a different form; for, like as the quantities $a$, $a^2$, $a^3$, &c. are expressed as *positive* powers of the root $a$, so the quantities $\frac{1}{a}$, $\frac{1}{a^2}$, $\frac{1}{a^3}$, &c. may be respectively expressed thus, $a^{-1}$, $a^{-2}$, $a^{-3}$, &c. and considered as *negative* powers of the root $a$.

30. This method of expressing the fractions $\frac{1}{a}$, $\frac{1}{a^2}$, $\frac{1}{a^3}$, as powers of the root $a$, but with negative indices, is a consequence of the rule which has been given for the division of powers; for we may consider $\frac{1}{a}$ as the quotient arising from the division of any power of $a$ by the next higher power; for example, from the division of the 2d by the 3d, and so we have $\frac{1}{a} = \frac{a^2}{a^3}$; but since powers of the same quantity are divided by subtracting the exponent of the divisor from that of the dividend (sect. 30), it follows, that $\frac{a^2}{a^3} = a^{2-3} = a^{-1}$; therefore the fraction $\frac{1}{a}$ may also be expressed thus, $a^{-1}$. By considering $\frac{1}{a}$ as equal to $\frac{a^2}{a^4}$, it will appear in the same manner that $\frac{1}{a^2} = \frac{a^2}{a^4} = a^{-2}$; and proceeding in this way, we get $\frac{1}{a^3} = \frac{a^2}{a^5} = a^{-3}$, $\frac{1}{a^4} = \frac{a^3}{a^6} = a^{-4}$, &c. and so on, as far as we please. It also appears that unity or 1 may be represented by $a^0$, where the exponent is a cypher, for $1 = \frac{a^2}{a^2} = a^{2-2} = a^0$.

31. The rules which have been given for the multiplication and division of powers with positive exponents will apply in every case, whether the exponents be positive or negative; and this must evidently take place; for the mode of notation, by which we represent fractional quantities as the powers of integers, but with negative exponents, has been derived from those rules. Thus, $\frac{1}{a^2} \times a^3$ or $a^{-2} \times a^3$

$= a^{-2+3} = a$, also $\frac{1}{x^2} \times \frac{1}{x^3}$ or $x^{-2} \times x^{-3} = x^{-2-3} = x^{-5}$ $= \frac{1}{x^5}$, and $\frac{1}{x^3} \times x^3$ or $x^{-3} \times x^{+3} = x^{-3+3} = x^0 = 1$.

From this method of notation it appears, that any quantity may be taken from the denominator of a fraction, and placed in the numerator, by changing the sign of its exponent; and hence it follows, that every fraction may also be represented as an integer quantity. Thus, $\frac{a^2}{bc^3}$ denotes the same thing as $\frac{a^2b^{-1}}{c^3}$ or as $a^2b^{-1}c^{-3}$; also $\frac{a^2}{(x-1)^3}$ may be otherwise expressed thus, $a^2(x-1)^{-3}$.

*Of Involution.*

32. Involution is the method of finding any power of any assigned quantity, whether it be simple or compound: hence its rules are easily derived from the operation of multiplication.

*Case* 1. When the quantity is simple.

*Rule.* Multiply the exponents of the letters by the index of the power required, and raise the co-efficient to the same power.

*Note.* If the sign of the quantity be $+$, all its powers will be positive; but if it be $-$, then all its powers whose exponents are even numbers are positive, and all its powers whose exponents are odd numbers are negative.

*Ex.* 1. Required the cube, or third power, of $2a^2x$. $(2a^2x)^3 = 2 \times 2 \times 2a^{2\times3}x^{1\times3} = 8a^6x^3$, the answer.

*Ex.* 2. Required the fifth power of $-3a^2x^3$. $(-3a^2x^3)^5 = -243a^{10}x^{15}$, the answer.

*Ex.* 3. Required the fourth power of $-\frac{2ax^2}{3b^2y}$.

$$\left(\frac{-2ax^2}{3b^2y}\right)^4 = \frac{16a^4x^8}{81b^8y^4}, \text{ the answer.}$$

*Case* 2. When the quantity is compound.

*Rule.* The powers must be found by a continual multiplication of the quantity by itself.

*Ex.* Required the first four powers of the binomial quantity $a+x$.

$a+x$ the root, or first power.
$a+x$

$a^2+ax$
$\quad +ax+x^2$

$a^2+2ax+x^2$ the square, or second power.
$a+x$

$a^3+2a^2x+ax^2$
$\quad + a^2x+2ax^2+x^3$

$a^3+3a^2x+3ax^2+x^3$ the cube, or third power.
$a+x$

$a^4+3a^3x+3a^2x^2+ax^3$
$\quad + a^3x+3a^2x^2+3ax^3+x^4$

$a^4+4a^3x+6a^2x^2+4ax^3+x^4$ the fourth power.

If it be required to find the same powers of $a-x$, it will be found that
$a-x$ being the root, or first power; then
$a^2-2ax+x^2$ is the square, or second power;
$a^3-3a^2x+3ax^2-x^3$, the cube, or third power;
$a^4-4a^3x+6a^2x^2-4ax^3+x^4$, the fourth power.

Hence it appears that the powers of $a+x$ differ from the powers of $a-x$ only in this respect, that in the former the signs of the terms are all positive, but in the latter they are positive and negative alternately.

33. Besides the method of finding the powers of a compound quantity by multiplication, which we have just now explained, there is another more general, as well as more expeditious, by which a quantity may be raised to any power whatever without the trouble of finding any of the inferior powers, namely, by means of what is commonly called the *binomial theorem.* This theorem may be expressed as follows: Let $a-x$ be a binomial quantity, which is to be raised to any power denoted by the number $n$, then $(a+x)^n=$

$$a^n + \frac{n}{1}a^{n-1}x + \frac{n(n-1)}{1 \cdot 2}a^{n-2}x^2 + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3}a^{n-3}x^3$$
$$+ \frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4}a^{n-4}x^4$$
$$+ \frac{n(n-1)(n-2)(n-3)(n-4)}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}a^{n-5}x^5 +, \text{ \&c.}$$

This series will always terminate when $n$ is any whole positive number, by reason of some one of the factors $n-1$, $n-2$, &c. becoming $=0$; but if $n$ be either a negative or fractional number, the series will consist of an infinite number of terms. As, however, we mean to treat in this section only of the powers of quantities when their exponents are whole positive numbers, we shall make no further remarks upon any other: we shall afterwards give a demonstration of the theorem, and show its application to fractional and negative powers, in treating of infinite series. The $n$th power of $a-x$ will not differ from the same power of $a+x$, but in the signs of the terms which compose it, for it will stand thus: $(a-x)^n = a^n - \frac{n}{1}a^{n-1}x$

$$+ \frac{n(n-1)}{1 \cdot 2}a^{n-2}x^2 - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3}a^{n-3}x^3$$
$$+ \frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4}a^{n-4}x^4 -, \text{ \&c.}$$

where the signs are $+$ and $-$ alternately.

*Ex.* 1. Let it be required to raise $a + x$ to the fifth power.

Here $n$, the exponent of the power, being 5, the first term $a^n$ of the general theorem will be equal to $a^5$, the second $na^{n-1}x = 5a^4x$, the third $\frac{n(n-1)}{1 \cdot 2}a^{n-2}x^2 = \frac{5\times4}{1\times2}a^3x^2 = 10a^3x^2$, the fourth $\frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3}a^{n-3}x^3 = \frac{5\times4\times3}{1\times2\times3}a^2x^3, = 10a^2x^3$, the fifth $\frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4}a^{n-4}x^4 = \frac{5\times4\times3\times2}{1\times2\times3\times4}ax^4 = 5ax^4$, and the sixth and last $\frac{n(n-1)(n-2)(n-3)(n-4)}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}a^{n-5}x^5 = \frac{5\times4\times3\times2\times1}{1\times2\times3\times4\times5}a^0x^5 = x^5$; the remaining terms of the general theorem all vanish, by reason of the factor $n - 5 = 0$ by which each of them is multiplied, so that we get $(a+x)^5 = a^5 + 5a^4x + 10a^3x^2 + 10a^2x^3 + 5ax^4 + x^5$.

*Ex.* 2. It is required to raise $2d - \frac{z}{3}$ to the third power.

In this case $n = 3$, so that if we put $a = 2d$ and $x = \frac{z}{3}$, we have the first term of the general theorem, or $a^n = 8d^3$, the second $\frac{n}{1}a^{n-1}x = 3 \times 4d^2 \times \frac{z}{3} = 4d^2z$, the third

$\frac{n(n-1)}{1\cdot 2}\,a^{n-2}\,x^2 = 3\times 2d\times\frac{z^2}{9}=\frac{2dz^2}{3}$, and the fourth and last term $\frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}\,a^{n-3}x^3=\frac{z^3}{27}$; and since the signs of the terms of any power of $a-x$ are $+$ and $-$ alternately, we have $\left(2d-\frac{z}{3}\right)^3=8d^3-4d^2z+\frac{2dz^2}{3}-\frac{z^3}{27}$.

34. If the quantity to be involved consists of more than two terms, as if $p+q-r$ were to be raised to the second power, put $p=a$ and $q-r=b$, then $(p+q-r)^2=(a+b)^2=a^2+2ab+b^2=p^2+2p\,(q-r)+(q-r)^2$, but $2p\,(q-r)=2pq-2pr$, and by the general theorem $(q-r)^2=q^2-2qr+r^2$, therefore we get $(p+q-r)^2=p^2+2pq-2pr+q^2-2qr+r^2$; and by a similar method of proceeding a quantity consisting of four or more terms may be raised to any power.

### *Of Evolution.*

35. Evolution is the reverse of involution, or it is the method of finding the root of any quantity, whether simple or compound, which is considered as a power of that root: hence it follows that its operations, generally speaking, must be the reverse of those of involution.

To denote that the root of any quantity is to be taken, the sign $\surd$ (called the *radical sign*) is placed before it, and a small number placed over the sign to express the denomination of the root. Thus $\sqrt[2]{a}$ denotes the square root of $a$, $\sqrt[3]{a}$ its cube root, $\sqrt[4]{a}$ its fourth root, and in general, $\sqrt[n]{a}$ its $n$th root. The number placed over the radical sign is called the *index* or *exponent* of the root, and is usually omitted in expressing the square root: thus, either $\sqrt[2]{a}$ or $\sqrt{a}$ denotes the square root of $a$.

*Case* 1. When roots of simple quantities are to be found.

*Rule.* Divide the exponents of the letters by the index of the root required, and prefix the root of the numeral co-efficient; the result will be the root required.

*Note* 1. The root of any positive quantity may be either positive or negative, if the index of the root be an even number; but if it be an odd number, the root can be positive only.

2. The root of a negative quantity is also negative when the index of the root is an odd number.

3. But if the quantity be negative, and the index of the root even, then no root can be assigned.

*Ex.* 1. Required the square root of $36a^2x^4$.

Here the index of the root is 2, and the root of the co-efficient 6, therefore $\sqrt{36a^2x^4}=+6ax^2$ or $\sqrt{36a^2x^4}=-6ax^2$; for either of these quantities, when multiplied by itself, produces $36a^2x^4$; so that the root required is $\pm 6ax^2$, where the sign $\pm$ denotes that the quantity to which it is prefixed may be considered either as positive or negative.

*Ex.* 2. Required the cube root of $125a^6x^9$.

Here the index of the root is 3, and the root of the co-efficient 5, therefore $\sqrt[3]{125a^6x^9}=5a^2x^3$, the root required; and in like manner the cube root of $-125a^6x^9$ is found to be $-5a^2x^3$.

If it be required to extract the square root of $-a^2$, it will immediately appear that no such root can be assigned; for it can neither be $+a$ nor $-a$, seeing that each of these quantities, when squared, produces $+a^2$: the root required is therefore said to be *impossible*, and may be expressed thus: $\sqrt{-a^2}$.

The root of a fraction is found by extracting that root out of both numerator and denominator. Thus the square root of $\frac{4a^2x^4}{9b^2y^6}$ is $\frac{2ax^2}{3by^3}$.

*Case* 2. When the quantity of which the root is to be extracted is compound.

36. I. To extract the square root.

Range the terms of the quantity according to the powers of the letters, as in division.

Find the square root of the first term for the first part of the root sought, subtract its square from the given quantity, and divide the remainder by double the part already found, and the quotient is the second term of the root.

Add the second part to double the first, and multiply their sum by the second part; subtract the product from the remainder, and if nothing remain, the square root is obtained. But if there is a remainder, it must be divided by the double of the parts already found, and the quotient will give the third term of the root, and so on.

*Ex.* 1. Required the square root of $a^2+2ax+x^2$.

$$\begin{array}{rl}
 & a^2+2ax+x^2\,(a+x, \text{ the root required.} \\
 & a^2 \\
\hline
2a+x\,) & +2ax+x^2 \\
\times x\,) & +2ax+x^2 \\
\hline
 & * \quad * 
\end{array}$$

*Ex.* 2. Required the square root of $x^4-2x^3+\frac{3}{2}x^2-\frac{x}{2}+\frac{1}{16}$.

$$\begin{array}{rl}
 & x^4-2x^3+\frac{3}{2}x^2-\frac{x}{2}+\frac{1}{16}\left(x^2-x+\frac{1}{4}\right. \\
 & x^4 \\
\hline
2x^2-x\,) & -2x^3+\frac{3}{2}x^2 \\
\times -x\,) & -2x^3+\ x^2 \\
\hline
2x^2-2x+\frac{1}{4}\,) & \frac{x^2}{2}-\frac{x}{2}+\frac{1}{16} \\
\times\frac{1}{4} & \frac{x^2}{2}-\frac{x}{2}+\frac{1}{16} \\
\hline
 & * \quad * \quad *
\end{array}$$

To understand the reason of the rule for finding the square root of a compound quantity, it is only necessary to involve any quantity, as $a+b+c$, to the second power, and observe the composition of its square; for we have $(a+b+c)^2=a^2+2ab+b^2+2ac+2bc+c^2$; but $2ab+b^2=(2a+b)b$ and $2ac+2bc+c^2=(2a+2b+c)c$, therefore,

$$(a+b+c)^2=a^2+(2a+b)b+(2a+2b+c)c;$$

and from this expression the manner of deriving the rule is obvious.

As an illustration of the common rule for extracting the square root of any proposed number, we shall suppose that the root of 59049 is required.

Accordingly we have $(a+b+c)^2=59049$, and from hence we are to find the values of $a$, $b$, and $c$.

$$\begin{array}{r|l}
 & 59049(200=a \\
a^2=200\times 200= & 40000 \quad 40=b \\
 & \qquad\ \ 3=c \\
2a=400 & 19049 \\
b=\ \ 40 & \\
2a+b=440 & 17600=(2a+b)b \\
2a+2b=480 & 1449 \\
c=\ \ \ 3 & \\
2a+2b+c=483 & 1449=(2a+2b+c)c
\end{array}$$

Hence 243 is the root required.

The same example when wrought by the common rule (see ARITHMETIC) will stand thus:

$$\begin{array}{l}
\quad 59049(243 \text{ the root required.} \\
\quad 4 \\
\hline
44)190 \\
\quad 176 \\
\hline
483)1449 \\
\quad\ \ 1449 \\
\hline
\end{array}$$

and by a comparison of the two operations, the reason of the common rule is obvious.

37. II. To extract the cube root.

Range the terms of the quantity according to the powers of some one of the letters.

Find the root of the first term, for the first part of the root sought; subtract its cube from the whole quantity, and divide the remainder by three times the square of the part already found, and the quotient is the second part of the root.

Add together three times the square of the part of the root already found, three times the product of that part and the second part of the root, and the square of the second part; multiply the sum by the second part, and subtract the product from the first remainder, and if nothing remain, the root is obtained; but if there is a remainder, it must be divided by three times the square of the sum of the parts already found, and the quotient is a third term of the root, and so on, till the whole root is obtained.

*Ex.* Required the cube root of $a^3+3a^2x+3ax^2+x^3$.

$$\begin{array}{l}
\qquad\qquad\qquad a^3+3a^2x+3ax^2+x^3(a+x \text{ the root required.} \\
\qquad\qquad\qquad a^3 \\
\hline
3a^2+3ax+x^2)3a^2x+3ax^2+x^3 \\
\qquad\qquad\qquad 3a^2x+3ax^2+x^3 \\
\hline
\qquad\qquad\qquad * \quad * \quad *
\end{array}$$

The reason of the preceding rule is evident from the composition of a cube; for if any quantity, as $a+b+c$ be raised to the third power, we have $(a+b+c)^3=a^3+(3a^2+3ab+b^2)b+3(a+b)^2+3(a+b)c+c^2)c$, and by considering in what manner the terms $a$, $b$, and $c$ are deduced from this expression for the cube of their sum, we also see the reason for the common rule for extracting the cube root in numbers. Let it be required to find the cube root of 13312053, where the root will evidently consist of three figures; let us suppose it to be represented by $a+b+c$, and the operation for finding the numerical values of these quantities may stand as follows.

$$\begin{array}{r|l}
 & 13312053(200=a \\
a^3= & 8000000 \quad 30=b \\
 & \qquad\qquad\ \ 7=c \\
3a^2=120000 & 5312053 \quad \overline{\ \ \ } \\
3ab=\ \ 18000 & \qquad\quad 237 \text{ the root required.} \\
b^2=\qquad 900 & \\
3a^2+3ab+b^2=138900 & 4167000=(3a^2+3ab+b^2)b \\
3(a+b)^2=158700 & 1145053 \\
3(a+b)c=\ \ \ 4830 & \\
c^2=\qquad\ 49 & \\
3(a+b)^2+3(a+b)c+c^2=163579 & 1145053=[3(a+b)^2+3(a+b)c+c^2]c
\end{array}$$

The operation as performed by the common rule (see ARITHMETIC) will stand thus:

$$\begin{array}{r|l}
 & 13312053(237 \text{ the root required.} \\
 & 8 \\
12.. & 5312 \\
18\ . & \\
9 & \\
\hline
1389 & 4167 \\
1587.. & 1145053 \\
483\ . & \\
49 & \\
\hline
163579 & 1145053
\end{array}$$

38. III. To extract any other root.

*Rule.* Range the quantity of which the root is to be found, according to the powers of its letters, and extract the root of the first term, and that shall be the first member of the root required.

Involve the first member of the root to a power less by unity than the number that denominates the root required, and multiply the power that arises by the number itself; divide the second term of the given quantity by the product, and the quotient shall give the second member of the root required.

Find the remaining members of the root in the same manner by considering those already found as making one term.

*Ex.* Required the cube root of $x^6+6x^5-40x^3+96x-64$.

$$\begin{array}{l}
\qquad\qquad\quad x^6+6x^5-40x^3+96x-64(x^2+2x-4 \\
(x^2)^3=x^6 \\
\hline
\quad 3x^4)6x^5 \\
\hline
(x^2+2x)^3=x^6+6x^5+12x^4+8x^3 \\
\hline
\quad 3x^4+,\ \&c.)-12x^4 \\
\hline
(x^2+2x-4)^3=x^6+6x^5-40x^3+96x-64 \\
\hline
\qquad\qquad\qquad *
\end{array}$$

In this example, the cube root of $x^6$, or $x^2$, is the first member of the root; and to find a second member, the first is raised to the power next lower, or to the second power, and also multiplied by 3, the index of the root required. Thus we get $3x^4$ for a divisor, by which the second term $6x^5$ being divided, we find $2x$ for the second member of the root. We must now consider $x^2+2x$ as forming one term: accordingly, having subtracted its cube from the quantity of which the root is sought, we have $-12x^4-$, &c. for a new dividend; and having also raised $x^2+2x$ to the second power, and multiplied the result by 3, we find $3x^4+$, &c. for a divisor. (As it is only the terms which contain the highest powers of the dividend and divisor that we have occasion for, the remaining terms are expressed by &c.) Having divided $-12x^4$ by $3x^4$, we find $-4$ for the third term of the root; and because it appears that $x^2+2x-4$, when raised to the third power, gives a result the very same with the proposed power, we conclude $x^2+2x-4$ to be the root sought.

39. In the preceding examples, the quantities whose roots were to be found have been all such as could have their roots expressed by a finite number of terms; but it will frequently happen that the root cannot be otherwise assigned than by a series consisting of an infinite number of terms. The preceding rules, however, will serve to determine any number of terms of the series. Thus, the square root of $a^2+x^2$ will be found to be $a+\frac{x^2}{2a}-\frac{x^4}{8a^3}+\frac{x^6}{16a^5}-\frac{5x^8}{128a^7}+$, &c., and the cube root of $a^3+x^3$ will stand thus, $a+\frac{x^3}{3a^2}-\frac{x^6}{9a^5}+\frac{5x^9}{81a^8}-\frac{10x^{12}}{243a^{11}}+$, &c. But as the extraction of roots in the form of series can be more easily performed by other methods, we shall refer the reader to sect. 19, which treats of series, where this subject is resumed.

## Sect. IV.—Of Surds.

40. It has been already observed (35), that the root of any proposed quantity is found by dividing the exponent of the quantity by the index of the root; and the rule has been illustrated by suitable examples, in all which, however, the quotient expressing the exponent of the result is a whole number; but there may be cases in which the quotient is a fraction. Thus, if the cube root of $a^2$ were required, it might be expressed, agreeably to the method of notation already explained, either thus, $\sqrt[3]{a^2}$, or thus, $a^{\frac{2}{3}}$.

Quantities which have fractional exponents are called *surds*, or imperfect powers, and are said to be *irrational*, in opposition to others with integral exponents, which are called *rational.*

Surds may be denoted by means of the radical sign, but it will be often more convenient to use the notation of fractional exponents. The following examples will show how they may be expressed either way.

$$\sqrt[3]{a} = a^{\frac{1}{3}}, \quad \sqrt{4ab^2} = 2ba^{\frac{1}{2}}, \quad \sqrt[4]{a^3b^2} = a^{\frac{3}{4}}b^{\frac{2}{4}},$$
$$\sqrt{a^2+b^2} = (a^2+b^2)^{\frac{1}{2}}, \quad \sqrt[5]{(a-b)^2} = (a-b)^{\frac{2}{5}},$$
$$\frac{\sqrt{a+b}}{\sqrt{ab}} = (a+b)^{\frac{1}{2}}\, a^{-\frac{1}{2}}b^{-\frac{1}{2}}.$$

The operations concerning surds depend on the following principle: If the numerator and denominator of a fractional exponent be either both multiplied or both divided by the same quantity, the value of the power is the same. Thus, $a^{\frac{m}{n}} = a^{\frac{cm}{cn}}$. For let $a^{\frac{m}{n}} = b$, then raising both to the power $n$, $a^m = b^n$, and further, raising both to the power $c$, we get $a^{cm} = b^{cn}$: let the root $cn$ be now taken, and we find $a^{\frac{cm}{cn}} = b = {}^{\frac{n}{n}}$.

41. Prob. I.—*To Reduce a Rational Quantity to the form of a Surd of any given denomination.*

*Rule.* Reduce the exponent of the quantity to the form of a fraction of the same denomination as the given surd.

*Ex.* I. Reduce $a^2$ to the form of the cube root.

Here the exponent 2 must be reduced to the form of a fraction having 3 for a denominator, which will be the fraction $\frac{6}{3}$; therefore $a^2 = a^{\frac{6}{3}} = \sqrt[3]{a^6}$.

*Ex.* 2. Reduce 5 to the form of the cube root, and $3ab^2$ to the form of the square root.

First, $5 = 5^{\frac{3}{3}} = \sqrt[3]{5\times5\times5} = \sqrt[3]{125}$,

And $3\,a\,b^2 = 3^{\frac{2}{2}}a^{\frac{2}{2}}b^{\frac{4}{2}} = (3^2a^2b^4)^{\frac{1}{2}} = \sqrt{9a^2b^4}$.

42. Prob. II.—*To Reduce Surds of different denominations to others of the same value, and of the same denomination.*

*Rule.* Reduce the fractional exponents to others of the same value, and having the same common denominator.

*Ex.* 1. Reduce $\sqrt{a}$ and $\sqrt[3]{b^2}$, or $a^{\frac{1}{2}}$ and $b^{\frac{2}{3}}$ to other equivalent surds of the same denomination.

The exponents $\frac{1}{2}$, $\frac{2}{3}$, when reduced to a common denominator, are $\frac{3}{6}$ and $\frac{4}{6}$; therefore the surds required are $a^{\frac{3}{6}}$ and $b^{\frac{4}{6}}$, or $\sqrt[6]{a^3}$ and $\sqrt[6]{b^4}$.

*Ex.* 2. Reduce $3^{\frac{1}{2}}$ and $2^{\frac{1}{3}}$ to surds of the same denomination.

The new exponents are $\frac{3}{6}$ and $\frac{2}{6}$, therefore we have $3^{\frac{1}{2}} = 3^{\frac{3}{6}} = \sqrt[6]{3^3} = \sqrt[6]{27}$, and $2^{\frac{1}{3}} = 2^{\frac{2}{6}} = \sqrt[6]{2^2} = \sqrt[6]{4}$.

And in the same way the surds $A^{\frac{1}{m}}$, $B^{\frac{1}{n}}$, are reduced to these two, $\sqrt[mn]{A^n}$ and $\sqrt[mn]{B^m}$.

43. Prob. III.—*To Reduce Surds to their most simple terms.*

*Rule.* Reduce the surd into two factors, so that one of them may be a complete power, having its exponent divisible by the index of the surd. Extract the root of that power, and place it before the remaining quantities, with the proper radical sign between them.

*Ex.* 1. Reduce $\sqrt{48}$ to its most simple terms.

The number 48 may be resolved into the two factors 16 and 3, of which the first is a complete square; therefore $\sqrt{48} = (4^2\times3)^{\frac{1}{2}} = 4\times3^{\frac{1}{2}} = 4\sqrt{3}$.

*Ex.* 2. Reduce $\sqrt{98a^4x}$, and $\sqrt[3]{24a^3x+40a^3x^2}$, each to its most simple terms.

First, $\sqrt{98a^4x} = (7^2a^4\times2x)^{\frac{1}{2}} = 7a^2\times(2x)^{\frac{1}{2}} = 7a^2\sqrt{2x}$.

Also $\sqrt[3]{24a^3x+40a^3x^2} = (2^3a^3(3x+5x^2))^{\frac{1}{3}} = 2a\sqrt[3]{3x+5x^2}$.

44. Prob. IV.—*To Add and Subtract Surds.*

*Rule.* If the surds are of different denominations, reduce them to others of the same denomination, by prob. 2, and then reduce them to their simplest terms by last problem. Then, if the surd part be the same in them all, annex it to the sum or difference of the rational parts, with the sign of multiplication, and it will give the sum or difference required. But if the surd part be not the same in all the quantities, they can only be added or subtracted by placing the signs $+$ or $-$ between them.

*Ex.* 1. Required the sum of $\sqrt{27}$ and $\sqrt{48}$.

By prob. 3 we find $\sqrt{27}=3\sqrt{3}$ and $\sqrt{48}=4\sqrt{3}$, therefore $\sqrt{27}+\sqrt{48}=3\sqrt{3}+4\sqrt{3}=7\sqrt{3}$.

*Ex.* 2. Required the sum of $3\sqrt[3]{\tfrac{1}{4}}$ and $5\sqrt[3]{\tfrac{1}{32}}$.

$3\sqrt[3]{\tfrac{1}{4}}=3\sqrt[3]{\tfrac{2}{8}}=\tfrac{3}{2}\sqrt[3]{2}$ and $5\sqrt[3]{\tfrac{1}{32}}=5\sqrt[3]{\tfrac{2}{64}}=\tfrac{5}{4}\sqrt[3]{2}$, therefore $3\sqrt[3]{\tfrac{1}{4}}+5\sqrt[3]{\tfrac{1}{32}}=\tfrac{3}{2}\sqrt[3]{2}+\tfrac{5}{4}\sqrt[3]{2}=\tfrac{11}{4}\sqrt[3]{2}$.

*Ex.* 3. Required the difference between $\sqrt{80a^4x}$ and $\sqrt{20a^2x^3}$.

$\sqrt{80a^4x}=(4^2a^4\times 5x)^{\frac{1}{2}}=4a^2\sqrt{5x}$, and $\sqrt{20a^2x^3}=(2^2a^2x^2\times 5x)^{\frac{1}{2}}=2ax\sqrt{5x}$; therefore $\sqrt{80a^4x}-\sqrt{20a^2x^3}=(4a^2-2ax)\sqrt{5x}$.

45. Prob. V.—*To Multiply and Divide Surds.*

*Rule.* If they are surds of the same rational quantity, add or subtract their exponents.

But if they are surds of different rational quantities, let them be brought to others of the same denomination, by prob. 2. Then, by multiplying or dividing these rational quantities, their product or quotient may be set under the common radical sign.

*Note.* If the surds have any rational co-efficients, their product or quotient must be prefixed.

*Ex.* 1. Required the product of $\sqrt[3]{a^2}$ and $\sqrt[5]{a^3}$.

$$\sqrt[3]{a^2}\times\sqrt[5]{a^3}=a^{\frac{2}{3}}\times a^{\frac{3}{5}}=a^{\frac{2}{3}+\frac{3}{5}}=a^{\frac{19}{15}}=\sqrt[15]{a^{19}},\ \text{Ans.}$$

*Ex.* 2. Divide $\sqrt{a^2-b^2}$ by $\sqrt[3]{a+b}$.

These surds, when reduced to the same denomination, are $(a^2-b^2)^{\frac{3}{6}}$ and $(a+b)^{\frac{2}{6}}$. Hence $\frac{\sqrt{a^2-b^2}}{\sqrt[3]{a+b}}$

$$=\left(\frac{(a^2-b^2)^3}{(a+b)^2}\right)^{\frac{1}{6}}=\left(\frac{(a+b)^3(a-b)^3}{(a+b)^2}\right)^{\frac{1}{6}}$$

$$=\left((a+b)(a-b)^3\right)^{\frac{1}{6}}=\sqrt[6]{(a+b)(a-b)^3}.$$

*Ex.* 3. Required the product of $5\sqrt{8}$ and $3\sqrt{5}$.

$5\sqrt{8}\times 3\sqrt{5}=5\times 3\times\sqrt{8}\times\sqrt{5}=15\times\sqrt{40}=15\times\sqrt{4\times 10}=30\sqrt{10}$.

*Ex.* 4. Divide $8\sqrt[3]{56}$ by $4\sqrt[3]{2}$.

$$\frac{8\sqrt[3]{56}}{4\sqrt[3]{2}}=2\sqrt[3]{\frac{56}{2}}=2\sqrt[3]{28}.$$

*Ex.* 5. Required the product of $x^{\frac{1}{m}}$ and $x^{\frac{1}{n}}$; also the quotient arising from the division of $a^{\frac{1}{m}}$ by $b^{\frac{1}{n}}$.

First, $x^{\frac{1}{m}}\times x^{\frac{1}{n}}=x^{\frac{1}{m}+\frac{1}{n}}=x^{\frac{m+n}{mn}}=\sqrt[mn]{x^{m+n}}$,

And $\frac{a^{\frac{1}{m}}}{b^{\frac{1}{n}}}=\left(\frac{a^n}{b^m}\right)^{\frac{1}{mn}}=\sqrt[mn]{\frac{a^n}{b^m}}$.

46. Prob. VI.—*To Involve and Evolve Surds.*

Surds are involved or evolved in the same manner as any other quantities, namely, by multiplying or dividing their exponents by the index of the power or root required. Thus, the square of $3\sqrt[3]{3}$ is $3\times 3\times(3)^{\frac{2}{3}}=9\sqrt[3]{9}$. The $n$th power of $x^{\frac{1}{m}}$ is $x^{\frac{n}{m}}$. The cube root of $\frac{1}{8}\sqrt{2}$ is $\frac{1}{2}(2)^{\frac{1}{6}}=\frac{\sqrt[6]{2}}{2}$, and the $n$th root of $x^{\frac{1}{m}}$ is $x^{\frac{1}{mn}}$.

47. If a compound quantity involve one or more surds, its powers may be found by multiplication. Thus, the square of $3+\sqrt{5}$ is found as follows:

$$\begin{array}{l} 3+\sqrt{5} \\ 3+\sqrt{5} \\ \hline 9+3\sqrt{5} \\ \quad +3\sqrt{5}+5 \\ \hline 9+6\sqrt{5}+5=14+6\sqrt{5},\ \text{the square required.} \end{array}$$

48. The square root of a binomial or residual surd, $A+B$, or $A-B$, may be found thus. Find $D=\sqrt{A^2-B^2}$,

then $\sqrt{A+B}=\sqrt{\frac{A+D}{2}}+\sqrt{\frac{A-D}{2}}$,

and $\sqrt{A-B}=\sqrt{\frac{A+D}{2}}-\sqrt{\frac{A-D}{2}}$.

Thus the square root of $8+2\sqrt{7}$ is $1+\sqrt{7}$; and the square root of $3-\sqrt{8}$ is $\sqrt{2}-1$. With respect to the extraction of the cube or any higher root, no general rule can be given.

Sect. V.—Of Proportion.

49. In comparing together any two quantities of the same kind in respect of magnitude, we may consider how much the one is greater than the other, or else how many times the one contains either the whole or some part of the other; or, which is the same thing, we may consider either what is the difference between the quantities, or what is the quotient arising from the division of the one quantity by the other: the former of these is called their *arithmetical ratio*, and the latter their *geometrical ratio*. These denominations, however, have been assumed arbitrarily, and have little or no connection with the relations they are intended to express.

I. *Of Arithmetical Proportion.*

50. When of four quantities the difference between the first and second is equal to the difference between the third and fourth, the quantities are called *arithmetical proportionals*. Such, for example, are the numbers 2, 5, 9, 12; and, in general, the quantities $a$, $a+d$, $b$, $b+d$. If the two middle terms are equal, the quantities constitute an *arithmetical progression*.

51. The principal property of four arithmetical proportionals is this:—If four quantities be arithmetically proportional, the sum of the extreme terms is equal to the sum of the means. Let the quantities be $a$, $a+d$, $b$, $b+d$; where $d$ is the difference between the first and second, and also between the third and fourth, the sum of the extremes is $a+b+d$, and that of the means $a+d+b$; so that the truth of the proposition is evident. Hence it follows, that if any three quantities be arithmetically proportional, the sum of the two extremes is double the mean.

52. If any three terms of four arithmetical proportionals be given, the fourth may be found from the preceding

proposition. Let $a$, $b$, $c$, be the first, second, and fourth terms, and let $x$, the third term, be required; because $a+c=b+x$, therefore $x=a+c-b$. In like manner any two of three arithmetical proportionals being supposed given, the remaining term may be readily found.

53. If a series of quantities be such, that the difference between any two adjacent terms is always the same, these terms form a *continued arithmetical progression.* Thus, the numbers 2, 4, 6, 8, 10, &c. form a series in continued arithmetical proportion, and, in general, such a series may be represented thus:

$a, a+d, a+2d, a+3d, a+4d, a+5d, a+6d$, &c. where $a$ denotes the first term, and $d$ the common difference.

By a little attention to this series, we readily discover that it has the following properties:

1. The last term of the series is equal to the first term, together with the common difference taken as often as there are terms after the first. Thus, when the number of terms is 7, the last term is $a+6d$; and so on. Hence if $z$ denote the last term, $n$ the number of terms, and $a$ and $d$ express the first term and common difference, we have $z=a+(n-1)\,d$.

2. The sum of the first and last term is equal to the sum of any two terms at the same distance from them. Thus, suppose the number of terms to be 7, then the last term is $a+6d$, and the sum of the first and last $2a+6d$; but the same is also the sum of the second and last but one, of the third and last but two, and so on till we come to the middle term, which, because it is equally distant from the extremes, must be added to itself.

From the last-mentioned property we derive a rule for finding the sum of all the terms of the series. For if the sum of the first and last be taken, as also the sum of the second and last but one, of the third and last but two, and so on along the series till we come to the sum of the last and first terms, it is evident that we shall have as many sums as there are terms, and each equal to the sum of the first and last terms; but the aggregate of those sums is equal to all the terms of the series taken twice, therefore the sum of the first and last term, taken as often as there are terms, is equal to twice the sum of all the terms; so that if $s$ denote that sum, we have $2s=n(a+z)$, and $s=\frac{n}{2}(a+z)$.

Hence the sum of the odd numbers 1, 3, 5, 7, 9, &c. continued to $n$ terms, is equal to the square of the number of terms. For in this case $a=1$, $d=2$, $z=1+(n-1)\,d$ $=2n-1$, therefore $s=\frac{n}{2}\times 2n=n^2$.

## II. *Of Geometrical Proportion.*

54. When, of four quantities, the quotient arising from the division of the first by the second is equal to that arising from the division of the third by the fourth, these quantities are said to be in *geometrical proportion,* or are called simply *proportionals.* Thus, 12, 4, 15, 5, are four numbers in geometrical proportion; and, in general, $na$, $a$, $nb$, $b$, may express any four proportionals, for $\frac{na}{a}=n$, and also $\frac{nb}{b}=n$.

To denote that any four quantities $a$, $b$, $c$, $d$, are proportionals, it is common to place them thus, $a:b::c:d$; or thus, $a:b=c:d$; which notation, when expressed in words, is read thus, $a$ is to $b$ as $c$ to $d$, or the ratio of $a$ to $b$ is equal to the ratio of $c$ to $d$.

The first and third terms of a proportion are called the *antecedents,* and the second and fourth the *consequents.*

When the two middle terms of a proportion are the same, the remaining terms, and that quantity, constitute three geometrical proportionals; such as 4, 6, 9, and in general $n\,a, a, \frac{a}{n}$. In this case the middle quantity is called a mean proportional between the other two.

55. The principal properties of four proportionals are the following:

1. If four quantities be proportionals, the product of the extremes is equal to the product of the means. Let $a$, $b$, $c$, $d$, be four quantities, such that $a:b::c:d$; then, from the nature of proportionals, $\frac{a}{b}=\frac{c}{d}$: let these equal quotients be multiplied by $b\,d$, and we have $\frac{abd}{b}=\frac{cbd}{d}$, or $ad=bc$. Hence it follows, that when three quantities are proportional, the product of the extremes is equal to the square of the middle term. It also appears, that if any three of four proportionals be given, the remaining one may be found. Thus, let $a$, $b$, $c$, the first three, be given, and let it be required to find $x$, the fourth term; because $a:b::c:x$, $ax=bc$, and dividing by $a$, $x=\frac{bc}{a}$. This conclusion may be considered as a demonstration of what is called the rule of three in arithmetic.

2. If four quantities be such, that the product of two of them is equal to the product of the other two, these quantities are proportionals.

Let $a$, $b$, $c$, $d$, be the quantities, which are such that $ad=bc$; if these equals be divided by $bd$, then $\frac{ad}{bd}=\frac{bc}{bd}$, or $\frac{a}{b}=\frac{c}{d}$; hence, from the definition given of proportionals (sect. 54), $a:b::c:d$. From this property of proportionals it appears, that if three quantities be such that the square of one of them is equal to the product of the other two, these quantities are three proportionals.

If four quantities are proportional, that is, if $a:b::c:d$, then will each of the following combinations or arrangements of the quantities be also four proportionals.

1*st*, By inversion, $b:a::d:c$.

2*d*, By alternation, $a:c::b:d$.

*Note.*—The quantities in the second case must be all of the same kind.

3*d*, By composition, $a+b:a::c+d:c$,
or, $a+b:b::c+d:d$.

4*th*, By division, $a-b:a::c-d:c$,
or, $a-b:b::c-d:d$.

5*th*, By mixing, $a+b:a-b::c+d:c-d$.

6*th*, By taking any equimultiples of the antecedents, and also any equimultiples of the consequents,

$$na:pb::nc:pd.$$

7*th*, Or, by taking any parts of the antecedents and consequents, $\frac{a}{n}:\frac{b}{p}::\frac{c}{n}:\frac{d}{p}$.

That the preceding combinations of the quantities $a$, $b$, $c$, $d$, are proportionals, may be readily proved, by taking the products of the extremes and means; for from each of them we derive this conclusion, that $ad=bc$, which is known to be true, from the original assumption of the quantities.

If four quantities be proportional, and also other four, the product of the corresponding terms will be proportional.

Let $a:b::c:d$,
And $e:f::g:h$;
Then $ae:bf::cg:dh$.

*Adv. Bib.*

Algebra. For $ad = bc$, and $eh = fg$ (sect. 55), therefore, multiplying together these equal quantities, $adeh = bcfg$, or $ae \times dh = bf \times cg$; therefore, by the second property (sect. 55), $ae : bf :: cg : dh$.

Hence it follows, that if there be any number of proportions whatever, the products of the corresponding terms will still be proportional.

56. If a series of quantities be so related to each other, that the quotient arising from the division of any term by that which follows it is always the same quantity, these are said to be in *continued geometrical proportion*; such are the numbers 2, 4, 8, 16, 32, &c. also $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}$, &c. and in general, a series of such quantities may be represented thus, $a, ar, ar^2, ar^3, ar^4, ar^5$, &c. Here $a$ is the first term, and $r$ the quotient of any two adjoining terms, which is also called the *common ratio.*

By inspecting this series, we find that it has the following properties:

1. The last term is equal to the first, multiplied by the common ratio raised to a power, the index of which is one less than the number of terms. Therefore, if $z$ denote the last term, and $n$ the number of terms, $z = ar^{n-1}$.

2. The product of the first and last term is equal to the product of any two terms equally distant from them: thus, supposing $ar^5$ the last term, it is evident that $a \times ar^5 = ar \times ar^4 = ar^2 \times ar^3$, &c.

The sum of $n$ terms of a geometrical series may be found thus:

Let $s = a + ar + ar^2 + ar^3 \ldots + ar^{n-1}$,

Then $rs = ar + ar^2 + ar^3 \ldots + ar^{n-1} + ar^n$.

Subtract, $rs - s = ar^n - a$;

That is, $(r - 1)\, s = a(r^n - 1)$.

Hence $s = \dfrac{r^n - 1}{r - 1}\, a$.

## Sect. VI.—Of the Resolution of Equations involving one Unknown Quantity.

57. The general object of algebraic investigation is to discover certain unknown quantities, by comparing them with other quantities which are given, or supposed to be known. The relation between the known and unknown quantities is either that of equality, or else such as may be reduced to equality; and a proposition which affirms that certain combinations of quantities are equal to one another is called an *equation.* Such are the following:—

$$\frac{x}{2} + \frac{x}{3} = \frac{24}{x},$$

$$2x + 3y = xy.$$

The first of these equations expresses the relation between an unknown quantity $x$ and certain known numbers; and the second expresses the relation which the two indefinite quantities $x$ and $y$ have to each other.

58. When a quantity stands alone on one side of an equation, the terms on the other side are said to be a *value* of that quantity. Thus, in the equation $x = ay + b - c$, the quantity $x$ stands alone on one side, and $ay + b - c$ is its value.

The conditions of a problem may be such as to require several equations and symbols of unknown quantities for their complete expression. These, however, by rules hereafter to be explained, may be reduced to one equation, involving only one unknown quantity and its powers, besides the known quantities; and the method of expressing that quantity by means of the known quantities constitutes the theory of equations, one of the most important as well as most intricate branches of algebraic analysis.

59. An equation is said to be *resolved* when the unknown quantity is made to stand alone on one side, and only known quantities on the other side; and the value of the unknown quantity is called a *root* of the equation. Algebra.

60. Equations containing only one unknown quantity and its powers, are divided into different *orders*, according to the highest power of that quantity contained in any one of its terms. The equation, however, is supposed to be reduced to such a form that the unknown quantity is found only in the numerators of the terms, and that the exponents of its powers are expressed by positive integers.

61. If an equation contains only the first power of the unknown quantity, it is called a *simple* equation, or an equation of the first order. Such is $ax + b = c$, where $x$ denotes an unknown, and $a, b, c$, known quantities.

If the equation contains the second power of the unknown quantity, it is said to be of the second degree, or is called a *quadratic* equation; such is $4x^2 + 3x = 12$, and in general $ax^2 + bx = c$. If it contains the third power of the unknown quantity, it is of the third degree, or is a *cubic* equation; such are $x^3 - 2x^2 + 4x = 10$, and $ax^3 + bx^2 + ca = d$; and so on with respect to equations of the higher orders. A simple equation is sometimes said to be *linear*, or of one *dimension*. In like manner, quadratic equations are said to be of two dimensions, and cubic equations of three dimensions.

62. When in the course of an algebraic investigation we arrive at an equation involving only one unknown quantity, that quantity will often be so entangled in the different terms as to render several previous reductions necessary before the equation can be expressed under its characteristic form, so as to be resolved by the rules which belong to that form.

These reductions depend upon the operations which have been explained in the former part of this treatise, and the application of a few self-evident principles, namely, that if equal quantities be added to or subtracted from equal quantities, the sums or remainders will be equal; if equal quantities be multiplied or divided by the same quantity, the products or quotients will be equal; and, lastly, if equal quantities be raised to the same power, or have the same root extracted out of each, the results will still be equal.

From these considerations are derived the following rules, which apply alike to equations of all orders, and are alone sufficient for the resolution of simple equations.

63. *Rule* 1. Any quantity may be transposed from one side of an equation to the other, by changing its signs.

Thus, if $x - 3 = 5$,

Then $x = 5 + 3$,

Or $x = 8$.

And if $3x - 10 = 2x + 5$,

Then $3x - 2x = 5 + 10$,

Or $x = 15$.

Again, if $ax + b = cx - dx + e$,

Then $ax - cx + dx = e - b$,

Or $(a - c + d)x = e - b$.

The reason of this rule is evident, for the transposing of a quantity from one side of an equation to the other is nothing more than adding the same quantity to each side of the equation, if the sign of the quantity transposed was $-$; or subtracting it, if the sign was $+$.

From this rule we may infer, that if any quantity be found on each side of the equation with the same sign, it may be left out of both. Also, that the signs of all the terms of an equation may be changed into the contrary, without affecting the truth of the equation.

Thus, if $a+x=b+a-c$,
Then $x=b+c$;
And if $a-x=b-d$,
Then $x-a=d-b$.

64. *Rule* 2. If the unknown quantity in an equation be multiplied by any quantity, that quantity may be taken away, by dividing all the other terms of the equation by it.

If $3x=24$,
Then $x=\frac{24}{3}=8$.
If $ax=b-c$,
Then $x=\frac{b-c}{a}=\frac{b}{a}-\frac{c}{a}$.

Here equal quantities are divided by the same quantity, and therefore the quotients are equal.

65. *Rule* 3. If any term of an equation be a fraction, its denominator may be taken away, by multiplying all the other terms of the equation by that denominator.

If $\frac{x}{5}=7$,
Then $x=35$.
If $\frac{x}{a}=b-c+d$,
Then $x=ab-ac+ad$.
If $a-\frac{b}{x}=c$,
We have $ax-b=cx$.

In these examples, equal quantities are multiplied by the same quantity, and therefore the products are equal.

66. The denominators may be taken away from several terms of an equation by one operation, if we multiply all the terms by any number which is a multiple of each of these denominators.

Thus, if $\frac{x}{2}+\frac{x}{3}+\frac{x}{4}=26$;

let all the terms be multiplied by 12, which is a multiple of 2, 3, and 4, and we have

$$\frac{12x}{2}+\frac{12x}{3}+\frac{12x}{4}=312;$$
Or $6x+4x+3x=312$;
Hence $13x=312$.

Universally, if $\frac{x}{a}-\frac{x}{b}+\frac{x}{c}=d-e$;

to take away the denominators $a$, $b$, $c$, let the whole equation be multiplied by $a\,b\,c$, their product, and we have

$$bcx-acx+abx=abc\,(d-e),$$
Or $(bc-ac+ab)\,x=abc\,(d-e)$.

From the last two rules it appears, that if all the terms of an equation be either multiplied or divided by the same quantity, that quantity may be left out of all the terms.

If $ax=ab-ac$,
Then $x=b-c$;
And if $\frac{x}{a}=\frac{b}{a}+\frac{c}{a}$,
Then $x=b+c$.

67. *Rule* 4. If the unknown quantity is found in any term which is a surd, let that surd be made to stand alone on one side of the equation, and the remaining terms on the opposite side; then involve each side to a power denoted by the index of the surd, and thus the unknown quantity shall be freed from the surd expression.

If $\sqrt{x}+6=10$,
Then, by transposition, $\sqrt{x}=10-6=4$;
And, squaring both sides, $\sqrt{x}\times\sqrt{x}=4\times 4$,
Or $x=16$.
Also, if $\sqrt{a^2+x^2}-b=x$,
By trans. $\sqrt{a^2+x^2}=b+x$,
And, squaring, $a^2+x^2=(b+x)^2=b^2+2bx+x^2$,
Hence $a^2=b^2+2bx$.
And if $\sqrt[3]{a^2x-b^2x}=x$,
Then $a^2x-b^2x=x^3$.

68. *Rule* 5. If the side of the equation which contains the unknown quantity be a perfect power, the equation may be reduced to another of a lower order, by extracting the root of that power out of each side of the equation.

Thus, if $x^3=64a^3$,
Then, by extracting the cube root, $x=8a$;
And if $(a+x)^2=b^2-a^2$,
Then $a+x=\sqrt{b^2-a^2}$.

69. The use of the preceding rules will be further illustrated by the following examples:

*Ex.* 1. Let $20-3x-8=60-7x$,
By rule 1, $7x-3x=60+8-20$,
Or $4x=48$,
Therefore, by rule 2, $x=12$.

*Ex.* 2. Let $ax-b=cx+d$,
By rule 1, $ax-cx=b+d$,
Or $(a-c)x=b+d$,
And by rule 2, $x=\frac{b+d}{a-c}$.

*Ex.* 3. Let $\frac{x+1}{2}+\frac{x+2}{3}=16-\frac{x+3}{4}$,

By rule 3, $\begin{cases} x+1+\frac{2x+4}{3}=32-\frac{2x+6}{4}, \\ 3x+3+2x+4=96-\frac{6x+18}{4}, \\ 12x+12+8x+16=384-6x-18, \end{cases}$
Or $20x+28=366-6x$,
Hence, by rule 1, $26x=338$,
And by rule 2, $x=13$.

In this example, instead of taking away the denominators one after another, they might have been all taken away at once, by multiplying the given equation by 12, which is divisible by the numbers 2, 3, and 4; thus we should have got $6x+6+4x+8=192-3x-9$, and hence, as before, $x=13$.

*Ex.* 4. Let $6x^3-20x^2=16x^2+2x^3$;
Then, dividing by $2x^2$, $3x-10=8+x$,
And transposing, $3x-x=8+10$,
Or $2x=18$,
And therefore $2x=9$.

*Ex.* 5. Let $a-\frac{b^2}{x}=c$,
Then $ax-b^2=cx$,
And $ax-cx=b^2$,
Whence $x=\frac{b^2}{a-c}$.

*Ex.* 6. Let $x-6=\frac{x^2}{x+24}$,
Then $(x-6)(x+24)=x^2$;

That is, $x^2+18x-144=x^2$,
Therefore $18x=144$,
And $x=8$.

*Ex.* 7. Let $ax+b^2=\frac{ax^2+ac^2}{a+x}$;
Then $(a+x)(ax+b^2)=ax^2+ac^2$,
Or $a^2x+ab^2+ax^2+b^2x=ax^2+ac^2$,
Hence $a^2x+b^2x=ac^2-ab^2$,
And $x=\frac{ac^2-ab^2}{a^2+b^2}$.

*Ex.* 8. Let $\frac{1-x}{1+a}=a$;
Then $1-x=a+ax$,
And $-x-ax=a-1$,
Or, changing the signs, $x+ax=1-a$;
Hence $x=\frac{1-a}{1+a}$.

*Ex.* 9. Let $\sqrt{12+x}=2+\sqrt{x}$;
Then, by rule 4, $12+x=4+4\sqrt{x}+x$,
And by transposition, $8=4\sqrt{x}$,
And by division, $2=\sqrt{x}$,
And again, by rule 4, $4=x$.

*Ex.* 10. Let $x+\sqrt{a^2+x^2}=\frac{2a^2}{\sqrt{a^2+x^2}}$;
Then, by rule 3, $x\sqrt{a^2+x^2}+a^2+x^2=2a^2$,
And by transposition, &c. $x\sqrt{a^2+x^2}=a^2-x^2$,
Therefore, by rule 4, $a^2x^2+x^4=a^4-2a^2x^2+x^4$,
Whence $3a^2x^2=a^4$,
And $x^2=\frac{a^2}{3}$, therefore, by rule 5, $x=\frac{a}{\sqrt{3}}$.

*Ex.* 11. Let $\frac{1-\sqrt{1-x^2}}{1+\sqrt{1-x^2}}=a$;
Then $1-\sqrt{1-x^2}=a+a\sqrt{1-x^2}$
And $1-a=a\sqrt{1-x^2}+\sqrt{1-x^2}=(1+a)\sqrt{1-x^2}$,
Whence $\frac{1-a}{1+a}=\sqrt{1-x^2}$;
And, taking the square of both sides, $\frac{(1-a)^2}{(1+a)^2}=1-x^2$,
Therefore, by transposition, $x^2=1-\frac{(1-a)^2}{(1+a)^2}$,
That is, $x^2=\frac{(1+a)^2-(1-a)^2}{(1+a)^2}=\frac{4a}{(1+a)^2}$,
Therefore $x=\frac{\sqrt{a}}{1+a}$.

*Ex.* 12. Let $a+x=\sqrt{a^2+x\sqrt{b^2+x^2}}$,
Then $(a+x)^2=a^2+x\sqrt{b^2+x^2}$,
That is, $a^2+2ax+x^2=a^2+x\sqrt{b^2+x^2}$,
Therefore $2ax+x^2=x\sqrt{b^2+x^2}$,
And dividing by $x$, $2a+x=\sqrt{b^2+x^2}$.
Again, taking the squares of both sides, $4a^2+4ax+x^2=b^2+x^2$,
Whence $4a^2+4ax=b^2$,
And $4ax=b^2-4a^2$; so that $x=\frac{b^2-4a^2}{4a}$.

In all these examples we have been able to determine the value of the unknown quantity by the rules already delivered, because in every case the first, or at most the second power of that quantity, has been made to stand alone on one side of the equation, while the other consisted only of known quantities; but the same methods of reduction serve to bring equations of all degrees to a proper form for solution. Thus, if $\frac{1-p+q+r}{x+1}=1-p-x+\frac{r}{x}$; by proper reduction, we have $x^3+px^2+qx=r$, a cubic equation, which may be resolved by rules to be afterwards explained.

## Sect. VII.—Of the Reduction of Equations involving more than one Unknown Quantity.

70. Having shown in the last section in what manner an equation involving one unknown quantity may be resolved, or at least fitted for a final solution, we are next to explain the methods by which two or more equations, involving as many unknown quantities, may at last be reduced to one equation and one unknown quantity.

As the unknown quantities may be combined together in very different ways, so as to constitute an equation, the methods most proper for their elimination must therefore be various. The three following, however, are of general application, and the last of them may be used with advantage, not only when the unknown quantity to be eliminated rises to the same power in all the equations, but also when the equations contain different powers of that quantity.

71. *Method* 1. Observe which of the unknown quantities is the least involved, and let its value be found from each equation, by the rules of last section.

Let the values thus found be put equal to each other, and hence new equations will arise, from which that quantity is wholly excluded. Let this operation be now repeated with these equations, thus eliminating the unknown quantities one by one, till at last an equation be found which contains only one unknown quantity.

*Ex.* Let it be required to determine $x$ and $y$ from these two equations.

$$2x+3y=23,$$
$$5x-2y=10.$$

From the first equation, $2x=23-3y$,
And $x=\frac{23-3y}{2}$.
From the second equation, $5x=10+2y$,
And $x=\frac{10+2y}{5}$.
Let these values of $x$ be now put equal to each other,
And we have $\frac{10+2y}{5}=\frac{23-2y}{2}$,
Or $20+4y=125-15y$;
Therefore $19y=95$,
And $y=5$:
And since $x=\frac{23-3y}{2}$, or $x=\frac{10+2y}{5}$, from either of these values we find $x=4$.

72. *Method* 2. Let the value of the unknown quantity which is to be eliminated be found from that equation wherein it is least involved. Let this value and its powers be substituted for that quantity, and its respective powers in the other equations; and with the new equations thus arising, let the operation be repeated till there remain only one equation and one unknown quantity.

*Ex.* Let the given equations, as in last method, be

$$2x+3y=23,$$
$$5x-2y=10.$$

From the first equation, $x=\frac{23-3y}{2}$;

And this value of $x$ being substituted in the second equation, we have $5\times\frac{23-3y}{2}-2y=10$,

Or $115-15y-4y=20$;
Therefore $95=19y$,
And $5=y$,
And hence $x=\frac{23-3y}{2}=4$, as before.

73. *Method* 3. Let the given equations be multiplied or divided by such numbers or quantities, whether known or unknown, that the term which involved the highest power of the unknown quantity may be the same in each equation.

Then, by adding or subtracting the equations, as occasion may require, that term will vanish, and a new equation emerge, wherein the number of dimensions of the unknown quantity in some cases, and in others the number of unknown quantities, will be diminished; and by a repetition of the same or similar operations, a final equation may be at last obtained, involving only one unknown quantity.

*Ex.* Let the same example be taken, as in the illustration of the former methods, namely,

$$2x+3y=23,$$
$$5x-2y=10;$$

and from these equations we are to determine $x$ and $y$. To eliminate $x$, let the first equation be multiplied by 5, and the second by 2; thus we have

$$10x+15y=115,$$
$$10x-\ 4y=\ 20.$$

Here the term involving $x$ is the same in both equations; and it is obvious, that by subtracting the one from the other, the resulting equation will contain only $y$, and known numbers; for by such subtraction we find $19y=95$, and therefore $y=5$.

Having got the value of $y$, it is easy to see how $x$ may be found, from either of the given equations; but it may also be found in the same manner as we found $y$. For let the first of the given equations be multiplied by 2, and the second by 3, and we have

$$4x+6y=46,$$
$$15x-6y=30.$$

By adding these equations, we find

$$19x=76, \text{ and } y=4.$$

74. The following examples will serve further to illustrate these different methods of eliminating the unknown quantities from equations.

*Ex.* 1. Given $\left\{\begin{array}{l}\frac{x}{2}+\frac{y}{3}=16,\\ \frac{x}{5}-\frac{y}{9}=\ 2;\end{array}\right\}$ required $x$ and $y$.

*By Method* 1.

From the first equation, $x=32-\frac{2y}{3}$,

And from the second, $x=10+\frac{5y}{9}$;

Therefore $10+\frac{5y}{9}=32-\frac{2y}{3}$,
Or $90+5y=288-6y$;
Hence $11y=198$ and $y=18$.

The value of $y$ being substituted in either of the values of $x$, namely, $32-\frac{2y}{3}$, or $10+\frac{5y}{9}$, we find $x=20$.

*By Method* 2.

Having found from the first equation

$$x=32-\frac{2y}{3},$$

let this value of $x$ be substituted in the second, and

$$\frac{1}{5}\left(32-\frac{2y}{3}\right)-\frac{y}{9}=2,$$

Or $\frac{32}{5}-\frac{2y}{15}-\frac{y}{9}=2$;

Hence $198=11y$ and $y=18$.

The value of $y$ being now substituted in either of the given equations, we thence find $x=20$, as before.

*By Method* 3.

The denominators of the two given equations being taken away by rule 3 of last section, we have

$$3x+2y=96,$$
$$9x-5y=90.$$

From three times the first of these, or $9x+6y=288$, let the second be subtracted, there remains

$$11y=198 \text{ and } y=18.$$

The value of $y$ being now substituted in either of the equations $3x+2y=96$, $9x-5y=90$, we readily find $x=20$.

75. Having shown in what way the different methods of eliminating the unknown quantities may be applied, we shall, in the remaining examples of this section, chiefly make use of the last method, because it is the most easy and expeditious in practice.

*Ex.* 2. Given $\left\{\begin{array}{l}\frac{x}{2}-12=\frac{y}{4}+8,\\ \frac{x+y}{5}+\frac{x}{3}-8=\frac{2y-x}{4}+27.\end{array}\right.$

It is required to determine $x$ and $y$.

From the 1st equation, $4x-96=2y+64$;
From the 2d, $12x+12y+20x-480=30y-15x+1620$.
These equations, when abridged, become

$$4x-2y=160,$$
$$47x-18y=2100.$$

To eliminate $y$; from this last equation let 9 times the one preceding it be subtracted.

Thus we find $11x=660$, and $x=60$;
And because $2y=4x-160=80$,
Therefore $y=40$.

*Ex.* 3. Given $\left\{\begin{array}{l}ax+by=c\\ dx+fy=g\end{array}\right\}$ to determine $x$ and $y$.

To eliminate $y$, let the first equation be multiplied by $f$, and the second by $b$, and we have

$$afx+bfy=cf,$$
$$bdx+bfy=bg.$$

Taking now the difference between these equations,

$$afx-bdx=cf-bg,$$
Or $(af-bd)x=cf-bg$,
And therefore $x=\frac{cf-bg}{af-bd}$.

In the same manner may $y$ be determined, by multiplying the first of the given equations by $d$, and the second by $a$; for we find

$$adx+bdy=cd,$$
$$adx+afy=ag.$$

And taking the difference as before, we get

$$bdy-afy=cd-ag,$$

And therefore $$y=\frac{cd-ag}{bd-af}.$$

This last example may be considered as a general solution of the following problem. Two equations expressing the relation between the first powers of two unknown quantities being given, to determine those quantities; for whatever be the number of terms in each equation, it will readily appear, as in example 2, that by proper reduction they may be brought to the same form as those given in the third example.

76. Let us next consider such equations as involve three unknown quantities.

*Ex.* 4. Given $\left.\begin{cases} x+y+z\quad=29 \\ x+2y+3z=62 \\ \frac{x}{2}+\frac{y}{3}+\frac{z}{4}\quad=10 \end{cases}\right\}$ to find $x$, $y$, and $z$.

We shall in this example proceed by the first method for eliminating the unknown quantities.

From the first equation, $x=29-y-z$,
From the second, $x=62-2y-3z$,
From the third, $x=20-\frac{2y}{3}-\frac{z}{2}$.

Let these values of $x$ be put equal to each other; thus we get the two following equations:

$$29-y-z=62-2y-3z,$$
$$29-y-z=20-\frac{2y}{3}-\frac{z}{2}.$$

Again, from these equations, by transposition, &c.

$$y=33-2z,$$
$$y=27-\frac{3z}{2}.$$

Therefore $$33-2z=27-\frac{3z}{2}.$$

And hence, by reduction, $z=12$;
Whence also, $y=33-2z=9$,
And $x=29-y-z=8$.

*Ex.* 5. Given $\left.\begin{cases} \frac{x}{2}+\frac{y}{3}+\frac{z}{4}=62 \\ \frac{x}{3}+\frac{y}{4}+\frac{z}{5}=47 \\ \frac{x}{4}+\frac{y}{5}+\frac{z}{6}=38 \end{cases}\right\}$ to find $x$, $y$, and $z$.

Here the given equations, when cleared from fractions, become

$$12x+8y+6z=1488,$$
$$20x+15y+12z=2820,$$
$$30x+24y+20z=4560.$$

To eliminate $z$ by the third method, let the first equation be multiplied by 10, the second by 5, and the third by 3, the results will be these:

$$120x+80y+60z=14880,$$
$$100x+75y+60z=14100,$$
$$90x+72y+60z=13680.$$

Let the second equation be now subtracted from the first, and the third from the second, and we have

$$20x+5y=780,$$
$$10x+3y=420.$$

Next, to eliminate $y$, let the first of these equations be multiplied by 3, and the second by 5; hence,

$$60x+15y=2340,$$
$$50x+15y=2100.$$

Subtracting now the latter equation from the former,

$$10x=240 \text{ and } x=24,$$

Therefore $$y=\frac{420-10x}{3}=60,$$

And $$z=\frac{1448-12x-8y}{6}=120.$$

77. From the preceding examples, it is manifest in what manner any number of unknown quantities may be determined by an equal number of equations, which contain only the first power of those quantities, in the numerators of the terms. Such are the following:

$$ax+by+cz=n,$$
$$dx+cy+fz=p,$$
$$gx+hy+kz=q;$$

where $a$, $b$, $c$, &c. represent known, and $x$, $y$, $z$, unknown quantities; and in every case the unknown quantities may be directly found, for they will be always expressed by whole numbers or rational fractions, provided that the known quantities, $a$, $b$, $c$, &c. are also rational.

78. We shall now add a few examples, in which the equations that result from the elimination of an unknown quantity rise to some of the higher degrees; and therefore their final solution must be referred to the sections which treat of those degrees.

*Ex.* 6. Let $x-y=2$, and $xy+5x-6y=120$; it is required to eliminate $x$.

From the first equation $x=y+2$; which value being substituted in the other equation according to the second general method (sect. 72) it becomes

$$(y+2)y+5(y+2)-6y=120,$$
that is, $y^2+2y+5y+10-6y=120$;
therefore the equation required is $y^2+y=110$.

*Ex.* 7. There is given $x+y=a$, and $x^2y^2=b$, to eliminate $x$.

From the first equation $x=a-y$, and $x^2=(a-y)^2$,
And from the second $x^2=b-y^2$;
Therefore $(a-y)^2=b-y^2$;
That is, $a^2-2ay+y^2=b-y^2$.

Hence $2y^2-2ay=b-a^2$; an equation involving only $y$.

*Ex.* 8. Given $\left.\begin{cases} axy+bx+cy=d \\ fxy+gx+hy=k \end{cases}\right\}$ to eliminate $y$.

From the first equation $y=\frac{d-bx}{ax+c}$,

And from the second $y=\frac{k-gx}{fx+h}$;

Therefore $$\frac{d-bx}{ax+c}=\frac{k-gx}{fx+h},$$

an equation in which the unknown quantity $y$ is not found.

*Ex.* 9. Given $\left.\begin{cases} y^2-3xy+ay=x^2 \\ y^2+2ax-by=4x^2-b^2 \end{cases}\right\}$ to eliminate $y$.

As the co-efficient of $y^2$ is unity in both equations, if their difference be taken, the highest power of $y$ will vanish; but to give a general solution, let the terms of the equations be all brought to one side and made equal to 0, thus,

$$y^2-(3x-a)\,y-x^2=0,$$
$$y^2-by+2ax-4x^2+b^2=0.$$

In the first equation put $1 = A$, $-(3x - a) = B$, $-x^2 = C$; and in the second, $1 = D$, $-b = E$, $2ax - 4x^2 + b^2 = F$; and the two become

$$Ay^2 + By + C = 0,$$
$$Dy^2 + Ey + F = 0.$$

To eliminate $y^2$, let the first equation be multiplied by D, and the second by A; then

$$ADy^2 + BDy + CD = 0,$$
$$ADy^2 + AEy + AF = 0.$$

Therefore, taking the difference of these equations,

$$(BD - AE)y + CD - AF = 0,$$

And $$y = \frac{AF - CD}{BD - AE}.$$

Again, to find another value of $y$, multiply the first equation by F, and the second by C; then

$$AFy^2 + BFy + CF = 0,$$
$$CDy^2 + CEy + CF = 0.$$

Therefore, subtracting as before,

$$(AF - CD)y^2 + (BF - CE)y = 0,$$

And dividing by $y$, $(AF - CD)y + BF - CE = 0.$

Therefore $y = \dfrac{CE - BF}{AF - CD}.$

Let this value of $y$ be put equal to the former, then

$$\frac{AF - CD}{BD - AE} = \frac{CE - BF}{AF - CD};$$

And therefore $(AF - CD)^2 = (BD - AE)(CE - BF)$.

Now, as $y$ does not enter this equation, if we restore the values of A, B, C, &c. we have the following equation, which involves only $x$ and known quantities. $(b^2 + 2ax - 3x^2)^2 = [a + b - 3x]\,[bx^2 - (a - 3x)(2ax - 4x^2 + b^2)]$. This equation, when properly reduced, will be of the fourth order, and therefore its final resolution belongs not to this place.

## Sect. VIII.—Questions producing Simple Equations.

79. When a problem is proposed to be resolved by the algebraic method of analysis, its true meaning ought in the first place to be perfectly understood, so that, if necessary, it may be freed from all superfluous and ambiguous expressions, and its conditions exhibited in the clearest point of view possible. The several quantities concerned in the problem are next to be denoted by proper symbols, and their relation to one another expressed agreeably to the algebraic notation. Thus we shall obtain a series of equations, which, if the question be properly limited, will enable us to determine all the unknown quantities required by the rules already delivered in the two preceding sections.

80. In reducing the conditions of a problem to equations, the following rule will be of service. Suppose that the quantities to be determined are actually found, and then consider by what operations the truth of the solution may be verified; then let the same operations be performed upon the quantities, whether known or unknown, and thus all the conditions of the problem will be reduced to a series of equations, such as is required. For example, suppose that it is required to find two numbers, such, that their sum is 20, and the quotient arising from the division of their difference by the lesser 3; then if we denote the greater of the two numbers by $x$, and the lesser by $y$, and proceed as if to prove the truth of the solution, we shall have $x + y$ for the sum of the numbers, and $x - y$ for their difference. Now, as the former must be equal to 20, and the latter divided by $y$ equal to 3, the first condition of the problem will be expressed by this equation, $x + y = 20$, and the second by $\dfrac{x - y}{y} = 3$; and from these the values of $x$ and $y$ may easily be found.

81. When the conditions of a problem have been expressed by equations, or translated from the common language into that of algebra, we must consider whether the problem be properly limited; for in some cases the conditions may be such as to admit of innumerable solutions, and in others they may involve an absurdity, and thus render the problem altogether impossible.

Now, by considering the examples of last section, it will appear, that to determine any number of unknown quantities, there must be given as many equations as there are unknown quantities. These, however, must be such as cannot be derived from each other, and they must not involve any contradiction; for in the one case the problem would admit of an unlimited number of answers, and in the other case it would be impossible. For example, if it were required to determine $x$ and $y$ from these two equations, $2x - 3y = 13$, $4x - 6y = 26$; as the latter equation is a consequence of the former (for each term of the one is the half of the corresponding term of the other), it is evident, that innumerable values of $x$ and $y$ might be found to satisfy both equations. Again, if $x$ and $y$ were to be determined from these equations, $x + 2y = 8$, $3x + 6y = 26$, it is easy to see that it is impossible to find such values of $x$ and $y$ as will satisfy both; for, from the first, we find $3x = 24 - 6y$; and from the second, $3x = 26 - 6y$; and therefore $24 - 6y = 26 - 6y$, or $24 = 26$, which is absurd; and so also must have been the conditions from which this conclusion is drawn.

82. But there is yet another case in which a problem may be impossible; and that is, when there are more equations than unknown quantities; for it appears, that in this case, by the rules of last section, we would at last find two equations, each involving the same unknown quantity. Now, unless these happened to agree, the problem would admit of no solution. On the whole therefore it appears, that a problem is limited when the conditions furnish just as many independent equations as there are known quantities to be determined: if there be fewer, the problem is indeterminate; but if there be more, the problem in general admits of no solution whatever.

83. In expressing the conditions of a problem by equations, it will sometimes be convenient to introduce as few symbols of unknown quantities as possible. Therefore, if two quantities be sought and their sum be given, suppose it $= s$; then if the one quantity be represented by $x$, the other may be denoted by $s - x$. If, again, their difference be given $= d$, the quantities may be denoted by $x$, and $d + x$, or by $x$, and $x - d$. If their product be given $= p$, the quantities are $x$, and $\dfrac{p}{x}$; and so on.

84. We shall now apply the preceding observations to some examples, which are so chosen as to admit of being resolved by simple equations.

*Ex.* 1. What is that number, to which if there be added its half, its third, and its fourth parts, the sum will be 50?

Let $x$ denote the number sought; then its half will be $\dfrac{x}{2}$, its third $\dfrac{x}{3}$, and its fourth $\dfrac{x}{4}$;

Therefore $$x + \frac{x}{2} + \frac{x}{3} + \frac{x}{4} = 50.$$

Hence $$24x + 12x + 8x + 6x = 1200,$$

Or $$50x = 1200;$$

Therefore $$x = 24.$$

Thus it appears, that the number sought is 24, which upon trial will be found to answer the conditions of the question.

*Ex.* 2. A post is $\frac{1}{4}$ of its length in the mud, $\frac{1}{3}$ in the water, and 10 feet above the water; what is its whole length?

Let its length be $x$ feet, then the part in the mud is $\frac{x}{4}$, and that in the water $\frac{x}{3}$; therefore, from the nature of the question,

$$\frac{x}{4}+\frac{x}{3}+10=x.$$

From this equation we find $7x+120=12x$, and $x=24$.

*Ex.* 3. Two travellers set out at the same time from London and York, the distance between which places is 150 miles; the one goes 8 miles a day, and the other 7: in what time will they meet?

Suppose that they meet after $x$ days.

Then the one traveller has gone $8x$ miles, and the other $7x$ miles; now the sum of the distances they travel is, by the question, equal to the distance from London to York.

Therefore $8x+7x=150$,

That is, $15x=150$, and $x=10$ days.

*Ex.* 4. A labourer engaged to serve for 40 days, upon these conditions; that for every day he worked he was to receive 20d., but for every day he played or was absent, he was to forfeit 8d.: now at the end of the time he had to receive L.1. 11s. 8d. It is required to find how many days he worked, and how many days he was idle.

Let $x$ be the number of days he worked;

Then will $40-x$ be the number of days he was idle,

Also $20\times x=20x=$ the sum he earned in pence,

And $8\times(40-x)=320-8x=$ the sum he forfeited.

Now the difference of these two was L.1. 11s. 8d. or 380d.;

Therefore $20x-(320-8x)=380$;

That is, $28x=700$.

Hence $x=25=$ the number of days he worked,

And $40-x=15=$ the number of days he was idle.

*Ex.* 5. A market-woman bought a certain number of eggs at 2 a penny, and as many at 3 a penny, and sold them all out again at 5 for 2d.; but, instead of getting her own money for them, as she expected, she lost 4d.: what number of eggs did she buy?

Let $x$ be the number of eggs of each sort;

Then will $\frac{x}{2}$ be the price of the first sort,

And $\frac{x}{3}=$ the price of the second sort.

Now, the whole number being $2x$, we have

$5:2x::2:\frac{4x}{5}=$ price of both sorts at 5 for 2d.;

Therefore $\frac{x}{2}+\frac{x}{3}-\frac{4x}{5}=4$, by the question.

Hence $15x+10x-24x=120$,

And $x=120$, the number of each sort.

*Ex.* 6. A bill of L.120 was paid in guineas and moidores: the number of pieces of both sorts used was 100; how many were there of each?

Let the number of guineas be $x$;

Then the number of moidores will be $100-x$;

Also the value of the guineas, reckoned in shillings, will be $21x$, and that of the moidores $27(100-x)=2700-27x$;

Therefore, by the question, $21x+2700-27x=2400$.

Hence $6x=300$, and $x=50$;

So that the number of pieces of each sort was 50.

*Ex.* 7. A footman agreed to serve his master for L.8 a year and livery, but was turned away at the end of 7 months, and received only L.2. 13s. 4d. and his livery; what was its value?

Suppose $x$ the value of the livery, in pence.

Then his wages for a year were to be $x+1920$ pence.

But for 7 months he received $x+640$ pence.

Now he was paid in proportion to the time he served;

Therefore $12:7::x+1920:x+640$.

And, taking the product of the extremes and means,

$$12x+7680=7x+13440.$$

Hence $5x=5760$d. and $x=1152$d.$=$L.4. 16s.

*Ex.* 8. A person at play lost $\frac{1}{4}$ of his money, and then won 3s.; after which he lost $\frac{1}{3}$ of what he then had, and then won 2s.; lastly, he lost $\frac{1}{7}$ of what he then had; and, this done, found he had only 12s. left: what had he at first?

Suppose he began to play with $x$ shillings.

He lost $\frac{1}{4}$ of his money, or $\frac{x}{4}$, and had left $x-\frac{x}{4}=\frac{3x}{4}$.

He won 3s. and had then $\frac{3x}{4}+3=\frac{3x+12}{4}$.

He lost $\frac{1}{3}$ of $\frac{3x+12}{4}$, or $\frac{x+4}{4}$, and had left

$\frac{3x+12}{4}-\frac{x+4}{4}=\frac{2x+8}{4}$.

He won 2s. and had then $\frac{2x+8}{4}+2=\frac{2x+16}{4}$.

He lost $\frac{1}{7}$ of $\frac{2x+16}{4}$ or $\frac{2x+16}{28}$, and had left

$\frac{2x+16}{4}-\frac{2x+16}{28}=\frac{12x+96}{28}$.

And because he had now 12s. left, we have this equation,

$$\frac{12x+96}{28}=12.$$

Hence $12x=240$, and $x=20$.

*Ex.* 9. Two tradesmen, A and B, are employed upon a piece of work; A can perform it alone in 15 hours, and B in 10 hours: in what time will they do it when working together?

Suppose that they can do it in $x$ hours, and let the whole work be denoted by 1.

Then $15:x::1:\frac{x}{15}=$ the part of the work done by A.

And $10:x::1:\frac{x}{10}$, the part done by B.

Now, by the question, they are to perform the whole work between them;

Therefore $\frac{x}{15}+\frac{x}{10}=1$.

Hence $25x=150$, and $x=6$ hours.

*Ex.* 10. The sum of any two quantities being given $=s$, and their difference$=d$, it is required to find each of the quantities.

Let $x$ denote the greater of the two quantities, and $y$ the lesser.

Then $x+y=s$, and $x-y=d$.

Taking the sum of the equations, we get $2x=s+d$,

And, subtracting the second from the first, $2y=s-d$;

Therefore $x=\frac{s+d}{2}$, and $y=\frac{s-d}{2}$.

*Ex.* 11. A gentleman distributing money among some poor people, found he wanted 10s. to be able to give each 5s.; therefore he gave only 4s. to each, and had 5s. left. Required the number of shillings and poor people.

Let the number of shillings be $x$, and that of the poor people $y$; then, from the nature of the question, we have these two equations,

$$5y=x+10 \qquad 4y=x-5.$$

From the first equation, $x=5y-10$,
And from the second, $x=4y+5$;
Therefore $5y-10=4y+5$;
Hence $y=15$, and $x=4y+5=65$.

*Ex.* 12. A farmer kept a servant for every 40 acres of ground he rented, and on taking a lease of 104 more acres, he engaged 5 additional servants, after which he had a servant for every 36 acres. Required the number of servants and acres.

Suppose that he had at first $x$ servants, and $y$ acres.

From the first condition of the question, $x=\frac{y}{40}$;

And from the second, $x+5=\frac{y+104}{36}$.

By comparing the values of $x$, as found from these equations, we have

$$\frac{y+104}{36}-5=\frac{y}{40}.$$

Hence $40y+4160-7200=36y$, so that $4y=3040$;

Therefore $y=760$, and $x=\frac{y}{40}=19$.

*Ex.* 13. Two persons, A and B, were talking of their ages; says A to B, seven years ago I was just three times as old as you were then, and seven years hence I shall be just twice as old as you will be. What is their present ages?

Let the ages of A and B be $x$ and $y$ respectively. Their ages seven years ago were $x-7$ and $y-7$, and seven years hence they will be $x+7$ and $y+7$.

Therefore by the question

$$x-7=3(y-7) \text{ and } x+7=2(y+7).$$

From the first equation, $x=3y-14$,
And from the second, $x=2y+7$;
Therefore $3y-14=2y+7$; hence $y=21$.
And because $x=2y+7$, therefore $x=49$.

*Ex.* 14. A hare is 50 leaps before a greyhound, and takes 4 leaps to the greyhound's 3, but 2 of the greyhound's leaps are as much as 3 of the hare's. How many leaps must the greyhound take to catch the hare?

In this example there is only one quantity required, it will, however, be convenient to make use of two letters; therefore let $x$ denote the number of leaps of the greyhound, and $y$ those of the hare; then, by considering the proportion between the number of leaps each takes in the same time, we have

$$3:4::x:y, \text{ hence } 3y=4x.$$

Again, by considering the proportion between the number of leaps each must take to run the same distance, we find $x:50+y::2:3$, hence $100+2y=3x$.

From the first equation we find $6y=8x$,
And from the second $6y=9x-300$.
Hence $9x-300=8x$, and $x=300$.

*Ex.* 15. To divide the number 90 into 4 such parts, that if the first be increased by 2, the second diminished by 2, the third multiplied by 2, and the fourth divided by 2, the sum, difference, product, and quotient, shall be all equal to each other.

In this question there are four quantities to be determined; but instead of introducing several letters, having put $x$ to denote the first of them, we may find an expression for each of the remaining ones, as follows:

Because $x+2=$second quantity $-2$,
Therefore $x+4=$the second quantity;
And because $x+2=$third $\times 2$,
Therefore $\frac{x+2}{2}=$the third quantity.

And in like manner $2(x+2)=$ the fourth quantity.
Now, by the question, the sum of all the four $=90$;

Therefore $x+x+4+\frac{x+2}{2}+2(x+2)=90$.

Hence $9x=162$, and $x=18$;
Therefore the numbers required are 18, 22, 10, and 40.

*Ex.* 16. A and B together can perform a piece of work in 12 hours, A and C in 20, and B and C in 15 hours; in what time will each be able to perform it when working separately?

That we may have a general solution, let us suppose A and B can perform the work in $a$ hours, A and C in $b$ hours, and B and C in $c$ hours. Let $x$, $y$, and $z$, denote the times in which A, B, and C, could perform it respectively, if each wrought alone; and let the whole work be represented by 1.

H H

$$\left.\begin{aligned} \text{Then } x:a::1:\frac{a}{x}&=\text{ the part done by A} \\ y:a::1:\frac{a}{y}&=\text{ the part done by B} \end{aligned}\right\} \text{in } a \text{ hours.}$$

$$\left.\begin{aligned} \text{Also } x:b::1:\frac{b}{x}&=\text{ the part done by A} \\ z:b::1:\frac{b}{z}&=\text{ the part done by C} \end{aligned}\right\} \text{in } b \text{ hours.}$$

$$\left.\begin{aligned} \text{And } y:c::1:\frac{c}{y}&=\text{ the part done by B} \\ z:c::1:\frac{c}{z}&=\text{ the part done by C} \end{aligned}\right\} \text{in } c \text{ hours.}$$

The question gives the three following equations;

$$\frac{a}{x}+\frac{a}{y}=1, \qquad \frac{b}{x}+\frac{b}{z}=1, \qquad \frac{c}{y}+\frac{c}{z}=1.$$

Let the first equation be divided by $a$, the second by $b$, and the third by $c$: thus we have

$$\frac{1}{x}+\frac{1}{y}=\frac{1}{a}, \quad \frac{1}{x}+\frac{1}{z}=\frac{1}{b}, \quad \frac{1}{y}+\frac{1}{z}=\frac{1}{c}.$$

If these be added, and their sum divided by 2, we find

$$\frac{1}{x}+\frac{1}{y}+\frac{1}{z}=\frac{1}{2a}+\frac{1}{2b}+\frac{1}{2c}.$$

From this equation let each of the three preceding be subtracted in its turn: thus we get

$$\frac{1}{z}=-\frac{1}{2a}+\frac{1}{2b}+\frac{1}{2c}=\frac{+ab+ac-bc}{2abc},$$

$$\frac{1}{y}=\frac{1}{2a}-\frac{1}{2b}+\frac{1}{2c}=\frac{ab-ac+bc}{2abc},$$

$$\frac{1}{x}=\frac{1}{2a}+\frac{1}{2b}-\frac{1}{2c}=\frac{-ab+ac+bc}{2abc}.$$

Algebra.

$$\text{Hence } z=\frac{2abc}{+ab+ac-bc}=\frac{7200}{120}=60,$$

$$y=\frac{2abc}{+ab-ac+bc}=\frac{7200}{360}=20,$$

$$x=\frac{2abc}{-ab+ac+bc}=\frac{7200}{240}=30.$$

### Sect. IX.—Of Quadratic Equations.

85. We are next to explain the resolution of equations of the second degree, or quadratic equations. These involve the second power of the unknown quantity, and may be divided into two kinds, *pure* and *adfected.*

I. *Pure* quadratic equations are such as after proper reduction have the square of the unknown quantity in one term, while the remaining terms contain only known quantities. Thus, $x^2=64$, and $ax^2+b=c$, are examples of pure quadratics.

II. *Adfected* quadratic equations contain the square of the unknown quantity in one term, and its first or simple power in another; the remaining terms consisting entirely of known quantities. Such are the following, $x^2+3x=28$, $2x^2=33-5x$, $ax^2+bx-c=d$.

The manner of resolving a pure quadratic equation is sufficiently evident. If the unknown quantity be made to stand alone on one side, with unity as a co-efficient, while the other side consists entirely of known quantities, and the square root of each side be taken, we immediately obtain the value of the simple power of the unknown quantity as directed by rule 5th of sect. VI.

86. In extracting the square root of any quantity, it is necessary to observe, that the sign of the root may be either $+$ or $-$. This is an evident consequence of the rule for the signs in multiplication; for since by that rule any quantity, whether positive or negative, if multiplied by itself, will produce a positive quantity, and therefore the square of $+a$, as well as that of $-a$, is $+a^2$; so, on the contrary, the square root of $+a^2$ is to be considered either as $+a$ or as $-a$, and may accordingly be expressed thus, $\pm a$.

87. Having remarked that the square of any quantity, whatever be its sign, is always positive, it evidently follows that no real quantity whatever, when multiplied by itself, can produce a negative quantity; therefore, if the square root of a negative quantity be required, no such root can be assigned. Hence it also follows, that if a problem requires for its solution the extraction of the square root of a negative quantity, some contradiction must necessarily be involved, either in the condition of the problem, or in the process of reasoning by which that solution has been obtained.

88. When an adfected quadratic equation is to be resolved, it may always, by proper reduction, be brought to one or other of the three following forms:

1. $x^2+px=q$.
2. $x^2-px=q$.
3. $x^2-px=-q$.

But as the manner of resolving each of the three forms is the very same, it will be sufficient if we consider any one of them.

Resuming therefore the first equation, or $x^2+px=q$, let us compare the side of it which involves the unknown quantity $x$ with the square of a binomial $x+a$; that is, let us compare $x^2+px$ with $x^2+2ax+a^2=(x+a)^2$, and it will presently appear, that if we suppose $p=2a$, or $\frac{p}{2}=a$, the quantities $x^2+px$ and $x^2+2ax$ will be equal; and as $x^2+2ax$ is rendered a complete square, by adding to it $a^2$, so also may $x^2+px$ be completed into a square by adding to it $\frac{p^2}{4}$, which is equal to $a^2$; therefore, let $\frac{p^2}{4}$ be added to both sides of the equation $x^2+px=q$, and we have

Algebra.

$$x^2+px+\frac{p^2}{4}=\frac{p^2}{4}+q, \text{ or } \left(x+\frac{p}{2}\right)^2=\frac{p^2}{4}+q;$$

and, extracting the square root of each side, $x+\frac{p}{2}=\pm\sqrt{\frac{p^2}{4}+q}$; hence $x=-\frac{p}{2}\pm\sqrt{\frac{p^2}{4}+q}$.

89. From these observations we derive the following general rules for resolving adfective quadratic equations.

1. Bring all the terms involving the unknown quantity to one side, and the known quantities to the other side, and so that the term involving the square of the unknown quantity may be positive.

2. If the square of the unknown quantity be multiplied by a co-efficient, let the other terms be divided by it, so that the co-efficient of the square of the unknown quantity may be 1.

3. Add to both sides the square of half the co-efficient of the unknown quantity itself, and the side of the equation involving the unknown quantity will now be a complete square.

4. Extract the square root of both sides of the equation, by which it becomes simple with respect to the unknown quantity; and by transposition, that quantity may be made to stand alone on one side of the equation, while the other side consists of known quantities; and therefore the equation is resolved.

*Note.* The square root of the first side of the equation is always equal to the sum or difference of the unknown quantity, and half the co-efficient of the second term. If the sign of that term be $+$, it is equal to the sum, but if it be $-$, then it is equal to the difference.

*Ex.* 1. Given $x^2+2x=35$, to determine $x$.

Here the co-efficient of the second term is 2; therefore, adding the square of its half to each side, we have

$$x^2+2x+1=35+1=36,$$

And, extracting the square root, $x+1=\sqrt{36}=\pm 6$.

Hence $x=\pm 6-1$, that is $x=+5$, or $x-7$, and either of these numbers will be found to satisfy the equation, for $5\times 5+2\times 5=35$, also $-7\times-7+2\times-7=35$.

*Ex.* 2. Given $\frac{x^2}{6}-12=x$, to find $x$.

This equation, when reduced, becomes $x^2-6x=72$,
And, by completing the square, $x^2-6x+9=72+9=81$.
Hence, by extracting the square root, $x-3=\pm 9$, and $x=\pm 9+3$;
Therefore $x=+12$, or $x=-6$; and upon trial we find that each of these values satisfies the original equation, for $\frac{12\times 12}{6}-12=12$, also $\frac{-6\times-6}{6}-12=-6$.

*Ex.* 3. Given $x^2+28=11x$, to find $x$,
Then $x^2-11x=-28$.

And, by completing the square, $x^2-11x+\frac{121}{4}=\frac{121}{4}-28=\frac{9}{4}$.

Therefore, by extracting the root, $x-\frac{11}{2}=\pm\frac{3}{2}$.

Hence $x=\frac{11}{2}\pm\frac{3}{2}$; that is, $x=+7$, or $x=+4$.

In the first two examples, we found one positive value for $x$ in each, and also one negative value; but in this example both the values of $x$ are positive, and, upon trial, each of them is found to satisfy the equation; for $7\times7+28=11\times7$, also $4\times4+28=11\times4$.

90. As at first sight it appears remarkable, that in every quadratic equation the unknown quantity admits always of two distinct values or roots, it will be proper to consider a little further the circumstances upon which this peculiarity depends. This is the more necessary, as the property of the unknown quantity admitting of several values is not peculiar to quadratics, but takes place also in equations of the higher degrees, where the cause of the ambiguity requires an explanation somewhat different from that which we have already given in the present case.

91. Let us again consider the equation $x^2+2x=35$, which forms the first of the three preceding examples. By bringing all the terms to one side, the same equation may be also expressed thus, $x^2+2x-35=0$; so that we shall have determined $x$, when we have found such a number as, when substituted for it in the quantity $x^2+2x-35$, will render the result equal to 0. But $x^2+2x-35$ is the product of these two factors $x-5$ and $x+7$, as may be proved by actual multiplication; therefore, to find $x$, we have $(x-5)(x+7)=0$; and as a product can only become $=0$ when one of its factors is reduced to 0, it follows that either of the two factors $x-5$ and $x+7$ may be assumed $=0$. If $x-5=0$, then $x=5$; but if $x+7=0$, then $x=-7$; so that the two values of $x$, or two roots of the equation $x^2+2x=35$, are $+5$ and $-7$, as we have already found in a different manner.

92. What has been shown in a particular case is true of any quadratic equation whatever; that is, if $x^2+px=q$, or, by bringing all the terms to one side, $x^2+px-q=0$, it is always possible to find two factors $x-a$, and $x+b$, such, that

$$x^2+px+q=(x-a)(x+b),$$

where $a$ and $b$ are known quantities, which depend only upon $p$ and $q$, the given numbers in the equation; and since that to have $(x-a)(x+b)=0$, we may either assume $x-a=0$ or $x+b=0$, it evidently follows that the conditions of the equation $x^2+px-q=0$, or $x^2+px=q$, are alike satisfied by taking $x=+a$ or $x=-b$.

From these considerations it follows, that $x$ can have only two values in a quadratic equation; for if it could be supposed to have three or more values, then it would be possible to resolve $x^2+px-q$ into as many factors, $x-c$, $x-d$, &c.; but the product of more than two factors must necessarily contain the third or higher powers of $x$, and as $x^2+px-q$ contains no higher power than the second, therefore no such resolution can take place.

93. Since it appears that $x^2+px-q$ may be considered as the product of the two factors $x-a$ and $x+b$, let us examine the nature of these factors. Accordingly, taking their product, we find it $x^2+(b-a)x-ab$; and since this quantity must be equal to $x^2+px-q$, it follows that $b-a=p$ and $ab=q$, or, changing the signs of the terms of both equations, $a-b=-p$, $-ab=-q$. Now, if we consider that $+a$ and $-b$ are the roots of the equation $x^2+px=q$, it is evident that $a-b$ is the sum of the roots, and $-ab$ their product. So that from the equations $a-b=-p$, and $-ab=q$, we derive the following proposition relating to the roots of any quadratic equation. The sum of the roots of any quadratic equation $x^2+px=q$ is equal to $-p$, that is, to the co-efficient of the second term, having its sign changed; and their product is equal to $-q$, or to the latter side of the equation, having its sign also changed.

This proposition enables us to resolve several important questions concerning the roots of a quadratic equation, without actually resolving that equation. Thus we learn from it, that if $q$, the term which does not involve the unknown quantity (called sometimes the absolute number), be positive, the equation has one of its roots positive and the other negative; but if that term be negative, the roots are either both positive or both negative. It also follows, that in the former case the root which is denoted by the least number will have the same sign with the second term; and in the latter case, the common sign of the roots will be the contrary to that of the second term.

94. From this property of the roots we may also derive a general solution to any quadratic equation $x^2+px=q$; for we have only to determine two quantities whose sum is $-p$ and product $-q$, and these shall be the two values of $x$, or the two roots of the equation.

Without considering the signs of the roots, let us call them $v$ and $z$; then

$$v+z=-p, \text{ and } vz=-q.$$

From the square of each side of the first equation let four times the second be subtracted, and we have

$$v^2-2vz+z^2=p^2+4q, \text{ or } (v-z)^2=p^2+4q;$$

therefore, $v-z=\pm\sqrt{p^2+4q}$.

From this equation, and from the equation

$v+z=-p$, we readily obtain $v=\frac{-p\pm\sqrt{p^2+4q}}{2}$

$z=\frac{-p\mp\sqrt{p^2+4q}}{2}$; that is, if $v=\frac{-p+\sqrt{p^2+4q}}{2}$,

then $z=\frac{-p-\sqrt{p^2+4q}}{2}$; and if $v=\frac{-p-\sqrt{p^2+4q}}{2}$,

then $z=\frac{-p+\sqrt{p^2+4q}}{2}$.

But the value of $v$ upon the one supposition is the same as the value of $z$ upon the other supposition, and *vice versa;* therefore, in reality, the only two distinct values of the roots $v$ and $z$ are $\frac{-p+\sqrt{p^2+4q}}{2}$ and $\frac{-p-\sqrt{p^2+4q}}{2}$, which agrees with the conclusion we have already found (sect. 89).

95. It appears, from what has been already shown, that the roots of a quadratic equation $x^2+px=q$ always involve the quantity $\sqrt{p^2+4q}$; hence it follows, that $p^2+4q$ must be a positive quantity; for if it were negative, as the square root of such a quantity could not be found, the value of $x$ could not possibly be obtained. If, for example, the value of $x$ were required from this equation, $x^2+13=4x$, or $x^2-4x=-13$, we should find $x=2\pm\sqrt{-9}$; and as this expression for the roots requires us to extract the square root of $-9$, the equation from which it is derived must necessarily have involved some contradiction. It is not difficult to see wherein the absurdity consists; for since in this case $p=-4$, and $q=-13$, the roots of the equation ought to be both positive (sect. 93), and such that

their sum $= 4$, while their product $= 13$ (sect. 93), which is impossible.

96. Although imaginary quantities serve no other purpose in the resolution of quadratic equations than to show that a particular problem cannot be resolved, by reason of some want of consistency in its data, yet they are not upon that account to be rejected. By introducing them into mathematical investigations, many curious theories may be explained, and problems resolved, in a more concise way than can be done without the use of such quantities. This is particularly the case in the higher parts of the mathematics.

The method which has been applied to the resolution of quadratic equations properly so called, namely, such as are of this form, $x^2+px = q$, will also apply to all equations of this form,

$$x^{2n}+px^n = q,$$

where the unknown quantity $x$ is found only in two terms, and such that its exponent in the one term is double that in the other; for let us assume $x^n = y$, then $x^{2n} = y^2$, and therefore the equation

$$x^{2n}+px^n = q \text{ becomes}$$
$$y^2+py = q,$$

a quadratic equation, from which $x$ may be found, and thence $x$, by considering that $x = \sqrt[n]{y}$.

97. Although every quadratic equation admits of two roots, yet it will frequently happen that only one of them can be of use, the other being excluded by the conditions of the question. This will often be the case with respect to the negative root; as, for example, when the unknown quantity denotes a number of men, a number of days, &c. And hence, in reckoning the cases of quadratic equations, it is common to neglect this one, $x^2+px=-q$, where the roots are both negative; for an equation of this form can only be derived from a question which has some fault in its enunciation, and which, by a proper change in its form, will produce another equation having both its roots positive.

98. The remainder of this section shall be employed in solving some questions which produce quadratic equations.

*Ex.* 1. It is required to divide the number 10 into two such parts that the sum of their squares may be 58.

Let $x$ be the one number;

Then, since their sum is 10, we have $10-x$ for the other;

And by the question $x^2+(10-x)^2=58$;

That is, $x^2+100-20x+x^2=58$,

Or $2x^2-20x = 58-100= -42$;

Hence $x^2-10x = -21$.

And completing the square, $x^2-10x+25=25-21=4$;

Hence, by extracting the root, $x-5=\pm\sqrt{4}=\pm 2$

And $x=5\pm 2$,

That is, $x=7$, or $x=3$.

If we take the greatest value of $x$, viz. 7, the other number $10-x$ will be 3; and if we take the least value of $x$, viz. 3, then the other number is 7. Thus it appears, that the greatest value of the one number corresponds to the least of the other; and indeed this must necessarily be the case, seeing that both are alike concerned in the question. Hence, upon the whole, the only numbers that will answer the conditions of the question are 7 and 3.

*Ex.* 2. What two numbers are those whose product is 28; and such, that twice the greater, together with thrice the lesser, is equal to 26?

Let $x$ be the greatest and $y$ the least number; then, from the nature of the question, we have these two equations,

$$xy=28,\ 2x+3y=26.$$

From the first equation we have $y=\dfrac{28}{x}$,

And from the second $y=\dfrac{26-2x}{3}$.

Hence $\dfrac{26-2x}{3}=\dfrac{28}{x}$;

And, reducing, $26x-2x^2=84$,

Or $2x^2-26x=-84$,

Hence $x^2-13x=-42$.

And comp. the sq. $x^2-13x+\frac{169}{4}=\frac{169}{4}-42=\frac{1}{4}$.

Hence, by extracting the root, $x-\frac{13}{2}=\pm\sqrt{\frac{1}{4}}=\pm\frac{1}{2}$,

Therefore $x=\frac{13}{2}\pm\frac{1}{2}$;

That is, $x=7$, or $x=6$.

And since $y=\dfrac{28}{x}$, we have $y=4$, or $y=\frac{14}{3}$.

Thus we have obtained two sets of numbers, which fulfil the conditions required, viz.

$$x=7,\ y=4: \text{ Or } x=6,\ y=\tfrac{14}{3}.$$

And besides these, there can be no other numbers.

*Ex.* 3. A company dining together at an inn, find their bill amount to 175 shillings; two of them were not allowed to pay, and the rest found that their shares amounted to 10 shillings a man more than if they had all paid. How many were in company?

Suppose their number to be $x$.

Then, if all had paid, the share of each would have been $\dfrac{175}{x}$.

But because only $x-2$ paid, the share of each was $\dfrac{175}{x-2}$.

Therefore, by the question, $\dfrac{175}{x-2}-\dfrac{175}{x}=10$.

And, by reduction, $175x-175x+350=10x^2-20x$;

That is, $10x^2-20x=350$,

Or $x^2-2x=35$.

And comp. the sq. $x^2-2x+1=35+1=36$;

Hence, by extracting the root, $x^2+1=\pm 6$.

Therefore $x=+5$, or $x=-7$. But from the nature of the question, the negative root can be of no use; therefore $x=6$.

*Ex.* 4. A mercer sold a piece of cloth for L.24, and gained as much per cent. as the cloth cost him. What was the price of the cloth?

Suppose that it cost $x$ pounds;

Then the gain was $24-x$,

And, by the question, $100 : x :: x : 24-x$.

Therefore, taking the product of the extremes and means,

$$2400-100x=x^2,$$

Or $x^2+100x=2400$;

And comp. the sq. $x^2+100x+2500=4900$;

Hence, taking the root, $x+50=\pm 70$,

And $x=+20$ or $-120$.

Here, as in the last question, the negative root cannot apply; therefore $x=20$ pounds, the price required.

*Ex.* 5. A grazier bought as many sheep as cost him L.60, out of which he reserved 15, and sold the remainder for L.54, and gained 2s. each upon them. How many sheep did he buy, and what did each cost him?

Suppose that he bought $x$ sheep;

Then each would cost him $\frac{1200}{x}$ shillings.

Therefore, after reserving 15, he sold each of the remaining $x-15$ for $\frac{1200}{x}+2$ shillings.

Hence, he would receive for them $(x-15)(\frac{1200}{x}+2)$ shillings. And, because L.54=1080 shillings, we have by the question

$$(x-15)(\frac{1200}{x}+2)=1080;$$

Which, by proper reduction, becomes $x^2+45x=9000$;

And, completing the square, $x^2+45x+\frac{2025}{4}=\frac{38025}{4}$.

Therefore, extracting the root, &c. $x=\pm\frac{195}{2}-\frac{45}{2}$.

And, taking the positive root, $x=75$, the number of sheep; and consequently $\frac{1200}{75}=16$ shillings, the price of each.

*Ex.* 6. What number is that which, when divided by the product of its two digits, the quotient is 3; and if 18 be added to it, the digits are inverted?

Let $x$ and $y$ denote the digits; then the number itself will be expressed by $10x+y$, and that number in which the digits are inverted, by $10y+x$. Thus the conditions of the problem will be expressed by these two equations,

$$\frac{10x+y}{xy}=3,\ 10x+y+18=10y+x.$$

From the first equation we have $y=\frac{10x}{3x-1}$,

And from the second, $y=x+2$;

Therefore $x+2=\frac{10x}{3x-1}$,

And $3x^2+5x-2=10x$.

Hence, $x^2-\frac{5}{3}x=\frac{2}{3}$,

And comp. sq. $x^2-\frac{5}{3}x+\frac{25}{36}=\frac{25}{36}+\frac{2}{3}=\frac{49}{36}$;

Therefore, taking the root, $x-\frac{5}{6}=\pm\frac{7}{6}$,

So that $x=2$, or $x=-\frac{1}{3}$.

Here it is evident that the negative root is useless; hence, $y=x+2=4$, and 24 is the number required.

*Ex.* 7. Find two numbers whose product is 100, and the difference of their square roots 3.

Let $x$ be the one number; then $\frac{100}{x}$ is the other.

Now by the question, $\frac{10}{\sqrt{x}}-\sqrt{x}=3$;

Hence we have $10-x=3\sqrt{x}=3x^{\frac{1}{2}}$,

Or $x+3x^{\frac{1}{2}}=10$;

And comp. the sq. $x+3x^{\frac{1}{2}}+\frac{9}{4}=10+\frac{9}{4}=\frac{49}{4}$,

and taking the root, $x^{\frac{1}{2}}+\frac{3}{2}=\pm\frac{7}{2}$;

So that $x^{\frac{1}{2}}=+5$, or $x^{\frac{1}{2}}=-2$,

and therefore $x=25$, or $x=4$.

If $x=4$, the other number is $\frac{100}{4}=25$, and if $x=25$, then the other number is 4; so that, in either case, the two numbers which answer the conditions of the question are 4 and 25.

*Ex.* 8. It is required to find two numbers, of which the product shall be 6, and the sum of their cubes 35.

Let $x$ be the one number; then $\frac{6}{x}$ will be the other.

Therefore, by the question, $x^3+\frac{216}{x^3}=35$;

Hence $x^6+216=35x^3$,

Or $x^6-35x^3=-216$.

This equation, by putting $x^3=y$, becomes

$$y^2-35y=-216;$$

Hence we find $y=27$, or $y=8$.

And since $x^3=y$, therefore $x=3$, or $x=2$

If $x=3$, then the other number is 2, and if $x=2$, the other number is 3; so that 2 and 3 are the numbers required.

In general, if it be required to find two numbers which are exactly alike concerned in a question that produces a quadratic equation, they will be the roots of that equation. A similar observation applies to any number of quantities which require for their determination the resolution of an equation of any degree whatever.

### Sect. X.—Of Equations in general

99. Before we proceed to the resolution of cubic and the higher orders of equations, it will be proper to explain some general properties which belong to equations of every degree, and also certain operations which must frequently be performed upon equations before they be fitted for a final solution.

In treating of equations in general, we shall suppose all the terms brought to one side, and put equal to 0; so that an equation of the fourth degree will stand thus:

$$x^4+px^3+qx^2+rx+s=0,$$

where $x$ denotes an unknown quantity, and $p$, $q$, $r$, $s$, known quantities, either positive or negative. Here the co-efficient of the highest power of $x$ is unity, but had it been any other quantity, that quantity might have been taken away, and the equation reduced to the above form, by rules already explained (Sect. VI).

The terms being thus arranged, if such a quantity be found as, when substituted for $x$, will render both sides $=0$, and therefore satisfy the equation, that quantity, whether it be positive or negative, or even imaginary, is to be considered as a root of the equation. But we have seen that every quadratic equation has always two roots, real or imaginary; we may therefore suppose that a similar diversity will take place in all equations of a higher degree; and this supposition appears to be well founded, by the following proposition, which is of great importance in the theory of equations.

If a root of any equation, as $x^4+px^3+qx+r=0$, be represented by $a$, the first side of that equation is divisible by $x-a$;

For since $x^4+px^3+qx^2+rx+s=0$,

And also $a^4+pa^3+qa^2+ra+s=0$;

Therefore, by subtraction,

$$x^4-a^4+p(x^3-a^3)+q(x^2-a^2)+r(x-a)=0.$$

But any quantity of this form $x^n-a^n$, where $n$ denotes a whole positive number, is equal to

$$(x-a)(x^{n-1}+ax^{n-2}+a^2x^{n-3}+\ldots+a^{n-2}x+a^{n-1}),$$

as may be proved by multiplication; therefore, putting $x=4$, 3, and 2 successively, we have

$$x^4-a^4=(x-a)(x^3+ax^2+a^2x+a^3),$$
$$x^3-a^3=(x-a)(x^2+ax+a^2),$$
$$x^2-a^2=(x-a)(x+a),$$
$$x-a=(x-a);$$

and by substitution, and collecting into one term the co-efficients of the like powers of $x$, the equation becomes

$(x-a)[x^3+(a+p)x^2+(a^2+pa+q)x+a^3+pa^2+qa+r]=0$; so that, putting $p'=a+p$, $q'=a^2+pa+q$, $r'=a^3+pa^2+qa+r$, we have

$$x^4+px^3+qx^2+rx+s=(x-a)(x^3+p'x^2+q'x+r').$$

Hence, if the proposed equation $x^4+px^3+qx^2+rx+s$ be divided by $x-a$, the quotient will be $x^3+p'x^2+q'x+r'$, an integer quantity; and since the same mode of reasoning will apply to any equation whatever, the truth of the proposition is evident.

We have found that $(x-a)(x^3+p'x^2+q'x+r')=0$; and as a product becomes $=0$, when any one of its factors $=0$, therefore the equation will have its conditions fulfilled, not only when $x-a=0$, but also when $x^3+p'x^2+q'x+r'=0$.

Let us now suppose that $b$ is a root of this equation; then, by reasoning exactly as in last article, and putting $p''=b+p'$, $q''=b^2+p'b+q'$, we shall have

$$x^3+p'x^2+q'x+r'=(x-b)(x^2+p''x+q'')=0.$$

By proceeding in the same manner with the quadratic equation $x^2+p''x+q''=0$, we shall find that if $c$ denote one of its roots, then

$$x^2+p''x+q''=(x-c)(x+c+p'').$$

So that if we put $d=-(c+p'')$, we at last find $x^4+px^3+qx^2+rx+s=(x-a)(x-b)(x-c)(x-d)$; and since each of the factors $x-a$, $x-b$, $x-c$, $x-d$ may be assumed $=0$, it follows that there are four different values of $x$, which will render the equation $x^4+px^3+qx^2+rx+s=0$, namely, $x=a$, $x=b$, $x=c$, $x=d$.

The mode of reasoning which has been just now employed in a particular case, may be applied to an equation of any order whatever; we may therefore conclude, that every equation may be considered as the product of as many simple factors as the number denoting its order contains unity, and therefore, that the number of roots in any equation is precisely equal to the exponent of the highest power of the unknown quantity contained in that equation.

100. By considering equations of all degrees as formed from the products of factors $x-a$, $x-b$, $x-c$, &c. we discover curious relations, which subsist between the roots of any equation and its co-efficients. Thus, if we limit the number of factors to four, and suppose that $a, b, c, d$, are the roots of this equation of the fourth degree,

$$x^4+px^3+qx^2+rx+s=0,$$

we shall also have $(x-a)(x-b)(x-c)(x-d)=0$; and therefore, by actual multiplication,

$$x^4 \left.\begin{array}{r} -a \\ -b \\ -c \\ -d \end{array}\right\} x^3 \left.\begin{array}{r} +ab \\ +ac \\ +ad \\ +bc \\ +bd \\ +cd \end{array}\right] x^2 \left.\begin{array}{r} -abc \\ -abd \\ -acd \\ -bcd \end{array}\right\} x+abcd=0.$$

If we compare together the co-efficients of the same powers of $x$, we find the following series of equations:

$$\begin{aligned} a+b+c+d &= -p, \\ ab+ac+ad+bc+bd+cd &= +q, \\ abc+abd+acd+bcd &= -r, \\ abcd &= +s; \end{aligned}$$

and as similar results will be obtained for equations of all degrees, we hence derive the following propositions, which are of great importance in the theory of equations.

1. The co-efficient of the second term of any equation, taken with a contrary sign, is equal to the sum of all the roots.

2. The co-efficient of the third term is equal to the sum of the products of the roots multiplied together two and two.

3. The co-efficient of the fourth term, taken with a contrary sign, is equal to the sum of the roots multiplied together three and three; and so on in the remaining co-efficients, till we come to the last term of the equation, which is equal to the product of all the roots having their signs changed.

Instead of supposing an equation to be produced by multiplying together simple equations, we may consider it as formed by the product of equations of any degree, provided that the sum of their dimensions be equal to that of the proposed equation. Thus, an equation of the fourth degree may be formed either from a simple and cubic equation, or from two quadratic equations.

101. If $n$ denote the degree of an equation, we have shown, that by considering it as the product of simple factors, that equation will have $n$ divisors of the first degree; but if we suppose the simple factors to be combined two and two, they will form quantities of the second degree, which are also factors of the equation; and since there may be formed $\frac{n(n-1)}{1\cdot 2}$ such combinations, any equation will admit of $\frac{n(n-1)}{1\cdot 2}$ divisors of the second degree.

For example, the equation $x^4+px^3+qx^2+rx+s=0$, which we have considered as equal to

$$(x-a)(x-b)(x-c)(x-d)=0,$$

may be formed of the product of two factors of the second degree, in these six different ways.

By the product of $(x-a)(x-b)$ and $(x-c)(x-d)$,
$(x-a)(x-c)$ $(x-b)(x-d)$,
$(x-a)(x-d)$ $(x-b)(x-c)$,
$(x-b)(x-c)$ $(x-a)(x-d)$,
$(x-b)(x-d)$ $(x-a)(x-c)$,
$(x-c)(x-d)$ $(x-a)(x-b)$.

Thus an equation of the fourth degree may have $\frac{4\times 3}{1\times 2}=6$ quadratic divisors.

By combining the simple factors three and three, we shall have divisors of the third degree, of which the number for an equation of the $n$th order will be

$$\frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}; \text{ and so on.}$$

102. When the roots of an equation are all positive, its simple factors will have this form, $x-a$, $x-b$, $x-c$, &c.; and if, for the sake of brevity, we take only these three, the cubic equation which results from their product will have this form,

$$x^3-px^2+qx-r=0,$$

where $p=a+b+c$, $q=ab+ac+bc$, $r=abc$; and here it appears that the signs of the terms are $+$ and $-$ alternately.

Hence we infer, that when the roots of an equation are all positive, the signs of its terms are positive and negative alternately.

If again the roots of the equation be all negative, and therefore its factors $x+a$, $x+b$, $x+c$, then $p$, $q$, and $r$ being as before, the resulting equation will stand thus:

$$x^3+px^2+qx+r=0.$$

And hence we conclude, that when the roots are all negative, there is no change whatever in the signs.

103. In general, if the roots of an equation be all real, that equation will have as many positive roots as there are changes of the signs from $+$ to $-$, or from $-$ to $+$; and the remaining roots are negative. This rule, however, does not apply when the equation has imaginary

roots, unless such roots be considered as either positive or negative.

That the rule is true when applied to quadratic equations will be evident from Sect. IX. With respect to cubic equations, the rule also applies when the roots are either all positive, or all negative, as we have just now shown.

When a cubic equation has one positive root, and the other two negative, its factors will be $x-a$, $x+b$, $x+c$, and the equation itself

$$x^3\left.\begin{matrix}-a\\+b\\+c\end{matrix}\right\} x^2 \left.\begin{matrix}-ab\\-ac\\+bc\end{matrix}\right\} x - abc = 0.$$

Here there must always be one change of the signs, since the first term is positive and the last negative; and there can be no more than one; for if the second term is negative, or $b+c$ less than $a$, then $(b+c)^2$ will be less than $(b+c)\,a$; but $(b+c)^2$ is always greater than $b\,c$, therefore $b\,c$ will be much less than $(b+c)\,a$, or $ab+ac$, so that the third term must also be negative, and therefore, in this case there can be only one change of the signs. If, again, the second term be positive, then, because the sign of the last term is negative, whatever be the sign of the third term, there can still be no more than one change of the signs.

When the equation has two positive roots, and one negative, its factors are $x-a$, $x-b$, $x+c$, and the equation

$$x^3\left.\begin{matrix}-a\\-b\\+c\end{matrix}\right\} x^2 \left.\begin{matrix}+ab\\-ac\\-bc\end{matrix}\right\} x + abc = 0.$$

Here there must always be two changes of the signs; for if $a+b$ be greater than $c$, the second term is negative, and the last term being always positive, there must be two changes, whether the sign of the third term be positive or negative. If, again, $a+b$ be less than $c$, and therefore the second term positive, it may be shown as before, that $ab$ is much less than $ac+bc$; and hence the third term will be negative; so that in either case there must be two changes of the signs. We may conclude, therefore, upon the whole, that in cubic equations there are always as many positive roots as changes of the signs from + to —, or from — to +; and, by the same method of reasoning, the rule will be found to extend to all equations whatever.

104. It appears, from the manner in which the co-efficients of an equation are formed from its roots, that when the roots are all real, the co-efficients must consist entirely of real quantities. But it does not follow, on the contrary, that when the co-efficients are real, the roots are also real; for we have already found, that in a quadratic equation, $x^2+px+q=0$, where $p$ and $q$ denote real quantities, the roots are sometimes both imaginary.

When the roots of a quadratic equation are imaginary, they have always this form, $a+\sqrt{-b^2}$, $a-\sqrt{-b^2}$, which quantities may also be expressed thus, $a+b\sqrt{-1}$, $a-b\sqrt{-1}$; so that we have these two factors $x-a-b\sqrt{-1}$, $x-a+b\sqrt{-1}$, and taking their product,

$$x^2-2ax+a+b^2=0.$$

Thus we see that two imaginary factors may be of such a form as to admit of their product being expressed by a real quantity; and hence the origin of imaginary roots in quadratic equations.

105. It appears by induction, that no real equation can be formed from imaginary factors, unless those factors be taken in pairs, and each pair have the form $x\pm a-b\sqrt{-1}$, $x\pm a+b\sqrt{-1}$; for the product of three, or any odd number of imaginary factors, whatever be their form, is still an imaginary quantity. Thus, if we take the product of any three of these four imaginary expressions, $x+a+b\sqrt{-1}$, $x+a-b\sqrt{-1}$, $x+c+d\sqrt{-1}$, $x+c-d\sqrt{-1}$, we may form four different equations, each of which will involve imaginary quantities. If, however, each equation be multiplied by the remaining factor, which had not previously entered into its composition, the product will be found to be rational, and the same for all the four.

Hence we may deduce the three following inferences respecting the roots of equations:

1. If an equation have imaginary roots, it must have two, or four, or some even number of such roots.

2. If the degree of an equation be denoted by an odd number, that equation must have at least one real root.

3. If the degree of an equation be denoted by an even number, and that equation have one real root, it will also have another real root.

106. We shall now explain some transformations which are frequently necessary to prepare the higher orders of equations for a solution.

Any equation may have its positive roots changed into negative roots of the same value, and its negative roots into such as are positive, by changing the signs of the terms alternately, beginning with the second. The truth of this remark will be evident, if we take two equations,

$$(x-a)(x-b)(x+c)=0,$$
$$(x+a)(x+b)(x-c)=0,$$

(which are such, that the positive roots of the one have the same values as the negative roots of the other), and multiply together their respective factors; for these equations will stand thus:

$$x^3\left.\begin{matrix}-a\\-b\\+c\end{matrix}\right\} x^2 \left.\begin{matrix}+ab\\-ac\\-bc\end{matrix}\right\} x + abc = 0,$$

$$x^3\left.\begin{matrix}+a\\+b\\-c\end{matrix}\right\} x^2 \left.\begin{matrix}+ab\\-ac\\-bc\end{matrix}\right\} x - abc = 0;$$

where it appears that the signs of the first and third terms are the same in each, but the signs of the second and fourth are just the opposite of each other. And this will be found to hold true, not only of cubic equations, but of all equations, to whatever order they belong.

107. It will sometimes be useful to transform an equation into another that shall have each of its roots greater or less than the corresponding roots of the other equation, by some given quantity.

Let $(x-a)(x-b)(x+c)=0$ be any proposed equation which is to be transformed into another, having its roots greater or less than those of the proposed equation by the given quantity $n$; then, because the roots of the transformed equation are to be $+a\pm n$, $+b\pm n$, and $-c\pm n$, the equation itself will be

$$(y\mp n-a)(y\mp n-b)(y\mp n+c)=0.$$

Hence the reason of the following rule is evident.

If the new equation is to have its roots greater than those of the proposed equation; instead of $x$ and its powers, substitute $y-n$ and its powers: but if the roots are to be less; then, instead of $x$ substitute $y+n$; and in either case, a new equation will be produced, the roots of which shall have the property required.

108. By the preceding rule, an equation may be changed into another, which has its roots either all positive, or all negative; but it is chiefly used in preparing cubic and biquadratic equations for a solution, by transforming them

into others of the same degrees, but which want their second term.

Let $x^3+px^2+qx+r=0$ be any cubic equation; if we substitute $y+n$ for $x$, the equation is changed into the following:

$$\left.\begin{matrix} y^3+3n \\ +\ p \end{matrix}\right\} y^2 \quad \left.\begin{matrix} +3n^2 \\ +2pn \\ +\ q \end{matrix}\right\} y \quad \left.\begin{matrix} +n^3 \\ +pn^2 \\ +qn \\ +\ r \end{matrix}\right\} = 0.$$

Now, that this equation may want its second term, it is evident that we have only to suppose $3n+p=0$, or $n=-\frac{p}{3}$; for this assumption being made, and the value of $n$ substituted in the remaining terms, the equation becomes

$$y^3 * +(q-\frac{p^2}{3})y+\frac{2p^3}{27}-\frac{pq}{3}+r=0;$$

or, putting $-\frac{p^2}{3}+q=q'$, and $+\frac{2p^3}{27}-\frac{pq}{3}+r=r'$, the same equation may also stand thus,

$$y^3+q'y+r'=0.$$

109. In general, any equation whatever may be transformed into another, which shall want its second term, by the following rule.

Divide the co-efficient of the second term of the proposed equation by the exponent of the first term, and add the quotient, with its sign changed, to a new unknown quantity; the sum being substituted for the unknown quantity in the proposed equation, a new equation will be produced, which will want the second term, as required.

By this rule any adfected quadratic equation may be readily resolved; for by transforming it into another equation which wants the second term, we thus reduce its solution to that of a pure quadratic. Thus, if the quadratic equation $x^2-5x+6=0$ be proposed; by substituting $y+\frac{5}{2}$ for $x$, we find

$$\left.\begin{matrix} y^2+5y+\frac{25}{4} \\ -5y-\frac{25}{2} \\ +6 \end{matrix}\right\} = 0, \text{ or } y^2-\tfrac{1}{4}=0.$$

Hence $y=\pm\frac{1}{2}$, and since $x=y+\frac{5}{2}$, therefore $x=\pm\frac{1}{2}+\frac{5}{2}=+3$, or $+2$.

110. It has been shown (sect. 100) that in any equation, the co-efficient of the second term, having its sign changed, is equal to the sum of all the roots; or, abstracting from their signs, it is equal to the difference between the sum of the positive and the sum of the negative roots: Therefore, if the second term be wanting, the sum of the positive roots in the equation must necessarily be equal to that of the negative roots.

111. Instead of taking away the second term from an equation, any other term may be made to vanish, by an assumption similar to that which has been employed to take away the second term. Thus, if in sect. 108 we assume $3n^2+2pn+q=0$, by resolving this quadratic equation, a value of $n$ will be found which, when substituted in the equation, will cause the third term to vanish; and, by the resolution of a cubic equation, the third term may be taken away; and so on.

112. Another species of transformation, of use in the resolution of equations, is that by which an equation, having the co-efficients of some of its terms expressed by fractional quantities, is changed into another, the co-efficients of which are all integers.

Let $x^3+\frac{p}{a}x^2+\frac{q}{b}x+\frac{r}{c}=0$ denote an equation to be so transformed, and let us assume $y=abcx$, and therefore $x=\frac{y}{abc}$; then, by substitution, our equation becomes

$$\frac{y^3}{a^3b^3c^3}+\frac{p}{a^3b^2c^2}y^2+\frac{q}{ab^2c}y+\frac{r}{c}=0;$$

and multiplying the whole equation by $a^3b^3c^3$, we have

$$y^3+bcpy^2+a^2bc^2qy+a^3b^3c^2r=0.$$

Thus we have an equation free from fractions, while at the same time the co-efficient of the highest power of the unknown quantity is unity, as before.

This transformation may always be performed by the following rule: Instead of the unknown quantity, substitute a new unknown quantity divided by the product of all the denominators; then, by proper reduction, the equation will be found to have the form required.

If, however, the equation have this form,

$$x^3+\frac{p}{a}x^2+\frac{q}{a}x+\frac{r}{a}=0,$$

it will be sufficient to assume $y=ax$, and therefore $x=\frac{y}{a}$; for then we have

$$\frac{y^3}{a^3}+\frac{p}{a^3}y^2+\frac{q}{a^2}y+\frac{r}{a}=0,$$

$$\text{and } y^3+py^2+aqy+a^2r=0;$$

which last equation has the form required.

### Sect. XI.—Of Cubic Equations.

113. Cubic equations, as well as equations of every higher degree, are, like quadratics, divided into two classes: they are said to be *pure* when they contain only one power of the unknown quantity; and *adfected* when they contain two or more powers of that quantity.

Pure cubic equations are therefore of this form, $x^3=125$, or $x^3=-27$, or, in general, $x^3=r$; and hence it appears, that the value of the simple power of the unknown quantity may always be found without difficulty, by extracting the cube root of each side of the equation; thus, from the first of the three preceding examples we find $x=+5$, from the second, $x=-3$, and from the third, $x=\sqrt[3]{r}$.

It would seem at first sight that the only value which $x$ can have in the cubic equation $x^3=r$, or putting $r=c^3$, $x^3-c^3=0$, is this one, $x=c$; but since $x^3-c^3$ may be resolved into these two factors, $x-c$ and $x^2+cx+c^2$, it follows, that besides the value of $x$ already found, which results from making the factor $x-c=0$, it has yet other two values, which may be found by making the other factor $x^2+cx+c^2=0$; and accordingly, by resolving the quadratic equation $x^2+cx=-c^2$, we find these values to be $\frac{-c+\sqrt{-3c^2}}{2}$ and $\frac{-c-\sqrt{-3c^2}}{2}$, or $\frac{-1+\sqrt{-3}}{2}c$ and $\frac{-1-\sqrt{-3}}{3}c$. Thus it appears, that any cubic equation of this form, $x^3=c^3$, or $x^3-c^3=0$, has these three roots,

$$x=c,\ x=\frac{-1+\sqrt{-3}}{2}c,\ x=\frac{-1-\sqrt{-3}}{2}c;$$

the first of which is real, but the two last are imaginary. If, however, each of the imaginary values of $x$ be raised to the third power, the same results will be obtained as from the real value of $x$: the original equation $x^3-c^3=0$ may also be reproduced, by multiplying together the three factors $x-c$, $x-\frac{-1+\sqrt{-3}}{2}c$, and $x-\frac{-1-\sqrt{-3}}{2}c$.

114. Let us now consider such cubic equations as have all their terms, and which are therefore of this form,

$$x^3 + Ax^2 + Bx + C = 0,$$

where A, B, and C, denote known quantities, either positive or negative.

It has been shown (sect. 108) how an equation having all its terms may be transformed into another which wants the second term; therefore, assume $x = y - \frac{A}{3}$, as directed in that article; then, by proper substitution, the above equation will be changed into another of this form,

$$y^3 + qy + r = 0,$$

where $q$ and $r$ denote known quantities, whether positive or negative; now the roots of this equation being found, it is evident that those of the former may be readily obtained by means of the assumed equation $x = y - \frac{A}{3}$.

Resuming, therefore, the equation $y^3 + qy + r = 0$, let us suppose $y = v + z$, and it becomes

$$\left.\begin{array}{r} v^3 + 3v^2z + 3vz^2 + z^3 \\ +qv + qz \\ +r \end{array}\right\} = 0.$$

Thus we have a new equation, which, as it involves two unknown quantities, $v$ and $z$, may be resolved into any two others, which will simplify the determination of those quantities.

Now it appears, that the only way in which we can divide that equation into two others, so as to simplify the question, is the following:

$$3v^2z + 3vz^2 + qv + qz = 0,$$
$$v^3 + z^3 + r = 0.$$

The first of these may also be expressed thus,

$$(3vz + q)(v + z) = 0.$$

Hence, we must either suppose that $v + z = 0$, or that $3vz + q = 0$; but the former supposition cannot be admitted without supposing also that $y = 0$, which does not agree with the hypothesis of the equation $y^3 + qy + r = 0$; therefore we must adopt the latter. So that to determine $v$ and $z$ we have these two equations,

$$3vz + q = 0, \qquad v^3 + z^3 + r = 0.$$

From the first, we find $vz = -\frac{q}{3}$, and $v^3z^3 = -\frac{q^3}{27}$; and from the second $v^3 + z^3 = -r$; so that to determine the quantities $v^3$ and $z^3$, we have given their sum and product: now this is a problem which we have already resolved when treating of quadratic equations; and by proceeding in the same manner in the present case, we shall find

$$v^3 = -\tfrac{1}{2}r + \sqrt{\tfrac{1}{27}q^3 + \tfrac{1}{4}r^2}; \quad z^3 = -\tfrac{1}{2}r - \sqrt{\tfrac{1}{27}q^3 + \tfrac{1}{4}r^2};$$

$$v = \sqrt[3]{-\tfrac{1}{2}r + \sqrt{\tfrac{1}{27}q^3 + \tfrac{1}{4}r^2}}; \quad z = \sqrt[3]{-\tfrac{1}{2}r - \sqrt{\tfrac{1}{27}q^3 + \tfrac{1}{4}r^2}};$$

and $y = v + z$

$$= \sqrt[3]{-\tfrac{1}{2}r + \sqrt{\tfrac{1}{27}q^3 + \tfrac{1}{4}r^2}} + \sqrt[3]{-\tfrac{1}{2}r - \sqrt{\tfrac{1}{27}q^3 + \tfrac{1}{2}r^2}}.$$

Thus we have at last obtained a value of the unknown quantity $y$, in terms of the known quantities $q$ and $r$; therefore the equation is resolved.

115. But this is only one of three values which $y$ may have. Let us, for the sake of brevity, put

$$A = -\tfrac{1}{2}r + \sqrt{\tfrac{1}{27}q^3 + \tfrac{1}{4}r^2}, \quad B = -\tfrac{1}{2}r - \sqrt{\tfrac{1}{27}q^3 + \tfrac{1}{4}r^2},$$

$$\text{and put} \left\{ \begin{array}{l} \alpha = \dfrac{-1 + \sqrt{-3}}{2}, \\[2ex] \beta = \dfrac{-1 - \sqrt{-3}}{2}. \end{array} \right.$$

Then, from what has been shown (sect. 113), it is evident that $v$ and $z$ have each these three values,

$$v = \sqrt[3]{A}, \quad v = \alpha\sqrt[3]{A}, \quad v = \beta\sqrt[3]{A};$$
$$z = \sqrt[3]{B}, \quad z = \alpha\sqrt[3]{B}, \quad z = \beta\sqrt[3]{B}.$$

To determine the corresponding values of $v$ and $z$, we must consider that $vz = -\frac{q}{3} = \sqrt[3]{AB}$: Now if we observe that $\alpha\beta = 1$, it will immediately appear that $v + z$ has these three values,

$$v + z = \sqrt[3]{A} + \sqrt[3]{B},$$
$$v + z = \alpha\sqrt[3]{A} + \beta\sqrt[3]{B},$$
$$v + z = \beta\sqrt[3]{A} + \alpha\sqrt[3]{B}.$$

Hence the three values of $y$ are also these,

$$y = \sqrt[3]{A} + \sqrt[3]{B},$$
$$y = \alpha\sqrt[3]{A} + \beta\sqrt[3]{B},$$
$$y = \beta\sqrt[3]{A} + \alpha\sqrt[3]{B}.$$

The first of these formulæ is commonly known by the name of Cardan's rule; but it is well known that Cardan was not the inventor, and that it ought to be attributed to Nicholas Tartalea and Scipio Ferreus, who discovered it much about the same time, and independently of each other. (See the *Introduction.*)

The formulæ given above for the roots of a cubic equation may be put under a different form, and better adapted to the purposes of arithmetical calculation as follows. Because $vz = -\frac{q}{3}$, therefore $z = -\frac{q}{3} \times \frac{1}{v} = -\frac{\frac{1}{3}q}{\sqrt[3]{A}}$; hence $v + z = \sqrt[3]{A} - \frac{\frac{1}{3}q}{\sqrt[3]{A}}$: thus it appears that the three values of $y$ may also be expressed thus:

$$y = \sqrt[3]{A} - \frac{\frac{1}{3}q}{\sqrt[3]{A}}$$
$$y = \alpha\sqrt[3]{A} - \frac{\frac{1}{3}q\beta}{\sqrt[3]{A}},$$
$$y = \beta\sqrt[3]{A} - \frac{\frac{1}{3}q\alpha}{\sqrt[3]{A}}.$$

116. To show the manner of applying these formulæ, let it be required to determine $x$ from the cubic equation

$$x^3 + 3x^2 + 9x - 13 = 0:$$

And as this equation has all its terms, the first step towards its resolution is to transform it into another which shall want the second term, by substituting $y - 1$ for $x$ as directed (sect. 109). The operation will stand thus:

$$\begin{array}{rrrrr} x^3 = & y^3 & -3y^2 & +3y & -1 \\ +3x^2 = & & +3y^2 & -6y & +3 \\ +9x = & & & +9y & -9 \\ -13 = & & & & -13 \end{array}$$

The transformed equation is $y^3 \quad + 6y - 20 = 0$, which being compared with the general equation,

$$y^3 + qy + r = 0,$$

gives $q = 6$, $r = -20$; hence

$$A = \sqrt[3]{-\tfrac{1}{2}r + \sqrt{\tfrac{1}{27}q^3 + \tfrac{1}{4}r^2}} = \sqrt[3]{10 + \sqrt{108}},$$

therefore the second formula of last article gives $y = \sqrt[3]{10 + \sqrt{108}} - \frac{2}{\sqrt[3]{10 + \sqrt{108}}}$; but as this expression involves a radical quantity, let the square root of 108 be taken and added to 10, and the cube root of the sum found; thus we have $\sqrt[3]{10+\sqrt{108}} = 2{\cdot}732$ nearly, and therefore $\dfrac{2}{\sqrt[3]{10+\sqrt{108}}} = \dfrac{2}{2{\cdot}732} = {\cdot}732$; hence we at last find one of the values of $y$ to be $2.732 - {\cdot}732 = 2$.

In finding the cube root of the radical quantity $\sqrt[3]{10+\sqrt{108}}$, we have taken only its approximate value, so as to have the expression for the root under a rational form, and in this way we can always find, as near as we please, the cube root of any surd of the form $a+\sqrt{b}$, where $b$ is a positive number. But it will sometimes happen that the cube root of such a surd can be expressed exactly by another surd of the same form; and accordingly, in the present case, it appears that the cube root of $10+\sqrt{108}$ is $1+\sqrt{3}$, as may be proved by actually raising $1+\sqrt{3}$ to the third power. Hence we find

$$\frac{2}{\sqrt[3]{10+\sqrt{108}}} = \frac{2}{1+\sqrt{3}} = \frac{2(1-\sqrt{3})}{(1-\sqrt{3})(1+\sqrt{3})} =$$

$-(1-\sqrt{3})$; so that $y = 1+\sqrt{3}+1-\sqrt{3} = 2$, as before.

The other two values of $y$ will be had by substituting $1+\sqrt{3}$ and $1-\sqrt{3}$ for $\sqrt[3]{A}$ and $\dfrac{\frac{1}{3}q}{\sqrt[3]{A}}$ in the second and third formulæ of last article, and restoring the values of $\alpha$ and $\beta$. We thus have

$$y = \frac{-1+\sqrt{-3}}{2} \times (1+\sqrt{3}) + \frac{-1-\sqrt{-3}}{2} \times (1-\sqrt{3})$$
$$= -1+\sqrt{-9}$$
$$y = \frac{-1-\sqrt{-3}}{2} \times (1+\sqrt{3}) + \frac{-1+\sqrt{-3}}{2} \times (1-\sqrt{3})$$
$$= -1-\sqrt{-9}.$$

So that the three values of $y$ are

$$+2, \quad -1+\sqrt{-9}, \quad -1-\sqrt{-9};$$

and since $x = y - 1$, the corresponding values of $x$ are

$$+1, \quad -2+\sqrt{-9}, \quad -2-\sqrt{-9}.$$

Thus it appears that one of the roots of the proposed equation is real, and the other two imaginary.

The two imaginary roots might have been found otherwise, by considering that since one root of the equation is 1, the equation must be divisible by $x-1$ (sect. 99). Accordingly, the division being actually performed, and the quotient put $= 0$, we have this quadratic equation,

$$x^2+4x+13 = 0;$$

which, when resolved by the rule for quadratics, gives $x = -2 \pm \sqrt{-9}$, the same imaginary value as before.

117. In the application of the preceding formulæ (sect. 114 and 115) to the resolution of the equation $y^3+qy+r=0$, it is necessary to find the square root of $\frac{1}{27}q^3+\frac{1}{4}r^2$; now, when that quantity is positive, as in the equation $y^3+6y-20=0$, which was resolved in last article, no difficulty occurs, for its root may be found either exactly or to as great a degree of accuracy as we please.

As, however, the co-efficients $q$ and $r$ are independent of each other, it is evident that $q$ may be negative, and such, that $\frac{1}{27}q^3$ is greater than $\frac{1}{4}r^2$. In this case, the expression $\frac{1}{27}q^3+\frac{1}{4}r^2$ will be negative, and therefore its square root an imaginary quantity. Let us take as an example, this equation, $y^3-6y+4=0$; here $q=-6$, $r=+4$, $\frac{1}{2}r=2$, $\frac{1}{27}q^3=-8$, $\frac{1}{4}r^2=+4$, $\sqrt{\frac{1}{27}q^3+\frac{1}{4}r^2} = \sqrt{-4} = 2\sqrt{-1}$; hence, by recurring to the formulæ (sect. 115), we have $A=2+2\sqrt{-1}$, $B=2-\sqrt{-1}$, and therefore the three roots of the equation are

$$y = \sqrt[3]{2+2\sqrt{-1}} + \sqrt[3]{2-2\sqrt{-1}},$$
$$y = \alpha\sqrt[3]{2+2\sqrt{-1}} + \beta\sqrt[3]{2-2\sqrt{-1}},$$
$$y = \beta\sqrt[3]{2+2\sqrt{-1}} + \alpha\sqrt[3]{2-2\sqrt{-1}}.$$

Here all the roots appear under an imaginary form; but we are certain, from the theory of equations, as explained in Section X. that every cubic equation must have at least one real root. The truth is, as we shall show immediately, that in this case, so far from any of the roots being imaginary, they are all real; for it appears by actual involution, that the imaginary expression $2+2\sqrt{-1}$ is the cube of this other imaginary expression, $-1+\sqrt{-1}$; and in like manner, that $2-2\sqrt{-1}$ is the cube of $-1-\sqrt{-1}$, so that we have

$y = \sqrt[3]{2+2\sqrt{-1}} + \sqrt[3]{2-2\sqrt{-1}} = -1+\sqrt{-1}-1-\sqrt{-1} = 2.$

$y = \dfrac{-1+\sqrt{-3}}{2} \times (-1+\sqrt{-1}) + \dfrac{-1-\sqrt{-3}}{2} \times (-1-\sqrt{-1}) = 1+\sqrt{3}.$

$y = \dfrac{-1-\sqrt{-3}}{2} \times (-1+\sqrt{-1}) + \dfrac{-1+\sqrt{-3}}{2} \times (-1-\sqrt{-1}) = 1-\sqrt{3}.$

118. We shall now prove, that as often as the roots of the equation $x^3+qx+r=0$ are real, $q$ is negative, and $\frac{1}{27}q^3$ greater than $\frac{1}{4}r^2$; and, on the contrary, that if $\frac{1}{27}q^3$ be greater than $\frac{1}{4}r^2$, the roots are all real.

Let us suppose $a$ to be a real root of the proposed equation;

Then $\quad x^3+qx+r=0,$

And $\quad a^3+qa+r=0.$

And therefore, by subtraction, $x^3-a^3+q(x-a)=0$; hence, dividing by $x-a$, we have

$$x^2+ax+a^2+q=0.$$

This quadratic equation is formed from the two remaining roots of the proposed equation, and by resolving it we find

$$x = -\tfrac{1}{2}a \pm \sqrt{-\tfrac{3}{4}a^2-q}.$$

And as, by hypothesis, all the roots are real, it is evident that $q$ must necessarily be negative, and greater than $\frac{3}{4}a^2$; for otherwise the expression $\sqrt{-\frac{3}{4}a^2-q}$ would be imaginary. Let us change the sign of $q$, and put $q=\frac{3}{4}a^2+d$; thus the roots of the equation $x^3-qx+r=0$ will be

$$a, \ -\tfrac{1}{2}a+\sqrt{d}, \ -\tfrac{1}{2}a-\sqrt{d},$$

and here $d$ is a positive quantity.

To find an expression for $r$ in terms of $a$ and $d$, let $\frac{3}{4}a^2+d$ be substituted for $q$ in the equation $a^3-qa+r=0$; we thence find $r=-\frac{1}{4}a^3+ad$; so that to compare together the quantities $q$ and $r$, we have these equations,

$$q=\tfrac{3}{4}a^2+d, \quad r=-\tfrac{1}{4}a^3+ad.$$

In order to make this comparison, let the cube of $\frac{1}{3}q$ be taken, also the square of $\frac{1}{2}r$, the results are

$$\tfrac{1}{27}q^3 = \tfrac{1}{64}a^6+\tfrac{1}{16}a^4d+\tfrac{1}{12}a^2d^2+\tfrac{1}{27}d^3,$$
$$\tfrac{1}{4}r^2 = \tfrac{1}{64}a^6-\tfrac{1}{8}a^4d+\tfrac{1}{4}a^2d^2;$$

and therefore, by subtraction,

$$\tfrac{1}{27}q^3-\tfrac{1}{4}r^2 = \tfrac{3}{16}a^4d-\tfrac{1}{6}a^2d^2+\tfrac{1}{27}d^3,$$
$$=3d(\tfrac{1}{16}a^4-\tfrac{1}{18}a^2d+\tfrac{1}{81}d^2),$$
$$=3d(\tfrac{1}{4}a^2-\tfrac{1}{9}d)^2.$$

Now the square of any real quantity being always positive, it follows that $3d(\frac{1}{4}a^2-\frac{1}{9}d)^2$ will be positive when $d$ is positive; hence it is evident that in this case $\frac{1}{27}q^3$ must be greater than $\frac{1}{4}r^2$, and that the contrary cannot be true, unless $d$ be negative, that is, unless that $-\frac{1}{2}a+\sqrt{d}$, $-\frac{1}{2}a-\sqrt{d}$, the two other roots of the equation, are imaginary. If we suppose $d=0$, then $\frac{1}{27}q^3=\frac{1}{4}r^2$; and the roots of the equations, which in this case are also real, are $a$, $-\frac{1}{2}a$, $-\frac{1}{2}a$.

Upon the whole, therefore, we infer, that since a cubic equation has always one real root, its roots will be all real as often as $q$ is negative, and $\frac{1}{27}q^3$ greater than $\frac{1}{4}r^2$; and consequently, that in this case the formulæ for the roots must express real quantities, notwithstanding their imaginary form.

119. Let $y^3-qy+r=0$ denote any equation of the form which has been considered in last article, namely, that which has its roots all real; then, if we put $a=-\frac{1}{2}r$, $b^2=\frac{1}{27}q^3-\frac{1}{4}r^2$, one of the roots, as expressed by the first formula, sect. 115, will be,

$$y=\sqrt[3]{a+b\sqrt{-1}}+\sqrt[3]{a-b\sqrt{-1}}.$$

This expression, although under an imaginary form, must (as we have shown in last article) represent a real quantity. It may happen, as in last example, sect. 117, that the two surds which compose the root are perfect cubes of the form $(A+B\sqrt{-1})^3$, and $(A-B\sqrt{-1})^3$, and then the value of $y$ becomes

$$A+B\sqrt{-1}+A-B\sqrt{-1}=2A.$$

But the rules for determining when this is the case depend upon trials, and are, besides, troublesome in the application; and if we attempt by a direct process to investigate the numerical values of A and B, we are brought to a cubic equation of the very same form as that whose root is required.

This imaginary expression for a real quantity has greatly perplexed mathematicians; and much pains has been taken to obtain the root under another form, but without success. Accordingly, the case of cubic equations, in which the roots are all real, is now called the *irreducible case.*

120. It is remarkable that the expression

$$\sqrt{a+b\sqrt{-1}}+\sqrt{a-b\sqrt{-1}},$$

and in general,

$$\sqrt[n]{a+b\sqrt{-1}}+\sqrt[n]{a-b\sqrt{-1}},$$

where $n$ is any power of 2, admits of being reduced to another form, in which no impossible quantity is found. Thus, $\sqrt{a+b\sqrt{-1}}+\sqrt{a-b\sqrt{-1}}=\sqrt{2a+2\sqrt{a^2+b^2}}$,

and $\sqrt[4]{a+b\sqrt{-1}}+\sqrt[4]{a-b\sqrt{-1}}=$

$$\sqrt{\left(\sqrt{2a+2\sqrt{a^2+b^2}}+2\sqrt[4]{a^2+b^2}\right)},$$

as is easily proved by first raising the imaginary formulæ to the second and fourth powers, and then taking the square and fourth root of each. But when $n$ is 3, it does not seem that such reduction can possibly take place.

If each of the surds be expanded into an infinite series, and their sum be taken, the imaginary quantity $\sqrt{-1}$ will vanish, and thus the root may be found by a direct process. There are, however, other methods which seem preferable. The following, which is derived from the calculus of sines, seems the best.

121. It will be demonstrated in Sect. XXV., that if $a$ denote an arch of a circle, the relation between the cosine of the arch and the cosine of $\frac{a}{3}$, one-third of that arch, is expressed by the following cubic equation:

$$\text{Cos.}^3\,\frac{a}{3}-\tfrac{3}{4}\cos.\frac{a}{3}=\tfrac{1}{4}\cos.\,a.$$

Let us assume $\cos.\,\frac{a}{3}=\frac{y}{n}$, then, by substitution, the equation is transformed into the following:

$$\frac{y^3}{n^3}-\frac{3y}{4n}=\tfrac{1}{4}\cos.\,a,$$

$$\text{Or}\quad y^3-\frac{3n^2}{4}y=n^3\times\tfrac{1}{4}\cos.\,a;$$

and in this cubic equation, one of the roots is evidently $y=n\times\cos.\frac{a}{3}$. Now from the calculus of sines it appears that $\cos.\,a$, $\cos.\,(360°-a)$, and $\cos.\,(360°+a)$, are all expressed by the same quantity; therefore the equation must have for a root not only $n\times\cos.\frac{a}{3}$, but also $n\times\cos.\frac{360°-a}{3}$, and $n\times\cos.\frac{360°+a}{3}$. But from the calculus of sines, $\cos.\frac{360°-a}{3}=$ $-\sin.\frac{90°-a}{3}$, and $\cos.\frac{360°+a}{3}=-\sin.\frac{90°+a}{3}$; therefore the roots of the equation are

$$n\times\cos.\frac{a}{3},\quad -n\times\sin.\frac{90°-a}{3},\quad -n\times\sin.\frac{90°+a}{3}.$$

Let us next suppose that $y^3-qy=r$ is a cubic equation whose roots are required, and let us compare it with the former equation $y^3-\frac{3n^2}{4}y=n^3\times\frac{1}{4}\cos.\,a$; then it is evident, that if we assume the quantities $n$ and $\cos.\,a$, such, that

$$\frac{3n^2}{4}=q,\quad n^3\times\tfrac{1}{4}\cos.\,a=r,$$

the two equations will become identical, and thus their roots will be expressed by the very same quantities. But from these two assumed equations we find

$$n=\sqrt{\frac{4q}{3}}=\frac{2\sqrt{q}}{\sqrt{3}},\quad \cos.\,a=\frac{4r}{n^3}=\sqrt{\frac{27\,r^2}{4q^3}}=\frac{3r\sqrt{3}}{2q\sqrt{q}};$$

and since the cosine of an arch cannot exceed unity, therefore $\frac{27\,r^2}{4\,q^3}$ must be a proper fraction, that is, $4q^3$ must exceed $27r^2$, or $\frac{1}{27}q^3$ must exceed $\frac{1}{4}r^2$. If we now recollect that $q$ is a negative quantity, it will immediately appear that the proposed equation must necessarily belong to the irreducible case.

The rule, therefore, which we derive from the preceding analysis for resolving that case is as follows:

Let $y^3-qy=r$ be the proposed equation.

Find in the trigonometrical tables an arch $a$, whose natural cosine$=\frac{3r\sqrt{3}}{2q\sqrt{q}}$;

the roots of the equation are

$$y=2\sqrt{\frac{q}{3}}\times\cos.\frac{a}{3},$$

$$y=-2\sqrt{\frac{q}{3}}\times\sin.\frac{90°-a}{3},$$

$$y=-2\sqrt{\frac{q}{3}}\times\sin.\frac{90°+a}{3}.$$

These formulæ will apply, whether $r$ be positive or negative, by proper attention to the signs. If, however, $r$ be negative, or the equation have this form, $y^3-qy=-r$, the following will be more convenient:

Find in the tables an arch $a$, whose sine $=\frac{3r\sqrt{3}}{2q\sqrt{q}}$.

Then the roots of the equation are

$$y=2\sqrt{\frac{q}{3}}\times\sin.\frac{a}{3},$$

$$y=2\sqrt{\frac{q}{3}}\times\cos.\frac{90°+a}{3},$$

$$y=-2\sqrt{\frac{q}{3}}\times\cos.\frac{90°-a}{3}.$$

The last formulæ are derived from the equation

$$\text{Sin.}^3\frac{a}{3}-\frac{3}{4}\sin.\frac{a}{3}=-\sin.a,$$

in the same manner as the former were found from the first equation of last article.

*Ex.* 1. It is required to find the roots of the equation $x^3-3x=1$.

$$\text{Here } \frac{3r\sqrt{3}}{2q\sqrt{q}}=\frac{3\times\sqrt{3}}{6\times\sqrt{3}}=\tfrac{1}{2}=\cos.60°=\cos.a, \text{ and}$$

$$x=2\cos.\frac{60°}{3}=2\cos.20°=1{\cdot}8793852,$$

$$x=-2\sin.\frac{150°}{3}=-2\sin.50°=-1{\cdot}5320888,$$

$$x=-2\sin.\frac{30°}{3}=-2\sin.10°=\cdot3472964.$$

*Ex.* 2. It is required to find the roots of the equation $x^3-3x=-1$.

$$\text{Here } \frac{3r\sqrt{3}}{2q\sqrt{q}}=\frac{3\sqrt{3}}{6\sqrt{3}}=\tfrac{1}{2}=\sin.30°=\sin.a, \text{ and}$$

$$x=2\sin.\frac{30°}{3}=2\sin.10°=\cdot3472964,$$

$$x=2\cos.\frac{120°}{3}=2\cos.40°=1{\cdot}5320888,$$

$$x=-2\cos.\frac{60°}{3}=-2\cos.20°=-1{\cdot}8793852.$$

## Sect. XII.—Of Biquadratic Equations.

122. When a biquadratic equation contains all its terms, it has this form,

$$x^4+Ax^3+Bx^2+Cx+D=0,$$

where A, B, C, D, denote any known quantities whatever.

We shall first consider pure biquadratics, or such as contain only the first and last terms, and therefore are of this form, $x^4=b^4$. In this case it is evident that $x$ may be readily had by two extractions of the square root; by the first we find $x^2=b^2$, and by the second $x=b$. This, however, is only one of the values which $x$ may have; for since $x^4=b^4$, therefore $x^4-b^4=0$; but $x^4-b^4$ may be resolved into two factors $x^2-b^2$ and $x^2+b^2$, each of which admits of a similar resolution; for $x^2-b^2=(x-b)(x+b)$ and $x^2+b^2=(x-b\sqrt{-1})(x+b\sqrt{-1})$. Hence it appears that the equation $x^4-b^4=0$ may also be expressed thus:

$$(x-b)(x+b)(x-b\sqrt{-1})(x+b\sqrt{-1})=0;$$

so that $x$ may have these four values,

$$+b,\quad -b,\quad +b\sqrt{-1},\quad -b\sqrt{-1},$$

two of which are real, and the others imaginary.

123. Next to pure biquadratic equations, in respect of easiness of resolution, are such as want the second and fourth terms, and therefore have this form,

$$x^4+qx^2+s=0.$$

These may be resolved in the manner of quadratic equations; for if we put $y=x^2$, we have

$$y^2+qy+s=0,$$

from which we find $y=\frac{-q\pm\sqrt{q^2-4s}}{2}$, and therefore

$$x=\pm\sqrt{\frac{-q\pm\sqrt{q^2-4s}}{2}}.$$

124. When a biquadratic equation has all its terms, the manner of resolving it is not so obvious as in the two former cases, but its resolution may be always reduced to that of a cubic equation. There are various methods by which such a reduction may be effected. The following, which we select as one of the most ingenious, was first given by Euler in the *Petersburg Commentaries*, and afterwards explained more fully in his *Elements of Algebra.*

We have already explained, sect. 109, how an equation which is complete in its terms may be transformed into another of the same degree, but which wants the second term; therefore any biquadratic equation may be reduced to this form,

$$y^4+py^2+qy+r=0,$$

where the second term is wanting, and where $p$, $q$, $r$, denote any known quantities whatever.

That we may form an equation similar to the above, let us assume $y=\sqrt{a}+\sqrt{b}+\sqrt{c}$, and also suppose that the letters $a$, $b$, $c$, denote the roots of the cubic equation

$$z^3+Pz^2+Qz-R=0;$$

then, from the theory of equations we have

$$a+b+c=-P,\quad ab+ac+bc=Q,\quad abc=R.$$

We square the assumed formula

$y=\sqrt{a}+\sqrt{b}+\sqrt{c}$, and obtain

$y^2=a+b+c+2(\sqrt{ab}+\sqrt{ac}+\sqrt{bc})$,

or, substituting $-P$ for $a+b+c$, and transposing;

$y^2+P=2(\sqrt{ab}+\sqrt{ac}+\sqrt{bc})$.

Let this equation be also squared, and we have

$y^4+2Py^2+P^2=4(ab+ac+bc)+8(\sqrt{a^2bc}+\sqrt{ab^2c}+\sqrt{abc^2})$; and since $ab+ac+bc=Q$, and

$\sqrt{a^2bc}+\sqrt{ab^2c}+\sqrt{abc^2}=\sqrt{abc}\,(\sqrt{a}+\sqrt{b}+\sqrt{c})=\sqrt{R}y$,

the same equation may be expressed thus:

$$y^4+2Py^2+P^2=4Q+8\sqrt{R}y.$$

Thus we have the biquadratic equation

$$y^4+2Py^2-8\sqrt{R}y+P^2-4Q=0,$$

one of the roots of which is $y=\sqrt{a}+\sqrt{b}+\sqrt{c}$, and in which $a$, $b$, $c$, are the roots of the cubic equation $z^3+Pz^2+Qz-R=0$.

125. In order to apply this resolution to the proposed equation $y^4+py^2+qy+r=0$, we must express the assumed co-efficients P, Q, R, by means of $p$, $q$, $r$, the co-

efficients of that equation. For this purpose, let us compare the equations

$$y^4+py^2+qy+r=0,$$
$$y^4+2Py^2-8\sqrt{R}\ y+P^2-4Q=0,$$

and it immediately appears that $2P=p, -8\sqrt{R}=q, P^2-4Q=r$; and from these three equations we find $P=\frac{p}{2}$, $Q=\frac{p^2-4r}{16}$, $R=\frac{q^2}{64}$. Hence it follows that the roots of the proposed equation are generally expressed by the formula $y=\sqrt{a}+\sqrt{b}+\sqrt{c}$; where $a, b, c$, denote the roots of this cubic equation,

$$z^3+\frac{p}{2}z^2+\frac{p^2-4r}{16}z-\frac{q^2}{64}=0.$$

But to find each particular root, we must consider, that as the square root of a number may be either positive or negative, so each of the quantities $\sqrt{a}, \sqrt{b}, \sqrt{c}$, may have either the sign $+$ or $-$ prefixed to it; and hence our formula will give eight different expressions for the root. It is, however, to be observed, that as the product of the three quantities $\sqrt{a}, \sqrt{b}, \sqrt{c}$, must be equal to $\sqrt{R}$ or to $-\frac{q}{8}$, when $q$ is positive, their product must be a negative quantity; and this can only be effected by making either one or three of them negative; again, when $q$ is negative, their product must be a positive quantity; so that in this case they must either be all positive, or two of them must be negative. These considerations enable us to determine, that four of the eight expressions for the root belong to the case in which $q$ is positive, and the other four to that in which it is negative.

126. We shall now give the result of the preceding investigation in the form of a practical rule; and as the co-efficients of the cubic equation which has been found involve fractions, we shall transform it into another, in which the co-efficients are integers, by supposing $z=\frac{v}{4}$. Thus the equation $z^3+\frac{p}{2}z^2+\frac{p^2-4r}{16}z-\frac{q^2}{64}=0$ becomes, after reduction, $v^3+2pv^2+(p^2-4r)v-q^2=0$; it also follows, that since the roots of the former equation are $a, b, c$, the roots of the latter are $\frac{a}{4}, \frac{b}{4}, \frac{c}{4}$, so that our rule may now be expressed thus:

Let $y^4+py^2+qy+r=0$ be any biquadratic equation wanting its second term. Form this cubic equation,

$$v^3+2pv^2+(p^2-4r)v-q^2=0,$$

and find its roots, which, let us denote by $a, b, c$.

Then the roots of the proposed biquadratic equation are,

| when $q$ is negative, | when $q$ is positive, |
|---|---|
| $y=\frac{1}{2}(\sqrt{a}+\sqrt{b}+\sqrt{c})$, | $y=\frac{1}{2}(-\sqrt{a}-\sqrt{b}-\sqrt{c})$, |
| $y=\frac{1}{2}(\sqrt{a}-\sqrt{b}-\sqrt{c})$, | $y=\frac{1}{2}(-\sqrt{a}+\sqrt{b}+\sqrt{c})$, |
| $y=\frac{1}{2}(-\sqrt{a}+\sqrt{b}-\sqrt{c})$, | $y=\frac{1}{2}(\sqrt{a}-\sqrt{b}+\sqrt{c})$, |
| $y=\frac{1}{2}(-\sqrt{a}-\sqrt{b}+\sqrt{c})$. | $y=\frac{1}{2}(\sqrt{a}+\sqrt{b}-\sqrt{c})$. |

127. This resolution of biquadratic equations suggests the following general remarks upon the nature of their roots.

1. It is evident from the form of the roots, that if the cubic equation

$$v^3+2pv^2+(p^2-4r)v-q^2=0,$$

have all its roots real and positive, those of the biquadratic equation will be all real.

2. Since the last term of the cubic equation is negative; when its three roots are real, they must either be all positive, or two of them must be negative and one positive; for the last term is equal to the product of all the roots taken with contrary signs, sect. 100; so that in this last case, two of the three quantities $a, b, c$, must be negative, and therefore all the four roots of the biquadratic equation imaginary. If, however, the two negative roots be equal, they will destroy each other in two of the roots of the biquadratic equation, which will then become real and equal. Let us suppose, for example, that $b$ and $c$ are negative and equal; the first two values of $y$ in each column become then imaginary, and the remaining values of $y$ are in the first set of roots, $y=-\frac{1}{2}\sqrt{a}$, $y=-\frac{1}{2}\sqrt{a}$, and in the second, $y=+\frac{1}{2}\sqrt{a}$, $y=\frac{1}{2}\sqrt{a}$.

3. When the cubic equation has only one real and two imaginary roots, its real roots must necessarily be positive; for the imaginary roots can only come from a quadratic equation having its last term positive, Sect. IX. and therefore are of this form, $v^2+Av+B=0$; hence the simple factor which contains the remaining root must have this form, $v-\gamma$, otherwise the last term of the cubic equation could not be negative.

By resolving the equation $v^2+Av+B=0$, we find

$$v=-\frac{A}{2}\pm\sqrt{\frac{A^2}{4}-B}.$$

Here, the roots being supposed imaginary, $\frac{A^2}{4}-B$ must be a negative quantity. That we may simplify the form of the roots, let us put $-\frac{A}{2}=\alpha$, and $\frac{A^2}{4}-B=-\beta^2$, then

$$v=-\alpha\pm\sqrt{-\beta^2}=-\alpha\pm\beta\sqrt{-1},$$

and $v=-\alpha+\beta\sqrt{-1}$, $v=-\alpha-\beta\sqrt{-1}$.

Hence we have

$$a=\alpha+\beta\sqrt{-1},\quad b=\alpha-\beta\sqrt{-1},\ c=\gamma;$$

so that in two of the four values of $y$, we have a quantity of this form,

$$\sqrt{\alpha+\beta\sqrt{-1}}+\sqrt{\alpha-\beta\sqrt{-1}};$$

but this quantity, although it appears to be imaginary, is indeed real; for if we first square it, and then take its square root, it becomes

$$\sqrt{2\alpha+2\sqrt{\alpha^2+\beta^2}},$$

which is a real quantity. The other two roots involve this other expression,

$$\sqrt{\alpha+\beta\sqrt{-1}}-\sqrt{\alpha-\beta\sqrt{-1}};$$

which being treated in the same manner as the former, becomes

$$\sqrt{2\alpha-2\sqrt{\alpha^2+\beta^2}},$$

an imaginary quantity, and therefore the roots into which it enters are imaginary.

4. We may discover from the co-efficients of the proposed biquadratic equation in what case the roots of the cubic equation are all real. For this purpose, the latter is to be transformed into another which shall want the second term, by assuming $v=u-\frac{2p}{3}$; thus it becomes

$$u^3-\left(\frac{p^3}{3}+4r\right)u-\frac{2p^3}{27}+\frac{8rp}{3}-q^2=0;$$

and in this equation the three roots will be real when $\frac{1}{27}\left(\frac{p^2}{3}+4r\right)^3$ is greater than $\frac{1}{4}\left(\frac{2p^3}{27}-\frac{8rp}{3}+q^2\right)^2$.

128. As an example of the method of resolving a biquadratic equation, let it be required to determine the roots of the following,

$$x^4-25x^2+60x-36=0.$$

Algebra. By comparing this equation with the general formula, we have $p=-25$, $q=+60$, $r=-36$; hence

$$2p=-50,\ p^2-4r=769,\ q^2=3600,$$

and the cubic equation to be resolved is

$$v^3-50v^2+769v-3600=0;$$

the roots of which are found, by the rules for cubics, to be 9, 16, and 25, so that $\sqrt{a}=3$, $\sqrt{b}=4$, $\sqrt{c}=5$. Now in this case $q$ is positive, therefore

$$x=\tfrac{1}{2}(-3-4-5)=-6,$$
$$x=\tfrac{1}{2}(-3+4+5)=+3,$$
$$x=\tfrac{1}{2}(+3-4+5)=+2,$$
$$x=\tfrac{1}{2}(+3+4-5)=+1.$$

129. We have now explained the particular rules by which the roots of equations belonging to each of the first four orders may be determined; and this is the greatest length mathematicians have been able to go in the direct resolution of equations; for as to those of the fifth, and all higher degrees, no general method has hitherto been found, either for resolving them directly, or reducing them to others of an inferior degree.

It even appears that the formulæ which express the roots of cubic equations are not of universal application; for in one case, that is, when the roots are all real, they become illusory, so that no conclusion can be drawn from them. The same observation will also apply to the formulæ for the roots of biquadratic equations, because, before they can be applied, it is always necessary to find the roots of a cubic equation. But in either cubics or biquadratic equations, even when the formulæ involve no imaginary quantities, and therefore can be always applied, it is more convenient in practice to employ some other methods, which we are hereafter to explain.

## Sect. XIII.—Of Reciprocal Equations.

130. Although no general resolution has hitherto been found of equations belonging to the fifth or any higher degree, yet there are particular equations of all orders, which, by reason of certain peculiarities in the nature of their roots, admit of being reduced to others of a lower degree; and thus, in some cases, equations of the higher orders may be resolved by the rules which have been already explained for the resolution of equations belonging to the first four orders.

When the co-efficients of the terms of an equation form the same numerical series, whether taken in a direct or an inverted order, as in this example,

$$x^4+px^3+qx^2+px+1=0,$$

it may always be transformed into another of a degree denoted by half the exponent of the highest power of the unknown quantity, if that exponent be an even number; or half the exponent diminished by unity, if it be an odd number.

The same observation will also apply to any equation of this form,

$$x^4+pax^3+qa^2x^2+pa^3x+a^4=0,$$

where the given quantity $a$ and the unknown quantity $x$ are precisely alike concerned; for by substituting $ay$ for $x$, it becomes

$$a^4y^4+pa^4y^3+qa^4y^2+pa^4y+a^4=0;$$

and dividing by $a^4$,

$$y^4+py^3+qy^2+py+1=0,$$

an equation of the same kind as the former.

131. That we may effect the proposed transformation upon the equation

$$x^4+px^3+qx^2+px+1=0,$$

let every two terms which are equally distant from the extremes be collected into one, and the whole be divided by $x^2$, then

$$x^2+\frac{1}{x^2}+p\left(x+\frac{1}{x}\right)+q=0.$$

Let us assume $x+\frac{1}{x}=z$;

then $x^2+2+\frac{1}{x^2}=z^2$, and $x^2+\frac{1}{x^2}=z^2-2$.

Thus the equation $x^2+\frac{1}{x^2}+p\left(x+\frac{1}{x}\right)+q=0$,

becomes $z^2+pz+q-2=0$;

and since $x+\frac{1}{x}=z$, therefore $x^2-zx+1=0$.

Hence, to determine the roots of the biquadratic equation

$$x^4+px^3+qx^2+px+1=0,$$

we have the following rule:

Form this quadratic equation,

$$z^2+pz+q-2=0,$$

and find its roots, which, let us suppose denoted by $z'$ and $z''$; then the four roots of the proposed equation will be found by resolving two quadratic equations, *viz.*

$$x^2-z'x+1=0,\quad x^2-z''x+1=0.$$

132. It may be observed, respecting these two quadratic equations, that since the last term of each is unity, if we put $a$, $a'$ to denote the roots of the one, and $b$, $b'$ those of the other, we have, from the theory of equations, $a\,a'=1$, and therefore $a'=\frac{1}{a}$; also $b\,b'=1$, and $b'=\frac{1}{b}$: now $a$, $a'$, $b$, $b'$ are also the roots of the equation

$$x^4+px^3+qx^2+px+1=0.$$

Hence it appears that the proposed equation has this peculiar property, that one half of its roots are the reciprocals of the other half; and to that circumstance we are indebted for the simplicity of its resolution.

133. The following equation,

$$x^6+px^5+qx^4+rx^3+qx^2+px+1=0,$$

which is of the sixth order, admits of a resolution in all respects similar to the former; for, by putting it under this form,

$$x^3+\frac{1}{x^3}+p\left(x^2+\frac{1}{x^2}\right)+q\left(x+\frac{1}{x}\right)+r=0,$$

and putting also $x+\frac{1}{x}=z$, so that $x^2-zx+1=0$, we

have $x^2+\frac{1}{x^2}=z^2-2$,

$$x^3+\frac{1}{x^3}=z^3-3\left(x+\frac{1}{x}\right)=z^3-3z.$$

Hence, by substitution, the proposed equation is transformed into the following cubic equation,

$$z^3+pz^2+(q-3)z+r-2p=0;$$

therefore, putting $z'$, $z''$, $z'''$, to denote its roots, the six roots of the proposed equation will be had by resolving these three quadratics,

$$x^2-z'x+1=0,\ x^2-z''x+1=0,\ x^2-z'''x+1=0;$$

and here it is evident, as in the former case, that the roots of each quadratic equation are the reciprocals of each other, so that the one half of the roots of the proposed equation are the reciprocals of the other half.

The method of resolution we have employed in the two preceding examples is general for all equations whatever, in which the terms placed at equal distances from the first and last have the same co-efficients, and which are called *reciprocal equations*, because any such equation has the same form when you substitute for $x$ its reciprocal, $\frac{1}{x}$.

134. If the greatest exponent of the unknown quantity in a reciprocal equation is an odd number, as in this example,

$$x^5+px^4+qx^3+qx^2+px+1=0,$$

the equation will always be satisfied by substituting $-1$ for $x$; hence, $-1$ must be a root of the equation, and therefore the equation must be divisible by $x+1$. Accordingly, if the division be actually performed, we shall have in the present case

$$x^4+(p-1)x^3-(p-q-1)x^2+(p-1)x+1=0,$$

another reciprocal equation, in which the greatest exponent of $x$ is an even number, and therefore resolvable in the manner we have already explained.

135. As an application of the theory of reciprocal equation, let it be proposed to find $x$ from this equation,

$$\frac{x^5+1}{(x+1)^5}=a,$$

where $a$ denotes a given number.

Every expression of the form $x^n+1$ is divisible by $x+1$ when $n$ is an odd number. In the present case, the numerator and denominator being divided by $x+1$, the equation becomes

$$\frac{x^4-x^3+x^2-x+1}{x^4+4x^3+6x^2+4x+1}=a;$$

and this again, by proper reduction,

$$(a-1)x^4+(4a+1)x^3+(6a-1)x^2+(4a+1)x+a-1=0;$$

and, putting $p=\frac{4a+1}{a-1}$, $q=\frac{6a-1}{a-1}$,

$$x^4+px^3+qx^2+px+1=0;$$

a reciprocal equation, resolvable into two quadratics.

## Sect. XIV.—Of Equations which have Equal Roots.

136. When an equation has two or more equal roots, these may always be discovered, and the equation reduced to another of an inferior degree, by a method of resolution which is peculiar to this class of equations.

Although the method of resolution we are to employ will apply alike to equations of every degree, having equal roots, yet, for the sake of brevity, we shall take a biquadratic equation,

$$x^4+px^3+qx^2+rx+s=0,$$

the roots of which may be generally denoted by $a$, $b$, $c$, and $d$. Thus we have, from the theory of equations,

$$(x-a)(x-b)(x-c)(x-d)=x^4+px^3+qx^2+rx+s=0.$$

Let us put

$A=(x-a)(x-b)(x-c)$, $A''=(x-a)(x-c)(x-d)$,
$A'=(x-a)(x-b)(x-d)$, $A'''=(x-b)(x-c)(x-d)$:

then, by actual multiplication, we have

$$A=x^3\left.\begin{matrix}-a\\-b\\-c\end{matrix}\right\}x^2\left.\begin{matrix}+ab\\+ac\\+bc\end{matrix}\right\}x-abc,$$

$$A'=x^3\left.\begin{matrix}-a\\-b\\-d\end{matrix}\right\}x^2\left.\begin{matrix}+ab\\+ad\\+bd\end{matrix}\right\}x-abd,$$

$$A''=x^3\left.\begin{matrix}-a\\-c\\-d\end{matrix}\right\}x^2\left.\begin{matrix}+ac\\+ad\\+bd\end{matrix}\right\}x-acd,$$

$$A'''=x^3\left.\begin{matrix}-b\\-c\\-d\end{matrix}\right\}x^2\left.\begin{matrix}+bc\\+bd\\+cd\end{matrix}\right\}x-bcd;$$

and taking the sum of these four equations;

$$A+A'+A''+A'''=4x^3\left.\begin{matrix}-3a\\-3b\\-3c\\-3d\end{matrix}\right\}x^2\left.\begin{matrix}+2ab\\+2ac\\+2ad\\+2bc\\+2bd\\+2cd\end{matrix}\right\}x\begin{matrix}-abc\\-abd\\-acd\\-bcd.\end{matrix}$$

But since $a$, $b$, $c$, $d$ are the roots of the equation

$$x^4+px^3+qx^2+rx+s=0,$$

we have $-3(a+b+c+d)=3p$,
$2(ab+ac+ad+bc+bd+cd)=2q$,
$-(abc+abd+acd+bcd)=r$;

therefore, by substitution,

$$A+A'+A''+A'''=4x^3+3px^2+2qx+r.$$

137. Let us now suppose that the proposed biquadratic equation has two equal roots, or $a=b$; then $x-a=x-b$, and since one or other of these equal factors enters each of the four products A, A′, A″, A‴, it is evident that $A+A'+A''+A'''$, or $4x^3+3px^2+2qx+r$ must be divisible by $x-a$, or $x-b$. Thus it appears that if the proposed equation

$$x^4+px^3+qx^2+rx+s=0$$

have two equal roots, each of them must also be a root of this equation,

$$4x^3+3px^2+2qx+r=0;$$

for when the first of these equations is divisible by $(x-a)^2$, the latter is necessarily divisible by $x-a$.

138. Let us next suppose that the proposed equation has three equal roots, or $a=b=c$; then, two at least of the three equal factors $x-a$, $x-b$, $x-c$, must enter each of the four products A, A′, A″, A‴; so that in this case, $A+A'+A''+A'''$, or $4x^3+3x^2+2qx+r$, must be twice divisible by $x-a$. Hence it follows, that as often as the proposed equation has three equal roots, two of them must also be equal roots of the equation

$$4x^3+3px^2+2qx+r=0.$$

139. Proceeding in the same manner, it may be shown, that whatever number of equal roots are in the proposed equation

$$x^4+px^3+qx^2+rx+s=0,$$

they will remain, except one, in this equation,

$$4x^3+3px^2+2qx+r=0,$$

which may be derived from the former, by multiplying each of its terms by the exponent of $x$ in that term, and then diminishing the exponent by unity.

140. If we suppose that the proposed equation has two equal roots, or $a=b$, and also two other equal roots, or $c=d$, then, by reasoning as before, it will appear that the equation derived from it must have one root equal to $a$ or $b$, and another equal to $c$ or $d$; so that when the former is divisible both by $(x-a)^2$ and $(x-c)^2$, the latter will be divisible by $(x-a)(x-c)$.

141. The same mode of reasoning may be extended to all equations whatever; so that if we suppose

$$x^m+Px^{m-1}+Qx^{m-2}\ \dots\ +Sx^2+Tx+U=0,$$

an equation of the $m$th degree, to have a divisor of this form,

$$(x-a)^n\,(x-d)^p\,(x-f)^q\dots\text{\&c.}$$

the equation

$$mx^{m-1}+(m-1)Px^{m-2}+(m-2)Qx^{m-3}\ \dots\ +2Sx+T=0,$$

which is of the next lower degree, will have for a divisor

$$(x-a)^{n-1}\,(x-d)^{p-1}\,(x-f)^{q-1}\dots\text{\&c.}$$

and as this last product must be a divisor of both equa-

Algebra. tions, it may always be discovered by the rule which has been given (sect. 20) for finding the greatest common divisor of two algebraic quantities.

142. Again, as this last equation must, in the case of equal roots, have the same properties as the original equation; therefore, if we multiply each of its terms by the exponent of $x$, and diminish that exponent by unity, as before, we have

$m(m-1)\,x^{m-2}+(m-1)\,(m-2)\,Px^{m-3}+(m-2)\,(m-3)\,Qx^{m-4}\ \ldots\ +2S=0,$

a new equation, which has for a divisor

$$(x-a)^{n-2}\,(x-d)^{p-2}\,(x-f)^{q-2},$$

where the exponents of the factors are one less than those of the equation from which it was derived; and as this last divisor is also a divisor of the original equation, it may be discovered in the same manner as the former, namely, by finding the greatest common measure of both equations; and so on we may proceed, as far as we please.

143. As a particular example, let us take this equation,

$$x^5-13x^4+67x^3-171x^2+216x-108=0,$$

and apply to it the method we have explained, in order to discover whether it has equal roots, and if so, what they are. We must therefore seek the greatest common measure of the proposed equation and this other equation, which is formed agreeably to what has been shown, sect. 139,

$$5x^4-52x^3+201x^2-342x+216=0\,;$$

and the operation being performed, we find that they have a common divisor, $x^3-8x^2+21x-18$, which is of the third degree, and consequently may have several factors. Let us therefore try whether the last equation, and the following,

$$20x^3-156x^2+402x-342=0,$$

which is derived from it, as directed in sect. 139, have any common divisor; and, by proceeding as before, we find that they admit of this divisor, $x-3$, which is also a factor of the last divisor, $x^3-8x^2+21x-18$; and therefore the product of remaining factors is immediately found by division to be $x^2-5x+6$, which is evidently resolvable into $x-2$ and $x-3$.

Thus it appears, upon the whole, that the common divisor of the original equation, and that which is immediately derived from it, is $(x-2)\,(x-3)^2$; and that the common divisor of the second and third equations is $x-3$. Hence it follows that the proposed equation has $(x-2)^2$ for one factor, and $(x-3)^3$ for another factor; so that the equation itself may be expressed thus, $(x-2)^2\,(x-3)^3=0$; and the truth of this conclusion may be easily verified by multiplication.

## Sect. XV.—Resolution of Equations whose Roots are Rational.

144. It has been shown in sect. 100, that the last term of any equation is always the product of its roots taken with contrary signs. Hence, when the roots are rational, they may be discovered by the following rule:

Bring all the terms of the equation to one side; find all the divisors of the last term, and substitute them successively for the unknown quantity. Then each divisor, which produces a result equal to 0, is a root of the equation.

*Ex.* 1. Let $x^3-4x^2-7x+10=0$.

The divisors of 10, the last term, are 1, 2, 5, 10, each of which may be taken either positively or negatively; and these being substituted successively for $x$, we obtain the following results: Algebra.

By putting $+1$ for $x$, $\quad 1-\ 4-\ 7+10=\ 0,$
$-1,\quad -1-\ 4+\ 7+10=\ 12,$
$+2,\quad 8-\ 16-14+10=-12,$
$-2,\quad -8-\ 16+14+10=\ 0,$
$+5,\quad 125-100-35+10=\ 0.$

Here the divisors which produce results equal to 0 are $+1$, $-2$, and $+5$; therefore these are the three roots of the proposed equation.

145. When the number of divisors to be tried is considerable, it will be convenient to transform the equation into another, in which the last term has fewer divisors. This may in general be done by forming an equation, the roots of which are greater or less than those of the proposed equation by some determinate quantity; as in the following example:

*Ex.* 2. Let $y^4-4y^3-8y+32=0$ be proposed.

Here the divisors to be tried are 1, 2, 4, 8, 16, 32, each taken either positively or negatively; but to prevent the trouble of so many substitutions, transform the equation, by putting $x+1$ for $y$.

$$\begin{array}{lrl} \text{Then} & y^4= & x^4+4x^3+\ 6x^2+\ 4x+\ 1,\\ & -4y^3= & \quad\ -4x^3-12x^2-12x-\ 4,\\ & -8y= & \qquad\qquad\qquad\ \ -\ 8x-\ 8,\\ & +32= & \qquad\qquad\qquad\qquad\quad +32.\\ \hline \text{Therefore} & & x^4\qquad -\ 6x^2-16x+21=0 \end{array}$$

is the transformed equation, and the divisors of the last term are $+1$, $-1$, $+3$, $-3$, $+7$, $-7$. These being put successively for $x$, we get $+1$ and $+3$ for two roots of the equation; as to the two remaining roots, it is easy to see that they must be imaginary. They may, however, be readily exhibited by considering that the equation $x^4-6x^2-16x+21=0$ is divisible by the product of the two factors $x-1$ and $x-3$, and therefore may be reduced to a quadratic. Accordingly, by performing the division, and putting the quotient equal 0, we have this equation,

$$x^2+4x+7=0,$$

the roots of which are the imaginary quantities $-2+\sqrt{-3}$ and $-2-\sqrt{-3}$; so that, since $y=x+1$, the roots of the equation $y^4-4y^3-8y+32=0$ are these, $y=+2$, $y=+4$, $y=-1+\sqrt{-3}$, $y=-1-\sqrt{-3}$.

If this literal equation were proposed,

$$x^3-(3a+b)x^2+(2a^2+3ab)x-2a^2b=0,$$

by proceeding as before, we should find $x=a$, $x=2a$, $x=b$ for the roots.

146. To avoid the trouble of trying all the divisors of the last term, a rule may be investigated for restricting the number to very narrow limits as follows:

Suppose that the cubic equation $x^3+px^2+qx+r=0$ is to be resolved. Let it be transformed into another, the roots of which are less than those of the proposed equation by unity. This may be done by assuming $y=x-1$, and the last term of the transformed equation will be $1+p+q+r$. Again, by assuming $y=x+1$, another equation will be formed whose roots exceed those of the proposed equation by unity, and the last term of this other transformed equation will be $-1+p-q+r$. And it is to be observed, that these two quantities $1+p+q+r$ and $-1+p-q+r$ are formed from the proposed equation $x^3+px^2+qx+r$ by substituting successively $+1$ and $-1$ for $x$.

Now the values of $x$ are some of the divisors of $r$, which is the term left in the proposed equation, when $x$ is supposed $=0$; and the values of $y$ are some of the divisors of $1+p+q+r$ and $-1+p-q+r$ respectively; and these are in arithmetical progression, increasing by the common difference, unity; because $x-1$, $x$, $x+1$, are in that progression; and it is obvious that the same reasoning will apply to an equation of any degree whatever. Hence the following rule:

Substitute in place of the unknown quantity, successively, three or more terms of the progression 1, 0, —1, &c. and find all the divisors of the sums that result; then take out all the arithmetical progressions that can be found among these divisors, whose common difference is 1, and the values of $x$ will be among these terms of the progressions, which are the divisors of the result arising from the substitution of $x=0$. When the series increases, the roots will be positive; and when it decreases, they will be negative.

*Ex.* 1. Let it be required to find a root of the equation $x^3-x^2-10x+6=0$.

| Substit. | | Result. | Divisors. | Prog. |
|---|---|---|---|---|
| $x=+1$ | $x^3-x^2$ | $-4$ | 1. 2. 4. | 4 |
| $x=\ \ 0$ | $-10x+6$ | $+6$ | 1. 2. 3. 6. | 3 |
| $x=-1$ | | $+14$ | 1. 2. 7. 14. | 2 |

In this example there is only one progression, 4, 3, 2, the term of which opposite to the supposition of $x=0$ being 3, and the series decreasing, we try if —3 substituted for $x$ makes the equation vanish; and as it succeeds, it follows that —3 is one of its roots. To find the remaining roots, if $x^3-x^2-10x+6$ be divided by $x+3$, and the quotient $x^2-4x+2$ put $=0$, they will appear to be $2+\sqrt{2}$, and $2-\sqrt{2}$.

*Ex.* 2. Let the proposed equation be

$$x^4+x^3-29x^2-9x+180=0.$$

To find its roots.

| Sub. | Res. | Divisors. | Progressions. | | | |
|---|---|---|---|---|---|---|
| 2 | 70 | 1. 2. 5. 7. 10. 14. 35. 70. | 1 | 2 | 5 | 7 |
| 1 | 144 | 1. 2. 3. 4. 6. 8. 9. 12, &c. | 2 | 3 | 4 | 6 |
| 0 | 180 | 1. 2. 3. 4. 5. 6. 9. 10, &c. | 3 | 4 | 3 | 5 |
| —1 | 160 | 1. 2. 4. 5. 8. 10. 16. 20, &c. | 4 | 5 | 2 | 4 |
| —2 | 90 | 1. 2. 3. 5. 6. 9. 10. 15, &c. | 5 | 6 | 1 | 3 |

Here there are four progressions, two increasing and two decreasing; hence, by taking their terms, which are opposite to the supposition of $x=0$, we have these four numbers, $+3$, $+4$, $-3$, $-5$, to be tried as roots of the equation, all of which are found to succeed.

147. If any of the co-efficients of the proposed equation be a fraction, the equation may be transformed into another having the co-efficient of the highest power unity, and those of the remaining terms integers by sect. 112, and the roots of the transformed equation being found, those of the proposed equation may be easily derived from them.

For example, if the proposed equation be $x^3-\frac{7}{4}x^2+\frac{35}{4}x-6=0$; let us assume $x=\frac{y}{4}$. Thus the equation is transformed to

$$\frac{y^3}{64}-\frac{7y^2}{64}+\frac{35y}{16}-6=0;$$

or $y^3-7y^2+140y-384=0$,

one root of which is $y=3$; hence $x=\frac{y}{4}=\frac{3}{4}$.

The proposed equation being now divided by $x-\frac{3}{4}$, is reduced to this quadratic, $x^2-x+8=0$, the roots of which are both impossible.

148. When the co-efficients of an equation are integers, and unity that of the highest power of the unknown quantity, if its roots are not found among the divisors of the last term, we may be certain that, whether the equation be pure or adfected, its roots cannot be exactly expressed either by whole numbers or rational fractions. This may be demonstrated by means of the following proposition. If a prime number P be a divisor of the product of two numbers A and B, it will also be a divisor of at least one of the numbers.

Let us suppose that it does not divide B, and that B is greater than P; then, putting $q$ for the greatest number of times that P can be had in B, and B′ for the remainder, we have $\frac{B}{P}=q+\frac{B'}{P}$, and therefore

$$\frac{AB}{P}=qA+\frac{AB'}{P}.$$

Hence it appears, that if P be a divisor of AB, it is also a divisor of AB′. Now B′ is less than P, for it is the remainder which is found in dividing B by P; therefore, seeing we cannot divide B′ by P, let P be divided by B′, and $q'$ put for the quotient, also B″ for the remainder. Again, let P be divided by B″, and $q''$ put for the quotient, and B‴ for the remainder, and so on; and as P is supposed to be a prime number, it is evident that this series of operations may be continued till a remainder be found equal to unity, which will at last be the case; for the divisors are the successive remainders of the divisions, and therefore each is less than the divisor which preceded it. By performing these operations, we obtain the following series of equations;

$$\left.\begin{array}{l} P=q'\,B'+B'', \\ P=q''\,B''+B''', \\ \&c. \end{array}\right\} \text{and therefore} \left\{\begin{array}{l} B'=\dfrac{P-B''}{q'}, \\ B''=\dfrac{P-B'''}{q''}, \\ \&c. \end{array}\right.$$

Hence we have $AB'=\dfrac{AP-AB''}{q'}$ and

$$\frac{q'AB'}{P}=\frac{AP-AB''}{P}=A-\frac{AB''}{P}.$$

Now, if AB be divisible by P, we have shown that AB′, and consequently $q'$AB′, is divisible by P; therefore, from the last equation, it appears that AB″ must also be divisible by P.

Again, from the preceding series of equations, we have $AB''=\dfrac{AP-AB'''}{q''}$, and therefore

$$\frac{q''AB''}{P}=\frac{AP-AB'''}{P}=A-\frac{AB'''}{P};$$

hence we conclude that AB‴ is also divisible by P.

Proceeding in this manner, and observing that the series of quantities B′, B″, B‴, &c. continually decrease till one of them $=1$, it is evident that we shall at last come to a product of this form, $A\times 1$, which must be divisible by P, and hence the truth of the proposition is manifest.

149. It follows from this proposition, that if the prime number P, which we have supposed not to be a divisor of

B, is at the same time not a divisor of A, it cannot be a divisor of AB, the product of A and B.

Let $\frac{b}{a}$ be a fraction in its lowest terms, then the numbers $a$ and $b$ have no common divisor; but from what has been just now shown, it appears, that if a prime number be not a divisor of $a$, it cannot be a divisor of $a \times a$ or $a^2$; and in like manner, that if a prime number is not a divisor of $b$, it cannot be a divisor of $b \times b$, or $b^2$; therefore it is evident that $a^2$ and $b^2$ have no common divisor, and thus the fraction $\frac{b^2}{a^2}$ is also in its lowest terms.

Hence it follows that the square of any fractional quantity is still a fraction, and cannot possibly be a whole number; and, on the contrary, that the square root of a whole number cannot possibly be a fraction; so that all such whole numbers as are not perfect squares can neither have their roots expressed by integers nor by fractions.

Seeing that if a prime number is not a divisor of $a$, it is also not a divisor of $a^2$; therefore, if it is not a divisor of $a$, it cannot be a divisor of $a \times a^2$ or $a^3$; and by reasoning in this way, it is obvious that if a prime number is not a divisor of $a$, it cannot be a divisor of $a^n$; also, that if it is not a divisor of $b$, it cannot be a divisor of $b^n$; therefore if $\frac{b}{a}$ is a fraction in its lowest terms, $\frac{b^n}{a^n}$ is also a fraction in its lowest terms; so that any power whatever of a fraction is also a fraction; and on the contrary, any root of a whole number is also a whole number. Hence it follows, that if the root of a whole number is not expressible by an integer, such root cannot be expressed by a fraction, but is therefore irrational or incommensurable.

150. Let us next suppose that

$$x^n + Px^{n-1} + Qx^{n-2} \dots + Tx + U = 0$$

is any equation whatever, in which P, Q, &c. denote integer numbers; then, if its roots are not integers, they cannot possibly be rational fractions. For, if possible, let us suppose $x = \frac{b}{a}$ a fraction reduced to its lowest terms; then, by substitution,

$$\frac{a^n}{b^n} + P\frac{a^{n-1}}{b^{n-1}} + Q\frac{a^{n-2}}{b^{n-2}} \dots + T\frac{a}{b} + U = 0;$$

and, reducing all the terms to a common denominator,

$$a^n + Pa^{n-1}b + Qa^{n-2}b^2 \dots + Tab^{n-1} + Ub^n = 0;$$

which equation may also be expressed thus,

$$a^n + b(Pa^{n-1} + Qa^{n-2}b^2 \dots + Tab^{n-2} + Ub^{n-1}) = 0,$$

where the equation consists of two parts, one of which is divisible by $b$. But by hypothesis $a$ and $b$ have no common measure, therefore $a^n$ is not divisible by $b$, sect. 149; hence it is evident that the two parts of the equation cannot destroy each other as they ought to do; therefore $x$ cannot possibly be a fraction.

## Sect. XVI.—Resolution of Equations by Approximation.

151. When the roots of an equation cannot be accurately expressed by rational numbers, it is necessary to have recourse to methods of approximation; and by these we can always determine the numerical values of the roots to as great a degree of accuracy as we please.

The application of methods of approximation is rendered easy by means of the following propositions:

I. If two numbers, either whole or fractional, be found, which, when substituted for the unknown quantity in any equation, produce results with contrary signs, we may conclude that at least one root of the proposed equation is between those numbers, and is consequently real.

Let the proposed equation be

$$x^3 - 5x^2 + 10x - 15 = 0,$$

which, by collecting the positive terms into one sum, and the negative into another, may also be expressed thus,

$$x^3 + 10x - (5x^2 + 15) = 0;$$

then, to determine a root of the equation, we must find such a number as, when substituted for $x$, will render

$$x^3 + 10x = 5x^2 + 15.$$

Let us suppose $x$ to increase and to have every degree of magnitude, from 0 upwards in the scale of number; then $x^3 + 10x$ and $5x^2 + 15$ will both continually increase, but with different degrees of quickness, as appears from the following table.

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Successive values of $x$; | 0, | 1, | 2, | 3, | 4, | 5, | 6, | &c. |
| ——— of $x^3+10x$; | 0, | 11, | 28, | 57, | 104, | 175, | 276, | &c. |
| ——— of $5x^2+15$; | 15, | 20, | 35, | 60, | 95, | 140, | 195, | &c. |

By inspecting this table, it appears that while $x$ increases from 0 to a certain numerical value, which exceeds 3, the positive part of the equation, or $x^3 + 10x$, is always less than the negative part, or $5x^2 + 15$; so that the expression

$$x^3 + 10x - (5x^2 + 15) \text{ or } x^3 - 5x^2 + 10x - 15$$

must necessarily be negative.

It also appears, that when $x$ has increased beyond that numerical value, and which is evidently less than 4, the positive part of the equation, instead of being less than the negative part, is now greater, and therefore the expression

$$x^3 - 5x^2 + 10x - 15$$

is changed from a negative to a positive quantity.

Hence we may conclude that there is some real and determinate value of $x$, which is greater than 3, but less than 4, and which will render the positive and negative parts of the equation equal to one another; therefore that value of $x$ must be a root of the proposed equation; and as what has been just now shown in a particular case will readily apply to any equation whatever, the truth of the proposition is obvious.

152. Two limits, between which all the roots of any equation are contained, may be determined by this other proposition:

II. Let N be the greatest negative co-efficient in any equation. Change the signs of the terms taken alternately, beginning with the second, and let N′ be the greatest negative co-efficient after the signs are so changed. The positive roots of the equation are contained between 0 and N+1, and the negative roots between 0 and —N′—1.

Suppose the equation to be

$$x^4 - px^3 + qx^2 - rx - s = 0,$$

which may be also expressed thus:

$$x^4\left(1 - \frac{p}{x} + \frac{q}{x^2} - \frac{r}{x^3} - \frac{s}{x^4}\right) = 0.$$

Then, whatever be the values of the co-efficients $p$, $q$, $r$, &c. it is evident that $x$ may be taken so great as to render each of the quantities $\frac{p}{x}$, $\frac{q}{x^2}$, $\frac{r}{x^3}$, $\frac{s}{x^4}$ as small as we please, and therefore their sum, or $-\frac{p}{x} + \frac{q}{x^2} - \frac{r}{x^3} - \frac{s}{x^4}$, less than 1; but in that case the quantity

$$x^4\left(1 - \frac{p}{x} + \frac{q}{x^2} - \frac{r}{x^3} + \frac{s}{x^4}\right),$$

$$\text{or } x^4 - px^3 + qx^2 - rx + s,$$

will be positive, and such, that the first term $x^4$ is greater than the sum of all the remaining terms; therefore also $x^4 + qx^2$, the sum of the positive terms, will be much greater than $px^3 + rx + s$, the sum of the negative terms alone.

Hence it follows, that if a number be found, which when substituted for $x$, renders the expression $x^4 - px^3 + qx^2 - rx - s$ positive, and which is also such, that every greater number has the same property, that number will exceed the greatest positive root of the equation.

Now, if we suppose N to be the greatest negative co-efficient, it is evident that the positive part of the equation, or $x^4+qx^2$, is greater than $px^3+rx+s$, provided that $x^4$ is greater than $N\,x^3+Nx^2+Nx+N$, or $N\,(x^3+x^2+x+1)$; but $x^3+x^2+x+1=\dfrac{x^4-1}{x-1}$, therefore a positive result will be obtained, if for $x$ there be substituted a number such that $x^4 > \dfrac{N(x^4-1)}{x-1}$*, or $x^5-x^4 > Nx^4-N$. Now this last condition will evidently be fulfilled if we take $x^5-x^4=Nx^4$, and from this equation we find $x=N+1$; but it further appears that the same condition will also be fulfilled as often as $x^5-x^4 > Nx^4$, or $x-1 > N$, that is, $x > N+1$, therefore $N+1$ must be a limit to the greatest positive root of the proposed equation, as was to be shown.

If $-y$ be substituted for $+x$, the equation $x^4-px^3+qx^2-rx-s=0$ will be transformed into $y^4+py^3+qy^2+ry-s=0$; which equation differs from the former only in the signs of the second, fourth, &c. terms; and as the positive roots of this last equation are the same as the negative roots of the proposed equation, it is evident that their limit must be such as has been assigned.

153. From the two preceding propositions it will not be difficult to discover, by means of a few trials, the nearest integers to the roots of any proposed numeral equation; and those being found, we may approximate to the roots continually, as in the following example:

$$x^4-4x^3 * -3x+27=0.$$

Here the greatest negative co-efficient being 4, it follows, sect. 152, that the greatest positive root is less than 5. If $-y$ be substituted for $x$, the equation is transformed to

$$y^4+4y^3 * +3y+27=0,$$

an equation having all its terms positive; therefore it can have no positive roots, and consequently the proposed equation can have no negative roots: its real roots must therefore be contained between 0 and $+5$.

To determine the limits of each root in particular, let 0, 1, 2, 3, 4, be substituted successively for $x$; thus we obtain the following corresponding results:

| | | | | | |
|---|---|---|---|---|---|
| Substitutions for $x$, | 0, | 1, | 2, | 3, | 4, |
| Results, | $+27$, | $+21$, | $+5$, | $-9$, | $+15$. |

Hence it appears that the equation has two real roots, one between 2 and 3, and another between 3 and 4.

That we may approximate to the first root, let us suppose $x=2+y$, where $y$ is a fraction less than unity, and therefore its second and higher powers but small in comparison to its first power: hence, in finding an approximate value of $y$, they may be rejected. Thus we have

$$\begin{aligned} x^4 &= +16+32y, \text{ \&c.} \\ -4x^3 &= -32-48y, \text{ \&c.} \\ -3x &= -\ \ 6-\ \ 3y \\ +27 &= +27 \\ \hline \text{Hence } 0 &= \ \ \ 5-19y \text{ nearly,} \end{aligned}$$

and $y=\dfrac{5}{19}=\cdot26$; therefore, for a first approximation we have $x=2\cdot26$.

Let us next suppose $x=2\cdot26+y'$; then, rejecting as before the second and higher powers of $y'$ on account of their smallness, and retaining three decimal places, we have

$$\begin{aligned} x^4 &= +26\cdot087+46\cdot172y', \text{ \&c.} \\ -4x^3 &= -46\cdot172-61\cdot291y', \text{ \&c.} \\ -3x &= -\ \ 6\cdot780-\ \ 3y' \\ +27 &= +27 \\ \hline 0 &= \ \ \ \cdot135-18\cdot119y' \text{ nearly.} \end{aligned}$$

Hence $y'=\dfrac{\cdot135}{18\cdot119}=\cdot0075$, and $x=2\cdot26+y'=2\cdot2675$. This value of $x$ is true to the last figure, but a more accurate value may be obtained by supposing $x=2\cdot2675+y''$, and finding the value of $y''$ in the same manner as we have already found those of $y'$ and $y$; and thus the approximation may be continued till any required degree of accuracy be obtained.

The second root of the equation, which we have already found to be between 3 and 4, may be investigated in the same manner as the first, and will appear to be 3·6797, the approximation being carried on to the fourth figure of the decimal, in determining each root.

154. In the preceding example we have shown how to approximate to the roots of an adfected equation; but the same method will also apply to pure equations.

For example, let it be required to determine $x$ from this equation, $x^3=2$.

Because $x$ is greater than 1 and less than 2, but nearer to the former number than to the latter, let us assume $x=1+y$; then, rejecting the powers of $y$ which exceed the first, we have $x^3=1+3y$, and therefore $2=1+3y$, and $y=\frac{1}{3}=\cdot3$ nearly; hence $x=1\cdot3$ nearly.

Let us next assume $x=1\cdot3+y$, then, proceeding as before, we find $2=2\cdot197+5\cdot07y$, hence $y=-\dfrac{\cdot197}{5\cdot07}=-\cdot039$, and $x=1\cdot3-\cdot039=1\cdot26$ nearly.

To find a still nearer approximation, let us suppose $x=1\cdot26+y$, then, from this assumption we find $y=-\cdot000079$, and therefore $x=1\cdot259921$, which value is true to the last figure.

155. By assuming an equation of any order with literal co-efficients, a general formula may be investigated for approximating to the roots of equations belonging to that particular order.

Let us take for an example the cubic equation

$$x^3+px^2+qx+r=0,$$

and suppose that $x=a+y$, where $a$ is nearly equal to $x$, and $y$ is a small fraction. Then, by substituting $a+y$ for $x$ in the proposed equation, and rejecting the powers of $y$ which exceed the first, on account of their smallness, we have

$$a^3+pa^2+qa+r+(3a^2+2pa+q)y=0.$$

Hence $y=-\dfrac{a^3+pa^2+qa+r}{3a^2+2pa+q}$,

and $x=a-\dfrac{a^3+pa^2+qa+r}{3a^2+2pa+q}=\dfrac{2a^3+pa^2-r}{3a^2+2pa+q}$.

Let it be required to approximate to a root of the cubic equation $x^3+2x^2+3x-50=0$. Here $p=2$, $q=3$, and $r=-50$; and by trials it appears that $x$ is between 2 and 3, but nearest the latter number; therefore, for the first approximation, $a$ may be supposed $=3$, hence we find

$$x=\frac{2a^3+pa^2-r}{3a^2+2pa+q}=\tfrac{122}{42}=\tfrac{61}{21}.$$

By substituting $\frac{61}{21}$ for $a$ in the formula, and proceeding as

* The sign $>$ denotes that the quantities between which it is placed are unequal. Thus $a > b$ signifies that $a$ is greater than $b$, and $a < c$, that $a$ is less than $c$.

before, a value of $x$ would be found more exact than the former, and so on we may go as far as we please.

156. The method we have hitherto employed for approximating to the roots of equations is known by the name of *the method of successive substitutions*, and was first proposed by Newton. It has been since improved by Lagrange, who has given it a form which has the advantage of showing the progress made in the approximation by each operation. This improved form we now proceed to explain.

Let $a$ denote the whole number next less to the root sought, and $\frac{1}{y}$ a fraction, which, when added to $a$, completes the root; then $x=a+\frac{1}{y}$. If this value of $x$ be substituted in the proposed equation, a new equation involving $y$ will be had, which, when cleared of fractions, will necessarily have a root greater than unity.

Let $b$ be the whole number which is next less than that root; then, for a first approximation, we have $x=a+\frac{1}{b}$. But $b$ being only an approximate value of $y$, in the same manner as $a$ is an approximate value of $x$, we may suppose $y=b+\frac{1}{y'}$; then, by substituting $b+\frac{1}{y'}$ for $y$, we shall have a new equation, involving only $y'$, which must be greater than unity. Putting therefore $b'$ to denote the next whole number less than the root of the equation involving $y'$, we have $y=b+\frac{1}{b'}=\frac{bb'+1}{b'}$; and substituting this value in that of $x$, the result is

$$x=a+\frac{b'}{bb'+1}$$

for a second approximate value of $x$.

To find a third value, we may take $y'=b'+\frac{1}{y''}$; then if $b''$ denote the next whole number less than $y''$, we have

$$y'=b'+\frac{1}{b''}=\frac{b'b''+1}{b''}, \text{ whence}$$

$$y=b+\frac{b''}{b'b''+1}=\frac{bb'b''+b''+b}{b'b''+1}, \text{ and}$$

$$x=a+\frac{b'b''+1}{bb'b''+b''+b'},$$

and so on, to obtain more accurate approximations.

We shall apply this method to the following example:

$$x^3-7x+7=0.$$

Here the positive roots must be between 0 and 8; let us therefore substitute successively, 0, 1, 2, . . . to 8, and we obtain the following results:

Substitutions.

0, 1, 2, 3, 4, 5, 6, 7, 8,

Results.

+7, +1, +1, +13, +43, +97, +181, +301, +463.

But as these results have all the same sign, nothing can be concluded respecting the magnitude of the roots from that circumstance alone. It is however observable, that while $x$ increases from 0 to 1, the results decrease; but that whatever successive magnitudes $x$ has greater than 2, the results increase. We may therefore reasonably conclude, that if the equation have any positive roots, they must be between 1 and 2. Accordingly, by substituting 1·2, 1·4, 1·6, and 1·8, successively for $x$, we find these results, +·328, —·056, —·104, +·232; and as there are here two changes of the signs, it follows that the equation has two positive roots, one between 1·2 and 1·4, and another between 1·6 and 1·8.

Hence it appears, that to find either value of $x$, we may assume $x=1+\frac{1}{y}$; then, by substitution, we have

$$y^3-4y^2+3y+1=0.$$

The limit of the positive root of this last equation is 5, and by substituting 0, 1, 2, 3, 4, successively for $y$, it will be found to have two, one between 1 and 2, and the other between 2 and 3. Therefore, for a first approximation, we have

$$x=1+\tfrac{1}{1},\ x=1+\tfrac{1}{2}, \text{ that is, } x=2,\ x=\tfrac{3}{2}.$$

To approach nearer to the first value of $y$, let us take $y=1+\frac{1}{y'}$, and therefore

$$y'^3-2y'^2-y'+1=0.$$

This last equation will be found to have only one real root between 2 and 3; from which it appears that $y=1+\frac{1}{2}=\frac{3}{2}$, and $x=1+\frac{2}{3}=\frac{5}{3}$.

Let us next suppose $y'=2+\frac{1}{y''}$; hence we find

$$y''^3-3y''^2-4y''-1=0,$$

and from this equation, $y''$ is found to be between 4 and 5. Taking the least limit we have

$$y'=2+\tfrac{1}{4}=\tfrac{9}{4},\ y=1+\tfrac{4}{9}=\tfrac{13}{9},\ x=1+\tfrac{9}{13}=\tfrac{22}{13}.$$

It is easy to continue this process, by assuming $y''=4+\frac{1}{y'''}$, and so on, as far as may be judged necessary.

We return to the second value of $x$, which was found $=\frac{3}{2}$ by the first approximation, and which corresponds to $y=2$. Putting $y=2+\frac{1}{y'}$, and substituting this value in the equation $y^3-4y^2+3y+1=0$, which was formerly found, we get

$$y'^3+y'^2-2y'-1=0.$$

This, as well as the corresponding equation employed in determining the other value of $x$, has only one root greater than unity, which root being between 1 and 2, let us take $y'=1$, we thence find

$$y=3, \text{ and } x=1+\tfrac{1}{3}=\tfrac{4}{3}.$$

Put $y'=1+\frac{1}{y''}$, and we thence find by substitution

$$y''^3-3y''^2-4y''-1=0,$$

an equation which gives $y''$ between 4 and 5; hence, as before,

$$y'=\tfrac{5}{4},\ y=\tfrac{14}{5},\ x=\tfrac{19}{14}.$$

That we may proceed in the approximation, we have only to suppose $y''=4+\frac{1}{y'''}$, and so on.

The equation $x^3-7x+7$ has also a negative root between $-3$ and $-4$; and to find a nearer value, put $x=-3-\frac{1}{y}$; hence, $y^3-20y^2-9y-1=0$, and $y>20$, $y<21$; and therefore, for the first approximation, $x=-3-\frac{1}{20}=-\frac{61}{20}$. By putting $y=20+\frac{1}{y'}$, &c. we may obtain successive values of $x$, each of which will be more exact than that which preceded it.

157. The successive equations which involve $y$, $y'$, $y''$, &c. have never more than one root greater than unity,

unless two or more roots of the proposed equation are contained between the limits $a$ and $a+1$; but then, as in the preceding example, some one of the equations involving $y$, $y'$, &c. will have more than one root greater than unity, and from each root a series of equations may be derived, by which we may approximate to the particular roots of the proposed equation contained between the limits $a$ and $a+1$.

## Sect. XVII.—Of Infinite Series.

158. The resolving of any proposed quantity into a series, is a problem of considerable importance in the application of algebra to the higher branches of the mathematics; and there are various methods by which it may be performed, suited to the particular forms of the quantities.

Any rational fraction may be resolved into a series, by the common operation of algebraic division, as in the following examples:

*Ex.* 1. To change $\frac{ax}{a-x}$ into an infinite series.

Operation.

$$\begin{array}{l} a-x)\,ax \quad \left(x+\frac{x^2}{a}+\frac{x^3}{a^2}+\frac{x^4}{a^3}, \text{ \&c.}\right. \\ \underline{ax-x^2} \\ \quad +x^2 \\ \quad \underline{+x^2-\frac{x^3}{a}} \\ \qquad +\frac{x^3}{a} \\ \qquad \underline{+\frac{x^3}{a}-\frac{x^4}{a^2}} \\ \qquad\quad +\frac{x^4}{a^2} \end{array}$$

Thus it appears that

$$\frac{ax}{a-x}=x+\frac{x^2}{a}+\frac{x^3}{a^2}+\frac{x^4}{a^3}+, \text{ \&c.}$$

Here the law of the series being evident, the terms may be continued at pleasure.

*Ex.* 2. By a like process we find

$$\frac{a^2}{(a+x)^2}=1-\frac{2x}{a}+\frac{3x^2}{a^2}-\frac{4x^3}{a^3}+\frac{5x^4}{a^4}-, \text{ \&c.}$$

the law of continuation being evident.

159. A second method by which algebraic quantities, whether rational or irrational, may be converted into series, and which is also of very extensive use in the higher parts of the mathematics, consists in assuming a series with indeterminate co-efficients, and having its terms arranged according to the powers of some quantity contained in the proposed expression.

That we may explain this method, let us suppose that the fraction $\frac{a^2}{a^2+ax+x^2}$ is to be converted into a series proceeding by the powers of $x$. We are therefore to assume

$$\frac{a^2}{a^2+ax+x^2}=A+Bx+Cx^2+Dx^3+Ex^4+, \text{ \&c.}$$

where A denotes those terms of the series into which $x$ does not at all enter, B$x$ the terms which contain only the first power of $x$, C$x^2$ the terms which contain only the second power, and so on. Let both sides of the equation be multiplied by $a^2+ax+x^2$, so as to take away the denominator of the fraction, and let the numerator $a^2$ be transposed to the other side, so that the whole expression may be $=0$; then

$$\left.\begin{array}{l} a^2A+a^2B \\ -a^2+aA \end{array}\right\} x \left.\begin{array}{l} +a^2C \\ +aB \\ +A \end{array}\right\} x^2 \left.\begin{array}{l} +a^2D \\ +aC \\ +B \end{array}\right\} x^3 \left.\begin{array}{l} +a^2E \\ +aD \\ +C \end{array}\right\} x^4, \text{ \&c.}=0.$$

Now the quantities A, B, C, D, &c. being supposed to be entirely independent of any particular value of $x$, it follows that the whole expression can only be $=0$, upon the supposition that the terms which multiply the same powers of $x$ are separately $=0$; for if that were not the case, it would follow that $x$ had a determinate relation to the quantities A, B, C, &c. which is contrary to what we have supposed. To determine the quantities A, B, C, &c. therefore, we have this series of equations,

$$\begin{array}{ll} a^2A-a^2 \quad =0, & \text{hence } A=1; \\ a^2B+aA \quad =0, & B=-\frac{A}{a}=-\frac{1}{a}; \\ a^2C+aB+A=0, & C=-\frac{B}{a}-\frac{A}{a^2}=0; \\ a^2D+aC+B=0, & D=-\frac{C}{a}-\frac{B}{a^2}=\frac{1}{a^3}; \\ a^2E+aD+C=0, & E=-\frac{D}{a}-\frac{C}{a^2}=-\frac{1}{a^4}, \\ \text{\&c.} & \text{\&c.} \end{array}$$

Here the law of relation which takes place among the quantities A, B, C, D, &c. is evident, viz. that if P, Q, R denote any three co-efficients which immediately follow each other,

$$a^2R+aQ+P=0;$$

and from this equation, by means of the co-efficients already determined, we find $F=0$, $G=\frac{1}{a^6}$, $H=-\frac{1}{a^7}$, $K=0$, &c.

Therefore, resuming the assumed equation, and substituting for A, B, C, &c. their respective values, we have

$$\frac{a^2}{a^2+ax+x^2}=1-\frac{x}{a} * +\frac{x^3}{a^3}-\frac{x^4}{a^4} * +\frac{x^6}{a^6}-\frac{x^7}{a^7} * +, \text{\&c.}$$

As a second example of the method of indeterminate co-efficients, let it be required to express the square root $a^2-x^2$ by means of a series. For this purpose we might assume

$$\sqrt{a^2-x^2}=A+Bx+Cx^2+Dx^3+Ex^4+, \text{ \&c.};$$

but as we would then find the co-efficients of the odd powers of $x$ to be each $=0$, let us rather assume

$$\sqrt{a^2-x^2}=A+Bx^2+Cx^4+Dx^6+, \text{ \&c.}$$

then, squaring both sides, and transposing, we have

$$0=\left\{\begin{array}{l} A^2+2AB \\ \quad + \quad 1 \\ -a^2 \end{array}\right\} x^2 \left.\begin{array}{l} +2AC \\ \\ +B^2 \end{array}\right\} x^4 \left.\begin{array}{l} +2AD \\ \\ +2BC \end{array}\right\} x^6+, \text{ \&c.}$$

$$\begin{array}{lll} \text{Hence } A^2-a^2 & =0, & \text{and } A=a; \\ 2AB+1 & =0, & B=-\frac{1}{2A}=-\frac{1}{2a}; \\ 2AC+B^2 & =0, & C=-\frac{B^2}{2A}=-\frac{1}{8a^3}; \\ AD+BC & =0, & D=-\frac{BC}{A}=-\frac{1}{16a^5}; \\ \text{\&c.} & & \text{\&c.} \end{array}$$

Algebra. and substituting for A, B, C, &c. their values;

$$\sqrt{a^2-x^2}=a-\frac{x^2}{2a}-\frac{x^4}{8a^3}-\frac{x^6}{16a^5}-, \text{\&c.}$$

This method of resolving a quantity into any infinite series will be found more expeditious than any other, as often as the operations of division and evolution are to be performed at the same time, as in these expressions,

$$\frac{1}{\sqrt{a^2+x^2}}, \text{ or } \frac{\sqrt{a^2-x^2}}{\sqrt[3]{a^3+x^3}}.$$

160. The binomial theorem affords a third method of resolving quantities into series; but we must first show how the theorem itself may be investigated.

Let $a+x$ be any binomial quantity which is to be raised to a power denoted by $\frac{m}{n}$, where $m$ and $n$ are any numbers either positive or negative.

Because $a+x=a\left(1+\frac{x}{a}\right)$, if we put $\frac{x}{a}=y$, then $(a+x)^{\frac{m}{n}}$ $=a^{\frac{m}{n}}\times(1+y)^{\frac{m}{n}}$; therefore, instead of $a+x$, we may consider $1+y$, which is somewhat more simple in its form.

By considering some integer powers of $1+x$, as

$$\begin{aligned}(1+x)&=1+x,\\(1+x)^2&=1+2x+x^2,\\(1+x)^3&=1+3x+3x^2+x^3,\\(1+x)^4&=1+4x+6x^2+4x^3+x^4,\\&\text{\&c.}\end{aligned}$$

it may be inferred that all powers of $1+x$ have this form,

$$1+Ax+Bx^2+Cx^3+Dx^4+Ex^5+, \text{\&c.}$$

where the co-efficients A, B, C, D, E, &c. are numbers which are altogether independent of any particular value of $x$. It also appears that the series cannot contain any negative power of $x$; for if any of its terms had this form, $\frac{Q}{x^r}$, then the supposition of $x=0$ would render that term indefinitely great; whereas the whole series ought in that case to be reduced to unity.

Let us therefore assume

$$(1+y)^{\frac{m}{n}}=1+Ay+By^2+Cy^3+Dy^4+, \text{\&c.}$$

Then we have also

$$(1+z)^{\frac{m}{n}}=1+Az+Bz^2+Cz^3+Dz^4+Ez^5+, \text{\&c.}$$

Let us put $(1+y)^{\frac{1}{n}}=u$, $(1+z)^{\frac{1}{n}}=v$, and therefore $(1+y)^{\frac{m}{n}}=u^m$, $(1+z)^{\frac{m}{n}}=v^m$; then, taking the difference between the two series, we have

$$u^m-v^m=A(y-z)+B(y^2-z^2)+C(y^3-z^3)+D(y^4-z^4)+E(y^5-z^5)+, \text{\&c.}$$

Because $u^n=1+y$ and $v^n=1+z$, by subtracting the latter equation from the former, we have $u^n-v^n=y-z$; hence, and from the last series, it follows that

$$\frac{u^m-v^m}{u^n-v^n}=\frac{A(y-z)}{y-z}+\frac{B(y^2-z^2)}{y-z}+\frac{C(y^3-z^3)}{y-z}+\frac{D(y^4-z^4)}{y-z}+\frac{E(y^5-z^5)}{y-z}+, \text{\&c.}$$

But every expression of the form $u^m-v^m$ is divisible by $u-v$, when $m$ is a whole number. Thus we have

$$\left.\begin{aligned}u^m-v^m&=(u-v)\,(u^{m-1}+u^{m-2}v\ldots+uv^{m-2}+v^{m-1})\\u^n-v^n&=(u-v)\,(u^{n-1}+u^{n-2}v\ldots+uv^{n-2}+v^{n-1})\end{aligned}\right\}$$

so that if we substitute for $\frac{u^m-v^m}{u^n-v^n}$ its value as found from these equations, and divide each term of the series by the denominator $y-z$, we have Algebra.

$$\frac{u^{m-1}+u^{m-2}v\ldots+uv^{m-2}+v^{m-1}}{u^{n-1}+u^{n-2}v\ldots+uv^{n-2}+v^{n-1}}=$$
$$A+B(y+z)+C(y^2+yz+z^2)+D(y^3+y^2z+yz^2+z^3)+E(y^4+y^3z+y^2z^2+yz^3+z^4)+, \text{\&c.}$$

Now, as this last equation must be true, whatever be the values of $y$ and $z$, we may suppose $y=z$, but in that case $1+y=1+z$, or $u^n=v^n$, and therefore $u=v$. Thus the equation is reduced to

$$\frac{mu^{m-1}}{nu^{n-1}}=A+2By+3Cy^2+4Dy^3+5Ey^4+, \text{\&c.}$$

or to the following:

$$\frac{m}{n}u^m=u^n\,(A+2\,By+3\,Cy^2+4\,Dy^3+5\,Ey^4+, \text{\&c.});$$

so that, putting for $u^m$ and $u^n$ their values $(1+y)^{\frac{m}{n}}$ and $1+y$, we have

$$\frac{m}{n}(1+y)^{\frac{m}{n}}=(1+y)(A+2By+3Cy^2+4Dy^3+5Ey^4+, \text{\&c.})$$
$$=\begin{cases}A+2\,By+3\,Cy^2+4\,Dy^3+5\,Ey^4+, \text{\&c.}\\ \quad+Ay+2\,By^2+3\,Cy^3+4\,Dy^4+, \text{\&c.}\end{cases}$$

But from the equation originally assumed we have

$$\frac{m}{n}(1+y)^{\frac{m}{n}}=$$
$$\frac{m}{n}+\frac{m}{n}Ay+\frac{m}{n}By^2+\frac{m}{n}Cy^3+\frac{m}{n}Dy^4+, \text{\&c.}$$

Therefore

$$\frac{m}{n}+\frac{m}{n}Ay+\frac{m}{n}By^2+\frac{m}{n}Cy^3+\frac{m}{n}Dy^4+, \text{\&c.}$$
$$=\begin{cases}A+2By+3Cy^2+4Dy^3+5Ey^4+, \text{\&c.}\\ \quad+Ay+2By^2+3Cy^3+4Dy^4+, \text{\&c.}\end{cases}$$

And as the co-efficients of the terms have no connection with any particular value of $y$, it follows that the co-efficient of any power of $y$ on the one side of the equation must be equal to the co-efficient of the same power of $y$ on the other side. Therefore, to determine A, B, C, &c. we have the following series of equations:

$$A=\frac{m}{n}, \qquad \text{hence } A=\frac{m}{n};$$

$$2B+A=\frac{m}{n}A, \qquad B=\frac{A\left(\frac{m}{n}-1\right)}{2}=\frac{A\,(m-n)}{2n};$$

$$3C+2B=\frac{m}{n}B, \qquad C=\frac{B\left(\frac{m}{n}-2\right)}{3}=\frac{B\,(m-2n)}{3n};$$

$$4D+3C=\frac{m}{n}C, \qquad D=\frac{C\left(\frac{m}{n}-3\right)}{4}=\frac{C\,(m-3n)}{4n};$$

$$5E+4D=\frac{m}{n}D, \qquad E=\frac{D\left(\frac{m}{n}-4\right)}{5}=\frac{D\,(m-4n)}{5n};$$

&c. &c.

Or, substituting for A, B, C, &c. their values as determined from the preceding equations:

$$A=\frac{m}{n},$$

$$B=\frac{m\,(m-n)}{1\ \ 2n^2},$$

$$C=\frac{m\,(m-n)\,(m-2n)}{1\cdot 2\cdot 3\ \ n^3},$$

$$D=\frac{m(m-n)(m-2n)(m-3n)}{1\cdot 2\cdot 3\cdot 4\ n^4},$$

$$E=\frac{m(m-n)(m-2n)(m-3n)(m-4n)}{1.2\ 3\ 4.5\ n^5},$$

&c.

Resuming now the assumed equation

$$(1+y)^{\frac{m}{n}}=1+Ay+By^2+Cy^3+,\ \&c.$$

and observing that $\frac{x}{a}=y$, and $(a+x)^{\frac{m}{n}}=a^{\frac{m}{n}}(1+y)^{\frac{m}{n}}$, we have $(a+x)^{\frac{m}{n}}$ expressed by the series

$$a^{\frac{m}{n}}\left(1+\frac{m}{n}\frac{x}{a}+\frac{A(m-n)}{2n}\frac{x^2}{a^2}+\frac{B(m-2n)}{3n}\frac{x^3}{a^3}+\frac{C(m-3n)}{4n}\frac{x^4}{a^4}+\frac{D(m-4n)}{5n}\frac{x^5}{a^5}+,\ \&c.\right)$$

where A, B, C, &c. denote the co-efficients of the preceding terms, or

$$(a+x)^{\frac{m}{n}}=a^{\frac{m}{n}}+\frac{m}{n}a^{\frac{m-n}{n}}x+\frac{m(m-n)}{1\cdot 2\ n^2}a^{\frac{m-2n}{n}}x^2+\frac{m(m-n)(m-2n)}{1\cdot 2\cdot 3\ n^3}a^{\frac{m-3n}{n}}x^3+\frac{m(m-n)(m-2n)(m-3n)}{1\cdot 2\cdot 3\cdot 4\ n^4}{}^{\frac{m-4n}{n}}ax^4+,\ \&c.;$$

and either of these formulæ may be considered as a general theorem for raising a binomial quantity $a+x$ to any power whatever.

161. In determining the value of the expression $\frac{u^m-v^m}{u^n-v^n}$, when $u=v$, it has been assumed that $\frac{m}{n}$ is positive; but the same conclusion will be obtained when $\frac{m}{n}$ is negative. For, changing $+m$ into $-m$, and observing that

$$u^{-m}-v^{-m}=\frac{1}{u^m}-\frac{1}{v^m}=\frac{v^m-u^m}{u^mv^m},$$

we have

$$\frac{u^{-m}-v^{-m}}{u^n-v^n}=\frac{1}{u^mv^m}\left(\frac{v^m-u^m}{u^n-v^n}\right)=-\frac{1}{u^mv^m}\left(\frac{u^m-v^m}{u^n-v^n}\right).$$

Now we have already found, that when $u=v$, the fraction $\frac{u^m-v^m}{u^n-v^n}$ becomes $\frac{mu^{m-1}}{nu^{n-1}}$; therefore, in the same case,

$$\frac{u^{-m}-v^{-m}}{u^n-v^n}=\frac{-1}{u^{2m}}\times\frac{mu^{m-1}}{nu^{n-1}}=\frac{-mu^{-m-1}}{nu^{n-1}};$$

and from this last expression we derive the same value for $u^{-m}$ or $(1+y)^{\frac{-m}{n}}$ as before, regard being had to the change of the sign of the exponent.

162. If we suppose $m$ to be a positive integer, and $n=1$, the series given in last article for the powers of $a+x$ will always terminate, as appears also from the operation of involution; but if $m$ be negative, or $\frac{m}{n}$ a fraction, the series will consist of an indefinite number of terms. Examples of the application of the theorem have been already given upon the first supposition, when treating of involution; we now proceed to show how it is to be applied to the expansion of algebraic quantities into series upon either of the last two hypotheses.

*Ex.* 1. It is required to express $\frac{r^3}{(r+z)^3}$ by means of a series.

Because $\frac{r}{r+z}=\frac{1}{1+\frac{z}{r}}$,

therefore $\frac{r^3}{(r+z)^3}=\frac{1}{\left(1+\frac{z}{r}\right)^3}=\left(1+\frac{z}{a}\right)^{-3}$

Let $\left(1+\frac{z}{r}\right)^{-3}$ be compared with $(a+x)^{\frac{m}{n}}$, and we have $a=1$, $x=\frac{z}{r}$, $m=-3$, $n=1$.

Hence, by substituting these values of $a$, $x$, $m$, $n$, in the first general formula of sect. 160, we have

$$\frac{r^3}{(r+z)^3}\begin{cases}=1-\frac{3z}{r}+\frac{3\cdot 4z^2}{1\cdot 2r^2}-\frac{3\cdot 4\cdot 5z^3}{1\cdot 2\cdot 3r^3}+,\ \&c.\\ =1-\frac{3z}{r}+\frac{6z^2}{r^2}-\frac{10z^3}{r^3}+\frac{15z^4}{r^4}-,\ \&c.\end{cases}$$

*Ex.* 2. It is required to express $\sqrt[3]{a+b}$ in the form of a series.

Because $a+b=a\left(1+\frac{b}{a}\right)$,

therefore $\sqrt[3]{a+b}=\sqrt[3]{a}\times\sqrt[3]{1+\frac{b}{a}}=a^{\frac{1}{3}}\left(1+\frac{b}{a}\right)^{\frac{1}{3}}$.

By comparing $\left(1+\frac{b}{a}\right)^{\frac{1}{3}}$ with $(a+x)^{\frac{m}{n}}$, we have $a=1$, $x=\frac{b}{a}$, $m=1$, $n=3$, and $\sqrt[3]{a+b}$

$$=a^{\frac{1}{3}}\left(1+\frac{1\cdot b}{3a}-\frac{1\cdot 2b^2}{3\cdot 6a^2}+\frac{1\cdot 2\cdot 5b^3}{3\cdot 6\cdot 9a^3}-\frac{1\cdot 2\cdot 5\cdot 8b^4}{3\cdot 6\cdot 9\cdot 12a^4}+,\ \&c.\right)$$

$$=a^{\frac{1}{3}}\left(1+\frac{b}{3a}-\frac{b^2}{9a^2}+\frac{5b^3}{81a^3}-\frac{10b^4}{243a^4}+,\ \&c.\right)$$

*Ex.* 3. It is required to resolve $\frac{r^2}{(r^3+z^3)^{\frac{2}{3}}}$ into a series.

Because $\frac{r^2}{(r^3+z^3)^{\frac{2}{3}}}=r^2(+z3)^{-\frac{2}{3}}$ if we raise $r^3+z^3$ to the $-\frac{2}{3}$ power, and multiply the resulting series by $r^2$, we shall have the series required. Or the given quantity may be reduced to a more simple form thus: because

$$r^3+z^3=r^3\times\left(1+\frac{z^3}{r^3}\right),$$

therefore $(r^3+z^3)^{\frac{2}{3}}=r^2\left(1+\frac{z^3}{r^3}\right)^{\frac{2}{3}}$,

and $\frac{r^2}{(r^3+z^3)^{\frac{2}{3}}}=\frac{1}{\left(1+\frac{z^3}{r^3}\right)^{\frac{2}{3}}}=\left(1+\frac{z^3}{r^3}\right)^{-\frac{2}{3}}$.

Hence $\frac{r^2}{(r^3+z^3)^{\frac{2}{3}}}=\left(1+\frac{z^3}{r^3}\right)^{-\frac{2}{3}}$

$$=1-\frac{2z^3}{3r^3}+\frac{2\cdot 5z^6}{3\cdot 6r^6}-\frac{2\cdot 5\cdot 8z^9}{3\cdot 6\cdot 9r^9}+\frac{2\cdot 5\cdot 8\cdot 11z^{12}}{3\cdot 6\cdot 9\cdot 12r^{12}}-,\ \&c.$$

$$=1-\frac{2z^3}{3r^3}+\frac{5z^6}{9}-\frac{40z^9}{81r^9}+\frac{110z^{12}}{243r^{12}}-.\ \&c.$$

*Ex.* 4. It is required to find a series equal to $\frac{\sqrt{a^2+x^2}}{\sqrt{a^2-x^2}}$

By the binomial theorem, we have

$$\sqrt{a^2+x^2}=(a^2+x^2)^{\frac{1}{2}}=a+\frac{x^2}{2a}-\frac{x^4}{8a^3}+\frac{x^6}{16a^5}-,\ \&c.$$

$$\frac{1}{\sqrt{a^2-x^2}}=(a^2-x^2)^{-\frac{1}{2}}=\frac{1}{a}+\frac{x^2}{2a^3}+\frac{3x^4}{8a^5}+\frac{5x^6}{16a^7}+, \&c.$$

Therefore, by taking the product of the two series, and proceeding in the operation only to such terms as involve the 6th power of $x$, we find

$$\frac{\sqrt{a^2+x^2}}{\sqrt{a^2-x^2}}=1+\frac{x^2}{a^2}-\frac{x^4}{2a^4}+\frac{x^6}{2a^6}, \&c.$$

## Sect. XVIII.—Of the Reversion of Series.

163. The method of indeterminate co-efficients, which we have already employed when treating of infinite series, may also be applied to what is called the reverting of series; that is, having any quantity expressed by an infinite series composed of the powers of another quantity, to express, on the contrary, the latter quantity by means of an infinite series composed of the powers of the former.

Let $y=n+ax+bx^2+cx^3+dx^4+$, &c.

Then, to revert the series, we must find the value of $x$ in terms of $y$. For this purpose, we transpose $n$, and put $z=y-n$; then

$$z=ax+bx^2+cx^3+dx^4+, \&c.$$

Now, when $x=0$, it is evident that $z=0$; therefore we may assume for $x$ a series of this form,

$$x=Az+Bz^2+Cz^3+Dz^4+, \&c.$$

where the co-efficients A, B, C, D, &c. denote quantities as yet unknown, but which are entirely independent of the quantity $x$. To determine these, let the first, second, third, &c. powers of the series

$$Az+Bz^2+Cz^3+Dz^4+, \&c.$$

be found by multiplication, and substituted for $x$, $x^2$, $x^3$, &c. respectively, in the equation

$$0=-z+ax+bx^2+cx^3, \&c.$$

thus we have

$$\left.\begin{array}{lllll}
-z & =-z & & & \\
+ax & =aAz & +aB\,z^2 & +\;aCz^3 & +\;aDz^4+, \&c. \\
+bx^2 & = & +bA^2z^2 & +2bABz^3 & +2bACz^4+, \&c. \\
 & & & & +\;bB^2z^4 \\
+cx^3 & = & & +\;cA^3z^3 & +3cA^2Bz^4+, \&c. \\
+dx^4 & = & & & +\;dA^4z^4+, \&c. \\
\&c. & & & &
\end{array}\right\}=0$$

Hence, putting the co-efficients of $z$, $z^2$, $z^3$, &c. each $=0$,

$$aA-1=0,\quad aB+bA^2=0,\quad aC+2bAB+cA^3=0,$$
$$aD+2bAC+bB^2+3cA^2B+dA^4=0, \&c.$$

these equations give

$$A=\frac{1}{a},$$

$$B=-\frac{b}{a^3},$$

$$C=\frac{2b^2-ac}{a^5},$$

$$D=-\frac{5b^3-5abc+a^2d}{a^7},$$

&c.

Therefore $$x=\frac{1}{a}z-\frac{b}{a^3}z^2+\frac{2b^2-ac}{a^5}z^3-\frac{5b^3-5abc+a^2d}{a^7}z^4+, \&c.$$

As an example of the application of this formula, let it be required to determine $x$ from the equation

$$y=x-\frac{x^2}{2}+\frac{x^3}{3}-\frac{x^4}{4}+, \&c.$$

In this case we have

$$z=y,\ a=1,\ b=-\tfrac{1}{2},\ c=\tfrac{1}{3},\ d=-\tfrac{1}{4}, \&c.$$

Therefore, substituting these values, we have

$$x=y+\frac{y^2}{2}+\frac{y^3}{6}+\frac{y^4}{24}+, \&c.$$

In the equation

$$ay+by^2+cy^3+, \&c. = a'x+b'x^2+c'x^3+, \&c.$$

in which both sides are expressed by series, and it is required to find $y$ in terms of $x$, we must assume, as before,

$$y=Ax+Bx^2+Cx^3+Dx^4+, \&c.$$

and substitute this series and its powers for $y$ and its powers in the proposed equation; afterwards, by bringing all the terms to one side, and making the co-efficients of each power of $y=0$, a series of equations will be had by which the quantities A, B, C, D, &c. may be determined.

## Sect. XIX.—Of Logarithms and Exponential Quantities.

164. All positive numbers may be considered as powers of any one given affirmative number. The powers of 2, for instance, may become equal, either exactly, or nearer than by any assignable difference, to all numbers whatever, from 1 upwards. If the exponents be integers, we shall have only the numbers which form the geometrical progression, 1, 2, 4, 8, 16, &c.; but the intermediate numbers may be expressed, at least nearly, by means of fractional exponents. Thus, the numbers from 1 to 10 may be expressed by the powers of 2 as follows:

| | |
|---|---|
| $2^0=1$ | $2^{2\cdot585}=6$ |
| $2^1=2$ | $2^{2\cdot807}=7$ |
| $2^{1\cdot585}=3$ | $2^{3\cdot}=8$ |
| $2^2=4$ | $2^{3\cdot170}=9$ |
| $2^{2\cdot322}=5$ | $2^{3\cdot322}=10$ |

In like manner may fractions be expressed by the powers of 2. Thus,

$$\cdot1=\frac{1}{2^{3\cdot322}}=2^{-3\cdot322},\quad \cdot2=\frac{1}{2^{2\cdot322}}=2^{-2\cdot322},$$

$$\cdot3=\frac{1}{2^{1\cdot737}}=2^{-1\cdot737}, \&c.$$

where it is observable that the exponents are now negative.

In the same manner may all numbers be expressed by the powers of 10.

| | |
|---|---|
| $10^0=1$ | $10^{-1}=\cdot1$ |
| $10^{\cdot301}=2$ | $10^{-\cdot699}=\cdot2$ |
| $10^{\cdot477}=3$ | $10^{-\cdot523}=\cdot3$ |
| &c. | &c. |

Even a fraction might be taken in place of 2, or 10, in the preceding examples; and such exponents might be found as would give its powers equal to all numbers, from 0 upwards. There are therefore no limitations with respect to the magnitude of the number, by the powers of which all other numbers may be expressed, except that it must neither be unity nor a negative quantity. If it were $=1$, then all its powers would also be $=1$; and if it were negative, there are numbers to which none of its powers could possibly be equal.

165. If therefore $y$ denote any number whatever, and $r$ a given number, a number $x$ may be found, such, that $r^x=y$, and $x$, that is, the exponent of $r$ which gives a number equal to $y$, is called the *logarithm* of $y$.

The given number $r$, by the powers of which all other numbers are expressed, is called the *radical number* of the logarithms, which are the indices of those powers.

166. From this definition of logarithms their properties are easily deduced as follows:

1. The sum of two logarithms is equal to the logarithm of their product. Let $y$ and $y'$ be two numbers, and $x$ and $x'$ their logarithms, so that $r^x=y$, and $r^{x'}=y'$; then $r^x\times r^{x'}=yy'$, or $r^{x+x'}=yy'$; hence, from the definition, $x+x'$ is the logarithm of $yy'$, that is, the sum of the logarithms of $y$ and $y'$ is the logarithm of $yy'$.

2. The difference of the logarithms of two numbers is equal to the logarithm of their quotient; for if $r^x=y$ and $r^{x'}=y'$, then $\frac{r^x}{r^{x'}}=\frac{y}{y'}$ or $r^{x-x'}=\frac{y}{y'}$, therefore, by the definition, $x-x'$ is the logarithm of $\frac{y}{y'}$; that is, the difference of the logarithms of $y$ and $y'$ is the logarithm of $\frac{y}{y'}$.

3. Let $n$ be any number whatever, then log. $y^n=n\times$ log. $y$. For $y^n$ is $y$ multiplied into itself $n$ times, therefore the logarithm of $y^n$ is equal to the logarithm of $y$ added to itself $n$ times, or to $n\times$ log. $y$.

167. From these properties of logarithms it follows, that if we possess tables by which we can assign the logarithm corresponding to any given number, and also the number corresponding to any given logarithm, the operations of multiplication and division of numbers may be reduced to the addition and subtraction of their logarithms, and the operations of involution and evolution, to the more simple operations of multiplication and division. Thus, if two numbers $x$ and $y$ are to be multiplied together, by taking the sum of their logarithms, we obtain the logarithm of their product, and, by inspecting the table, the product itself. A similar observation applies to the quotient of two numbers, and also to any power or to any root of a number.

168. The general properties of logarithms are independent of any particular value of the radical number, and hence there may be various systems of logarithms, according to the radical number employed in their construction. Thus, if the radical number be 10, we shall have the *common* or Briggs's system of logarithms; but if it were 2·7182818, we should have the logarithms first constructed by Lord Napier, which are sometimes called *hyperbolic logarithms.*

We have already observed (sect. 165), that the relation between any number and its logarithm is expressed by the equation $r^x=y$, where $y$ denotes a number, $x$ its logarithm, and $r$ the radical number of the system; and any two of these three quantities being given, the remaining one may be found. If either $y$ or $r$ were the quantity required, the problem would involve no difficulty; if, however, the exponent $x$ were considered as the unknown quantity, while $r$ and $y$ were supposed given, the equation to be resolved would be of a different kind from any we have hitherto considered. Equations of this form are called *exponential* equations. To resolve such an equation is evidently the same thing as to determine the logarithm of a given number.

169. We therefore resume the equation $r^x=y$, where $r$, $x$, and $y$ denote as before. We are now to find a value of $x$ in terms of $r$ and $y$. Let us suppose $r=1+a$ and $y=1+v$, then our equation will stand thus:

$$(1+a)^x=1+v.$$

So that, by raising both sides to a power $n$, where $n$ denotes an indeterminate number, which is to disappear in the course of the investigation, we have $(1+a)^{nx}=(1+v)^n$; and resolving both sides of the equation into series by means of the binomial theorem,

$$1+nxa+\frac{nx(nx-1)}{1\cdot 2}a^2+\frac{nx(nx-1)(nx-2)}{1\cdot 2\cdot 3}a^3$$
$$+\frac{nx(nx-1)(nx-2)(nx-3)}{1\cdot 2\cdot 3\cdot 4}a^4+,\ \&c.$$
$$=1+nv+\frac{n(n-1)}{1\cdot 2}v^2+\frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}v^3$$
$$+\frac{n(n-1)(n-2)(n-3)}{1\cdot 2\cdot 3\cdot 4}v^4+,\ \&c.$$

Therefore, subtracting unity from both sides, and dividing by $n$, we have

$$xa+\frac{x(nx-1)}{1\cdot 2}a^2+\frac{x(nx-1)(nx-2)}{1\cdot 2\cdot 3}a^3$$
$$+\frac{x(nx-1)(nx-2)(nx-3)}{1\cdot 2\cdot 3\cdot 4}a^4+,\ \&c.$$
$$=v+\frac{n-1}{2}v^2+\frac{(n-1)(n-2)}{2\cdot 3}v^3$$
$$+\frac{(n-1)(n-2)(n-3)}{2\cdot 3\cdot 4}v^4+,\ \&c.;$$

and by supposing the factors which constitute the terms of each series to be actually multiplied, and the products arranged according to the power of $n$, the last equation will have this form,

$$xa+\left(Pn-\frac{x}{2}\right)a^2+\left(P'n+Qn^2+\frac{x}{3}\right)a^3$$
$$+\left(P''n+Q'n^2+Rn^3-\frac{x}{4}\right)a^4+,\ \&c.$$
$$=v+(pn-\tfrac{1}{2})v^2+(p'n+qn^2+\tfrac{1}{3})v^3$$
$$+(p''n+q'n^2+rn^3-\tfrac{1}{4})v^4+,\ \&c.$$

Here the co-efficients of the power $n$, viz. P, P′, P″, &c. Q, Q′, &c. R, &c. also $p$, $p'$, $p''$, &c. $q$, $q'$, &c. $r$, &c. are expressions which denote certain combinations of the powers of $x$ in the first series, and certain numbers in the second; but as they are all to vanish in the course of the investigation, it is not necessary that they should be expressed in any other way than by a single letter.

Now each side of this last equation may evidently be resolved into two parts, one of which is entirely free from the quantity $n$, and the other involves that quantity; hence the same equation may also stand thus:

$$\left.\begin{array}{l} xa-\frac{x}{2}a^2+\frac{x}{3}a^3-\frac{x}{4}a^4+,\ \&c. \\ +Pna^2+(P'n+Qn^2)a^3+(P''n+Q'n^2+Rn^3)a^4+,\ \&c. \end{array}\right\}$$
$$=\left\{\begin{array}{l} +v-\tfrac{1}{2}v^2+\tfrac{1}{3}v^3-\tfrac{1}{4}v^4+,\ \&c. \\ +pnv^2+(p'n+qn^2)v+(p''n+q'n^2+rn^3)v^4+,\ \&c. \end{array}\right.$$

This equation must hold true, whatever be the value of $n$, which is a quantity entirely arbitrary, and therefore ought to vanish from the equation expressing the relation between $x$ and $v$; hence it follows that the terms on each side of the equation, which involve $n$, ought to destroy each other, and thus there will remain only the part of each side which does not involve $n$; that is,

$$xa-\frac{xa^2}{2}+\frac{xa^3}{3}-\frac{xa^4}{4}+,\ \&c.$$
$$=v-\frac{v^2}{2}+\frac{v^3}{3}-\frac{v^4}{4}+,\ \&c.$$
$$\text{or } (a-\frac{a^2}{2}+\frac{a^3}{3}-\frac{a^4}{4}+,\ \&c.)x$$
$$=v-\frac{v^2}{2}+\frac{v^3}{3}-\frac{v^4}{4}+\frac{v^5}{5}-,\ \&c.$$

Let us now put A to denote the constant multiplier

Algebra.

$$a-\frac{a^2}{2}+\frac{a^3}{3}-\frac{a}{4}+, \&c.$$

$$=(r-1)-\frac{(r-1)^2}{2}+\frac{(r-1)^3}{3}-\frac{(r-1)^4}{4}+, \&c.$$

and substitute for $v$ its value, $y-1$; thus we find $x=$

$$\text{log.}\ y=\frac{1}{A}(y-1)-\frac{(y-1)^2}{2}+\frac{(y-1)^3}{3}-\frac{(y-1)^4}{4}+, \&c.$$

and by this formula, the logarithm of any number a little greater than unity may be readily found.

170. If $y$ be nearly $=2$, the series will converge too slowly to be of use, and if it exceed 2, the series will diverge, and therefore cannot be directly applied to the finding of its logarithm. But a series which converges faster, and is applicable to every case, may be investigated as follows:

Because $\text{log.}\ (1+v)=\frac{1}{A}(v-\frac{v^2}{2}+\frac{v^3}{3}-\frac{v^4}{4}+, \&c.)$;

by substituting $-v$ for $+v$, we have

$$\text{log.}\ (1-v)=\frac{1}{A}\left(-v-\frac{v^2}{2}-\frac{v^3}{3}-\frac{v^4}{4}-, \&c.\right)$$

Now, $\text{log.}\ (1+v)-\text{log.}\ (1-v)=\text{log.}\ \frac{1+v}{1-v}$; therefore, subtracting the latter series from the former, we have

$$\text{log.}\ \frac{1+v}{1-v}=\frac{2}{A}\left(v+\frac{v^3}{3}+\frac{v^5}{5}+\frac{v^7}{7}+, \&c.\right)$$

Put $\frac{1+v}{1-v}=y$, then $v=\frac{y-1}{y+1}$, and the last series becomes

$$\text{log.}\ y=\frac{2}{A}\left\{\frac{y-1}{y+1}+\frac{1}{3}\left(\frac{y-1}{y+1}\right)^3+\frac{1}{5}\left(\frac{y-1}{y+1}\right)^5+, \&c.\right\}$$

This series will always converge, whatever be the value of $y$; and by means of it the logarithms of small numbers may be found with great facility.

171. When a number is composite, its logarithm will most easily be found, by adding together the logarithms of its factors; but if it be a prime number, its logarithm may be derived from that of some convenient composite number, either greater or less, and an infinite series. Let $n$ be a number of which the logarithm is already found; then, substituting $\frac{n+z}{n}$ for $y$ in the last formula, we have

$$\text{log.}\ \frac{n+z}{n}=\frac{1}{A}\left(\frac{2z}{2n+z}+\frac{1}{3}\,\frac{2z^3}{(2n+z)^3}+\frac{1}{5}\,\frac{2z^5}{(2n+z)^5}+, \&c.\right)$$

But $\text{log.}\ \frac{n+z}{n}=\text{log.}\ (n+z)-\text{log.}\ n$, therefore $\text{log.}\ (n+z)=$

$$\text{log.}\ n+\frac{1}{A}\left(\frac{2z}{2n+z}+\frac{1}{3}\,\frac{2z^3}{(2n+z)^3}+\frac{2z^5}{(2n+z)^5}+, \&c.\right)$$

This series gives the logarithm of $n+z$ by means of the logarithm of $n$, and converges very fast when $n$ is considerable.

172. It appears, from the series which have been found for log. $y$, that the logarithm of a number is always the product of two quantities: one of these is variable, and depends upon the number itself; but the other, viz. $\frac{1}{A}$, is constant, and depends entirely on the radical number of the system. This quantity has been called by writers on logarithms the *modulus* of the system.

173. The most simple system, in respect to facility of computation, is that in which $\frac{1}{A}=1$ or $A=1$. The logarithms of this system are the same as those first invented by Napier. They have been called *Hyperbolic* Logarithms, because they serve to express the area of an hyperbola; but this may be done by logarithms of any system. We shall therefore distinguish them by calling them *Napierian Logarithms*. The Napierian logarithm of any number $y$ is therefore

Algebra.

$$(y-1)-\tfrac{1}{2}(y-1)^2+\tfrac{1}{3}(y-1)^3-\tfrac{1}{4}(y-1)^4+, \&c.$$

and that of $r$, the radical number of any system, is

$$(r-1)-\tfrac{1}{2}(r-1)^2+\tfrac{1}{3}(r-1)^3-\tfrac{1}{4}(r-1)^4+, \&c.$$

But this last series is the same as we have denoted by A; hence it follows, that the *modulus* of any system is the reciprocal of the Napierian logarithm of the radical number of that system. Thus it appears that the logarithms of numbers, according to any proposed system, may be readily found from the Napierian logarithm of the same numbers, and the Napierian logarithm of the radical number of that system.

174. Let L denote the Nap. log. of any number, and $l$, $l'$ the logarithms of the same number according to two other systems whose *moduli* are $m$ and $m'$; then

$$l=mL,\ l'=m'L;$$

therefore, $\frac{l}{m}=\frac{l'}{m'}$, and $m:m'::l:l'$.

That is, the logarithms of the same number, according to different systems, are directly proportional to the *moduli* of these systems, and therefore have a given ratio to one another.

175. We shall now apply the series here investigated to the calculation of Napier's logarithm of 10, the reciprocal of which is the *modulus* of the common system of logarithms; and also to the calculation of the common logarithm of 2. The Nap. log. of 10 may be obtained by substituting 10 for $y$ in the formula

$$\text{Nap. log.}\ y=\frac{2(y-1)}{y+1}+\frac{2}{3}\left(\frac{y-1}{y+1}\right)+\frac{2}{5}\left(\frac{y-1}{y+1}\right)+, \&c.;$$

but the resulting series $\frac{2\cdot9}{11}+\frac{2\cdot9^3}{3\cdot11^3}+\frac{2\cdot9^5}{5\cdot11^5}+$, &c. converges too slowly to be of any practical utility: it will therefore be better to derive the logarithm of 10 from those of 2 and 5. By substituting 2 in the formula, we have

$$\text{Nap. log.}\ 2=2\left(\frac{1}{3}+\frac{1}{3\cdot3^3}+\frac{1}{5\cdot3^5}+\frac{1}{7\cdot3^7}+, \&c.\right)$$

This series converges very fast, so that by reducing its terms to decimal fractions, and taking the sum of the first seven terms, we find the Nap. log. of 2 to be ·6931472.

The Nap. log. of 5 may be found in the same manner, but more easily from the formula given in sect. 171. For the log. of 2 being given, that of $4=2^2$ is also given (sect. 166); therefore, substituting log. $4=2$ log. 2 for log. $n$, and 1 for $z$, in the series

Nap. log. $(n+z)=$ Nap. log. $n$

$$+2\left(\frac{z}{2n+z}+\tfrac{1}{3}\,\frac{z^3}{(2n+z)^3}+\tfrac{1}{5}\,\frac{z^5}{(2n+z)^5}+, \&c.\right)$$

we have

$$\text{Nap. log.}\ 5=2\ \text{Nap. log.}\ 2+2\left(\frac{1}{9}+\frac{1}{3\cdot9^3}+\frac{1}{5\cdot9^5}+, \&c.\right)$$

The first three terms of this series are sufficient to give the result true to the seventh decimal, so that we have

Nap. log. 5=1.6094379, and

Nap. log. 10= Nap. log. 2+Nap. log. 5=2·3025851.

Hence the *modulus* of the common system of logarithms, or $\frac{1}{\text{Nap. log. }10}$, is found $=$ ·4342945. The same number, because of its great utility in the construction of tables of logarithms, has been calculated to a much greater number of decimals. A celebrated calculator of the last century, Mr A. Sharp, found it to be

0·434294481903251827651128918916605082294397005803666566114454.

Having found the Nap. log. of 2 to be ·6931472, the common logarithm of 2 is got immediately, by multiplying the Nap. log. of 2 by the modulus of the system: thus, we find

com. log. $2=4·342945\times·6931472=·3010300$.

We have seen, sect. 169, that to determine the logarithm of a given number, is the same problem as to determine the value of $x$ in an equation of this form, $a^x=b$, where the unknown quantity is an exponent. But in order to resolve such an equation, it is not necessary to have recourse to series; for a table of logarithms being once supposed constructed, the value of $x$ may be determined thus: It appears, from sect. 166, that $x\times\log. a=\log. b$; hence it follows, that $x=\frac{\log. b}{\log. a}$. The use of this formula will appear in next Section, which treats of computations relative to interest and annuities.

176. The theory of logarithms requires the solution of this other problem. Having given the radical number of a system, and a logarithm, to determine the corresponding number. Or, having given the equation $r^x=y$ (where $r$, $x$, and $y$ denote, as in sect. 165), to find a series which shall express $y$ in terms of $r$ and $x$.

For this purpose, let us suppose $r=1+a$, then our equation becomes $y=(1+a)^x$, which may also be expressed thus:

$$y=[(1+a)^n]^{\frac{x}{n}},$$

where $n$ is an arbitrary quantity, which is to disappear in the course of the investigation.

By the binomial theorem we have

$$(1+a)^n=1+na+\frac{n(n-1)}{1\cdot 2}a^2+\frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}a^3+, \&c.$$

This equation, by multiplying together the factors which compose the terms of the series, and arranging the results according to the powers of $n$, may also be expressed thus:

$$(1+a)^n=1+An+Bn^2+Cn^3+, \&c.$$

where it will readily appear that

$$A=a-\frac{a^2}{2}+\frac{a^3}{3}-\frac{a^4}{4}+, \&c.$$

As to the values of B, C, &c. it is of no importance to know them, for they will all disappear in the course of the investigation. Hence, by substituting for $(1+a)^n$ its value, as expressed by this last series, we have

$$y=(1+An+Bn^2+Cn^3+, \&c.)^{\frac{x}{n}};$$

and expanding the latter part of this equation by means of the binomial theorem, it becomes

$$y=1+\frac{x}{n}(An+Bn^2+, \&c.)+\frac{x(x-n)}{1\cdot 2\,n^2}(An+Bn^2+, \&c.)^2$$
$$+\frac{x(x-n)(x-2n)}{1\cdot 2\cdot 3n^3}(An+Bn^2+, \&c.)^3+, \&c.$$

But $An+Bn^2+, \&c. = n\,(A+Bn+, \&c.)$,
$(An+Bn^2+, \&c.)^2=n^2\,(A+Bn+, \&c.)^2$,
$(An+Bn^2+, \&c.)^3=n^3\,(A+Bn+, \&c.)^3$, &c.;

therefore, by leaving out of each term of the series the powers of $n$, which are common to the numerator and denominator, the equation will stand thus:

$$y=1+x(A+Bn+, \&c.)+x\frac{(x-n)}{1\cdot 2}(A+Bn+, \&c.)^2$$
$$+\frac{x(x-n)(x-2n)}{1\cdot 2\cdot 3}(A+Bn+, \&c.)^3+, \&c.$$

Now $n$ is here an arbitrary quantity, and ought, from the nature of the original equation, to disappear from the value of $y$; the terms of the equation which are multiplied by $n$ ought therefore to destroy each other, and then the equation is reduced to

$$r^x=y=1+\frac{xA}{1}+\frac{x^2A^2}{1\cdot 2}+\frac{x^3A^3}{1\cdot 2\cdot 3}+\frac{x^4A^4}{1\cdot 2\cdot 3\cdot 4}+, \&c.;$$

and since we have found

$$A=a-\frac{a^2}{2}+\frac{a^3}{3}-\frac{a^4}{4}+, \&c.$$
$$=(r-1)-\frac{(r-1)^2}{2}+\frac{(r-1)^3}{3}-\frac{(r-1)^4}{4}+, \&c.$$

it is evident, from sect. 173, that A is Napier's logarithm of the radical number of the system.

177. If, in the equation $r^x=y$, we suppose $x=1$, the value of $y$ becomes

$$r=1+\frac{A}{1}+\frac{A^2}{1·2}+\frac{A^3}{1·2·3}+, \&c.$$

Here the radical number is expressed by means of its Napierian logarithm. Again, if we suppose $x=\frac{1}{A}$, then

$$r^{\frac{1}{A}}=1+\frac{1}{1}+\frac{1}{1·2}+\frac{1}{1·2·3}+\frac{1}{1·2·3·4}+, \&c.$$

Thus it appears that the quantity $r^{\frac{1}{A}}$ is equal to a constant number, which, by taking the sum of a sufficient number of terms of the series, will be found $=$ 2.718281828459045 ... Let us denote this number by $e$, then $r^{\frac{1}{A}}=e$, and hence $r=e^A$. Now, if we remark that A is the Nap. log. of $r$, it must be evident (sect. 165 and 173), that $e$ is the radical number of Napier's system of logarithms.

Again, since $r^{\frac{1}{A}}=e$, therefore $\frac{1}{A}\times\log. r=\log. e$, and $A=\frac{\log. r}{\log. e}$. Here log. $r$ and log. $e$ denote logarithms taken according to any system whatever.

178. If we now resume the equation

$$r^x=y=1+\frac{xA}{1}+\frac{x^2A^2}{1\cdot 2}+\frac{x^3A^3}{1·2·3}+, \&c.$$

and substitute for A its value $\frac{\log. r}{\log. e}$, we shall have the following general expression for any exponential quantity whatever:

$$r^x=1+\frac{x}{1}\left(\frac{\log. r}{\log. e}\right)+\frac{x^2}{1·2}\left(\frac{\log. r}{\log. e}\right)^2+\frac{x^3}{1·2·3}\left(\frac{\log. r}{\log. e}\right)^3+, \&c.$$

which, by supposing $r=e$, becomes

$$e^x=1+\frac{x}{1}+\frac{x^2}{1·2}+\frac{x^3}{1·2·3}+, \&c.$$

## Sect. XX.—Of Interest and Annuities.

179. The theory of logarithms admits of extensive application to calculations relating to interest and annuities: these we now proceed to explain. There are two hypotheses, according to either of which money put out at interest may be supposed to be improved. We

may suppose that the interest, which is always proportional to the sum lent, or principal, is also proportional to the time during which the principal is employed; and on this hypothesis, the money is said to be improved at *simple* interest. Or we may suppose that the interest which ought to be paid to the lender at successive stated periods is added to the principal, instead of being actually paid, and thus their amount converted into a new principal. When money is lent according to this second hypothesis, it is said to be improved at *compound* interest.

180. In calculations relating to interest, the things to be considered are the *principal*, or sum lent; the *rate of interest*, or sum paid for the use of L.100 for one year; the *time* during which the principal is lent; and the *amount*, or sum of the principal and interest, at the end of that time.

Let $p$ denote the principal, L.1 being the unit;
$r$ the interest of L.1 for one year, at the given rate;
$t$ the time, one year being the unit;
$a$ the amount.

We shall now examine the relations which subsist between these quantities, according to each of the two hypotheses of simple and compound interest.

*Simple Interest.*

181. Because the interest of L.1 for one year is $r$, the interest of L.1 for $t$ years must be $rt$, and the interest of $p$ pounds for the same time $prt$; hence we have this formula,

$$p+prt=a,$$

from which we find

$$p=\frac{a}{1+rt} \qquad r=\frac{a-p}{pt} \qquad t=\frac{a-p}{pr}.$$

As the manner of applying these formulæ to questions relating to simple interest is sufficiently obvious, we proceed to consider compound interest.

*Compound Interest.*

182. In addition to the symbols already assumed, let $R=1+r$ = amount of L.1 in one year; then, from the nature of compound interest, R is also the principal at the beginning of the second year. Now, interest being always proportional to the principal, we have

$$1:r::R:rR= \text{ the interest of R for a year,}$$

and $R+rR=(1+r)R=R^2=$ amount of R in a year; therefore $R^2$ is the amount of L.1 in two years, which sum being assumed as a new principal, we find, as before, its interest for a year to be $rR^2$, and its amount $R^2+rR^2=(1+r)R^2=R^3$; so that $R^3$ is the amount of L.1 in three years. Proceeding in this manner, we find, in general, that the amount of L.1 in $t$ years is $R^t$, and of $p$ pounds, $pR^t$; hence we have this formula,

$$pR^t=a;$$

which, from the nature of logarithms, may also be expressed thus:

$$\log. p+t\times\log. R=\log. a.$$

We have also

$$p=\frac{a}{R^t} \qquad R=\sqrt[t]{\frac{a}{p}};$$

or, by logarithms,

$$\log. p=\log. a-t\times\log. R. \quad \log. R=\frac{\log. a-\log. p}{t}$$

$$t=\frac{\log. a-\log. p}{\log. R}.$$

*Ex.* 1. As an example of the use of these formulæ, let it be required to determine what sum improved at 5 per cent. compound interest will amount to L.500 in 42 years. In this case we have given $a=500$, $r=\cdot05$, $R=1\cdot05$, $t=42$, to find $p$.

| | | |
|---|---|---|
| From | $\log. a=\log. 500=$ | 2·6989700 |
| subtract | $t\times\log. R=42\times\log. 1\cdot05=$ | 0·8899506 |
| remains $\log. p$. | | 1·8090194 |

therefore $p$=L.64·42=L.64. 8s. 5d. the sum required.

*Ex.* 2. In what time will a sum laid out at 4 per cent. compound interest be doubled?

Let any sum be expressed by unity; then we have given $p=1$, $r=\cdot04$, $R=1\cdot04$, $a=2$, to find $t$.

From the formula, $t=\frac{\log. a-\log. p}{\log. R}=\frac{\log. 2}{\log. 1\cdot04}$, we find $t=\frac{\cdot3010300}{\cdot0170333}=17\cdot7$ years nearly.

In treating of compound interest, we have supposed the interest to be joined to the principal at the end of the year. But we might have supposed it to be added at the end of every half-year, or every quarter, or even every instant; and suitable rules might have been found for performing calculations, according to each hypothesis. As such suppositions are, however, never made in actual business, we shall not at present say any thing more of them.

*Annuities.*

183. An annuity is a payment made annually for a term of years; and the chief problem relating to it is to determine its present worth, that is, the sum a person ought to pay immediately to another, upon condition of receiving from the latter a certain sum annually for a given time. In resolving this problem, it is supposed that the buyer improves his annuity from the time he receives it, and the seller the purchase-money, in a certain manner, during the continuance of the annuity, so that at the end of the time the amount of each may be the same. There may be various suppositions as to the way in which the annuity and its purchase-money may be improved; but the only one commonly applied to practice is the highest improvement possible of both, viz. by compound interest. As the taking of compound interest is, however, prohibited by law, the realizing of this supposed improvement requires punctual payment of interest, and therefore the interest in such calculations is usually made low.

184. Let A denote the annuity,
P the present worth, or purchase-money,
$t$ the time of its continuance;
let $r$ and R denote as before.

The seller, by improving the price P at compound interest during the time $t$, has $PR^t$.
