The purchaser is supposed to receive the first annuity A at the end of one year, which, being improved for $t-1$ years, amounts to $AR^{t-1}$. He receives the second year's annuity at the end of the second year, which, being improved for $t-2$ years, amounts to $AR^{t-2}$. In like manner, the third year's annuity becomes $AR^{t-3}$, and so on, to the last year's annuity, which is simply A. Therefore, the whole amount of the improved annuities is the geometrical series

Algebra.

$$A+AR+AR^2+AR^3 \ldots +AR^{t-1},$$

the sum of which, by sect. 56, is $A\,\frac{R^t-1}{R-1}=A\,\frac{R^t-1}{r}$; and since this sum must be equal to the amount of the purchase-money, or $PR^t$, we have

$$PR^t=A\,\frac{R^t-1}{r};$$

and from this equation we find

$$P=\frac{A}{r}\left(1-\frac{1}{R^t}\right).\quad A=\frac{rPR^t}{R-1}.\quad t=\frac{\log. A-\log. (A-rP)}{\log. R}.$$

As to $r$, it can only be found by the resolution of an equation of the $t$ order.

185. To find the present value of an annuity in *reversion*, that is, an annuity which is to commence at the end of $n$ years, and continue during $t$ years; first find its value for $n+t$ years, and then for $n$ years, and subtract the latter from the former; we thus obtain the following formula:

$$P=\frac{A}{rR^n}\left(1-\frac{1}{R^t}\right).$$

186. If the annuity is to commence immediately, and to continue for ever, then, because in this case $R^t$ is infinitely great, and therefore $\frac{1}{R^t}=0$, the formula $P=\frac{A}{r}\left(1+\frac{1}{R}\right)$ becomes simply $P=\frac{A}{r}$.

And if the annuity is to commence after $n$ years, and continue for ever, the formula $P=\frac{A}{rR^n}\left(1-\frac{1}{R^t}\right)$ becomes

$$P=\frac{A}{rR^n}.$$

*Note.* The subject of life annuities forms by itself a distinct article.

## Sect. XXI.—Of Continued Fractions.

187. Every quantity which admits of being expressed by a common fraction may also be expressed in the form of what is called a *continued fraction*. The nature of such fractions will be easily understood by the following example.

Let the common fraction be $\frac{314159}{100000}$, or, which is the same, $3+\frac{14159}{100000}$. Since $100000=7\times 14159+887$, therefore $\frac{14159}{100000}=\frac{14159}{7\times 14159+887}=\cfrac{1}{7+\cfrac{887}{14159}}$, and

$$\frac{314159}{100000}=3+\cfrac{1}{7+\cfrac{887}{14159}}.$$

Now $\frac{887}{14159}=\frac{887}{15\times 887+854}=\cfrac{1}{15+\cfrac{854}{887}}$, and substituting this for $\frac{887}{14159}$ in the value of $\frac{314159}{100000}$, already found, we have

$$\frac{314159}{100000}=3+\cfrac{1}{7+\cfrac{1}{15+\cfrac{854}{887}}}.$$

Again, $\frac{854}{887}=\frac{854}{854+33}=\cfrac{1}{1+\cfrac{33}{854}}$, which being substituted as before, gives

$$\frac{314159}{100000}=3+\cfrac{1}{7+\cfrac{1}{15+\cfrac{1}{1+\cfrac{33}{854}}}}.$$

By operations similar to the preceding, we find $\frac{33}{854}=\cfrac{1}{25+\cfrac{29}{33}}$, $\frac{29}{33}=\cfrac{1}{1+\cfrac{4}{29}}$, $\frac{4}{29}=\cfrac{1}{7+\cfrac{1}{4}}$; therefore, by substitution,

$$\frac{314159}{100000}=3+\cfrac{1}{7+\cfrac{1}{15+\cfrac{1}{1+\cfrac{1}{25+\cfrac{1}{1+\cfrac{1}{7+\cfrac{1}{4}}}}}}}.$$

By an operation in all respects the same as has been just now performed, may any fraction whatever be reduced to the form

$$a+\cfrac{1}{b+\cfrac{1}{c+\cfrac{1}{d+\text{, \&c.}}}}$$

and it is then called a *continued fraction.*

188. It is easy to see in what manner the inverse of the preceding operation is to be performed, or a continued fraction reduced to a common fraction.

Thus, if the continued fraction be

$$a+\cfrac{1}{b+\cfrac{1}{c+\cfrac{1}{d}}},$$

it will evidently be reduced to a common fraction by adding the reciprocal of $d$ to $c$, and the reciprocal of that sum to $b$, and again the reciprocal of this last sum to $a$: now the reciprocal of $d$, or $\frac{1}{d}$, added to $c$, is $c+\frac{1}{d}=\frac{cd+1}{d}$; again, the reciprocal of this sum, or $\frac{d}{cd+1}$, added to $b$, is $b+\frac{d}{cd+1}=\frac{bcd+b+d}{cd+1}$, and the reciprocal of this last quantity, viz. $\frac{cd+1}{bcd+b+d}$, when added to $a$, gives

$$\frac{abcd+ab+ad+cd+1}{bcd+b+d}=a+\cfrac{1}{b+\cfrac{1}{c+\cfrac{1}{d}}}.$$

189. This manner of expressing a fraction enables us to find a series of other fractions, that approach in value to any given one, and each of them expressed in the smallest numbers possible. Thus, in the example $\frac{314159}{100000}$, which has been resolved into a continued fraction, sect. 187, and which is known to express nearly the proportion of the diameter of a circle to its circumference, if we take only the first two terms of the continued fraction, and

put $\pi$ for $\frac{314159}{100000}$, we shall have $\pi=3+\frac{1}{7}=\frac{22}{7}$ nearly; and this is the proportion which was found by Archimedes.

Again, by taking the first three terms, we have

$$\pi=3+\cfrac{1}{7+\cfrac{1}{15}}=3+\frac{15}{106}=\frac{333}{106},$$

which is nearer the truth than the former.

And by taking the first four terms, we have

$$\pi=3+\cfrac{1}{7+\cfrac{1}{15+\cfrac{1}{1}}}=\frac{355}{113},$$

which is the proportion assigned by Metius, and is more exact than either of the preceding. The results are alternately greater and less than the truth.

190. Among continued fractions, those have been particularly distinguished in which the denominators, after a certain number of changes, are continually repeated in the same order. Such, for example, is the fraction

$$1+\cfrac{1}{2+\cfrac{1}{3+\cfrac{1}{2+\cfrac{1}{3+}}}}, \&c.$$

The value of this fraction, though continued *ad infinitum*, may be easily found; for leaving out the first term, which is an integer, let us suppose

$$x=\cfrac{1}{2+\cfrac{1}{3+\cfrac{1}{2+\cfrac{1}{3+}}}}, \&c.$$

Then, since after the second, all the terms return in the same order, it follows that their amount is also $=x$. Thus we have

$$x=\cfrac{1}{2+\cfrac{1}{3+x}};$$

hence $x=\frac{3+x}{6+2x+1}$, and $x^2+3x=\frac{3}{2}$, and $x=\frac{-3+\sqrt{15}}{2}$:

therefore $x+1$, or the sum of the series, $=\frac{-1+\sqrt{15}}{2}$.

In general, if $x=\cfrac{1}{a+\cfrac{1}{b+\cfrac{1}{a+}}}$, &c.

we find $x=-\frac{b}{2}\pm\sqrt{\frac{b^2}{4}+\frac{b}{a}}$. Though the denominators did not return in the same order till after a greater interval, the value of the fraction would still be expressed by the root of a quadratic equation. And conversely, the roots of all quadratic equations may be expressed by periodical continued fractions, and may often by that means be very readily approximated in numbers, without the trouble of extracting the square root.

191. The reduction of a decimal into the form of a continued fraction sometimes renders the law of its continuation evident. Thus we know that $\sqrt{2}=1{\cdot}4121356\ldots$; but from the bare inspection of this decimal we discover no rule for its further continuation. If, however, it be reduced into a continued fraction, it becomes

$$=1+\cfrac{1}{2+\cfrac{1}{2+\cfrac{1}{2+}}}, \&c.$$

and hence we see in what way it may be continued to any degree of accuracy.

When the root of any equation is found by the method explained in sect. 156, the value of the unknown quantity is evidently expressed by a continued fraction

For if $x$ be the root sought. we have $x=a+\frac{1}{y}$, $y=b+\frac{1}{y'}$, $y'=b'+\frac{1}{y''}$, $y''=b''+\frac{1}{y'''}$, &c. where $a, b', b'', b'''$, &c. denote the whole numbers, which are next less than the true values of $x, y, y', y''$, &c. If, therefore, in the value of $x$ we substitute $b+\frac{1}{y'}$ for $y$, it becomes

$$x=a+\cfrac{1}{b+\cfrac{1}{y'}}.$$

Again, if in this second value of $x$ we substitute $b'+\frac{1}{y''}$ for $y$, it becomes

$$x=a+\cfrac{1}{b+\cfrac{1}{b'+\cfrac{1}{y''}}}.$$

The next value of $x$ is in like manner found to be

$$x=a+\cfrac{1}{b+\cfrac{1}{b'+\cfrac{1}{b''+\cfrac{1}{y'''}}}};$$

and so on continually.

## Sect. XXII.—Of Indeterminate Problems.

192. When the conditions of a question are such that the number of equations exceeds the number of unknown quantities, that question will admit of innumerable solutions, and is therefore said to be indeterminate. Thus, if it be required to find two numbers subject to no other limitation than that their sum be 10, we have two unknown quantities $x$ and $y$, and only one equation, viz. $x+y=10$, which may evidently be satisfied by innumerable different values of $x$ and $y$, if fractional solutions be admitted. It is, however, usual, in such questions as this, to restrict values of the numbers sought to positive integers, and therefore, in this case, we can have only these nine solutions,

$$x = 1, 2, 3, 4, 5, 6, 7, 8, 9;$$
$$y = 9, 8, 7, 6, 5, 4, 3, 2, 1;$$

which indeed may be reduced to five; for the first four become the same as the last four, by simply changing $x$ into $y$, and the contrary.

193. Indeterminate problems are of different orders, according to the dimensions of the equation which is obtained after all the unknown quantities but two have been exterminated by means of the given equations. Those of the first order lead always to equations of this form,

$$ax+by=c,$$

where $a, b, c$, denote given whole numbers, and $x, y$, two numbers to be found, so that both may be integers. That this condition may be fulfilled, it is necessary that the coefficients $a, b$, have no common divisor which is not also a divisor of $c$; for if $a=md$ and $b=me$, then $ax+by=mdx$

$+ mey = c$, and $dx + ey = \frac{c}{m}$; but $d, e, x, y$, are supposed to be whole numbers, therefore $\frac{c}{m}$ is a whole number; hence $m$ must be a divisor of $c$.

We proceed to illustrate the manner of resolving indeterminate equations of the first order, by some numerical examples.

*Ex.* 1. Given $2x + 3y = 25$, to determine $x$ and $y$ in whole positive numbers.

From the given equation we have $x = \frac{25-3y}{2} = 12 - y + \frac{1-y}{2}$. Now, since $x$ must be a whole number, it follows that $\frac{1-y}{2}$ must be a whole number. Let us assume $\frac{1-y}{2} = z$, then $1 - y = 2z$ and $y = 1 - 2z$; and since $x = 12 - y + \frac{1-y}{2} = 12 - y + z$, therefore $x = 12 - 1 + 2z + z$; hence we have

$$x = 11 + 3z, \qquad y = 1 - 2z,$$

where $z$ might be any whole number whatever, if there were no limitation as to the signs of $x$ and $y$. But since these quantities are required to be positive, it is evident, from the value of $y$, that $z$ must be either 0 or negative, and from the value of $x$, that, abstracting from the sign, it must be less than 4; hence $z$ may have these three values, 0, — 1, — 2, — 3.

$$\text{If } z = 0, \quad z = -1, \quad z = -2, \quad z = -3;$$
$$\text{Then} \begin{cases} x = 11, & x = 8, \quad x = 5, \quad x = 2, \\ y = 1, & y = 3, \quad y = 5, \quad y = 7. \end{cases}$$

*Ex.* 2. It is required to divide 100 into such parts that the one may be divisible by 7 and the other by 11.

Let $7x$ be the first part, and $11y$ the second; then, by the question, $7x + 11y = 100$, and

$$x = \frac{100 - 11y}{7} = 14 - y + \frac{2 - 4y}{7}.$$

Hence it appears, that $\frac{2 - 4y}{7}$ must be a whole number. Let us assume $\frac{2-4y}{7} = z$, then $x = 14 - y + z$, and $4y = 2 - 7z$, or $y = \frac{2 - 7z}{4} = \frac{2 - 3z}{4} - z$; therefore $\frac{2 - 3z}{4}$ must be a whole number. Assume $\frac{2-3z}{4} = t$, then $y = t - z$, and $3z = 2 - 4t$, or $z = \frac{2 - 4t}{3} = \frac{2 - t}{3} - t$; therefore $\frac{2-t}{3}$ must be a whole number.

Assume now $\frac{2-t}{3} = v$, then $z = v - t$, and $t = 2 - 3v$.

Here it is evident that $v$ may be any whole number taken at pleasure: so that to determine $x$ and $y$ we have the following series of equations:

$$\begin{aligned} t &= 2 - 3v, \\ z &= v - t = 4v - 2, \\ y &= t - z = 4 - 7v, \\ x &= 14 - y + z = 11v + 8. \end{aligned}$$

From the value of $y$, it appears that $v$ must either be $= 0$ or negative; but from the value of $x$, $v$ cannot be a negative whole number; therefore $v$ can only be $= 0$; hence the only values which $a$ and $y$ can have in whole numbers, are $x = 8$, $y = 4$.

*Ex.* 3. It is required to find all the possible ways in which L.60 can be paid in guineas and moidores only.

Let $x$ be the number of guineas, and $y$ the number of moidores. Then the value of the guineas, expressed in shillings, is $21x$, and that of the moidores $27y$; therefore, from the nature of the question, $21x + 27y = 1200$, or, dividing the equation by 3, $7x + 9y = 400$; hence $x = \frac{400 - 9y}{7} = 57 - y + \frac{1 - 2y}{7}$, so that $\frac{1-2y}{7}$ must be a whole number.

Assume $\frac{1-2y}{7} = z$, then $x = 57 - y + z$, and $2y = 1 - 7z$ or $y = \frac{1 - 7z}{2} = \frac{1 - z}{2} - 3z$; therefore $\frac{1-z}{2}$ must be a whole number.

Assume $\frac{1-z}{2} = v$, then $y = v - 3z$, and $z = 1 - 2v$; therefore $v$ may be taken any whole number at pleasure, and $x$ and $y$ may be determined by the following equations:

$$\begin{aligned} z &= 1 - 2v, \\ y &= v - 3z = 7v - 3, \\ x &= 57 - y + z = 61 - 9v. \end{aligned}$$

From the value of $x$, it appears that $v$ cannot exceed 6, and from the value of $y$, that it cannot be less than 1.

$$\begin{array}{llllllll} \text{Hence if } & v = & 1, & 2, & 3, & 4, & 5, & 6, \\ \text{we have } & x = & 52, & 43, & 34, & 25, & 16, & 7, \\ & y = & 4, & 11, & 18, & 25, & 32, & 39. \end{array}$$

194. In the foregoing examples the unknown quantities $x$ and $y$ have each a determinate number of positive values; and this will evidently be the case as often as the proposed equation is of this form, $ax + by = c$. If, however, $b$ be negative, that is, if the equation be of this form, $ax - by = c$, or $ax = by + c$, we shall have questions of a different kind, admitting each of an infinite number of solutions; these, however, may be resolved in the same manner as the preceding, as will appear from the following example.

*Ex.* 4. A person buys some horses and oxen: he pays 31 crowns for each horse, and 20 crowns for each ox, and he finds that the oxen cost him seven crowns more than the horses. How many did he buy of each?

Let $x$ be the number of horses, and $y$ that of the oxen; then, by the question,

$$20x = 31y + 7, \text{ and } x = \frac{31y + 7}{20} = y + \frac{11y + 7}{20}.$$

Therefore $\frac{11y+7}{20}$ must be a whole number.

Let $\frac{11y+7}{20} = v$, then $x = y + v$, and $y = \frac{20v - 7}{11} = v + \frac{9v - 7}{11}$; hence $\frac{9v-7}{11}$ must be a whole number.

Let $\frac{9v - 7}{11} = t$, then $y = v + t$, and $v = \frac{11t + 7}{9} = t + \frac{2t+7}{9}$; therefore $\frac{2t+7}{9}$ is a whole number.

Let $\frac{2t+7}{9} = s$, then $v = t + s$, and $t = \frac{9s - 7}{2} = 4s + \frac{s - 7}{2}$; therefore $\frac{s-7}{2}$ is a whole number.

Put $\frac{s-7}{2}=r$, then $t=4s+r$ and $s=2r=7$.

Having now no longer any fractions, we return to the values of $x$ and $y$ by the following series of equations:

$$\begin{aligned}
s&=2r+7,\\
t&=4s+r=\ 9r+28,\\
v&=\ t+s=11r+35,\\
y&=\ v+t=20r+63=\text{ number of oxen},\\
x&=\ y+v=31r+98=\text{ number of horses.}
\end{aligned}$$

The least positive values of $x$ and $y$ will evidently be obtained by making $r=-3$, and innumerable other values may be had by putting $r=-2$, $r=-1$, $r=0$, $r=+1$, &c. Thus we have

$x=5,\ 36,\ 67,\ 98,\ 129,\ 160,\ 191,\ 222$, &c.
$y=3,\ 23,\ 43,\ 63,\ 83,\ 103,\ 123,\ 143$, &c.

each series forming an arithmetical progression, the common difference in the first being 31, and in the second 20.

195. If we consider the manner in which the numbers $x$, $y$, in this example, are determined from the succeeding quantities $v$, $t$, &c. we shall immediately perceive that the co-efficients of those quantities are the same as the successive quotients which arise in the arithmetical operation for finding the greatest common measure of 20 and 31, the co-efficients of the given equation $20x=31y+7$. The operation performed at length will stand thus:

```
20)31(1
   20
   --
   11)20(1
      11
      --
       9)11(1
          9
          --
          2)9(4
            8
            --
            1)2(2
              2
              --
              0
```

Hence we may form a series of numeral equations which, when compared with the series of literal equations expressing the relations between $x$, $y$, $v$, &c. as put down in the following table, will render the method of determining the latter from the former sufficiently obvious.

$$\begin{array}{ll}
31=1\times20+11 & x=1\times y+v,\\
20=1\times11+\ 9 & y=1\times v+t,\\
11=1\times\ 9+\ 2 & v=1\times t+s,\\
9=4\times\ 2+\ 1 & t=4\times s+r,\\
2=2\times\ 1+\ 0 & s=2\times r+7.
\end{array}$$

And as every question of this kind may be analyzed in the same manner, we may hence form the following general rule for resolving indeterminate problems of the first order.

196. Let $bx=ay+n$ be the proposed equation, in which $a$, $b$, $n$, are given integers, and $x$, $y$, numbers to be found. Let $a$ be the greatest of the two numbers $a$, $b$, and let A denote the greatest multiple of $b$ which is contained in $a$, and $c$ the remainder; also let B denote the greatest multiple of $c$ contained in $b$, and $d$ the remainder; and C the greatest multiple of $d$ contained in $c$, and $e$ the remainder; and so on, till one of the remainders be found equal to 0. The numbers A, B, C, afford a series of equations from which another series may be derived, as in the following table:

$$\begin{array}{ll}
a=\mathrm{A}b+c,\ \text{hence we find} & x=\mathrm{A}y+v,\\
b=\mathrm{B}c+d & y=\mathrm{B}v+t,\\
c=\mathrm{C}d+e & v=\mathrm{C}t+s,\\
d=\mathrm{D}e+f & t=\mathrm{D}s+r,\\
e=\mathrm{E}f+g & s=\mathrm{E}r+q,\\
f=\mathrm{F}g+0 & r=\mathrm{F}q\pm n.
\end{array}$$

And in the last equation of the second series any number whatever may be put for $q$. It is also to be observed, that the given number $n$ is to have the sign $+$ prefixed to it, if the number of equations be odd, but $-$ if that number be even. Having formed the second series of equations, the values of $x$ and $y$ may be thence found as in the foregoing examples. We proceed to show the application of the rule.

*Ex.* 5. Required a number which, being divided by 11, leaves the remainder 3, but being divided by 19, leaves the remainder 5.

Let N be the number, and $x$, $y$, the quotients which arise from the respective divisions; then we have $\mathrm{N}=11x+3$, also $\mathrm{N}=19y+5$; hence $11x+3=19y+5$, and $11x=19y+2$, an equation which furnishes the following table:

$$\begin{array}{ll}
19=1\times11+8 & x=\ y+v,\\
11=1\times\ 8+3 & y=\ v+t,\\
8=2\times\ 3+2 & v=2t+s,\\
3=1\times\ 2+1 & t=\ s+r,\\
2=2\times\ 1+0 & s=2r+2.
\end{array}$$

Here $r$ may be assumed of any value whatever Hence we have

$$\begin{aligned}
s&=2r+2,\\
t&=\ s+r=\ 3r+\ 2,\\
v&=2t+s=\ 8r+\ 6,\\
y&=\ v+t=11r+\ 8,\\
x&=\ y+v=19r+14;
\end{aligned}$$

and the number required, $\mathrm{N}=209u+157$, where it is evident that the least number which can express N is 157.

*Ex.* 6. Given $\left.\begin{cases}3x+\ 5y+\ 7z=560\\ 9x+25y+49z=2920\end{cases}\right\}$ To determine $x, y, z$, in whole numbers.

From 7 times the first equation subtract the second; thus we have $12x+10y=1000$, or $6x+5y=500$; and from this last equation, by proceeding as in the foregoing example, we find

$$x=500-5v, \qquad y=6v-500.$$

Let these values of $x$ and $y$ be substituted in either of the original equations; in the first, for example, as being the most simple, and we find $7z+15v=1560$. This last equation being resolved in the same manner, we find

$$\begin{aligned}
v&=1560-7t,\\
z&=15t\ -3120,\\
y&=8860-42t,\\
x&=35t\ -7300;
\end{aligned}$$

and hence it appears that the only values which $t$ can have, so as to give whole positive numbers for $x$, $y$, $z$, are 209 and 210: thus we have

$$\begin{array}{lll}
x=15 & y=82 & z=15,\\
\text{or } x=50 & y=40 & z=30.
\end{array}$$

197. If an equation were proposed involving three unknown quantities, as $ax+by+cz=d$, by transposition we have $ax+by=d-cz$, and, putting $d-cz=d'$, $ax+by=d'$. From this last equation we may find values of $x$ and $y$ of this form,

$$x=mr+nd',\ y=m'r+n'd',$$
$$\text{or } x=mr+n(d-cz),\ y=m'r+n'(d-cz);$$

where $z$ and $r$ may be taken at pleasure, except in so far as the values of $x, y, z$, may be required to be all positive; for from such restriction the values of $z$ and $r$ may be confined within certain limits to be determined from the given equation.

198. We proceed to indeterminate problems of the second degree. These produce equations of the three following forms:

$$\text{I. } y=\frac{a}{b+cx}, \quad \text{II. } y=\frac{a+bx}{c+dx}, \quad \text{III. } y=\sqrt{a+bx+cx^2}.$$

In all these equations $a, b, c$, denote given numbers. In the first two, $x$ is to be determined so that $y$ may be an integer; and in the third, $x$ is to be determined so that $y$ may be a rational quantity.

In the equation $y=\frac{a}{b+cx}$, it is evident, $b+cx$ must be a divisor of $a$; let $d$ be one of its divisors, then $b+cx=d$, and $x=\frac{d-b}{c}$: hence, to find $x$ we must search among the divisors of $a$ for one such, that if $b$ be subtracted from it, the remainder may be divisible by $c$, and the quotient will be such a value of $x$ as is required.

When $y=\frac{a+bx}{c+dx}$, if $d$ be a divisor of $b$, $x$ will be taken out of the numerator if we divide it by $c+dx$, and this form is then reduced to the preceding. But if $d$ is not a divisor of $b$, multiply both sides by $d$, then $dy=\frac{da+dbx}{c+dx}$ or $dy=b+\frac{ad-bc}{c+dx}$, and so $x$ is found by making $c+dx$ equal to a divisor of $ad-bc$.

*Example.* Given $x+y+2xy=195$, to determine $x$ and $y$ in whole numbers.

From the given equation, $y=\frac{195-x}{1+2x}$, therefore $2y=\frac{390-2x}{1+2x}=-1+\frac{391}{1+2x}$. Now $391=17\times 23$, hence we must assume $1+2x=17$, or $1+2x=23$: the first supposition gives us $x=8$, $y=11$; and the second $x=11$, $y=8$, the same result in effect as the former.

199. We are next to consider the formula $y=\sqrt{a+bx+cx^2}$, where $x$ is to be found, so that $y$ may be a rational quantity; but as the condition of having $x$ and $y$ also integers would add greatly to the difficulty of the problem, and produce researches of a very intricate nature, we must be satisfied for the most part with fractional values. The possibility of rendering the proposed formula a square depends altogether upon the co-efficients $a, b, c$; and there are four cases of the problem, the solution of each of which is connected with some peculiarity in its nature.

*Case* 1. Let $a$ be a square number; then, putting $g^2$ for $a$, we have $y=\sqrt{g^2+bx+cx^2}$. Suppose $\sqrt{g^2+bx+cx^2}=g+mx$; then $g^2+bx+cx^2=g^2+2gmx+m^2x^2$, or $bx+cx^2=2gmx+m^2x^2$, that is, $b+cx=2gm+m^2x$; hence

$$x=\frac{2gm-b}{c-m^2}, \; y=\sqrt{g^2+bx+cx^2}=\frac{cg-bm+gm^2}{c-m^2}.$$

Here $m$ may be any rational quantity, either whole or fractional.

*Case* 2. Let $c$ be a square number $=g^2$; then, putting $\sqrt{a+bx+g^2x^2}=m+gx$, we find $a+bx+g^2x^2=m^2+2mgx+g^2x^2$, or $a+bx=m^2+2mgx$; hence we find

$$x=\frac{m^2-a}{b-2mg}, \; y=\sqrt{a+bx+g^2x^2}=\frac{bm-gm^2-ag}{b-2mg}.$$

Here $m$, as before, may be taken at pleasure.

*Case* 3. When neither $a$ nor $c$ is a square number, yet if the expression $a+bx+cx^2$ can be resolved into two simple factors, as $f+gx$ and $h+kx$, the irrationality may be taken away as follows.

Assume $\sqrt{a+bx+cx^2}=\sqrt{(f+gx)(h+kx)}=m(f+gx)$, then $(f+gx)(h+kx)=m^2(f+gx)^2$, or $h+kx=m^2(f+gx)$; hence we find

$$x=\frac{fm^2-h}{k-gm^2}, \; y=\sqrt{(f+gx)(h+kx)}=\frac{(fk-gh)m}{k-gm^2};$$

and in these formulæ $m$ may be taken at pleasure.

*Case* 4. The expression $a+bx+cx^2$ may be transformed into a square as often as it can be resolved into two parts, one of which is a complete square, and the other a product of two simple factors; for then it has this form, $p^2+qr$, where $p, q$, and $r$ are quantities which contain no power of $x$ higher than the first. Let us assume $\sqrt{p^2+qr}=p+mq$; thus we have $p^2+qr=p^2+2mpq+m^2q^2$ and $r=2mp+m^2q$, and as this equation involves only the first power of $x$, we may by proper reduction obtain from it rational values of $x$ and $y$, as in the three foregoing cases.

200. If we can by trials discover any one value of $x$ which renders the expression $\sqrt{a+bx+cx^2}$ rational, we may immediately reduce the quantity under the radical sign to the above-mentioned form, and thence find a general expression from which as many more values of $x$ may be determined as we please. Thus, let us suppose that $p$ is a value of $x$ which satisfies the condition required, and that $q$ is the corresponding value of $y$; then

$$y^2=a+bx+cx^2$$
$$q^2=a+bq+cp^2.$$

Therefore, by subtraction,

$$y^2-q^2=b(x-p)+c(x^2-p^2)=(b+cp+cx)(x-p)$$

and $y=\sqrt{q^2+(b+cp+cx)(x-p)}$. The quantity under the radical sign being now reduced to the prescribed form, it may be rendered rational by the substitution pointed out in the last article.

The application of the preceding general methods of resolution to any particular case is very easy; we shall therefore conclude with a very few examples.

*Ex.* 1. It is required to find two square numbers whose sum is a given square number.

Let $a^2$ be the given square number, and $x^2, y^2$, the numbers required; then, by the question, $x^2+y^2=a^2$, and $y=\sqrt{a^2-x^2}$. This equation is evidently of such a form as to be resolvable by the method employed in case 1. Accordingly, by comparing $\sqrt{a^2-x^2}$ with the general expression $\sqrt{g^2+bx+cx^2}$, we have $g=a$, $b=0$, $c=-1$, and substituting these values in the formulæ of sect. 199, also $-n$ for $+m$, we find

$$x=\frac{2an}{n^2+1}, \; y=\frac{a(n^2-1)}{n^2+1};$$ hence the numbers required are

$$x^2=\frac{4a^2n^2}{(n^2+1)^2} \quad y^2=\frac{a^2(n^2-1)^2}{(n^2+1)^2}.$$

If $a=n^2+1$, where $n$ is any number whatever, the square numbers $x^2$ and $y^2$ will both be integers, viz. $x^2=4n^2$ and $y^2=(n^2-1)^2$. Let us suppose $n=2$, then $a=n^2+1=5$, and $a^2=25$, hence $x^2=4n^2=16$, $y=(n^2-1)^2=9$. Thus it appears that the square number 25 may be resolved into two other square numbers, 9 and 16.

Algebra.

*Ex.* 2. It is required to find two square numbers whose difference shall be equal to a given square number $b^2$.

This question may be resolved in the same manner as the last. Or, without referring to any former investigation, let $(x+n)^2$ and $x^2$ be the numbers sought, then $(x+n)^2 - x^2 = b^2$; that is, $2nx + n^2 = b^2$, hence $x=\frac{b^2-n^2}{2n}$ and $x+n=\frac{b^2+n^2}{2n}$. So that the numbers sought are

$$\frac{(b^2+n^2)^2}{4n^2}, \qquad \frac{(b^2-n^2)}{4n^2},$$

where $n$ may be any number whatever. If, for example, $b^2=25$ and $n=1$, then $x=12$ and $x+n=13$; so that the numbers required are 144 and 169.

*Ex.* 3. It is required to determine $x$, so that $\frac{x^2+x}{2}$ may be a rational square.

Let $y$ be the side of the square required; then $\frac{x^2+x}{2}=y^2$ and $4x^2+4x=8y^2$. Let the first part of this equation be completed into a square by adding 1 to each side, then $4x^2+4x+1=1+8y^2$; and taking the root, $2x+1=\sqrt{1+8y^2}$, so that we have to make $1+8y^2$ a square. Assume

$1+8y^2=\left(1+\frac{p}{q}y\right)^2=1+\frac{2p}{q}y+\frac{p^2}{q^2}y^2$, then $8y=\frac{2p}{q}+\frac{p^2}{q^2}y$. Hence, by proper reduction, $y=\frac{2pq}{8q^2-p^2}$, and since $2x+1=\sqrt{1+8y^2}=\frac{8q^2+p^2}{8q^2-p^2}$, therefore $x=\frac{p^2}{8q^2-p^2}$, and $\frac{x^2+x}{2}=\frac{4p^2\,q^2}{(8q^2-p^2)^2}$, a rational square, as was required.

## Sect. XXIII.—Of the Resolution of Geometrical Problems.

201. When a geometrical problem is to be resolved by algebra, the figure which is to be the subject of investigation must be drawn, so as to exhibit as well the known quantities connected with the problem, as the unknown quantities which are to be found. The conditions of the problem are next to be attentively considered, and such lines drawn, or produced, as may be judged necessary to its resolution. This done, the known quantities are to be denoted by symbols in the usual manner, and also such unknown quantities as can most easily be determined; which may be either those directly required, or others from which they can be readily found. We must next proceed to deduce from the known geometrical properties of the figure a series of equations, expressing the relations between the known and unknown quantities; these equations must be independent of each other, and as many in number as there are unknown quantities. Having obtained a suitable number of equations, the unknown quantities are to be determined in the same manner as in the resolution of numerical problems.

No general rule can be given for drawing the lines, and selecting the quantities most proper to be represented by symbols, so as to bring out the simplest conclusion; because different problems require different methods of solution. The best way to gain experience in this matter, is to try the solution of the same problem in different ways, and then apply that which succeeds best to other cases of the same kind, when they afterwards occur. The following particular directions, however, may be of some use.

Algebra.

1. In preparing the figure by drawing lines, let them be either parallel or perpendicular to other lines in the figure, so as to form similar triangles. And if an angle be given, it will be proper to let the perpendicular be opposite to that angle, and to fall from one end of a given line, if possible.

2. In selecting the quantities for which symbols are to be substituted, those are to be chosen, whether required or not, which lie nearest the known or given parts of the figure, and by means of which the next adjacent parts may be expressed by addition and subtraction only, without the intervention of surds.

3. When two lines, or quantities, are alike related to other parts of the figure, or problem, the best way is to substitute for neither of them separately, but to substitute for their sum, or difference, or rectangle, or the sum of their alternate quotients, or some line or lines in the figure, to which they have both the same relation.

4. When the area or the perimeter of a figure is given, or such like parts of it as have only a remote relation to the parts required, it is sometimes of use to assume another figure similar to the proposed one, having one side equal to unity, or some other known quantity. For thence the other parts of the figure may be found by the known proportions of like sides or parts, and so an equation will be obtained.

202. We shall now give the algebraical solutions of some geometrical problems.

Prob. 1. In a right-angled triangle, having given the base, and the sum of the hypothenuse and perpendicular, to find both these sides.

Let ABC (Plate XVIII. fig. 1) represent the proposed triangle, right-angled at B. Let AB, the given base, be denoted by $b$, and AC+BC, the sum of the hypothenuse and perpendicular, by $s$; then if $x$ be put for BC the perpendicular, the hypothenuse AC will be $=s-x$. But from the nature of a right-angled triangle, $AC^2=AB^2+BC^2$, that is,

$$b^2+x^2=(s-x)^2=s^2-2sx+x^2.$$

Hence $b^2=s^2-2sx$, and $x=\frac{s^2-b^2}{2s}=BC$.

Also $s-x=s-\frac{s^2-b^2}{2s}=\frac{s^2+b^2}{2s}=AC$. Thus the perpendicular and hypothenuse are expressed by means of the known quantities $b$ and $s$, as required.

If a solution in numbers be required, we may suppose $AB=b=3$, and $AC+CB=s=9$; then

$$BC=\frac{s^2-b^2}{2s}=4, \text{ and } AC=\frac{s^2+b^2}{2s}=5.$$

Prob. 2. In a right-angled triangle, having given the hypothenuse, also the sum of the base and perpendicular, it is required to determine these two sides.

Let ABC (fig. 1) represent the proposed triangle, right-angled at B. Put $a$=AC the given hypothenuse, and $s$=AB+BC the given sum of the sides; then, if $x$ be put for AB the base, $s-x$ will denote BC the perpendicular.

Now, from the nature of right-angled triangles, $AC^2=AB^2+BC^2$; therefore $x^2+(s-x)^2=a^2$, or $x^2+s^2-2sx+x^2=a^2$; hence we have this quadratic equation, $x^2-sx=\frac{a^2-s^2}{2}$, which being resolved, by completing the square, we find $x=\frac{s\pm\sqrt{2a^2-s^2}}{2}=$ AB, and $s-x=\frac{s\mp\sqrt{2a^2-s^2}}{2}=$ BC. Thus it appears, that either of the two quantities $\frac{s+\sqrt{2a^2-s^2}}{2}$, $\frac{s-\sqrt{2a^2-s^2}}{2}$, may be taken for AB; but whichever of the two be taken, the remaining one is necessarily equal to BC.

Prob. 3. It is required to inscribe a square in a given triangle.

Let ABC (fig. 2) be the given triangle, and EFHG the inscribed square. Draw the perpendicular AD, cutting EF, the side of the square, in K; then, because the triangle is given, the perpendicular AD may be considered as given. Let BC$=b$, AD$=p$, and considering AK as the unknown quantity (because from it the square may be readily determined), let AK$=x$; then KD$=$EF$=p-x$.

The triangles ABC, AEF, are similar; therefore AD : BC : : AK : EF, that is, $p:b::x:p-x$. Hence, by taking the product of the extremes and means, $p^2-px=bx$, and $x=\frac{p^2}{p+b}=$ AK. If the side of the square be required, it may be immediately found by subtracting AK from AD the perpendicular. Thus we have $p-\frac{p^2}{p+b}=\frac{pb}{p+b}=$KD$=$EF. Hence it appears that we may either take AK, a third proportional to AD+BC and AD, or take DK, a fourth proportional to AD+BC, AD and BC; and the point K being found, the manner of describing the square is sufficiently obvious.

Prob. 4. Having given the area of a rectangle inscribed in a given triangle; it is required to determine the sides of the rectangle.

Let ABC (fig. 3) be the given triangle, and EDGF the rectangle whose sides are required. Draw the perpendicular CI, cutting DG in H. Put AB$=b$, CI$=p$, DG$=$EF$=x$, DE$=$HI$=y$; then CH$=p-y$. Let $a^2$ denote the given area.

The triangles CDG, CAB, are similar; hence

CH : DG : : CI : AB, or $p-y:x::p:b$.

So that to determine $x$ and $y$, we have these two equations,

$$xy=a^2, \quad bp-by=px.$$

From the first equation we find $y=\frac{a^2}{x}$, and from the second, $y=\frac{bp-px}{b}$, therefore $\frac{bp-px}{b}=\frac{a^2}{x}$; hence $x^2-bx=-\frac{a^2b}{p}$, and from this quadratic equation, by completing the square, &c. we find

$$x=\frac{b}{2}\pm\sqrt{\frac{b^2}{4}-\frac{a^2b}{p}}, \text{ and } y=\frac{a^2}{x}=\frac{p}{2}\pm\sqrt{\frac{p^2}{4}-\frac{pa^2}{b}}.$$

Hence it appears, that if $\frac{a^2b}{p}$ be less than $\frac{b^2}{4}$, that is, if $a^2$ be less than $\frac{pb}{4}$, there are two different rectangles, having the same area, which may be inscribed in the given triangle. It also appears that, to render the problem possible, the given space $a^2$ must not be greater than $\frac{pb}{4}$, that is, than half the area of the given triangle.

Prob. 5. In a triangle, there are given the base, the vertical angle, and the sum of the sides about that angle; to determine each of these sides.

Let us suppose that ABC (fig. 4) is the triangle, of which there is given the base AC, the vertical angle ABC, and the sum of the sides AB, BC. Put AC$=a$, AB+BC$=b$, cosine of $\angle$ABC$=c$; and let AB, BC, the sides required, be denoted by $x$ and $y$.

Let CD be drawn from either of the angles at the base perpendicular to the opposite side AB; then, rad. : cos. B : : CB : BD; therefore BD$=$cos. B$\times$CB$=cy$.

Now, from the principles of geometry, AC$^2=$AB$^2$+BC$^2-2$AB$\times$BD. Hence, and from the question, we have these two equations,

$$x+y=b, \quad x^2-2cxy+y^2=a^2.$$

From the square of the first of these equations, viz. $x^2+2xy+y^2=b^2$, let the second be subtracted; thus we have $2(1+c)xy=b^2-a^2$, and $2xy=\frac{b^2-a^2}{1+c}$. Again, from the square of the first equation let the double of this last equation, viz. $4xy=\frac{2(b^2-a^2)}{1+c}$, be subtracted, and the result is $x^2-2xy+y^2=\frac{2a^2-(1-c)b^2}{1+c}$; so that by taking the square root of this last equation, we obtain

$$x-y=\sqrt{\frac{2a^2-(1-c)b^2}{1+c}}.$$

Thus we have found the difference between the sides, now their sum is given $=b$; hence, by adding $\frac{1}{2}$ the difference to $\frac{1}{2}$ the sum, we find

$$x=\frac{b}{2}+\tfrac{1}{2}\sqrt{\frac{2a^2-(1-c)b^2}{1+c}};$$

and subtracting $\frac{1}{2}$ the difference from $\frac{1}{2}$ the sum,

$$y=\frac{b}{2}-\tfrac{1}{2}\sqrt{\frac{2a^2-(1-c)b^2}{1+c}}.$$

If the angle at B be a right angle, this problem becomes the same as prob. 2.

Prob. 6. To draw a straight line through a given point P (fig. 5), so as to form with AB, AC, two straight lines given in position, a triangle DAE equal to a given space.

Draw PF parallel to AC, one of the lines; and DH, PG, perpendicular to AB, the other line: then PF will be given in position; and AF, PG, will be given in magnitude.

Put the known magnitudes AF$=a$, PG$=b$, and AE, a side of the triangle which is to be determined, $=x$. Also, let the given space to which the triangle ADE is to be equal, be $c^2$.

By similar triangles, FE : PG : : AE : DH;

that is, $x-a:b::x:$DH;

hence DH $=\frac{bx}{x-a}$; and triangle ADE$=\frac{bx^2}{2x-2a}$.

Therefore $\frac{bx^2}{2x-2a}=c^2$, and $bx^2=2c^2x-2ac^2$.

and $x^2-\frac{2c^2}{b}x=-\frac{2ac^2}{b}$.

This is a quadratic equation, which, by completing the square, becomes

$$x^2-\frac{2c^2}{b}x+\frac{c^4}{b^2}=\frac{c^2(c^2-2ab)}{b^2}.$$

Hence, by taking the square root, and transposing,

$$x=\frac{c^2\pm c\sqrt{c^2-2ab}}{b}.$$

It appears, from this expression, that $x$ will have two values, viz.

$$x=\frac{c^2+c\sqrt{c^2-2ab}}{b},\quad x=\frac{c^2-c\sqrt{c^2-2ab}}{b};$$

therefore there are two positions of the line DE, which will satisfy the problem. It further appears, that the problem will only be possible when $c^2 > 2ab$; for if $c^2 < 2ab$, then $c^2-2ab$ will be a negative quantity, and can have no real square root. Since, then, $c^2$ cannot be less than $2ab$, it follows that the least triangle which can be formed by drawing a line throughout P, a point in the angle CAB, is equal to $2ab$, that is, to $2\text{AF}\times\text{PG}$.

If the point P were in the angle DAB′, adjacent to DAE (fig. 6), the solution would be the same; but in this case, the same notation being employed,

$$x=\frac{c^2\pm c\sqrt{c^2+2ab}}{b}.$$

The quantity under the radical sign is always positive, therefore there is no limitation to the problem.

Prob. 7. To find the area of a triangle whose sides are given.

In the triangle ABC (fig. 7) draw the perpendicular CD; put $\text{BC}=a$, $\text{AC}=b$, $\text{AB}=c$, $\text{CD}=p$.

By the elements of Geometry (see Geometry),

$$\text{CB}^2=\text{BA}^2+\text{CA}^2-2\text{AB}\cdot\text{AD};$$

that is, $a^2=c^2+b^2-2c\times\text{AD}$;

hence $\text{AD}=\dfrac{c^2+b^2-a^2}{2c}$; and since

$$p^2=\text{AC}^2-\text{AD}^2=b^2-\left(\frac{c^2+b^2-a^2}{2c}\right)^2,$$

therefore $4c^2p^2=4c^2b^2-(c^2+b^2-a^2)^2$.

The second side of this equation is the difference of two squares; therefore it admits of being resolved into the product of the sum and difference of the roots, thus,

$$[c^2+2cb+b^2-a^2]\,[a^2-(c^2-2cb+b^2)];$$

$$\text{or, } [(c+b)^2-a^2]\,[a^2-(c-b)^2].$$

Again, $(c+b)^2-a^2=(a+b+c)(c+b-a)$;

and $a^2-(c-b)^2=(a+c-b)(a-c+b)$;

therefore,

$$4c^2p^2=(a+b+c)(a+b-c)(a-b+c)(b+c-a).$$

If we put $s=\frac{1}{2}(a+b+c)$, then

$$a+b+c=2s,\quad a+b-c=2(s-c),$$
$$a-b+c=2(s-b),\quad b+c-a=2(s-a).$$

We have now

$$\frac{c^2p^2}{4}=s(s-a)(s-b)(s-c);$$

and hence, observing that $\dfrac{cp}{2}=$ area of triangle,

$$\text{area}=\sqrt{[s(s-a)(s-b)(s-c)]}.$$

203. By a method of investigation in all respects similar to that which has been employed in these examples, any proposed geometrical problem may be reduced to an algebraic equation, the roots of which will exhibit arithmetical values of that geometrical magnitude which constitutes the unknown quantity in the equation. But the roots of algebraic equations may also be expressed by geometrical magnitudes, and hence a geometrical construction of a problem may be derived from its algebraic solution. For example, quadratic equations, which all belong to one or other of these three forms,

$$x^2+ax=bc,\quad x^2-ax=bc,\quad x^2-ax=-bc,$$
$$\text{or, } x(x+a)=bc,\quad x(x-a)=bc,\quad x(a-x)=bc,$$

may be constructed as follows.

*Construction of the first and second forms.*—Let a circle EABD (fig. 8) be described with a radius $=\frac{1}{2}a$, in which, from any point A in the circumference, apply a chord $\text{AB}=b-c$, ($b$ being supposed greater than $c$) and produce AB so that $\text{BC}=c$; then $\text{AC}=b$.

Let H be the centre of the circle; join CH cutting the circumference in D and E, then, in the first case, the positive value of $x$ will be represented by CD, and in the second by CE; for by construction $\text{DE}=a$; therefore, if CD be called $x$, then $\text{CE}=x+a$; but if $\text{CE}=x$, then $\text{CD}=x-a$. Now, by the elements of geometry, $\text{EC}\times\text{CD}=\text{AC}\times\text{CB}$; that is, $x(x\pm a)=bc$, or $x^2\pm ax=bc$, which equation comprehends the first and second cases.

If the negative roots be required, that of the first case will be CE and that of the second CD.

When $b$ and $c$ are equal, the construction will be rather more simple; for then AB vanishing, AC will coincide with the tangent CF. Therefore, if a right-angled triangle HFC be constructed, whose legs HF and FC are equal respectively to $\frac{1}{2}a$ and $b$, then will CD, the value of $x$ in the first case, be equal to CH—HF, and CE, the value of $x$ in the latter, $=\text{CH}+\text{HF}$.

*Construction of the third form.*—Let a circle EADB (fig. 9) be described with a radius $=\frac{1}{2}a$ as before, in which apply a chord $\text{AB}=b+c$, and take $\text{AC}=b$. Through C draw the diameter DCE, then either DC or EC will be positive roots of the equation. For since $\text{ED}=a$, if either EC or $\text{CD}=x$, the remaining part of the diameter will be $a-x$; now by the nature of the circle $\text{EC}\times\text{CD}=\text{AC}\times\text{CB}$, that is, $x(a-x)=bc$, or $x^2-ax=-bc$; hence it is evident that the roots are rightly determined.

If $b$ and $c$ are equal, the construction will be the same, only it will then not be necessary to describe the whole circle; for since AC will be perpendicular to the diameter, if a right-angled triangle HCA be constructed, having its hypothenuse $\text{HA}=\frac{1}{2}a$ and base $\text{AC}=b$, the roots of the equation will be expressed by AH+HC and AH—HC.

If $b$ and $c$ be so unequal that $b-c$ in the first two cases, or $b+c$ in the third, is greater than $a$, then, instead of these quantities, $\frac{1}{2}b$ and $2c$, or in general $\frac{b}{n}$ and $nc$ (where $n$ is any number whatever) may be used. Or a mean proportional may be found between $b$ and $c$, and the construction performed as directed in each case when $b$ and $c$ are equal.

It appears from this section, that every geometrical problem which produces a quadratic equation may be constructed by means of a straight line and a circle, or is a *plane* problem; hence, on the contrary, if a problem can be constructed by straight lines and circles, its algebraic resolution will not produce an equation higher than a quadratic. Cubic and biquadratic equations may be constructed geometrically by means of any two conic sections; hence it follows that every geometrical problem which requires for its construction two conic sections, will, when resolved by algebra, produce a cubic or biquadratic equation.

## Sect. XXIV. Of the Loci of Equations.

204. When an equation contains two indeterminate quantities $x$ and $y$, then for each particular value of $x$

Algebra. there may be as many values of $y$ as it has dimensions in that equation. So that if in an indefinite line AE (fig. 10) there be taken a part AP to represent $x$, and a perpendicular PM be drawn to represent $y$, there will be as many points M, M′, &c. the extremities of these perpendiculars, as there are dimensions of $y$ in the proposed equation; and the values of PM, PM′, &c. will be the roots of the equation, which are found by substituting for $x$ its value in any particular case. Hence it appears that in any particular equation we may determine as many points M as we please; and a line which passes through all these points is called the *locus* of the equation. The line AP, which expresses any value of $x$, is called an *absciss;* and PM, which expresses the corresponding value of $y$, is called an *ordinate.* Any two corresponding values of $x$ and $y$ are also called *co-ordinates.*

205. When the equation that arises by substituting for $x$ any particular value AP has all its roots positive, the points M, M′, &c. will lie all on one side of AE; but if any of them be negative, these must be set off on the other side of AE towards $m$.

If $x$ be supposed to become negative, then the line A$p$, which represents it, is to be taken in a direction the opposite to that which represents the positive values of $x$; the points M, $m$, are to be taken as before, and the *locus* is only complete when it passes through all the points M, $m$, so as to exhibit a value of $y$ corresponding to every possible value of $x$.

If in any case one of the values of $y$ vanish, then the point M coincides with P, and the *locus* meets AE in that point. If one of the values of $y$ becomes infinite, then it shows that the curve has an infinite arc, and in that case the line PM becomes an *asymptote* to the curve, or touches it at an infinite distance, if AP itself is finite.

If, when $x$ is supposed infinitely great, a value of $y$ vanish, then the curve approaches to AE as an asymptote.

If any values of $y$ become impossible, then so many points M vanish.

206. From these observations, and the theory of equations, it appears that when an equation is proposed involving two indeterminate quantities $x$ and $y$, there may be as many intersections of the curve which is the *locus* of the equation, and of the line PM, as there are dimensions of $y$ in the equation; and as many intersections of the curve and the line AE as there are dimensions of $x$ in the equation.

207. A curve line is called *geometrical,* or *algebraic,* when the equation which expresses the relation between $x$ and $y$ (any absciss and its corresponding ordinate), consists of a finite number of terms, and contains, besides these quantities, only known quantities. Algebraic curves are divided into *orders,* according to the dimensions of the equations which express the relations between their abscisses and ordinates, or according to the number of points in which they can intersect a straight line.

*Straight lines* themselves constitute the first order of lines; and when the equation expressing the relation between $x$ and $y$ is only of one dimension, the points M, &c. must be all found in a straight line which contains with AE a given angle. Suppose, for example, that the given equation is $ay-bx-cd=0$, and that its *locus* is required.

Since $y=\frac{bx+cd}{a}$, it follows that APM (fig. 11) being a right angle, if AN be drawn making the angle NAP such that its cosine is to its sine as $a$ to $b$, and drawing AD parallel to the ordinates PM, and equal to $\frac{cd}{a}$, if DF be drawn parallel to AN, then will DF be the *locus* required; where it is to be observed that AD and PN are to be taken on the same side of AE if $bx$ and $cd$ have the same sign, but on opposite sides of AE if they have contrary signs. Algebra.

Curves whose equations are of two dimensions constitute the *second* order of lines, and the *first* kind of curves. Their intersections with a straight line can never exceed two (sect. 204).

Curves whose equations are of three dimensions form the *third* order of lines and the *second* kind of curves, and their intersections with a straight line can never exceed three; and after the same manner curves of the higher orders are denominated.

Some curves, if they were completely described, would cut a straight line in an infinite number of points; but these belong to none of the orders we have mentioned, for the relation between their ordinates and abscisses cannot be expressed by a finite equation, involving only ordinates and abscisses with determinate quantities. Curves of this kind are called *mechanical* or *transcendental.*

208. As the roots of an equation become impossible always in pairs, so the intersections of a curve and its ordinate PM must vanish in pairs, if any of them vanish. Let PM (fig. 12) cut the curve in the points M and $m$, and, by moving parallel to itself, come to touch it in the point N, then the two points of intersection M and $m$ go to form one point of contact N. If PM still move on, parallel to itself, the points of intersection will, beyond N, become imaginary, as the two roots of an equation first become equal, and then imaginary.

The curves of the 3d, 5th, 7th orders, and all whose dimensions are odd numbers, have always one real root at least; and consequently for every value of $x$ the equation by which $y$ is determined must have at least one real root; so that as $x$ or AP may be increased *in infinitum* on both sides, it follows that M must go off on both sides without limit.

In curves whose dimensions are even numbers, as the roots of their equations may become all impossible, it follows that the figure of the curve may be like a circle, or oval, that is, limited within certain bounds, beyond which it cannot extend.

209. When two roots of the equation by which $y$ is determined become equal, either the ordinate PM touches the curve, two points of intersection in that case going into a point of contact; or the point M is a *punctum duplex* in the curve, two of its arcs intersecting each other there; or some oval that belongs to that kind of curve becoming infinitely little in M, it vanishes into what is called a *punctum conjugatum.*

If, in the equation, $y$ be supposed $=0$, then the roots of the equation by which $x$ is determined will give the distances of the points where the curve meets AE from A; and if two of those roots be found equal, then either the curve touches the line AE, or AE passes through a *punctum duplex* in the curve. When $y$ is supposed $=0$, if one of the values of $x$ vanish, the curve in that case passes through A; if two vanish, then either AE touches the curve in A, or A is a *punctum duplex.*

As a *punctum duplex* is determined from the equality of two roots, so is a *punctum triplex* from the equality of three roots.

210. To illustrate these observations, we shall take a few examples.

*Ex.* 1. It is required to describe the line that is the *locus* of this equation, $y^2=ax+ab$, or $y^2-ax-ab=0$, where $a$ and $b$ denote given quantities. Since $y^2$

$= \pm\sqrt{ax+ab}$; if AP $= x$ (fig. 13) be assumed of a known value, and PM, P$m$, set off on each side equal to $\sqrt{ax+ab}$, the points M, $m$, will belong to the *locus* required; and for every positive value of AP there may thus be found a point of the *locus* on each side. The greater that AP or $x$ is taken, the greater does $\sqrt{ax+ab}$ become, and consequently PM and P$m$ the greater; and if AP be supposed infinitely great, PM and P$m$ will also become infinitely great; therefore the *locus* has two infinite arcs, that go off to an infinite distance from AE and from AD. If $x$ be supposed to vanish, then $y = \pm\sqrt{ab}$, so that $y$ does not vanish in that case, but passes through D and $d$, taking AD and A$d$ each $= \sqrt{ab}$.

If P be supposed to move on the other side of A, then $x$ becomes negative, and $y = \pm\sqrt{ab - ax}$, so that $y$ will have two values as before, while $x$ is less than $b$; but if AB $= b$, and the point P be supposed to come to B, then $ab = ax$, and $y = \pm\sqrt{ab - ax} = 0$; that is, PM and P$m$ vanish, and the curve there meets the line AE. If P be supposed to move from A beyond B, then $x$ becomes greater than $b$, and $ax$ greater than $ab$, so that $ab - ax$ being negative, $\sqrt{ab - ax}$ becomes imaginary; that is, beyond B there are no ordinates which meet the curve, and consequently, on that side the curve is limited at B.

All this agrees very well with what is known by other methods, that the curve whose equation is $y^2 = ax + ab$ is a parabola whose vertex is B, axis BE, and parameter equal to $a$. For since $b \pm x =$ BP, and $y =$ PM, from the equation $ab \pm ax = y^2$, or $a(b \pm x) = y^2$, we have $a \times \text{BP} = \text{PM}^2$, which is the well-known property of the parabola.

*Ex.* 2. It is required to describe the line that is the *locus* of the equation $xy + ay + cy = bc + bx$, or

$$y = \frac{bc + bx}{a + c + x}.$$

Here it is evident (fig. 14) that the ordinate PM can meet the curve in one point only, there being but one value of $y$ corresponding to each value of $x$. When $x = 0$, then $y = \frac{bc}{a+c}$; so that the curve does not pass through A. If $x$ be supposed to increase, then $y$ will increase, but will never become equal to $b$, since $y = b \times \frac{c+x}{a+c+x}$, and $a+c+x$ is always greater than $c+x$. If $x$ be supposed infinite, then the terms $a$ and $c$ vanish compared with $x$, and consequently $y = b \times \frac{x}{x} = b$; from which it appears, that taking AD $= b$, and drawing GD parallel to AE, it will be an asymptote, and touch the curve at an infinite distance. If $x$ be now supposed negative, and AP be taken on the other side of A, then $y = b \times \frac{c-x}{a+c-x}$; and if $x$ be taken on that side $= c$, then $y = b \times \frac{c-c}{a} = 0$; so that the curve must pass through B, if AB $= c$. If $x$ be supposed greater than $c$, then will $c - x$ become negative, and the ordinate will become negative, and lie on the other side of AE, till $x$ become equal to $a+c$, and then $y = b\frac{-a}{0}$, that is, because the denominator is 0, $x$ becomes *infinite*; so that if AK be taken $= a+c$, the ordinate KF will be an asymptote to the curve.

If $x$ be taken greater than $a+c$, or AP greater than AK, then both $c - x$ and $a+c-x$ become negative, and consequently $y = b \times \frac{x-c}{x-a-c}$ becomes a positive quantity; and since $x-c$ is always greater than $x-a-c$, it follows that $y$ will be always greater than $b$ or KG, and consequently the rest of the curve lies in the angle FGH. And as $x$ increases, since the ratio of $x-c$ to $x-a-c$ approaches still nearer to a ratio of equality, it follows that PM approaches to an equality with PN, therefore the curve approaches to its asymptote GH on that side also.

The curve is the common hyperbola, for since $b(c+x) = y(a+c+x)$, by adding $ab$ to both sides, $b(a+c+x) = y(a+c+x) + ab$, and $(b-y)(a+c+x) = ab$, that is, NM $\times$ GN $=$ GC $\times$ BC, which is the property of the common hyperbola.

*Ex.* 3. It is required to describe the *locus* of the equation $ay^2 - xy^2 = x^3 + bx^2$.

Here $y^2 = \frac{x^3 + bx^2}{a - x}$, and therefore $y = \pm\sqrt{\frac{x^3 + bx^2}{a - x}}$, hence PM and PM (fig. 15) are to be taken on each side, and equal to $\sqrt{\frac{x^3 + bx^2}{a - x}}$. This expression, by supposing $x = a$, becomes infinite, because its denominator is then $= 0$; therefore if AB be taken $= a$, and BK be drawn perpendicular to AB, the line BK will be an asymptote to the curve. If $x$ be supposed greater than $a$, or AP greater than AB, then $a - x$ being negative, the fraction $\frac{x^3 + bx^2}{a - x}$ will become negative, and its square root impossible; so that no part of the *locus* can lie beyond B. If $x$ be supposed negative, or P taken on the other side of A, then $y = \pm\sqrt{\frac{-x^3 + bx^2}{a + x}}$; hence the values of $y$ will be real and equal as long as $x$ is less than $b$; but if $x = b$, then $y = \sqrt{\frac{-x^3 + bx^2}{a + x}} = \sqrt{\frac{-b^3 + b^3}{a + b}} = 0$, and consequently if AD be taken $= b$, the curve will pass through D, and there touch the ordinate. If $x$ be taken greater than $b$, then $\pm\sqrt{\frac{-x^3 - bx^2}{a + x}}$ becomes imaginary, so that no part of the curve is found beyond D. The portion between A and D is called a *nodus*. If $y$ be supposed $= 0$, then will $x^3 + bx^2 = 0$ be an equation whose roots are $-b$, 0, 0; from which it appears that the curve passes twice through A, and has in A a *punctum duplex*. This *locus* is a line of the third order.

If $b$ is supposed to vanish in the supposed equation, so that $ay^2 - xy^2 = x^3$, then will A and D coincide (fig. 16) and the *nodus* vanish, and the curve will have in the point A a *cuspis*, the two arcs AM and A$m$, in this case, touching one another in that point. This is the same curve which the ancients called the *Cissoid of Diocles*.

If, instead of supposing $b$ positive, or equal to 0, we suppose it negative, the equation will be $ay^2 - xy^2 = x^3 - bx^2$; the curve will in this case pass through D as before (fig. 17), and taking AB $= a$, BK will be its asymptote. It will have a *punctum conjugatum* in A, because when $y$ vanishes, two values of $x$ vanish, and the third becomes $= b$, or AD. The whole curve, except this point, lies between DQ and BK. These remarks are demonstrated after the same manner as in the first case.

211. If an equation have this form,

$$y=ax^n+bx^{n-1}+cx^{n-2}+, \text{ \&c.}$$

and $n$ is an even number, then will the *locus* of the equation have two infinite arcs lying on the same side of AE (fig. 18); for if $x$ become infinite, whether positive or negative, $x^n$ will be positive and $ax^n$ have the same sign in either case; and as $ax^n$ becomes infinitely greater than the other terms $bx^{n-1}$, &c. it follows that the infinite values of $y$ will have the same sign in these cases, and consequently the two infinite arcs of the curve will lie on the same side of AE.

But if $n$ be an odd number, then when $x$ is negative, $x^n$ will be negative, and $ax^n$ will have the contrary sign to what it has when $x$ is positive; and therefore the two infinite arcs will in this case lie on different sides of AE, as in fig. 19, and tend towards parts directly opposite.

212. If an equation have this form, $yx^n=a^{n+1}$, and $n$ be an odd number, then when $x$ is positive, $y=\dfrac{a^{n+1}}{x^n}$; but when $x$ is negative, $y=-\dfrac{a^{n+1}}{x^n}$; so that this curve must all lie in the vertically opposite angles KAE, FA$e$ (fig. 20), as the common hyperbola, FK, E$c$ being asymptotes.

But if $n$ be an even number, then $y$ is always positive, whether $x$ be positive or negative, because $x^n$ in this case is always positive; and therefore the curve must all lie in the two adjacent angles KAE and KA$e$ (fig. 21), and have AK and AE for its asymptotes.

213. If an equation be such as can be reduced into two other equations of lower dimensions, without affecting $y$ or $x$ with any radical sign, then the *locus* will consist of the two *loci* of those inferior equations. Thus, the *locus* of the equation $y^2-2xy+by+x^2-bx=0$, which may be resolved into these two, $x-y=0$, $y-x+b=0$, is found to be two straight lines cutting the absciss AE (fig. 22) in angles of 45° in the points A, B, whose distance AB$=b$. In like manner some cubic equations can be resolved into three simple equations, and then the *locus* is three straight lines; or may be resolved into a quadratic and simple equation, and then the *locus* is a straight line and a conic section. In general, curves of the superior orders include all the curves of the inferior orders, and what is demonstrated generally of any one order is also true of the inferior orders. Thus, for example, any general property of the conic sections holds true of two straight lines as well as a conic section, particularly, that the rectangles of the segments of parallels bounded by them will always be to one another in a given ratio.

214. From the analogy which subsists between algebraic equations and geometrical curves, it is easy to see that the properties of the former must suggest corresponding properties of the latter. Hence the principles of algebra admit of the most extensive application to the theory of curve lines. It may be demonstrated, for example, that the *locus* of every equation of the second order is a conic section; and, on the contrary, the various properties of the diameters, ordinates, tangents, &c. of the conic sections may be readily deduced from the theory of equations.

## Sect. XXV. Arithmetic of Sines.

215. The calculus of sines is one of the mathematical theories which have been produced by the application of algebra to geometry. It treats of the relations which sines, cosines, tangents, &c. of angles have one to another.

216. The geometrical principles of this theory were known to the ancients. They may be deduced from the beautiful property of a quadrilateral inscribed in a circle, namely, that the rectangle contained by its diagonals is equal to the sum of the rectangles contained by its opposite sides; which we find in the writings of Ptolemy, and which was employed in the trigonometry of the Greeks. In comparatively modern times we find the same propositions distinctly recognised in the *Opus Palatinum*, the great work on triangles begun by Rhetius, and finished by Otho, who published it in 1596; also in the trigonometry of Pitiscus, first printed in 1599; and probably they may be found in still earlier works. Montucla, in his *Histoire des Mathématiques*, says, "I do not see that any one before the beginning of this century (the 18th) had thought of seeking formulæ proper to express the sines or cosines, tangents or co-tangents, of the sum or difference of arcs of a circle, or their powers, &c. It seems to me to have been very natural; and that there must have been frequently occasion to know what was the sine or cosine, the tangent or co-tangent, of an arc, that was the sum or difference of two arcs of which the sines or cosines, or tangents or co-tangents, were known. The first theorems on this subject appear to be the work of Frederic-Christian Mayer, one of the first members of the Petersburg Academy." Montucla, however, seems to have overlooked the trigonometry of Pitiscus, who, in problems 8 and 9 of his second book, gives rules for finding the sines and cosines of the sum and difference of two arcs, when the sines and cosines of the arcs are given. These are in the edition of 1612. The formula which expresses the tangent of the sum of several arcs by the tangent of the arcs themselves, was given, for the first time, we believe, by John Bernoulli, in the Leipsic Acts for July 1722. Both these are prior to Mayer's Memoir, which is in the Petersburg Commentaries with the date 1727. It was probably here, however, that the first essay of analytical trigonometry was given. Euler, who stands pre-eminent in every branch of the mathematics, has contributed more especially to this doctrine, as in his *Subsidium Calculi Sinuum*, in the New Petersburg Commentaries, vol. v. (for 1754 and 1755), and his *Introductio in Analysin Infinitorum*. The doctrine of spherical trigonometry was given in an analytic form by the same writer, in a memoir entitled *Trigonometria Spherica universa ex primis principiis derivata*, in the Petersburg Acts for 1779; and also by De Gua in the volume of the Academy of Sciences for 1783; and, lastly, by Lagrange in a memoir of the *Journal Polytechnique*, vol. ii.

217. The calculus of sines is of great importance as a branch of analysis. It enables us in a great measure to dispense with the complicated diagrams which the earlier writers on geometry, and on the physico-mathematical theories, employed in their investigations and demonstrations. In geometry, when combined with the modern analysis, it gives the power of expressing the most complicated relations of figure, and magnitude, and position, almost without the help of graphic representations. As an example, we may give the fine discovery by Gauss, of formulæ by which a regular polygon of seventeen sides may be inscribed in a circle by a geometrical construction. In algebra it has served to extend greatly the theory of equations; in astronomy, when applied to the theories of the planets and comets, it gives elegant and convenient expressions for their angular motions, and compact formulæ for computing the elements of their orbits, and their true and apparent positions; and in statics and dynamics, it gives, without diagrams, the relations of forces which produce rest or motion, and the laws of the motions. The precious invention of logarithms abridged the irksome

labour of calculation, even in the simplest applications of geometry; but this, combined with the trigonometrical tables, and the theory of the calculus of sines, affords a still more powerful instrument for abridging labour; just as two mechanical inventions, which apart can overcome considerable resistance, yet are vastly more potent when united.

218. In the calculus of sines, as well as in other applications of algebra to geometry, all quantities, whether lines or angles, are considered as expressed by numbers; some line or angle is assumed as a *unit*, and the number of times that unit is contained in the line or angle is its numerical value.

The magnitude of the unit is altogether arbitrary; and since, in general, the magnitude to be expressed in numbers may not contain the unit an exact number of times, it ought to be so small, that the remainders may, in respect of the wholes, be rejected.

219. The primary unit, by which angles are expressed in numbers, is one ninetieth part of a right angle, that is, one 360th part of four right angles. Each of these is called a *degree*, and is conceived to contain 60 units of a lower order, called *minutes;* and each minute, again, 60 units of the next lower order, called *seconds;* and so on to *thirds*, &c.

The degrees, minutes, &c. in an angle, are usually written thus: $12° 15' 10'' 25'''$. This means an angle of 12 degrees, 15 minutes, 10 seconds, and 25 thirds. It is not common to estimate angles to a greater degree of accuracy than seconds and tenths of a second: thus $3{\cdot}4''$ means three seconds and four tenths of a second.

The French mathematicians attempted, in the time of the Revolution, to introduce a new unit for angles. They supposed a right angle to be divided into 100 equal parts, called degrees; and each degree to be subdivided into 100 minutes; and each minute into 100 seconds; and so on. This division, however, was not adopted out of France. Unfortunately, Laplace had employed it in his *Mécanique Céleste*, to the inconvenience of its readers; but now the French mathematicians themselves have almost all returned to the old sexagenary division.

220. Although an angle and a circle are not necessarily related, because we can form a distinct notion of each independently of the other; yet there is such an analogy between them, as to make it convenient to consider them together. Therefore (Plate XVIII. fig. 23), let PO, QO, be straight lines which contain an angle whose vertex is O. Let OQ, one of the lines, be given in position, and let OE, a segment of the other line adjacent to O, be an *invariable magnitude.* Let us now suppose the line PO to coincide at first with QO, and, departing from that position, to turn about O as a centre: the line PO will now generate an angle POQ, and E, the extremity of the constant radius, will describe an arc AE. When the line has made a complete revolution about the centre O, it will have generated four right angles, and the point E will have described a complete circle; and it is manifest that any angle POQ will have the same ratio to four right angles that the arc AE has to the whole circumference. Hence it follows that the arc may conveniently serve as a *geometrical measure* of the angle; and if we suppose the circumference to be divided into 360 equal parts, called degrees, and each of these to be subdivided into 60 minutes, and so on, then the angle and arc will be expressed by the same number of degrees, minutes, &c.

221. Let the diameters AC, BD, be perpendicular to each other. These divide the circumference into four *quadrants*, and the circle into four regions AOB, BOC, COD, DOA. The difference between an angle and a right angle, or between an arc and a quadrant, is called the *complement* of the angle or arc; and the difference between an angle and two right angles, or between an arc and a semicircle, is called the *supplement* of the angle or arc. Thus, the angle POB is the complement of POQ, and POC is its supplement; and the arc BE is the complement of AE, and CE its supplement.

222. Assuming A as the origin of the variable arc AE, a straight line EF, drawn from its extremity E, perpendicular to the diameter AC, is called the *sine* of the arc AE; and a straight line EG, drawn perpendicular to BD (which is the sine of the arc EB, the complement of AE), is called the *cosine* of the arc AE. Hence it appears that the cosine of an arc is equal to the distance of the sine from the centre of the circle.

223. Supposing now the arc AE to increase continually by the revolving of the radius OE, departing from the position OA, and moving in the direction ABCD, &c. the sine EF, which at first is $=0$, will increase until the arc become a quadrant; afterwards, while the arc increases from one to two quadrants, the sine E′F′ will decrease, and at last again become $=0$. The arc continuing to increase, the sine will be reproduced; but its direction F″E″ will now be the opposite to its first direction FE. It will increase in magnitude, until the arc become three quadrants ABCD; and it will again decrease, while the arc is increasing from three to four quadrants: and when the radius has made a complete revolution, the sine will have decreased to *zero.* We may, however, suppose the revolving radius OE still to proceed: there will thus be generated an arc, ABCDAE, greater than a complete circumference, of which EF will be the sine; and, in the second and every succeeding revolution, the sine will pass through the same changes as in the first.

224. We may trace the changes in the magnitude and direction of the cosine just in the same way. While the arc AE increases from zero to a quadrant, the cosine OF, at first equal to the radius OA, decreases, and at last vanishes; and while the arc continues to increase, and has any value ABE′ between one and two quadrants, the cosine OF′ is reproduced, with a direction the opposite to the first. When the arc is exactly two quadrants, the cosine becomes in magnitude OC, equal to OA, but opposite in direction. The arc still increasing to ACE″, the cosine decreases to OF″; and when the arc becomes ABCD, three quadrants, the cosine again becomes $=0$: between three and four quadrants the cosine OF‴ re-appears in its original direction; and when the revolution is completed, the cosine acquires its first value OA. In a second revolution the same changes are repeated, and so on continually.

We may suppose the radius to turn round O in the contrary direction ADC, and the very same changes will be produced on the direction and magnitude of the sine and cosine of the generated arc AE‴.

225. In conformity to the principles of analytic geometry, the contrary position of the arcs AE, AE′, and the sines EF, E′F′, in respect of the position of the arcs AE″, AE‴, and the sines E″F″, E‴F‴, may be indicated by the signs $+$ and $-$; and the same is true of the cosines OF, OF‴, which are opposed in direction to the cosines OF′, OF″, the arcs and sines on opposite sides of the diameter AC being regarded as having opposite signs, and a like contrariety being supposed in the cosines on opposite sides of the diameter BD, which is perpendicular to AC. The arc AE being regarded as positive, it does not signify whether we reckon the sines and cosines positive or negative in the beginning, provided we change the signs,

when, after having decreased to *zero*, they are reproduced with a contrary direction.

Let us suppose the sine and cosine of any positive arc AE in the first quadrant to be positive; then, from what has been explained, the sine will continue to be positive in the second quadrant, but the cosine will have become negative; in the third the sine and cosine will both be negative; and in the fourth the sine will be negative, but the cosine positive.

Again, if the radius OE turn about O in the contrary direction, ADCB, &c. the arc AE‴, &c. thus generated will be negative; the sines will also be negative in the first semicircle, but the cosines positive in the quadrant AD, and negative in DC, and so on; the changes from + to —, and from — to +, following each other exactly as in the generation of a positive arc.

226. Let a straight line AH, perpendicular to the diameter AC, meet the radius OE produced in H (fig. 24): the line AH is called the *tangent* of the arc AE, and the line OH the *secant* of that arc.

227. A line BK, perpendicular to OB (which is at right angles to OA), and which meets OH in K, will be the tangent of the complement of the arc AE; and OK will be its secant. The former is therefore called the *co-tangent* of the arc AE, and the latter its *co-secant*.

228. The segment AF of the diameter, between the beginning of the arc and its sine, is called the versed sine of the arc; and, similarly, the segment BG, the versed sine of the complement, is its *co-versed sine*.

229. Since the arc AE is assumed as a geometrical measure of the angle POQ, we may regard the lines which are the sine, tangent, secant, &c. of the arc, as also the sine, tangent, secant, &c. of the angle; or, since all quantities in this calculus are to be expressed in numbers, we may take any numbers proportional to these lines. Hence we may assume the fraction $\frac{arc\ AE}{rad.OA}$ as the measure of the angle POQ, and, similarly, $\frac{EF}{OE}$ as the sine of the angle POQ, $\frac{OF}{OE}$ its cosine, $\frac{HA}{OA}$ its tangent, and $\frac{OH}{OA}$ its secant; then $\frac{BK}{OB}=\frac{AO}{AH}$ will be the co-tangent, and $\frac{OK}{OB}=\frac{HO}{AH}$ will be the co-secant of the angle. These quantities will have among themselves the same ratios as the lines which bear the same designations; and it is evident, from the nature of similar figures, that supposing the angle POQ to remain of the same magnitude, its sine, tangent, secant, &c. thus defined, are the same, whatever be the magnitude of the circle, which now serves merely to connect them as related quantities.

We may consider OA, the radius of the circle, as a unit, and then the sines, tangents, &c. will be expressed in parts of that unit, according to the decimal notation. This is the common form in which they are given in the trigonometrical tables.

230. The power of algebra, as an instrument of investigation, depends greatly on the proper employment of conventional signs: it is common to express the sine of an arc $a$ by the abbreviation *sin. a*, its cosine by *cos. a*, its tangent by *tan. a*, its secant by *sec. a*, its co-tangent by *cot. a*, its co-secant by *cosec. a*, and its versed sine by *ver. sin. a*.

231. From the definition given of an angle by the ancient geometers, its measure cannot exceed half the circumference of a circle. When, however, we regard an angle as generated by the rotation of a line about a fixed point, the arc, which is its measure, may be regarded as capable of continual increase. In astronomy, the angular motion of the sun and planets is reckoned from an angle or arc of 0° forward to 360°. We are thus led to consider the sines of arcs which exceed 180°, and even which exceed a whole circumference, or any number of circumferences.

232. Let $\pi$ denote half the circumference of the circle which is assumed as a scale for measuring angles. It is easy, by induction, to infer from what has been explained, that $a$ being any arc,

$$\begin{array}{ll}
\text{Cos.}\ (\ \pi+a)=-\text{cos.}\ a, & \text{Sin.}\ (\ \pi+a)=-\text{sin.}\ a,\\
\text{Cos.}\ (2\pi+a)=+\text{cos.}\ a, & \text{Sin.}\ (2\pi+a)=+\text{sin.}\ a,\\
\text{Cos.}\ (3\pi+a)=-\text{cos.}\ a, & \text{Sin.}\ (3\pi+a)=-\text{sin.}\ a,\\
\text{Cos.}\ (4\pi+a)=+\text{cos.}\ a, & \text{Sin.}\ (4\pi+a)=+\text{sin.}\ a,\\
\&c. & \&c.
\end{array}$$

And in general, $n$ being 0, or any whole number,

$$\left.\begin{array}{l}
\text{Cos.}\ [(2n+1)\ \pi+a]=-\text{cos.}\ a,\\
\text{Cos.}\ [\ 2n\pi+a]\ \ldots\ldots=+\text{cos.}\ a,\\
\text{Sin.}\ [(2n+1)\ \pi+a]=-\text{sin.}\ a,\\
\text{Sin.}\ [\ 2n\pi+a]\ \ldots\ldots=+\text{sin.}\ a.
\end{array}\right\}\ (1)$$

It is also evident that

$$\begin{array}{ll}
\text{Cos.}\ (\ \pi-a)=-\text{cos.}\ a, & \text{Sin.}\ (\ \pi-a)=+\text{sin.}\ a,\\
\text{Cos.}\ (2\pi-a)=+\text{cos.}\ a, & \text{Sin.}\ (2\pi-a)=-\text{sin.}\ a,\\
\text{Cos.}\ (3\pi-a)=-\text{cos.}\ a, & \text{Sin.}\ (3\pi-a)=+\text{sin.}\ a,\\
\text{Cos.}\ (4\pi-a)=+\text{cos.}\ a, & \text{Sin.}\ (4\pi-a)=-\text{sin.}\ a,\\
\&c. & \&c.
\end{array}$$

And in general that

$$\left.\begin{array}{l}
\text{Cos.}\ [(2n+1)\pi-a]=-\text{cos.}\ a,\\
\text{Cos.}\ [\ 2n\pi-a]\ \ldots\ldots=+\text{cos.}\ a,\\
\text{Sin.}\ [(2n+1)\ \pi-a]=+\text{sin.}\ a,\\
\text{Sin.}\ [\ 2n\pi-a]\ \ldots\ldots=-\text{sin.}\ a.
\end{array}\right\}\ (2)$$

When the arc $a=0$, we have

$$\begin{array}{ll}
\text{Cos.}\ (2n+1)\ \pi=-1, & \text{Sin.}\ (2n+1)\ \pi=0,\\
\text{Cos.}\ 2n\pi\ \ \ =+1, & \text{Sin.}\ 2n\pi\ \ \ =0.
\end{array}$$

233. If $a$ and $\alpha$ be arcs which differ by a quadrant, that is, if $\alpha=\frac{1}{2}\pi+a$; then it will appear by inspection of figure 23, and a little consideration, that

$$\text{Cos.}\ \alpha=-\text{sin.}\ a,\qquad \text{Sin.}\ \alpha=+\text{cos.}\ a.$$

Now, by changing $a$ into $\alpha$, formulæ (1) of last section become

$$\begin{array}{l}
\text{Cos.}\ [(2n+1)\pi+\alpha]=-\text{cos.}\ \alpha,\\
\text{Cos.}\ [\ 2n\pi+\alpha]\ \ldots\ldots=+\text{cos.}\ \alpha,\\
\text{Sin.}\ [(2n+1)\pi+\alpha]=-\text{sin.}\ \alpha,\\
\text{Sin.}\ [\ 2n\pi+\alpha]\ \ldots\ldots=+\text{sin.}\ \alpha.
\end{array}$$

In these substitute $\frac{1}{2}\pi+a$ for $\alpha$, $-$sin. $a$ for cos. $\alpha$, and cos. $a$ for sin. $\alpha$, and they become

$$\left.\begin{array}{l}
\text{Cos.}\ [(4n+3)\ \frac{\pi}{2}+a]=+\text{sin.}\ a,\\
\text{Cos.}\ [(4n+1)\ \frac{\pi}{2}+a]=-\text{sin.}\ a,\\
\text{Sin.}\ [(4n+3)\ \frac{\pi}{2}+a]=-\text{cos.}\ a,\\
\text{Sin.}\ [(4n+1)\ \frac{\pi}{2}+a]=+\text{cos.}\ a.
\end{array}\right\}\ (3)$$

If, again, there be two arcs $a$ and $\alpha$, whose sum is a quadrant, that is, $\alpha=\frac{1}{2}\pi-a$, then

$$\text{Cos.}\ \alpha=\text{sin.}\ a,\qquad \text{Sin.}\ \alpha=\text{cos.}\ a.$$

If, in the above formulæ, we now put $\frac{1}{2}\pi-a$ for $\alpha$, and sin. $a$ for cos. $\alpha$, and cos. $a$ for sin. $\alpha$, we shall have

$$\left.\begin{array}{l}
\text{Cos.}\ [(4n+3)\ \frac{\pi}{2}-a]=-\text{sin.}\ a,\\
\text{Cos.}\ [(4n+1)\ \frac{\pi}{2}-a]=+\text{sin.}\ a,\\
\text{Sin.}\ [(4n+3)\ \frac{\pi}{2}-a]=-\text{cos.}\ a,\\
\text{Sin.}\ [(4n+1)\ \frac{\pi}{2}-a]=+\text{cos}\ a.
\end{array}\right\}\ (4)$$

234. The formulæ investigated in the last two sections may be brought together in an abridged form, as in the following table:

$$\text{Cos.}\,[(2n+1)\pi\pm a]=-\text{cos.}\,a, \quad (1)$$
$$\text{Cos.}\,[\,2n\pi\pm a]\ \ldots =+\text{cos.}\,a, \quad (2)$$
$$\text{Sin.}\,[(2n+1)\pi\pm a]=\mp\,\text{sin.}\,a, \quad (3)$$
$$\text{Sin.}\,[\,2n\pi\pm a]\ \ldots =\pm\,\text{sin.}\,a; \quad (4)$$

$$\text{Cos.}\,[(4n+1)\tfrac{\pi}{2}\pm a]=\mp\,\text{sin.}\,a, \quad (5)$$

$$\text{Cos.}\,[(4n+3)\tfrac{\pi}{2}\pm a]=\pm\,\text{sin.}\,a, \quad (6)$$

$$\text{Sin.}\,[(4n+1)\tfrac{\pi}{2}\pm a]=+\,\text{cos.}\,a, \quad (7)$$

$$\text{Sin.}\,[(4n+3)\tfrac{\pi}{2}\pm a]=-\,\text{cos.}\,a. \quad (8)$$

235. The perfection of the modern analysis consists in the employment of the fewest possible principles, and in deducing from these all the truths which can be extracted by the power of the analysis itself. We have therefore occasion for very few of the simplest propositions in geometry, and these only at the outset.

By the nature of a right-angled triangle (fig. 24),

$$OF^2+FE^2=OE^2;\ OA^2+AH^2=OH^2;\ OB^2+BK^2=OK^2.$$

The triangles OFE, OAH, OBK, being similar,

$$OF : FE :: OA : AH :: BK : BO;$$
$$FE : EO :: AH : HO :: BO : OK;$$
$$EO : OF :: HO : OA :: OK : KB.$$

Hence, observing that $OA=OB=OE=1$, and employing our premised notation, we have

$$\text{Cos.}\,a : \text{sin.}\,a :: 1 : \text{tan.}\,a :: \text{cot.}\,a : 1;$$
$$\text{Sin.}\,a : 1 :: \text{tan.}\,a : \text{sec.}\,a :: 1 : \text{cosec.}\,a;$$
$$1 : \text{cos.}\,a :: \text{sec.}\,a : 1 :: \text{cosec.}\,a : \text{cot.}\,a.$$

From these we obtain the following table of formulæ, exhibiting the relations among trigonometrical quantities, where $\text{cos.}^2\,a$ and $\text{sin.}^2\,a$ denote the squares of the cosine and sine of the arc or angle $a$.

(A)

$$\text{Cos.}^2\,a+\text{sin.}^2\,a=1 \ldots\ldots (1)$$
$$\text{Sec.}^2\,a-\text{tan.}^2\,a=1 \ldots\ldots (2)$$
$$\text{Cosec.}^2\,a-\text{cot.}^2\,a=1 \ldots\ldots (3)$$
$$\text{Cos.}\,a\ \text{sec.}\,a=1 \ldots\ldots (4)$$
$$\text{Sin.}\,a\ \text{cosec.}\,a=1 \ldots\ldots (5)$$
$$\text{Tan.}\,a\ \text{cot.}\,a=1 \ldots\ldots (6)$$
$$\text{Tan.}\,a\ \text{cos.}\,a=\text{sin.}\,a \ldots\ldots (7)$$
$$\text{Cot.}\,a\ \text{sin.}\,a=\text{cos.}\,a \ldots\ldots (8)$$
$$\text{Sin.}\,a\ \text{sec.}\,a=\text{tan.}\,a \ldots\ldots (9)$$
$$\text{Cos.}\,a\ \text{cosec.}\,a=\text{cotan.}\,a \ldots\ldots (10)$$
$$\text{Tan.}\,a\ \text{cosec.}\,a=\text{sec.}\,a \ldots\ldots (11)$$
$$\text{Cotan.}\,a\ \text{sec.}\,a=\text{cosec.}\,a \ldots\ldots (12)$$

It appears from formulæ 7, 8, 4, 5, that

$$\text{tan.}\,a=\frac{\text{sin.}\,a}{\text{cos.}\,a},\qquad \text{cot.}\,a=\frac{\text{cos.}\,a}{\text{sin.}\,a},$$
$$\text{sec.}\,a=\frac{1}{\text{cos.}\,a},\qquad \text{cosec.}\,a=\frac{1}{\text{sin.}\,a}.$$

Hence it follows that the tangent and co-tangent must be regarded as positive quantities when the sine and cosine are both positive, or both negative quantities; but as negative when, of the sine and cosine, one is positive and the other negative; and that the secant and cosine, also the co-secant and sine, must always have the same sign. Therefore the tangent will be positive in the first quadrant, negative in the second, positive in the third, negative in the fourth, and so on; and the secant will be positive in the first, negative in the second and third, positive in the fourth and fifth, and so on to any number of quadrants.

236. We have seen that the sines and cosines, when changing their sign from + to —, or from — to +, in the transition become $=0$. Now, since $\text{tan.}\,a=\frac{\text{sin.}\,a}{\text{cos.}\,a}$, and $\text{sec.}\,a=\frac{1}{\text{cos.}\,a}$; when $a$ is a quadrant, and therefore $\text{cos.}\,a=0$, and $\text{sin.}\,a=1$, then both tan. $a$ and sec. $a$ become infinite: and when $a$ is between a quadrant and a semicircumference, cos. $a$ being then negative, both tan. $a$ and sec. $a$ are negative. Hence it appears that the tangent and secant become both infinite in changing their sign from + to —. In passing from the second to the third quadrant, the tangent, from being negative, becomes positive, because the numerator of the fraction $\frac{\text{sin.}\,a}{\text{cos.}\,a}$ changes from + to —. In this transition the tangent becomes $=0$. The secant, however, continues negative; and when the arc has attained a magnitude between three and four quadrants, both tangent and secant change their signs, after having become infinite, the tangent being now negative, and the secant positive. When the circumference is completed, the tangent is reduced to 0, and the secant to the radius; and the arc being supposed to increase, the same changes will be repeated.

237. Let the sides of any triangle A B C (Fig. 7. Plate XVIII.) be……$a$, $b$, $c$,
and the opposite angles……A, B, C.

From C, any one of the angles, draw C D perpendicular to the opposite side $c$, dividing it into the two segments AD, BD; then, by the definitions (sect. 229),

$$\text{cos. B}=\frac{BD}{BC}=\frac{BD}{a},\ \text{and hence}$$

$$BD=a\ \text{cos. B, and, similarly, } AD=b\ \text{cos. A};$$
$$\text{and } c=AB=BD+AD=a\ \text{cos. B}+b\ \text{cos. A}.$$

Hence we have this property of a triangle:

*If each of any two of its sides be multiplied by the cosine of the angle it makes with the third side, the sum of the products is equal to that third side.* This theorem, combined with these formulæ,

$$\text{Cos.}^2\,A+\text{sin.}^2\,A=1,$$
$$\text{Cos.}\,(\pi-A)=-\text{cos.}\,A,$$
$$\text{Sin.}\,(\pi-A)=\text{sin.}\,A,$$

is to serve as the basis of the whole calculus of sines.

From the preceding theorem, we obtain the following system of formulæ:

I.

$$a=b\ \text{cos. C}+c\ \text{cos. B}, \quad 1.$$
$$b=a\ \text{cos. C}+c\ \text{cos. A}, \quad 2.$$
$$c=a\ \text{cos. B}+b\ \text{cos. A}. \quad 3.$$

From the first of these we get

$$a\ \text{cos. C}=b\ \text{cos.}^2\,C+c\ \text{cos. B cos. C},$$
$$a\ \text{cos. B}=b\ \text{cos. B cos. C}+c\ \text{cos.}^2\,B;$$

and from these again, by transposing,

$$b\ \text{cos.}^2\,C=a\ \text{cos. C}-c\ \text{cos. B cos. C},$$
$$c\ \text{cos.}^2\,B=a\ \text{cos. B}-b\ \text{cos. B cos. C}.$$

Subtract each side of the first of these two from the corresponding side of 2 of system I., and each side of the second from the corresponding side of 3, and write in the results $\sin.^2 C$ for $1-\cos.^2 C$, and $\sin.^2 B$ for $1-\cos.^2 B$; we then get

$$b \sin.^2 C = c(\cos. A + \cos. B \cos. C),$$
$$c \sin.^2 B = b(\cos. A + \cos. B \cos. C).$$

Take now the product of the sides of these equations, and leave out the common factors $b$, $c$, of the result; we thus obtain

$$\text{Sin.}^2 B \sin.^2 C = (\cos. A + \cos. B \cos. C)^2.$$

Hence, taking the square roots,

$$\text{Sin. } B \sin. C = \cos. A + \cos. B \cos. C.$$

Here we have a property of the angles of any triangle, which is independent of its sides; this, by interchanging the angles, gives the following system of formulæ:

II.

$$\text{Cos. } A = -\cos. B \cos. C + \sin. B \sin. C, \quad 1.$$
$$\text{Cos. } B = -\cos. A \cos. C + \sin. A \sin. C, \quad 2.$$
$$\text{Cos. } C = -\cos. A \cos. B + \sin. A \sin. B. \quad 3.$$

Again, from the first of these we have

$$\text{Cos. } A \cos. C = -\cos. B \cos.^2 C + \sin. B \sin. C \cos. C;$$

and hence, by transposition,

$$\text{Cos. } B \cos.^2 C = -\cos. A \cos. C + \sin. B \sin. C \cos. C.$$

Subtract now the sides of this equation from the corresponding sides of 2; the result is

$$\text{Cos. } B(1-\cos.^2 C) = \sin. C(\sin. A - \sin. B \cos. C).$$

Substitute $\sin.^2 C$ for $1-\cos.^2 C$, and divide by $\sin. C$; then,

$$\text{Cos. } B \sin. C = \sin. A - \sin. B \cos. C.$$

This gives us a third system of formulæ, viz.

III.

$$\text{Sin. } A = \sin. B \cos. C + \cos. B \sin. C, \quad 1.$$
$$\text{Sin. } B = \sin. A \cos. C + \cos. A \sin. C, \quad 2.$$
$$\text{Sin. } C = \sin. A \cos. B + \cos. A \sin. B. \quad 3.$$

If it be now considered that $A+B+C=$ two right angles $=\pi$, so that $A+B=\pi-C$, and therefore

$$\text{Sin. }(A+B) = \sin. C, \qquad \cos.(A+B) = -\cos. C,$$

we obtain, from the third formulæ of systems II. and III.,

$$\text{Cos. }(A+B) = \cos. A \cos. B - \sin. A \sin. B,$$
$$\text{Sin. }(A+B) = \sin. A \cos. B + \cos. A \sin. B.$$

238. In this investigation, we have supposed that A and B are two angles of a triangle,—an hypothesis which requires that their sum shall not exceed two right angles, and that the sum of the arcs which measure them do not exceed a semicircumference. The formulæ, however, hold true, whatever be the magnitude of the arcs: for, let A, $\alpha$, and B, $\beta$, denote arcs, such, that $\alpha+A=\pi$, $\beta+B=\pi$; and therefore $(\alpha+\beta)+(A+B)=2\pi$: then,

$$A=\pi-\alpha,\ B=\pi-\beta, \text{ and (sect. 232)}$$
$$\text{Cos. } A = -\cos. \alpha, \qquad \text{Sin. } A = \sin. \alpha,$$
$$\text{Cos. } B = -\cos. \beta, \qquad \text{Sin. } B = \sin. \beta.$$

Hence it follows, that

$$\text{Cos. } A \cos. B - \sin. A \sin. B$$
$$= \cos. \alpha \cos. \beta - \sin. \alpha \sin. \beta,$$
$$\text{Sin. } A \cos. B + \cos. A \sin. B$$
$$= -\sin. \alpha \cos. \beta - \cos. \alpha \sin. \beta.$$

And since (sect. 232)

$$\text{Cos. }(\alpha+\beta) = \cos.(A+B) = \cos. A \cos. B - \sin. A \sin. B,$$
$$\text{Sin. }(\alpha+\beta) = -\sin.(A+B) = -\sin. A \cos. B - \cos. A \sin. B;$$

therefore, $\cos.(\alpha+\beta) = \cos. \alpha \cos. \beta - \sin. \alpha \sin. \beta$;

$$\text{Sin. }(\alpha+\beta) = \sin. \alpha \cos. \beta + \cos. \alpha \sin. \beta.$$

Now, on the hypothesis that $A+B \angle \pi$; then, because $A+B+\alpha+\beta=2\pi$, it follows that $\alpha+\beta \,7\, \pi$. Hence it appears that the formulæ for the cosine and sine of the sum of A, B, arcs less than a semicircle, apply equally to arcs $\alpha$, $\beta$, whose sum is greater than the half, but less than the whole circumference.

Again, if we suppose that $\alpha$, $\alpha'$, and $\beta$, $\beta'$, are such arcs, that

$\alpha'+\alpha=2\pi$, $\beta'+\beta=2\pi$, and therefore $(\alpha'+\beta')+(\alpha+\beta)=4\pi$,

then we shall have $\alpha=2\pi-\alpha'$, $\beta=2\pi-\beta'$,

$$\text{Cos. } \alpha = \cos. \alpha', \qquad \text{Sin. } \alpha = -\sin. \alpha',$$
$$\text{Cos. } \beta = \cos. \beta', \qquad \text{Sin. } \beta = -\sin. \beta',$$
$$\text{Cos. }(\alpha'+\beta') = \cos.(\alpha+\beta),\ \text{Sin. }(\alpha'+\beta') = -\sin.(\alpha+\beta).$$

Here, again, we shall have

$$\text{Cos. }(\alpha'+\beta') = \cos. \alpha' \cos. \beta' - \sin. \alpha' \sin. \beta',$$
$$\text{Sin. }(\alpha'+\beta') = \sin. \alpha' \cos. \beta' + \cos. \alpha' \sin. \beta';$$

and because $\alpha+\beta$ is greater than $\pi$, but less than $2\pi$, therefore $\alpha'+\beta'$ is an arc between two and three semicircumferences.

It is evident we may proceed in this way continually, and thus be assured that the formulæ are true, when A and B are any arcs of a circle, even although they should exceed a circumference, or any number of circumferences.

239. If, in these formulæ, we substitute $a-b$ for A, and $b$ for B, they become

$$\text{Cos. } a = \cos. b \cos.(a-b) - \sin. b \sin.(a-b),$$
$$\text{Sin. } a = \sin. b \cos.(a-b) + \cos. b \sin.(a-b).$$

To abridge, let us put

$$P = \cos.(a-b), \text{ and } Q = \sin.(a-b);$$

we have now, by transposition,

$$P \cos. b - Q \sin. b = \cos. a,$$
$$P \sin. b + Q \cos. b = \sin. a.$$

From these equations, by the ordinary process of elimination, we can determine P and Q: thus, proceeding by sect. 73, we get

$$P \cos.^2 b - Q \sin. b \cos. b = \cos. a \cos. b, \quad 1.$$
$$P \sin.^2 b + Q \sin. b \cos. b = \sin. a \sin. b, \quad 2.$$
$$P \cos. b \sin. b - Q \sin.^2 b = \cos. a \sin. b, \quad 3.$$
$$P \cos. b \sin. b + Q \cos.^2 b = \sin. a \cos. b. \quad 4.$$

By adding equations (1) and (2), and substituting 1 for $\cos.^2 b + \sin.^2 b$, we obtain

$$P = \cos.(a-b) = \cos. a \cos. b + \sin. a \sin. b.$$

And again, by subtracting (3) from (4), we get

$$Q = \sin.(a-b) = \sin. a \cos. b - \cos. a \sin. b.$$

For the sake of reference, and a uniform notation, we shall now bring together the formulæ of this and sect. 237 into one group.

(B)

$$\text{Cos. }(a+b) = \cos. a \cos. b - \sin. a \sin. b, \quad (1)$$
$$\text{Cos. }(a-b) = \cos. a \cos. b + \sin. a \sin. b, \quad (2)$$
$$\text{Sin. }(a+b) = \sin. a \cos. b + \cos. a \sin. b, \quad (3)$$
$$\text{Sin. }(a-b) = \sin. a \cos. b - \cos. a \sin. b. \quad (4)$$

These constitute what we have termed the fundamental theorems of this calculus.

240. By adding and subtracting these formulæ, we obtain others equivalent to them, but under a different form, viz. these:

(C)

$$\text{Cos. } a \cos. b = \tfrac{1}{2}\cos.(a-b) + \tfrac{1}{2}\cos.(a+b), \quad (1)$$
$$\text{Sin. } a \sin. b = \tfrac{1}{2}\cos.(a-b) - \tfrac{1}{2}\cos.(a+b), \quad (2)$$
$$\text{Sin. } a \cos. b = \tfrac{1}{2}\sin.(a+b) + \tfrac{1}{2}\sin.(a-b), \quad (3)$$
$$\text{Cos. } a \sin. b = \tfrac{1}{2}\sin.(a+b) - \tfrac{1}{2}\sin.(a-b). \quad (4)$$

If we now put $a+b=A$, and $a-b=B$, so that $a=\frac{1}{2}(A+B)$, $b=\frac{1}{2}(A-B)$, and substitute these values of $a$, $b$, $a+b$, $a-b$, in the above formulæ, and, for the sake of uniformity, write the letters $a$ and $b$ instead of A and B, we obtain

(D)

$$\text{Cos. } b + \text{cos. } a = 2 \text{ cos. } \tfrac{1}{2}(a+b) \text{ cos. } \tfrac{1}{2}(a-b), \quad (1)$$
$$\text{Cos. } b - \text{cos. } a = 2 \text{ sin. } \tfrac{1}{2}(a+b) \text{ sin. } \tfrac{1}{2}(a-b), \quad (2)$$
$$\text{Sin. } a + \text{sin. } b = 2 \text{ sin. } \tfrac{1}{2}(a+b) \text{ cos. } \tfrac{1}{2}(a-b), \quad (3)$$
$$\text{Sin. } a - \text{sin. } b = 2 \text{ cos. } \tfrac{1}{2}(a+b) \text{ sin. } \tfrac{1}{2}(a-b). \quad (4)$$

In formulæ (C), let $n$A be written instead of $a$, and A instead of $b$; and consequently $(n-1)$A instead of $a-b$, and $(n+1)$A instead of $a+b$; the result, after putting $a$ and $b$ for A and B, will be

(E)

$$2 \text{ cos. } a \text{ cos. } na = \text{cos. } (n-1)a + \text{cos. } (n+1)a, \quad (1)$$
$$2 \text{ sin. } a \text{ sin. } na = \text{cos. } (n-1)a - \text{cos. } (n+1)a, \quad (2)$$
$$2 \text{ cos. } a \text{ sin. } na = \text{sin. } (n+1)a + \text{sin. } (n-1)a, \quad (3)$$
$$2 \text{ sin. } a \text{ cos. } na = \text{sin. } (n+1)a - \text{sin. } (n-1)a. \quad (4)$$

241. Resuming the first system of formulæ, viz

$$\text{Sin. } (a+b) = \text{sin. } a \text{ cos. } b + \text{cos. } a \text{ sin. } b,$$
$$\text{Cos. } (a+b) = \text{cos. } a \text{ cos. } b - \text{sin. } a \text{ sin. } b,$$

let each side of the first be divided by the corresponding side of the second; then we have

$$\frac{\text{Sin. } (a+b)}{\text{Cos. } (a+b)} = \frac{\text{sin. } a \text{ cos. } b + \text{cos. } a \text{ sin. } b}{\text{cos. } a \text{ cos. } b - \text{sin. } a \text{ sin. } b}$$
$$= \frac{\dfrac{\text{sin. } a}{\text{cos. } a} + \dfrac{\text{sin. } b}{\text{cos. } b}}{1 - \dfrac{\text{sin. } a \text{ sin. } b}{\text{cos. } a \text{ cos. } b}}.$$

Hence, observing that tan. $\text{A} = \dfrac{\text{sin. A}}{\text{cos. A}}$, we obtain

$$\text{Tan. } (a+b) = \frac{\text{tan. } a + \text{tan. } b}{1 - \text{tan. } a \text{ tan. } b}.$$

By a like process we obtain from the formulæ for sin. $(a-b)$, and cos. $(a-b)$, a formula for tan. $(a-b)$. The two, for the sake of reference, may be put together.

(F)

$$\text{Tan. } (a+b) = \frac{\text{tan. } a + \text{tan. } b}{1 - \text{tan. } a \text{ tan. } b}, \quad (1)$$
$$\text{Tan. } (a-b) = \frac{\text{tan. } a - \text{tan. } b}{1 + \text{tan. } a \text{ tan. } b}. \quad (2)$$

242. The expressions which have been found for tan. $(a+b)$, tan. $(a-b)$, give like formulæ for the co-tangent of the sum and difference of two arcs; we have only to substitute in them

$\dfrac{1}{\text{cot.}(a \pm b)}$ for tan. $(a \pm b)$, $\dfrac{1}{\text{cot. } a}$ for tan. $a$, and $\dfrac{1}{\text{cot. } b}$ for tan. $b$. The results are,

(G)

$$\text{Cot. } (a+b) = -\frac{1 - \text{cot. } a \text{ cot. } b}{\text{cot. } a + \text{cot. } b}, \quad (1)$$
$$\text{Cot. } (a-b) = -\frac{1 + \text{cot. } a \text{ cot. } b}{\text{cot. } a - \text{cot. } b}. \quad (2)$$

243. We have found, formulæ (C), that

$$2 \text{ sin. } a \text{ sin. } b = \text{cos. } (a-b) - \text{cos. } (a+b),$$
$$2 \text{ cos. } a \text{ cos. } b = \text{cos. } (a-b) + \text{cos. } (a+b);$$

therefore, $\dfrac{\text{sin. } a \text{ sin. } b}{\text{cos. } a \text{ cos. } b} = \dfrac{\text{cos. } (a-b) - \text{cos. } (a+b)}{\text{cos. } (a-b) + \text{cos. } (a+b)}.$

From these formulæ we also obtain like expressions for

$$\frac{\text{Sin. } a \text{ cos. } b}{\text{Cos. } a \text{ sin. } b}, \quad \frac{\text{cos. } a \text{ sin. } b}{\text{sin. } a \text{ cos. } b}, \quad \frac{\text{cos. } a \text{ cos. } b}{\text{sin. } a \text{ sin. } b};$$

and from these, putting tan. $a$ for $\dfrac{\text{sin. } a}{\text{cos. } a}$, and cot. $a$ for $\dfrac{\text{cos. } a}{\text{sin. } a}$, &c. we deduce this new set of formulæ:

(H)

$$\text{Tan. } a \text{ tan. } b = \frac{\text{cos. } (a-b) - \text{cos. } (a+b)}{\text{cos. } (a-b) + \text{cos. } (a+b)}, \quad (1)$$
$$\text{Tan. } a \text{ cot. } b = \frac{\text{sin. } (a+b) + \text{sin. } (a-b)}{\text{sin. } (a+b) - \text{sin. } (a-b)}, \quad (2)$$
$$\text{Cot. } a \text{ tan. } b = \frac{\text{sin. } (a+b) - \text{sin. } (a-b)}{\text{sin. } (a+b) + \text{sin. } (a-b)}, \quad (3)$$
$$\text{Cot. } a \text{ cot. } b = \frac{\text{cos. } (a-b) + \text{cos. } (a+b)}{\text{cos. } (a-b) - \text{cos. } (a+b)}. \quad (4)$$

244. Because, by formulæ (B),

$$\text{Sin. } a \text{ cos. } b + \text{cos. } a \text{ sin. } b = \text{sin. } (a+b);$$

therefore, $\dfrac{\text{sin. } a}{\text{cos. } a} + \dfrac{\text{sin. } b}{\text{cos. } b} = \dfrac{\text{sin. } (a+b)}{\text{cos. } a \text{ cos. } b}.$

By treating the remaining formulæ in the same way, and substituting the tangent and co-tangent for their values, we obtain

(K)

$$\text{Tan. } a + \text{tan. } b = \frac{\text{sin. } (a+b)}{\text{cos. } a \text{ cos. } b}, \quad (1)$$
$$\text{Tan. } a - \text{tan. } b = \frac{\text{sin. } (a-b)}{\text{cos. } a \text{ cos. } b}, \quad (2)$$
$$\text{Cot. } a + \text{cot. } b = \frac{\text{sin. } (a+b)}{\text{sin. } a \text{ sin. } b}, \quad (3)$$
$$\text{Cot. } a - \text{cot. } b = \frac{\text{sin. } (a-b)}{\text{sin. } a \text{ sin. } b}, \quad (4)$$
$$\text{Tan. } a + \text{cot. } b = \frac{\text{cos. } (a-b)}{\text{cos. } a \text{ sin. } b}, \quad (5)$$
$$\text{Cot. } a - \text{tan. } b = \frac{\text{cos. } (a+b)}{\text{sin. } a \text{ cos. } b}. \quad (6)$$

245. Because, by formulæ (D),

$$\text{Sin. } a + \text{sin. } b = 2 \text{ sin. } \tfrac{1}{2}(a+b) \text{ cos. } \tfrac{1}{2}(a-b),$$
$$\text{Sin. } a - \text{sin. } b = 2 \text{ cos. } \tfrac{1}{2}(a+b) \text{ sin. } \tfrac{1}{2}(a-b).$$

Hence, multiplying equals by equals, and considering that by formula (3) of (B)

$$2 \text{ sin. } \tfrac{1}{2}(a+b) \text{ cos. } \tfrac{1}{2}(a+b) = \text{sin. } [\tfrac{1}{2}(a+b) + \tfrac{1}{2}(a+b)] = \text{sin. } (a+b),$$
$$2 \text{ sin. } \tfrac{1}{2}(a-b) \text{ cos. } \tfrac{1}{2}(a-b) = \text{sin. } [\tfrac{1}{2}(a-b) + \tfrac{1}{2}(a-b)] = \text{sin. } (a-b),$$

we find

$$(\text{sin. } a + \text{sin. } b)(\text{sin. } a - \text{sin. } b) = \text{sin. } (a+b) \text{ sin. } (a-b).$$

If we write $90 - a$ for $a$, the formula becomes

$$(\text{cos. } a + \text{sin. } b)(\text{cos. } a - \text{sin. } b) = \text{cos. } (a+b) \text{ cos. } (a-b).$$

The two may be written thus:

(L)

$$\text{Sin.}^2 a - \text{sin.}^2 b = \text{sin. } (a+b) \text{ sin. } (a-b),$$
$$\text{Cos.}^2 a - \text{sin.}^2 b = \text{cos. } (a+b) \text{ cos. } (a-b).$$

246. We have found, formulæ (D),

$$\text{Sin. } a + \text{sin. } b = 2 \text{ sin. } \tfrac{1}{2}(a+b) \text{ cos. } \tfrac{1}{2}(a-b),$$
$$\text{Sin. } a - \text{sin. } b = 2 \text{ cos. } \tfrac{1}{2}(a+b) \text{ sin. } \tfrac{1}{2}(a-b).$$

Therefore, dividing equals by equals, and putting

Tan. $\tfrac{1}{2}(a \pm b)$ for $\dfrac{\text{sin. } \tfrac{1}{2}(a \pm b)}{\text{cos. } \tfrac{1}{2}(a \pm b)}$, we obtain

$$\frac{\text{Sin. } a + \text{sin. } b}{\text{Sin. } a - \text{sin. } b} = \frac{\text{tan. } \tfrac{1}{2}(a+b)}{\text{tan. } \tfrac{1}{2}(a-b)}.$$

By a similar process we may deduce other five formulæ of the same nature from formulæ (D). The whole are contained in this table.

(M)

$$\frac{\text{Sin. } a + \text{sin. } b}{\text{Sin. } a - \text{sin. } b} = \frac{\text{tan. } \frac{1}{2}(a+b)}{\text{tan. } \frac{1}{2}(a-b)}, \quad (1)$$

$$\frac{\text{Sin. } a + \text{sin. } b}{\text{Cos. } a + \text{cos. } b} = \text{tan. } \tfrac{1}{2}(a+b), \quad (2)$$

$$\frac{\text{Sin. } a + \text{sin. } b}{\text{Cos. } a - \text{cos. } b} = \text{cot. } \tfrac{1}{2}(a-b), \quad (3)$$

$$\frac{\text{Sin. } a - \text{sin. } b}{\text{Cos. } a + \text{cos. } b} = \text{tan. } \tfrac{1}{2}(a-b), \quad (4)$$

$$\frac{\text{Sin. } a - \text{sin. } b}{\text{Cos. } a - \text{cos. } b} = \text{cot. } \tfrac{1}{2}(a+b), \quad (5)$$

$$\frac{\text{Cos. } b + \text{cos. } a}{\text{Cos. } b - \text{cos. } a} = \frac{\text{cot. } \frac{1}{2}(a-b)}{\text{tan. } \frac{1}{2}(a+b)}. \quad (6)$$

247. We have found (formulæ K, No. 4) that

$$\frac{\text{Sin. } (a-b)}{\text{Sin. } a \text{ sin. } b} = \text{cot. } a - \text{cot. } b,$$

$$\frac{\text{Sin. } (b-c)}{\text{Sin. } b \text{ sin. } c} = \text{cot. } b - \text{cot. } c,$$

$$\frac{\text{Sin. } (c-a)}{\text{Sin. } c \text{ sin. } a} = \text{cot. } c - \text{cot. } a.$$

Hence, by adding, we obtain

$$\frac{\text{Sin. } (a-b)}{\text{Sin. } a \text{ sin. } b} + \frac{\text{sin. } (b-c)}{\text{sin. } b \text{ sin. } c} + \frac{\text{sin. } (c-a)}{\text{sin. } c \text{ sin. } a} = 0.$$

In like manner, it appears, from No. 2, that

$$\frac{\text{Sin. } (a-b)}{\text{Cos. } a \text{ cos. } b} + \frac{\text{sin. } (b-c)}{\text{sin. } b \text{ sin. } c} + \frac{\text{sin. } (c-a)}{\text{sin. } c \text{ sin. } a} = 0.$$

Therefore, taking away the denominators, and observing that sin. $(c-a) = -$ sin. $(a-c)$, we have

(N)

$$\text{Sin. } b \text{ sin.} (a-c) = \text{sin. } c \text{ sin.} (a-b) + \text{sin. } a \text{ sin.} (b-c), \quad (1)$$
$$\text{Cos.} b \text{ sin.} (a-c) = \text{cos.} c \text{ sin.} (a-b) + \text{cos.} a \text{ sin.} (b-c). \quad (2)$$

These formulæ are true, $a$, $b$, $c$ being any arcs whatever; and they are sufficient to indicate how innumerable others of the same kind may be obtained.

248. If in the formula for cos. $(a+b)$ we suppose $a=b$, it becomes cos. $2a =$ cos.$^2 a -$ sin.$^2 a$; and, since cos.$^2 a = 1 -$ sin.$^2 a$, and sin.$^2 a = 1 -$ cos.$^2 a$, we have also

$$\text{Cos. } 2a = 1 - 2 \text{ sin.}^2 a = 2 \text{ cos.}^2 a - 1.$$

By assuming $b = a$, we get from the formulæ for sin. $(a+b)$, tan. $(a+b)$, cot. $(a+b)$, other formulæ for the sine, tangent, and co-tangent, of the double of an arc. These, being frequently wanted, may be put together in a table.

(O)

$$\text{Cos. } 2a = \text{cos.}^2 a - \text{sin.}^2 a = 2 \text{ cos.}^2 a - 1 = 1 - 2 \text{sin.}^2 a, \quad (1)$$

$$\text{Sin. } 2a = 2 \text{ sin. } a \text{ cos. } a, \quad (2)$$

$$\text{Tan. } 2a = \frac{2 \text{ tan. } a}{1 - \text{tan.}^2 a} = \frac{2}{\text{cot. } a - \text{tan. } a}, \quad (3)$$

$$\text{Cot. } 2a = \tfrac{1}{2} (\text{cot. } a - \text{tan. } a). \quad (4)$$

249. From the first formula we may get formulæ for the sine and cosine of the half of an arc in terms of the cosine of the whole arc. But we may also express the sine and cosine of the half arc by the sine of the whole arc: thus,

$$\text{Cos.}^2 \tfrac{1}{2}a + \text{sin.}^2 \tfrac{1}{2}a = 1,$$
$$\text{and } 2 \text{ cos. } \tfrac{1}{2}a \text{ sin. } \tfrac{1}{2}a = \text{sin. } a,$$

we have $\text{cos.}^2 \tfrac{1}{2}a + 2 \text{ cos. } \tfrac{1}{2}a \text{ sin. } \tfrac{1}{2}a + \text{sin.}^2 \tfrac{1}{2}a = 1 + \text{sin. } a$,
and $\text{cos.}^2 \tfrac{1}{2}a - 2 \text{cos. } \tfrac{1}{2}a \text{ sin. } \tfrac{1}{2}a + \text{sin.}^2 \tfrac{1}{2}a = 1 - \text{sin. } a$;
whence, taking the square roots,

$$\text{Cos. } \tfrac{1}{2}a + \text{sin. } \tfrac{1}{2}a = \sqrt{1 + \text{sin. } a},$$
$$\text{Cos. } \tfrac{1}{2}a - \text{sin. } \tfrac{1}{2}a = \sqrt{1 - \text{sin. } a};$$

which, by addition and subtraction, give

$$\text{Cos. } \tfrac{1}{2}a = \tfrac{1}{2} \left[\sqrt{1 + \text{sin. } a} + \sqrt{1 - \text{sin. } a}\right],$$
$$\text{Sin. } \tfrac{1}{2}a = \tfrac{1}{2} \left[\sqrt{1 + \text{sin. } a} - \sqrt{1 - \text{sin. } a}\right].$$

Again, because sin. $a = 2$ sin. $\tfrac{1}{2}a$ cos. $\tfrac{1}{2}a$, therefore

$$\text{Sin. } a = \frac{\text{sin. } \frac{1}{2}a}{\text{cos. } \frac{1}{2}a} \times 2 \text{ cos.}^2 \tfrac{1}{2}a:$$

but $\frac{\text{sin. } \frac{1}{2}a}{\text{cos. } \frac{1}{2}a} = \text{tan. } \tfrac{1}{2}a$, and $2 \text{ cos.}^2 \tfrac{1}{2}a = 1 + \text{cos. } a$ (by No. 1 of O),

therefore sin. $a =$ tan. $\tfrac{1}{2}a$ $(1 + \text{cos. } a)$,

$$\text{tan. } \tfrac{1}{2}a = \frac{\text{sin. } a}{1 + \text{cos. } a} = \frac{1 - \text{cos. } a}{\text{sin. } a};$$

$$\text{cotan. } \tfrac{1}{2}a = \frac{1 + \text{cos. } a}{\text{sin. } a} = \frac{\text{sin. } a}{1 - \text{cos. } a};$$

Again, since $\frac{1 - \text{cos. } a}{\text{sin. } a} = \frac{1}{\text{sin. } a} - \frac{\text{cos. } a}{\text{sin. } a} = \text{cosec. } a - \text{cot. } a$,

and $\frac{1 + \text{cos. } a}{\text{sin. } a} = \frac{1}{\text{sin. } a} + \frac{\text{cos. } a}{\text{sin. } a} = \text{cosec. } a + \text{cot. } a$,

therefore tan. $\tfrac{1}{2}a =$ cosec. $a -$ cot. $a$,
and cot. $\tfrac{1}{2}a =$ cosec. $a +$ cot. $a$.

The formulæ investigated in this article may now be brought into one table, viz.

(P)

$$\text{Cos. } \tfrac{1}{2}a = \sqrt{\frac{1 + \text{cos. } a}{2}} = \tfrac{1}{2}\left[\sqrt{1 + \text{sin.} a} + \sqrt{1 - \text{sin.} a}\right], (1)$$

$$\text{Sin. } \tfrac{1}{2}a = \sqrt{\frac{1 - \text{cos. } a}{2}} = \tfrac{1}{2}\left[\sqrt{1 + \text{sin.} a} - \sqrt{1 - \text{sin.} a}\right], (2)$$

$$\text{Tan. } \tfrac{1}{2}a = \frac{\text{sin. } a}{1 + \text{cos. } a} = \text{cosec. } a - \text{cot. } a, \quad (3)$$

$$\text{Cot. } \tfrac{1}{2}a = \frac{\text{sin. } a}{1 - \text{cos. } a} = \text{cosec. } a + \text{cot. } a. \quad (4)$$

250. We shall now investigate formulæ for the cosines and sines of the multiples of any arc.

By the first of formulæ (E) we find that

$$\text{Cos. } (n+1)\, a = 2 \text{ cos. } a \text{ cos. } na - \text{cos. } (n-1)\, a.$$

Let $x$ denote cos. $a$; then,

$$\text{Cos. } a = x,$$
$$\text{Cos. } 2a = 2x \text{ cos. } a - \text{cos. } 0a,$$
$$\text{Cos. } 3a = 2x \text{ cos. } 2a - \text{cos. } a,$$
$$\text{Cos. } 4a = 2x \text{ cos. } 3a - \text{cos. } 2a,$$
&c.

Hence, by substituting successively for cos. $a$, cos. $2a$, &c. their values in the second members of these formulæ,

(Q)

$$\text{Cos. } a = x,$$
$$\text{Cos. } 2a = 2\, x^2 - 1,$$
$$\text{Cos. } 3a = 4\, x^3 - 3x,$$
$$\text{Cos. } 4a = 8\, x^4 - 8x^2 + 1,$$
$$\text{Cos. } 5a = 16x^5 - 20x^3 + 5x,$$
$$\text{Cos. } 6a = 32x^6 - 48x^4 + 18x^2 - 1,$$
$$\text{Cos. } 7a = 64x^7 - 112x^5 + 56x^3 - 7x,$$
&c.

 The law of the series is 2 cos. $na=$

$$(2x)^n-n(2x)^{n-2}+\frac{n(n-3)}{1\cdot 2}(2x)^{n-4}$$
$$-\frac{n(n-4)(n-5)}{1\cdot 2\cdot 3}(2x)^{n-6}+,\ \&c.$$

251. The third formula of (E) gives

$$\text{Sin. }(n+1)\,a=2\cos.\,a\,\sin.\,na-\sin.\,(n-1)a.$$

Let $x$ denote the cosine, and $y$ the sine of $a$; then

Sin. $a=y$,
Sin. $2a=2x$ sin. $a$ — sin. $0a$,
Sin. $3a=2x$ sin. $2a$ — sin. $a$,
Sin. $4a=2x$ sin. $3a$ — sin. $2a$,
&c.

Therefore, proceeding as in last article,

(R)

Sin. $a=y$,
Sin. $2a=2yx$,
Sin. $3a=y(4x^2-1)$,
Sin. $4a=y(8x^3-4x)$,
Sin. $5a=y(16x^4-12x^2+1)$,
Sin. $6a=y(32x^5-32x^3+6x)$,
Sin. $7a=y(64x^6-80x^4+24x^2-1)$,
&c.

Here the law of the series is sin. $na=$

$$y[(2x)^{n-1}-(n-2)(2x)^{n-3}+\frac{(n-3)(n-4)}{1\cdot 2}(2x)^{n-5}$$
$$-\frac{(n-4)(n-5)(n-6)}{1\cdot 2\cdot 3}(2x)^{n-7}+,\ \&c.].$$

252. The series for the cosines and sines of the multiples of an arc are arranged according to the descending powers of the cosine of the arc; but we may find others which proceed according to the ascending powers. It is, however, then necessary to distinguish between the even and odd multiples of the arc.

Let $n$ be odd, and we have, from table (Q),

(S)

Cos. $a=x$,
Cos. $3a=-(3x-4x^3)$,
Cos. $5a=5x-20x^3+16x^5$,
&c.

and in general, cos. $na=$

$$\pm\left[nx-\frac{n(n^2-1)}{2\cdot 3}x^3+\frac{n(n^2-1)(n^2-9)}{2\cdot 3\cdot 4\cdot 5}x^5-,\ \&c.\right].$$

The upper sign is to be taken when $n$ is any number in the series 1, 5, 9, &c. that is, when $n$ has the form $4m+1$; and the lower, when $n$ is one of these, 3, 7, 11, &c. or when it is of the form $4m+3$.

Next, for the even multiples of the arc we find

(2 S)

Cos. $2a=-(1-2x^2)$,
Cos. $4a=+\ 1-8x^2+8x^4$,
Cos. $6a=-(1-18x^2+48x^4-32x^6)$,
&c.

and in general, cos. $na=$

$$\pm\left[1-\frac{n^2}{2}x^2+n^2\frac{(n^2-4)}{2\cdot 3\cdot 4}x^4\right.$$
$$\left.-\frac{n^2(n^2-4)(n^2-16)}{2\cdot 3\cdot 4\cdot 5\cdot 6}x^6+,\&c.\right].$$

Here the upper sign is to be taken when $n$ has the form $4m+2$, and the lower when it has the form $4m$.

253. The corresponding expressions for the sines are obtained from table (R), viz.

(T)

Sin. $a=y$,
Sin. $3a=-y(1-4x^2)$,
Sin. $5a=y(1-12x^2+16x^4)$,
&c.

and in general, sin. $na=$

$$\pm y\left\{1-\frac{n^2-1}{2}x^2+\frac{(n^2-1)(n^2-9)}{2\cdot 3\cdot 4}x^4\right.$$
$$\left.-\frac{(n^2-1)(n^2-9)(n^2-25)}{2\cdot 3\cdot 4\cdot 5\cdot 6}x^6+,\&c.\right\};$$

the upper sign to be taken when $n$ has the form $4n+1$. and the lower when it has the sign $4n+3$.

Also we have

(2 T)

Sin. $2a=2xy$,
Sin. $4a=-y(4x-8x^3)$,
Sin. $6a=y(6x-32x^3+32x^5)$,
&c.

and in general, sin. $na=$

$$\pm\left\{nx-\frac{n(n^2-4)}{2\cdot 3}x^3+\frac{n(n^2-4)(n^2-16)}{2\cdot 3\cdot 4\cdot}x^5-,\&c.\right\};$$

the upper sign to be taken when $n$ has the form $4n+2$, and the lower when it has the form $4n$.

254. Because $x^2=1-y^2$, we have, from table (Q),

(V)

Cos. $a=x$,
Cos. $3a=x(1-4y^2)$,
Cos. $5a=x(1-12y^2+16y^4)$,
&c.

and in general, when $n$ is an odd number, cos. $na=$

$$x\left\{1-\frac{n^2-1}{2}y^2+\frac{(n^2-1)(n^2-9)}{2\cdot 3\cdot 4}y^4\right.$$
$$\left.-\frac{(n^2-1)(n^2-9)(n^2-25)}{2\cdot 3\cdot 4\cdot 5\cdot 6}y^6-,\ \&c.\right\}:$$

and when $n$ is even,

(2 V)

Cos. $2a=1-2y^2$,
Cos. $4a=1-8y^2+8y^4$,
Cos. $6a=1-18y^2+48y^4-32y^6$,
&c.

and in general, cos. $na=$

$$1-\frac{n^2}{2}y^2+\frac{n^2(n^2-4)}{2\cdot 3\cdot 4}y^4-\frac{n^2(n^2-4)(n^2-16)}{2\cdot 3\cdot 4\cdot 5\cdot 6}y^6+,\ \&c.$$

255. In like manner, for the sines, when $n$ is odd, we find

(X)

Sin. $a=y$,
Sin. $3a=3y-4y^3$,
Sin. $5a=5y-20y^3+16y^5$,
&c.

and in general, sin. $na=$

$$ny-\frac{n(n^2-1)}{2\cdot 3}y^3+\frac{n(n^2-1)(n^2-9)}{2\cdot 3\cdot 4\cdot 5}y^5-,\ \&c.$$

Again, when $n$ is even,

(2 X)

Sin. $2a=2xy$,
Sin. $4a=x(4y-8y^3)$,
Sin. $6a=x(6y-32y^3+32y^5)$,
&c.

And in general, sin. $na=$

$$x\left\{ny-\frac{n(n^2-4)}{2\cdot 3}y^3+\frac{n(n^2-4)(n^2-16)}{2\cdot 3\cdot 4\cdot 5}y^5-\text{, \&c.}\right\}.$$

256. We owe to Vieta the formulæ in tables (Q), (R), (2 V), and (X). He, however, enunciated them as properties of the chords of arcs, to which they may be transformed, by considering that chord $a=2$ sin. $\frac{1}{2}a$, and chord $(\pi-a)=$ sup. chord $a=2$ cos. $\frac{1}{2}a$; he did not indicate the general law of the series, but merely showed how the cosines and sines of the multiple arcs might be formed one from another. John Bernoulli gave, in the Leipsic Acts for 1701, a general formula for the chords of multiple arcs, but without demonstration. This is equivalent to table (R). Afterwards, James Bernoulli gave, in the *Memoirs of the Academy of Sciences* for 1702, two formulæ for the chords of multiple arcs: these answer to the general formulæ of tables (2 V) and (X); but the latter had previously been given by Newton in his first letter to Oldenburg, the secretary of the Royal Society. The general formulæ of tables (Q), (R), (X), and (2 X), and these only, are given in the *Introductio in Analysin Infinitorum* of Euler; and the whole are given by Lagrange, in his *Leçons sur le Calcul des Fonctions,* where they are also strictly demonstrated by his calculus, which is equivalent to the differential calculus.

257. If in the formula

$$\tan.(a+b)=\frac{\tan. a+\tan. b}{1-\tan. a\tan. b},$$

we make $b=na$, it becomes

$$\tan.(n+1)a=\frac{\tan. na+\tan. a}{1-\tan. a\tan. na}.$$

Let us make tan. $a=t$, then, making $n$ equal to the numbers 2, 3, 4, &c. successively, and substituting for tan. $na$ its value in tan. $(n+1)\,a$, we get

(Y)

$$\text{Tan. } a=t,$$
$$\text{Tan. } 2a=\frac{2t}{1-t^2},$$
$$\text{Tan. } 3a=\frac{3t-t^3}{1-3t^2},$$
$$\text{Tan. } 4a=\frac{4t-4t^3}{1-6t^2+t^4},$$
$$\text{Tan. } 5a=\frac{5t-10t^3+t^5}{1-10t^2+5t^4},$$

&c.

In general, if we put $\alpha=\frac{n}{1}, \beta=\frac{n(n-1)}{1\cdot 2}, \gamma=\frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}$, $\delta=\frac{n(n-1)(n-2)(n-3)}{1\cdot 2\cdot 3\cdot 4}$, &c.; that is, if $\alpha, \beta, \gamma, \delta, \varepsilon$, &c. denote the co-efficients of the second, third, fourth, and following terms of a binomial raised to the $n$th power, we have

$$\text{Tan.} na=\frac{\alpha t-\gamma t^3+\varepsilon t^5-\text{, \&c.}}{1-\beta t^2+\delta t^4-\text{, \&c.}}.$$

This formula was first given by John Bernoulli, in the Leipsic Acts for 1722.

258. We shall next investigate formulæ for the successive integer powers of the cosine and sine of an arc.

By formula (1) of (E) we have, making $n=1$,

$$2\cos.^2 a=\cos. 2a+1.$$

Let both sides be multiplied by 2 cos. $a$, the result is

$$4\cos.^3 a=2\cos. a\cos. 2a+2\cos a;$$

but, by the same formulæ (E),

$$2\cos. a\cos. 2a=\cos. 3a+\cos. a;$$

therefore, $4\cos.^3 a=\cos. 3a+3\cos. a$.

Again, multiplying both sides by 2 cos. $a$, we have

$$8\cos.^4 a=2\cos. a\cos. 3a+6\cos. a\cos. a.$$

Now, $2\cos. a\cos. 3a=\cos. 4a+\cos. 2a$,
and $6\cos. a\cos. a=3\cos. 2a+3$;
therefore, $8\cos.^4 a=\cos. 4a+4\cos. 2a+3$

By proceeding in this way, multiplying both sides of each new formula by 2 cos. $a$, and substituting cos. $(n+1)a$, $+\cos.(n-1)a$ for 2 cos. $a$ cos. $na$, there is obtained a series of formulæ for the successive powers of the cosine of an arc, in terms of the cosines of the multiples of the arc. These are given in the following table:

(Z)

$$\text{Cos. } a=\cos. a,$$
$$2\cos.^2 a=\cos. 2a+1,$$
$$4\cos.^3 a=\cos. 3a+3\cos. a,$$
$$8\cos.^4 a=\cos. 4a+4\cos. 2a+3,$$
$$16\cos.^5 a=\cos. 5a+5\cos. 3a+10\cos. a,$$
$$32\cos.^6 a=\cos. 6a+6\cos. 4a+15\cos. 2a+10,$$
$$64\cos.^7 a=\cos. 7a+7\cos. 5a+21\cos. 3a+35\cos. a,$$

&c.

The general law of the series is $2^{n-1}\cos.^n a=$

$$\cos. na+\frac{n}{1}\cos.(n-2)a+\frac{n(n-1)}{1\cdot 2}\cos.(n-4)a,$$
$$+\frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}\cos.(n-6)\,a+\text{, \&c.}$$

The series is to be continued until we come to a negative arc, and if $n$ be an even number, the half of the coefficient of the last term (viz. that in which the arc $=0a$) is to be taken.

259. Next, for the powers of the sine; from (2) of (E), we have $2\sin.^2 a=-\cos. 2a+1$:
multiply both sides by 2 sin. $a$; then,

$$4\sin.^3 a=-2\sin. a\cos. 2a+2\sin. a.$$

Now, by formula (4) of (E),

$$2\sin. a\cos. 2a=\sin. 3a-\sin. a;$$

therefore $4\sin.^3 a=-\sin. 3a+3\sin. a$.

Again, multiplying both sides by 2 sin. $a$,

$$8\sin.^4 a=-2\sin. a\sin. 3a+6\sin. a\sin. a.$$

But by formula (2) of (E),

$$2\sin. a\sin. 3a=-\cos. 4a+\cos. 2a,$$
and $6\sin. a\sin. a=-3\cos. 2a+3$;

therefore $8\sin.^4 a=\cos. 4a-4\cos. 2a+3$.

In this way we may form the following table:

(A 2)

$$\text{Sin. } a=+\sin. a,$$
$$2\sin.^2 a=-\cos. 2a+1,$$
$$4\sin.^3 a=-\sin. 3a+3\sin. a,$$
$$8\sin.^4 a=+\cos. 4a-4\cos. 2a+3,$$
$$16\sin.^5 a=+\sin. 5a-5\sin. 3a+10\sin. a,$$
$$32\sin.^6 a=-\cos. 6a+6\cos. 4a-15\cos. 2a+10,$$
$$64\sin.^7 a=-\sin. 7a+7\sin. 5a-21\sin. 3a+35\sin. a.$$

In general, when $n$ is an odd number, $\pm 2^{n-1}\sin.^n a$

$$=\sin. na-\frac{n}{1}\sin.(n-2)\,a+\frac{n(n-1)}{1\cdot 2}\sin.(n-4)\,a$$
$$-\frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}\sin.(n-6)\,a+\text{, \&c.}$$

The upper sign is to be taken when $n$ is a number in the series 1, 5, 9, &c.; that is, when $n$ has the form $4m+1$; and the lower when $n$ is one of the intermediate odd numbers, 3, 7, 11, &c. In either case the series terminates with a multiple of sin. $a$.

When $n$ is an even number, then $\mp 2^{n-1}\sin.^n a =$

$$\cos. na - n\cos.(n-2)a + \frac{n(n-1)}{1\cdot 2}\cos.(n-4)a - \frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}\cos.(n-6)a +, \&c.$$

Here the upper sign applies when $n$ is an even number in the series 2, 6, 10, &c.; that is, when $\frac{n}{2}$ is an odd number; and the lower when $n$ has the form $4m$. In either case the series is to be continued until a term contain cos. $(0a)$ (which is $=1$), and then the numeral co-efficient must be divided by 2.

260. The same formulæ (E) serve to resolve any expression of the form $\cos.^m a\ \sin.^n a$ into sines and cosines of multiples of $a$: thus,

$$2\cos. a\sin. a = \sin. 2a;$$
$$4\cos.^2 a\sin. a = 2\cos. a\sin. 2a, \quad = \sin. 3a + \sin. a;$$

$$4\cos. a\sin.^2 a = 2\sin. a\sin. 2a, \quad = -\cos. 3a + \cos. a.$$

In like manner we find

$$8\cos. a\sin.^3 a = -\sin. 4a + 2\sin. 2a,$$
$$8\cos.^2 a\sin.^2 a = -\cos. 4a + 1,$$
$$8\cos.^3 a\sin. a = +\sin. 4a + 2\sin. 2a.$$

$$16\cos. a\sin.^4 a = \cos. 5a - 3\cos. 3a + 2\cos. a,$$
$$16\cos.^2 a\sin.^3 a = -\sin. 5a + \sin. 3a + 2\sin. a,$$
$$16\cos.^3 a\sin.^2 a = -\cos. 5a - \cos. 3a + 2\cos. a,$$
$$16\cos.^4 a\sin. a = \sin. 5a + 3\sin. 3a + 2\sin. a.$$

261. The introduction of the imaginary symbol $\sqrt{-1}$ into analysis, has given great assistance in all investigations connected with the calculus of sines. Let $x$ denote the cosine of any arc $a$, and $y$ its sine; then, by formulæ (B),

$$\text{Cos. } (n+1)a = x\cos. na - y\sin. na, \qquad (1)$$
$$\text{Sin. } (n+1)a = y\cos. na + x\sin. na. \qquad (2)$$

Let $v$ denote a quantity at present indefinite, but to be determined in the course of the investigation; then, from formula (2),

$$v\sin.(n+1)a = vy\cos. na + vx\sin. na. \qquad (3)$$

The sum and difference of formula (1) and (3) give us

$$\text{Cos. } (n+1)a + v\sin.(n+1)a = (x+vy)\cos. na + (x - \tfrac{1}{v}y)\,v\sin. na,$$

$$\text{Cos. } (n+1)a - v\sin.(n+1)a = (x-vy)\cos. na - (x + \tfrac{1}{v}y)\,v\sin. na.$$

Let us now assume that $v^2=-1$, so that $v=\sqrt{-1}$, and $v=-\frac{1}{v}$; the two last formulæ will become

$$\text{Cos. } (n+1)a + v\sin.(n+1)a = (x+vy)(\cos. na + v\sin. na),$$
$$\text{Cos. } (n+1)a - v\sin.(n+1)a = (x-vy)(\cos. na - v\sin. na).$$

By giving to $n$ the values 0, 1, 2, 3, &c. in succession, we obtain from the first of these,

$$\text{Cos. } a + v\sin. a = x+vy,$$
$$\text{Cos. } 2a + v\sin. 2a = (x+vy)^2,$$
$$\text{Cos. } 3a + v\sin. 3a = (x+vy)^3,$$

and, in general, $m$ being any whole number,

$$\text{Cos. } ma + v\sin. ma = (x+vy)^m. \qquad (4)$$

The other equation gives us

$$\text{Cos. } a - v\sin. a = x - vy,$$
$$\text{Cos. } 2a - v\sin. 2a = (x-vy)^2,$$
$$\text{Cos. } 3a - v\sin. 3a = (x-vy)^3;$$

and in general,

$$\text{Cos. } ma - v\sin. ma = (x-vy)^m. \qquad (5)$$

Formulæ (4) and (5), when the quantities denoted by $x$, $y$, and $v$, have been restored, may stand thus:

(B 2)

$$\text{Cos. } na + \sqrt{-1}\sin. na = (\cos. a + \sqrt{-1}\sin. a)^n,$$
$$\text{Cos. } na - \sqrt{-1}\sin. na = (\cos. a - \sqrt{-1}\sin. a)^n.$$

These have been investigated on the hypothesis that $n$ is a whole positive number, but they are also true when $n$ is a fraction, or negative; for we have manifestly

$$\text{Cos. } a + \sqrt{-1}\sin. a \begin{cases} = (\cos. na + \sqrt{-1}\sin. na)^{\frac{1}{n}} \\ = (\cos. ma + \sqrt{-1}\sin. ma)^{\frac{1}{m}}: \end{cases}$$

therefore, raising these equal expressions to the power $m$, we have

$$\text{Cos. } ma + \sqrt{-1}\sin. ma = (\cos. na + \sqrt{-1}\sin. na)^{\frac{m}{n}};$$

and, putting $na=a'$, and therefore $ma=\frac{m}{n}a'$,

$$\text{Cos. } \frac{m}{n}a' + \sqrt{-1}\sin. \frac{m}{n}a' = (\cos. a' + \sqrt{-1}\sin. a')^{\frac{m}{n}}.$$

Exactly in the same way it may be proved that

$$\text{Cos. } \frac{m}{n}a' - \sqrt{-1}\sin. \frac{m}{n}a' = (\cos. a' - \sqrt{-1}\sin. a')^{\frac{m}{n}}.$$

Thus it appears that formulæ (B 2) are true, whether $n$ be whole or fractional.

Again, we have manifestly

$$\frac{1}{\text{Cos. } na + \sqrt{-1}\sin. na} = (\cos. a + \sqrt{-1}\sin. a)^{-n}.$$

Let the numerator and denominator of the first member of this equation be multiplied by $\cos. na - \sqrt{-1}\sin. na$; then, observing that

$$(\cos. na + \sqrt{-1}\sin. na)(\cos. na - \sqrt{-1}\sin. a) = \cos.^2 na + \sin.^2 na = 1,$$

also, that $\cos. na = \cos.(-na)$, and $-\sin. na = \sin.(-na)$, we have

$$\text{Cos.}(-na) - \sqrt{-1}\sin.(-na) = (\cos. a + \sqrt{-1}\sin. a)^{-n}.$$

Exactly in the same way it may be shown, that

$$\text{Cos.}(-na) - \sin.\sqrt{-1}(-na) = (\cos. a - \sqrt{-1}\sin.)^{-n};$$

so that the formulæ are universally true, $n$ being either a positive or negative whole number or fraction. We may even extend the proof to the case of $n$, an irrational quantity; for every such quantity may be expressed to any degree of nearness by numbers.

262. These very remarkable and important expressions (B 2) were first found by Abraham de Moivre, and appeared in his *Miscellanea Analytica*, which was published in 1730. He was led to them by considering the analogy between the circle and hyperbola; but we owe to Euler their introduction into analysis as elementary formulæ. By taking their sum and difference, we obtain them in a different shape, as follows:

(C 2)

$$\text{Cos. } na = \frac{(\cos. a + \sqrt{-1}\sin. a)^n + (\cos. a - \sqrt{-1}\sin. a)^n}{2};$$

$$\text{Sin. } na = \frac{(\cos. a + \sqrt{-1}\sin. a)^n - (\cos. a - \sqrt{-1}\sin. a)^n}{2\sqrt{-1}}.$$

In either case, they are purely symbolical expressions of the kind found by Cardan's rule for the roots of a cubic equation belonging to the irreducible case. (Sect. XI.) Like them, they cannot be immediately applied to calculation; but when treated by the rules of analysis, they reveal some of the most elegant and recondite theorems in geometry.

263. The formulæ (C 2) admit of an immediate application to the determination of the cosine and sine of any multiple of an arc. Let $x=\cos. a$, $y=\sin. a$, so that

$$\text{Cos.}\,na=\frac{(x+\sqrt{-1}\,y)^n+(x-\sqrt{-1}\,y)^n}{2};$$

$$\text{Sin.}\,na=\frac{(x+\sqrt{-1}\,y)^n-(x-\sqrt{-1}\,y)^n}{2\sqrt{-1}}.$$

Now, by the binomial theorem,

$$(x+\sqrt{-1}\,y)^n=x^n+nx^{n-1}y\sqrt{-1}-\frac{n(n-1)}{1\cdot 2}x^{n-2}y^2$$
$$-\frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}x^{n-3}y^3\sqrt{-1}+,\ \&c.$$

$$(x-\sqrt{-1}\,y)^n=x^n-nx^{n-1}y\sqrt{-1}-\frac{n(n-1)}{1\cdot 2}x^{n-2}y^2$$
$$+\frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}x^{n-3}y^3\sqrt{-1}+,\ \&c.$$

Hence, taking half the sum and difference of these series, and in the latter case dividing by $\sqrt{-1}$, we obtain

(D 2)

$$\text{Cos.}\,na=x^n-\frac{n(n-1)}{1\cdot 2}x^{n-2}y^2$$
$$+\frac{n(n-1)(n-2)(n-3)}{1\cdot 2\cdot 3\cdot 4}x^{n-4}y^4-,\ \&c.$$

$$\text{Sin.}\,na=\frac{n}{1}x^{n-1}y-\frac{n(n-1)(n-2)}{1\cdot 2}x^{n-3}y^3$$
$$+\frac{n(n-1)(n-2)(n-3)(n-4)}{1\cdot 2\cdot 3\cdot 4\cdot 5}x^{n-5}y^5-,\ \&c.$$

These series terminate as often as $n$ is a whole positive number. They were first given in 1701, by John Bernoulli, in the Leipsic Acts, but without demonstration. They also appear in letter 129 of the *Commercium Epistolicum* of Leibnitz and Bernoulli, and in the *Sections Coniques* of M. de l'Hôpital. It is remarkable that John Bernoulli should have fallen on these beautiful theorems, and yet missed the formulæ of De Moivre, which are easily deducible from them, but which were not discovered until twenty years later.

If it be observed that $\sin. a = \tan. a \cos. a$, and $\sin. na = \tan. na \cos. na$; and if, after substitution, the second formula be divided by the first, the result, after due reduction, will be the expression for the tangent which was given in sect. 257.

264. The same powerful instrument of analysis might enable us to investigate all the general expressions for the cosines and sines of multiple arcs from (R) to (2 X); but we shall rather reserve them to show the application of the differential calculus, or method of fluxions. We shall, however, now exemplify their use in the investigation of general series for the powers of the cosine and sine of an arc, in terms of the cosines and sines of its multiples.

Let us put $p=\cos. a+\sqrt{-1}\sin. a$, $q=\cos. a-\sqrt{-1}\sin. a$;

then $pq=\cos.^2 a+\sin.^2 a=1$, and $q=\frac{1}{p}$.

De Moivre's formulæ may now be expressed thus:

(E 2)

$$2\cos. na=p^n+q^n=p^n+\frac{1}{p^n},$$

$$2\sqrt{-1}\sin. na=p^n-q^n=p^n-\frac{1}{p^n};$$

and since $2\cos. a=p+q$, therefore, putting $c'$, $c''$, $c'''$, &c. for the numeral co-efficients of the second, third, fourth, &c. terms of a binomial, we have

$$(2\cos. a)^n=p^n+c'p^{n-1}q+c''p^{n-2}q^2+c'''p^{n-3}q^3+,\ \&c.$$

Because $2\cos. a=q+p$, we have also

$$(2\cos. a)^n=q^n+c'q^{n-1}p+c''q^{n-2}p^2+c'''q^{n-3}p^3+,\ \&c.$$

Taking now the sum of both series, and observing that $pq=1$, we obtain

$$2(2\cos. a)^n=p^n+q^n+c'(p^{n-2}+q^{n-2})+c''(p^{n-4}+q^{n-4})$$
$$+c'''(p^{n-6}+q^{n-6})+,\ \&c.$$

Now,
$$p^n+q^n=2\cos. na,$$
$$p^{n-2}+q^{n-2}=2\cos.(n-2)a,$$
$$p^{n-4}+q^{n-4}=2\cos.(n-4a),$$
$$p^{n-6}+q^{n-6}=2\cos.(n-6)a,$$
&c.

Therefore, substituting and dividing by 2,

$$(2\cos. n)^n=\cos. na+c'\cos.(n-2)a+c''\cos.(n-4)a$$
$$+c'''\cos.(n-6)a+,\ \&c.$$

By continuing the series, we come to the cosines of negative arcs, which are exactly the same as the cosines of positive arcs having the same co-efficient: Thus, $\cos.(m-n)a=\cos.(n-m)a$, for each is equal to $\cos. ma\cos. na+\sin. ma\sin. a$. Now, in the series which is the expansion of $(p+q)^n$, the terms at equal distances from the first and last have the same co-efficient; therefore the series for $(2\cos. a)^n$ must have the same property; and further, the cosines of the arcs at equal distances from the extremes are, as has been just proved, equal; we may therefore omit the terms which are the cosines of negative arcs, and in their stead take the doubles of these, which are the cosines of positive arcs. The above formula will then be abbreviated to

$$(2\cos. a)^n=2\,[\cos. na+c'\cos.(n-2)a+c''\cos.(n-4)a$$
$$+,\ \&c.].$$

When $n$ is an even number, the series has a term at equal distances from both extremes, which, being single in the expansion, must not be doubled; but when $n$ is an odd number, the cosines of the negative arcs are equal in number to those of the positive arcs. Lastly, by considering that the cosine of $(n-n)a=1$, the truth of the general formulæ of table (Z) will be sufficiently obvious.

265. The general formulæ of table (A 2) may be established by a process quite similar to the above, by the expression $2\sqrt{-1}\sin. a=p^n-q^n$; but more easily by substituting $\frac{1}{2}\pi-a'$ instead of $a$, and remarking that $\cos.(\frac{1}{2}\pi-a')=\sin. a$: we have thus

$$(2\sin. a')^n=2\cos. n(\tfrac{1}{2}\pi-a')+2c'\cos.(n-2)(\tfrac{1}{2}\pi-a')$$
$$+2c''\cos.(n-4)(\tfrac{1}{2}\pi-a')+,\ \&c.$$

The terms of this series being all of the form

$$\cos. m\,[\tfrac{1}{2}\pi-a']=\cos. m\frac{\pi}{2}\cos. ma'+\sin. m\frac{\pi}{2}\sin. ma'$$

will have the form $\pm\sin. ma'$, when $m$ is an odd number; and the form $\pm\cos. ma'$, when $m$ is an even number.

266. Before we proceed to other applications of De Moivre's formulæ, it will be convenient to establish some analytic principles of frequent application, regarding the limits between which certain expressions involving arcs and their sines, tangents, &c. are always contained.

It is an axiom in geometry, that any arc is less than its tangent (as defined sect. 224), but greater than its sine, therefore, $\frac{a}{n}$ being any arc,

$$\tan.\frac{a}{n} > \frac{a}{n}, \qquad \sin.\frac{a}{n} < \frac{a}{n}.$$

Multiplying the first of these by $n$, and the second by sec. $\frac{a}{n}$, and observing that sec. $\frac{a}{n}$ sin. $\frac{a}{n} = \tan.\frac{a}{n}$, we have

$$n\tan.\frac{a}{n} > a, \qquad n\tan.\frac{a}{n} < a\sec.\frac{a}{n}.$$

Suppose now $n$ to increase continually, while the arc $a$ is invariable, it is manifest, that since $\frac{a}{n}$ will decrease, and may become less than any assignable arc, sec. $\frac{a}{n}$ will continually approach to the radius $= 1$, and may differ from it by less than any assignable quantity. Hence it follows that $n$ being supposed to increase continually, the expression $n$ tan. $\frac{a}{n}$ approaches continually to $a$, which is its limit.

In like manner, because

$$n\sin.\frac{a}{n} < a, \qquad n\sin.\frac{a}{n} > a\cos.\frac{a}{n};$$

and because, while $n$ increases, cos. $\frac{a}{n}$ approaches to radius $= 1$, which is its limit; therefore the limit of $n$ sin. $\frac{a}{n}$ is the arc $a$.

Hence, it appears that the arc $a$ being supposed to decrease continually,

$$\text{limit of } \frac{a}{\sin. a} = 1, \text{ and limit of } \frac{a}{\tan. a} = 1.$$

267. It is sufficiently evident that the limit of cos. $\frac{a}{n}$ is 1; but, in what is to follow, it will be necessary to find the limit of cos.$^n \frac{a}{n}$ when $n$ increases indefinitely.

By a known formula, cos. $\frac{a}{n} = \sqrt{1-\sin.^2\frac{a}{n}}$. Let us put $\omega = n\sin.\frac{a}{n}$; then $\omega$ will be less than $a$, and

$$\text{Cos.}^n\frac{a}{n} = \left(1-\frac{\omega^2}{n^2}\right)^{\frac{n}{2}}.$$

By the binomial theorem, the second member of this equation is

$$1-\frac{\omega^2}{2n}+\left(1-\frac{2}{n}\right)\frac{\omega^4}{2\cdot 4n^2}-\left(1-\frac{2}{n}\right)\left(1-\frac{4}{n}\right)\frac{\omega^6}{2\cdot 4\cdot 6n^3}+,\&c.$$

But since, by hypothesis, $n$ may be greater than any assignable number, and $\omega$ is not greater than $a$, every term of this series, except the first, will evidently be $= 0$, when $n$ is indefinitely great; therefore, in that case, cos.$^n \frac{a}{n}$ is accurately $= 1$.

268. Resuming now De Moivre's formulæ (261), we have

$$\text{Cos.}\,a+\sqrt{-1}\sin.\,a = \left(\cos.\frac{a}{n}+\sqrt{-1}\sin.\frac{a}{n}\right)^n,$$

$$\text{Cos.}\,a-\sqrt{-1}\sin.\,a = \left(\cos.\frac{a}{n}-\sqrt{-1}\sin.\frac{a}{n}\right)^n.$$

Let $t$ denote the tangent of the arc $\frac{a}{n}$, then observing that sin. $\frac{a}{n} = \cos.\frac{a}{n}\tan.\frac{a}{n}$, we have

$$\text{Cos.}\,a+\sqrt{-1}\sin.\,a = \cos.^n\frac{a}{n}\left(1+\sqrt{-1}\,t\right)^n,$$

$$\text{Cos.}\,a-\sqrt{-1}\sin.\,a = \cos.^n\frac{a}{n}\left(1-\sqrt{-1}\,t\right)^n.$$

By the binomial theorem $(1+\sqrt{-1}\,t)^n =$

$$1-\left(1-\frac{1}{n}\right)\frac{n^2t^2}{1\cdot 2}+\left(1-\frac{1}{n}\right)\left(1-\frac{2}{n}\right)\left(1-\frac{3}{n}\right)\frac{n^4t^4}{1\cdot 2\cdot 3\cdot 4}-,\&c.$$

$$+\sqrt{-1}\left\{nt-\left(1-\frac{1}{n}\right)\left(1-\frac{2}{n}\right)\frac{n^3t^3}{1\cdot 2\cdot 3}+,\&c.\right\}.$$

(Here we have resolved the whole expansion into two parts; one entirely free from the imaginary sign, and the other having that sign as a common factor of all its terms.) Let us denote the first of these series by P, and the second, setting aside its imaginary factor $\sqrt{-1}$, by Q; then

$$(1+\sqrt{-1}\,t)^n = \text{P}+\sqrt{-1}\,\text{Q}.$$

By a like process we find

$$(1-\sqrt{-1}\,t)^n = \text{P}-\sqrt{-1}\,\text{Q};$$

and hence again

$$\text{Cos.}\,a+\sqrt{-1}\sin.\,a = \cos.^n\frac{a}{n}(\text{P}+\sqrt{-1}\,\text{Q});$$

$$\text{Cos.}\,a-\sqrt{-1}\sin.\,a = \cos.^n\frac{a}{n}(\text{P}-\sqrt{-1}\,\text{Q}).$$

and from these, by adding and subtracting,

$$\text{Cos.}\,a = \cos.^n\frac{a}{n}\text{P}, \qquad \sin.\,a = \cos.^n\frac{a}{n}\text{Q};$$

or, substituting for P, Q, and $t$, their values,

$$\text{Cos.}\,a = \cos.^n\frac{a}{n}\left\{1-\left(1-\frac{1}{n}\right)\frac{n^2t^2}{1\cdot 2} + \left(1-\frac{1}{n}\right)\left(1-\frac{2}{n}\right)\left(1-\frac{3}{n}\right)\frac{n^4t^4}{1\cdot 2\cdot 3\cdot 4}-,\&c.\right\}$$

$$\text{Sin.}\,a = \cos.^n\frac{a}{n}\left\{nt-\left(1-\frac{1}{n}\right)\left(1-\frac{2}{n}\right)\frac{n^3t^3}{1\cdot 2\cdot 3} + \left(1-\frac{1}{n}\right)\left(1-\frac{2}{n}\right)\left(1-\frac{3}{n}\right)\left(1-\frac{4}{n}\right)\frac{n^5t^5}{1\cdot 2\cdot 3\cdot 4\cdot 5}-,\&c.\right\}$$

These formulæ must hold true, whatever value we give to $n$. But let us now suppose $n$ indefinitely great; then, from what was proved in last section,

$$\text{Cos.}^n\frac{a}{n}=1, \quad nt = n\tan.\frac{a}{n} = a, \quad \frac{1}{n}=0, \quad \frac{2}{n}=0, \ \&c.$$

We have therefore, by substitution,

$$\text{(F 2)} \quad \text{Cos.}\,a = 1-\frac{a^2}{1\cdot 2}+\frac{a^4}{1\cdot 2\cdot 3\cdot 4}-,\&c.$$

$$\text{Sin.}\,a = a-\frac{a^3}{1\cdot 2\cdot 3}+\frac{a^5}{1\cdot 2\cdot 3\cdot 4\cdot 5}-,\&c.$$

These elegant theorems, discovered by Newton, were among the first fruits of his analytical methods.

269. It has been shown (sect. 177) that if $e$ denote the number 2·7182818, viz. that whose Napierian logarithm is 1, then

$$e^x = 1+\frac{x}{1}+\frac{x^2}{1\cdot 2}+\frac{x^3}{1\cdot 2\cdot 3}+\frac{x^4}{1\cdot 2\cdot 3\cdot 4}+\frac{x^5}{1\cdot 2\cdot 3\cdot 4\cdot 5}+,\&c.$$

Now, $a$ being any arc, let $x = a\sqrt{-1}$; then, by substituting and separating the real and imaginary terms, so as to form two series, we have

$$e^{a\sqrt{-1}} = \begin{cases} 1-\dfrac{a^2}{2}+\dfrac{a^4}{1\cdot 2\cdot 3\cdot 4}-,\&c. \\ +\sqrt{-1}\left(a-\dfrac{a^3}{1\cdot 2\cdot 3}+\dfrac{a^5}{1\cdot 2\cdot 3\cdot 4\cdot 5}-,\&c.\right).\end{cases}$$

Again, putting $x = -a\sqrt{-1}$, we obtain, in like manner,

$$e^{-a\sqrt{-1}} = \begin{cases} 1 - \dfrac{a^2}{1\cdot 2} + \dfrac{a^4}{1\cdot 2\cdot 3\cdot 4} -, \text{\&c.} \\ -\sqrt{-1}\left(a - \dfrac{a^3}{1\cdot 2\cdot 3} + \dfrac{a^5}{1\cdot 2\cdot 3\cdot 4\cdot 5} -, \text{\&c.}\right). \end{cases}$$

But it was found that

$$\text{Cos.}\, a = 1 - \frac{a^2}{1\cdot 2} + \frac{a^4}{1\cdot 2\cdot 3\cdot 4} -, \text{\&c.}$$

$$\text{Sin.}\, a = a - \frac{a^3}{1\cdot 2\cdot 3} + \frac{a^5}{1\cdot 2\cdot 3\cdot 4\cdot 5} -, \text{\&c.}$$

Hence it follows that

(G 2)

$$e^{a\sqrt{-1}} = \cos.\, a + \sqrt{-1}\,\sin.\, a,$$

$$e^{-a\sqrt{-1}} = \cos.\, a - \sqrt{-1}\,\sin.\, a;$$

and consequently that

$$\text{Cos.}\, a = \frac{e^{a\sqrt{-1}} + e^{-a\sqrt{-1}}}{2}, \quad \text{Sin.}\, a = \frac{e^{a\sqrt{-1}} - e^{-a\sqrt{-1}}}{2\sqrt{-1}}.$$

Here the cosine and sine are expressed by imaginary exponentials. Lagrange considered these formulæ to be the happiest analytical inventions of the age. The series for the cosine and sine from which they have been here deduced had been given by Newton before the end of the 17th century. They might therefore then have been found, and a perfection given to this subject which it did not attain until fifty years later, by the labours of Euler.

270. From formulæ (G 2) we find

$$\frac{\cos.\, a + \sqrt{-1}\,\sin.\, a}{\cos.\, a - \sqrt{-1}\,\sin.\, a} = \frac{e^{a\sqrt{-1}}}{e^{-a\sqrt{-1}}} = e^{2a\sqrt{-1}};$$

or, putting, instead of sin. $a$, its equivalent tan. $a$ cos. $a$, and leaving out the common factor cos. $a$,

$$\frac{1+\sqrt{-1}\,\tan.\, a}{1-\sqrt{-1}\,\tan.\, a} = e^{2a\sqrt{-1}}.$$

Now, observing that $e$ is the base or radical number of Napier's logarithms, it follows, from the theory of logarithms (Sect. XIX.), that

$$2a\sqrt{-1} = \text{Nap. log.}\,\frac{1+\sqrt{-1}\,\tan.\, a}{1-\sqrt{-1}\,\tan.\, a}.$$

But it was shown, sect. 167, that $v$ being any number,

$$\log.\,\frac{1+v}{1-v} = 2\left(v + \frac{v^3}{3} + \frac{v^5}{5} + \frac{v^7}{7} +, \text{\&c.}\right).$$

Put now $\sqrt{-1}$ tan. $a$ instead of $v$, and the result equal to $2a\sqrt{-1}$, and divide both sides by $2\sqrt{-1}$, and we have

(H 2)

$$a = \tan.\, a - \tfrac{1}{3}\tan.^3 a + \tfrac{1}{5}\tan.^5 a - \tfrac{1}{7}\tan.^7 a +, \text{\&c.}$$

This elegant expression for an arc of a circle was first found by James Gregory, from whom it was received by Collins, an eminent mathematician of that period, in the beginning of 1671. It was sent to Leibnitz in 1675 (see *Commercium Epistolicum*, p. 98 and 120), and it appears that this celebrated person had communicated the same series to his friends on the Continent as his own discovery, and even sent it to England in 1676. (*Com. Ep.* 133.) He was accused by the English mathematicians of appropriating to himself the discovery of Gregory: but this, of course, he denied. (*Com. Ep. Leibnitii et Bernoullii*, tom. ii. p. 313.) We have been thus particular, because Lagrange has given it to Leibnitz. (*Calcul des Fonctions*, p. 68.) John Bernoulli, however, in expressing his belief that Leibnitz had found the series himself, admits that it was first discovered by Gregory.

271. If we suppose $a$ to be an arc of 45°, the Gregorian series gives

$$1 - \tfrac{1}{3} + \tfrac{1}{5} - \tfrac{1}{7} + \tfrac{1}{9} - \tfrac{1}{11} +, \text{\&c.}$$

for one eighth of the circumference. This, however, converges too slowly to be of any practical use. Newton found a different series, viz.

$$1 + \tfrac{1}{3} - \tfrac{1}{5} - \tfrac{1}{7} + \tfrac{1}{9} + \tfrac{1}{11} - \tfrac{1}{13} - \tfrac{1}{15} +, \text{\&c.}$$

for the length of the quadrantal arc of a circle of which the chord $= 1$. This converges somewhat faster than Gregory's series; but Newton says that the addition of no fewer than 5000,000,000 of the terms would be required to give the length of the quadrant true to twenty decimal places of figures; a labour which would require about one thousand years.

272. The simplicity of Gregory's series is a great recommendation; and as the determination of the ratio of the diameter of a circle to the circumference is a problem of primary importance, we shall investigate an auxiliary formula, which will make it the fittest of any for the solution.

Let $n$, $x$, $y$, be three whole numbers, such, that the arc whose tangent is $\frac{1}{n}$ is equal to the sum of the arcs whose tangents are $\frac{1}{x}$ and $\frac{1}{y}$; then, by formulæ (F),

$$\frac{1}{n} = \frac{\frac{1}{x}+\frac{1}{y}}{1-\frac{1}{xy}} = \frac{x+y}{xy-1};$$

hence we find $y = \dfrac{nx+1}{x-n} = n + \dfrac{n^2+1}{x-n}$.

Now as $y$ is a whole number, $n^2+1$ must be divisible by $x-n$. Let $p$ be any divisor of $n^2+1$, and $q$ the quotient, so that $pq = n^2+1$; then $x-n$ may be assumed $= p$, and $x = n+p$, and therefore

$$y = n + \frac{n^2+1}{x-n} = n + p.$$

Hence we have the following *theorem;*

Let $n$ be any whole number, and let $n^2+1$ be resolved into any two factors $p$ and $q$, one of which may be unity. The arc whose tangent is $\frac{1}{n}$ is equal to the sum of the arcs whose tangents are $\dfrac{1}{n+p}$ and $\dfrac{1}{n+q}$.

As a convenient notation, let $\mathrm{A}\frac{1}{n}$ denote the arc whose tangent is $\frac{1}{n}$, and similarly, $\mathrm{A}\,\dfrac{1}{n+p}$ and $\mathrm{A}\,\dfrac{1}{n+q}$, the arcs whose tangents are $\dfrac{1}{n+p}$, and $\dfrac{1}{n+q}$; our theorem will then stand thus:

(K 2)

$$\mathrm{A}\,\frac{1}{n} = \mathrm{A}\,\frac{1}{n+p} + \mathrm{A}\,\frac{1}{n+q}.$$

By giving to $n$ different values, we form the following table:

(L 2)

$$\begin{array}{lll l}
n=1,\ n^2+1 & =1\times 2, & \mathrm{A}\frac{1}{1}=\mathrm{A}\frac{1}{2}+\mathrm{A}\frac{1}{3}, & (1) \\
n=2,\ n^2+1 & =1\times 5, & \mathrm{A}\frac{1}{2}=\mathrm{A}\frac{1}{3}+\mathrm{A}\frac{1}{7}, & (2) \\
n=3,\ n^2+1 & \begin{cases}=1\times 10, \\ =2\times 5,\end{cases} & \begin{array}{l}\mathrm{A}\frac{1}{3}=\mathrm{A}\frac{1}{4}+\mathrm{A}\frac{1}{13}, \\ \mathrm{A}\frac{1}{3}=\mathrm{A}\frac{1}{5}+\mathrm{A}\frac{1}{8},\end{array} & \begin{array}{l}(3) \\ (4)\end{array} \\
n=4,\ n^2+1 & =1\times 17, & \mathrm{A}\frac{1}{4}=\mathrm{A}\frac{1}{5}+\mathrm{A}\frac{1}{21}, & (5) \\
n=5,\ n^2+1 & =2\times 13, & \mathrm{A}\frac{1}{5}=\mathrm{A}\frac{1}{7}+\mathrm{A}\frac{1}{18}, & (6) \\
n=6,\ n^2+1 & =1\times 37, & \mathrm{A}\frac{1}{6}=\mathrm{A}\frac{1}{7}+\mathrm{A}\frac{1}{43}, & (7) \\
n=7,\ n^2+1 & =2\times 25, & \mathrm{A}\frac{1}{7}=\mathrm{A}\frac{1}{9}+\mathrm{A}\frac{1}{32}, & (8) \\
\quad\text{\&c.} & & \quad\text{\&c.} &
\end{array}$$

We may proceed with this series to any extent; and from these formulæ, by elimination, we obtain the following:

Algebra. Algebra.

(M 2)

$$A\tfrac{1}{1} = A\tfrac{1}{2} + A\tfrac{1}{3}$$

From 1 and 2, $A\tfrac{1}{1} = 2A\tfrac{1}{3} + A\tfrac{1}{7}$, (9)

4 and 9, $A\tfrac{1}{1} = 2A\tfrac{1}{5} + A\tfrac{1}{7} + 2A\tfrac{1}{8}$, (10)

6 and 10, $A\tfrac{1}{1} = 3A\tfrac{1}{7} + 2A\tfrac{1}{8} + 2A\tfrac{1}{18}$, (11)

8 and 11, $A\tfrac{1}{1} = 2A\tfrac{1}{8} + 3A\tfrac{1}{9} + 2A\tfrac{1}{18} + 3A\tfrac{1}{32}$, (12)

&c.

By any one of these the circumference of a circle may be found with great facility, particularly by the two last. The first and simplest, but not the best, is Euler's formula; and it shows that $\tfrac{1}{4}$ of the semi-circumference is the sum of the arcs whose tangents are $\tfrac{1}{2}$ and $\tfrac{1}{3}$.

By putting $\tfrac{1}{2}$ and $\tfrac{1}{3}$ in the general series instead of tan. $a$, we get two series whose sum multiplied by 4 gives for half the circumference,

$$4\left\{\begin{array}{l} \dfrac{1}{2} - \dfrac{1}{3\cdot 2^3} + \dfrac{1}{5\cdot 2^5} - \dfrac{1}{7\cdot 2^7} + \dfrac{1}{9\cdot 2^9} -, \\ +\dfrac{1}{3} - \dfrac{1}{3\cdot 3^3} + \dfrac{1}{5\cdot 3^5} - \dfrac{1}{7\cdot 3^7} + \dfrac{1}{9\cdot 3^9} -, \&c. \end{array}\right\}.$$

The arithmetical calculation being performed, the result gives half the circumference to the radius 1, which we have expressed by $\pi$, or the whole circumference to the diameter 1 equal to

3·14159,26535,89793,23846,26433,83279,50288.

We have put down this important *datum* true to 35 places of decimals, not because such accuracy can ever be wanted, but as a memorial of the almost incredible patience of Ludolph Van Ceulen, a Flemish mathematician, who obtained this result by the most laborious but most obvious of all methods, namely, the inscription and circumscription of polygons in and about a circle. He so highly estimated this effort, that he directed the number to be inscribed on his sepulchre, in imitation of the tomb of Archimedes, which was inscribed with a sphere and cylinder; but, by methods which have been here explained, it might have been accomplished with no great labour. De Lagny, a Frenchman, carried the calculation, by an easier method, to 128 figures; and Euler ascertained that his result could be verified with 80 hours' labour. It is said that the same important number has even been carried as far as 150 figures, and that this labour may be seen in manuscript in the Radcliffe Library at Oxford.

273. The importance of the problem to determine the ratio of the diameter to the circumference, which is called the rectification of the circle, makes it desirable to have an elementary solution; we shall therefore give another, which is entirely independent of the binomial theorem, or the doctrine of imaginary quantities.

Supposing A to be any arc of a circle, we found, sect. 257, that

$$\text{tan. } 2A = \frac{2 \text{ tan. } A}{1 - \text{tan.}^2 A}, \text{ and therefore } \frac{1}{\text{tan. } 2A} = \frac{1}{2 \text{ tan. } A} - \tfrac{1}{2} \text{ tan. } A.$$

From this formula we deduce the following equations:

$$\frac{1}{\text{tan. } a} = \frac{1}{2 \text{ tan. } \frac{1}{2}a} - \tfrac{1}{2} \text{ tan. } \tfrac{1}{2}a,$$

$$\frac{1}{2 \text{ tan. } \frac{1}{2}a} = \frac{1}{4 \text{ tan. } \frac{1}{4}a} - \tfrac{1}{4} \text{ tan. } \tfrac{1}{4}a,$$

$$\frac{1}{4 \text{ tan. } \frac{1}{4}a} = \frac{1}{8 \text{ tan. } \frac{1}{8}a} - \tfrac{1}{8} \text{ tan. } \tfrac{1}{8}a.$$

By adding both sides, and rejecting what is common to the results, we find

$$\frac{1}{\text{tan. } a} = \frac{1}{8 \text{ tan. } \frac{1}{8}a} - \tfrac{1}{2} \text{ tan. } \tfrac{1}{2}a - \tfrac{1}{4} \text{ tan. } \tfrac{1}{4}a - \tfrac{1}{8} \text{ tan. } \tfrac{1}{8}a;$$

and hence, by transposing,

$$\frac{1}{8 \text{ tan. } \frac{1}{8}a} = \frac{1}{\text{tan. } a} + \tfrac{1}{2} \text{ tan. } \tfrac{1}{2}a + \tfrac{1}{4} \text{ tan. } \tfrac{1}{4}a + \tfrac{1}{8} \text{ tan. } \tfrac{1}{8}a.$$

In general, $n$ being any integer power of 2, we have

$$\frac{1}{n \text{ tan. } \frac{1}{n}a} = \frac{1}{\text{tan. } a} + \tfrac{1}{2} \text{ tan. } \tfrac{1}{2}a + \tfrac{1}{4} \text{ tan. } \tfrac{1}{4}a + \tfrac{1}{8} \text{ tan. } \tfrac{1}{8}a + \tfrac{1}{16} \text{ tan. } \tfrac{1}{16}a \ldots\ldots + \frac{1}{n} \text{ tan. } \frac{a}{n}.$$

Suppose now $n$ to be increased indefinitely, the series will then consist of an infinite number of terms; and since it was proved in sect. 266 that $n \text{ tan. } \frac{1}{n}a = a$, we have

(N 2)

$$\frac{1}{a} = \frac{1}{\text{tan. } a} + \tfrac{1}{2} \text{ tan. } \tfrac{1}{2}a + \tfrac{1}{4} \text{ tan. } \tfrac{1}{4}a + \tfrac{1}{8} \text{ tan. } \tfrac{1}{8}a +, \&c.$$

This very simple and neat expression for the reciprocal of an arc was found by Professor Wallace, and given along with various others in the sixth volume of the *Transactions of the Royal Society of Edinburgh*, about the year 1812. He believed it to be new, and indeed it was not then known in this country; but it had been given before by Euler, in his *Opuscula Analytica*, tom. i. p. 350. This series converges pretty fast; for the tangent of the half of an arc being less than half the tangent of the whole arc, as is easily proved, each term is less than one fourth of the term before it. As, however, the series proceeds, the ratio of any two consecutive terms approaches continually to that of 4 to 1; and hence any term somewhat advanced in the series will be nearly three times the sum of all that follow it; and, by this property, as soon as a term is found to be nearly one fourth of that before it, one third of that term will give the sum of all that follow it, very near.

From the formula $\text{tan. } \frac{1}{2}a = \text{cosec. } a - \text{cot. } a$ (sect. 249), we get

$$\text{tan. } \tfrac{1}{2}a = \sqrt{1 + \text{cot.}^2 a} - \text{cot. } a = \text{cot. } a(\sqrt{1 + \text{tan.}^2 a} - 1).$$

But by the binomial theorem

$$\sqrt{1 + \text{tan.}^2 a} = 1 + \tfrac{1}{2} \text{ tan.}^2 a - \tfrac{1}{8} \text{ tan.}^4 a + \tfrac{1}{16} \text{ tan.}^6 a -, \&c.$$

therefore, $\text{tan. } \frac{1}{2}a = \frac{1}{2} \text{ tan. } a - \frac{1}{8} \text{ tan.}^3 a + \frac{1}{16} \text{ tan.}^5 a$, &c.

By the first of these expressions we may compute the terms of the series until the seventh or fifth power may be neglected, and then the remaining terms may be more readily computed by the second.

Let $a$ be a quadrant $= \frac{1}{2}\pi$. In this case, $\dfrac{1}{\text{tan.} a} = 0$.

The calculation of the length of the arc will stand thus:

$$\begin{aligned}
\text{Tan.} \tfrac{1}{2}a &= \cdot 50000000000 \\
\text{Tan.} \tfrac{1}{4}a &= \cdot 41421356237 \\
\text{Tan.} \tfrac{1}{8}a &= \cdot 19891236738 \\
\text{Tan.} \tfrac{1}{16}a &= \cdot 09849140336 \\
\text{Tan.} \tfrac{1}{32}a &= \cdot 04912684977 \\
\text{Tan.} \tfrac{1}{64}a &= \cdot 02454862211 \\
\text{Tan.} \tfrac{1}{128}a &= \cdot 01227246238 \\
\text{Tan.} \tfrac{1}{256}a &= \cdot 00613600016 \\
\text{Tan.} \tfrac{1}{512}a &= \cdot 00306797120
\end{aligned}$$

$$\begin{aligned}
\tfrac{1}{2} \text{ tan.} \tfrac{1}{2}a &= \cdot 50000000000 \\
\tfrac{1}{4} \text{ tan.} \tfrac{1}{4}a &= \cdot 10355339059 \\
\tfrac{1}{8} \text{ tan.} \tfrac{1}{8}a &= \cdot 02486404592 \\
\tfrac{1}{16} \text{ tan.} \tfrac{1}{16}a &= \cdot 00615571271 \\
\tfrac{1}{32} \text{ tan.} \tfrac{1}{32}a &= \cdot 00153521406 \\
\tfrac{1}{64} \text{ tan.} \tfrac{1}{64}a &= \cdot 00038357222 \\
\tfrac{1}{128} \text{ tan.} \tfrac{1}{128}a &= \cdot 00009587861 \\
\tfrac{1}{256} \text{ tan.} \tfrac{1}{256}a &= \cdot 00002396875 \\
T = \tfrac{1}{512} \text{ tan.} \tfrac{1}{512}a &= \cdot 00000599213 \\
\tfrac{1}{3}T &= \cdot 00000199737
\end{aligned}$$

$$\frac{2}{\pi} = \cdot 63661977236$$

$$\pi = 3\cdot 1415926536.$$

Algebra.

274. It appears from Sect. X. that the resolution of any equation depends on our being able to resolve it into its factors, whether of the first or second degree. In one class of equations this can be effected by the calculus of sines, as will appear from the following analysis:

Since $\cos.(m+1)x=2\cos.x\cos.mx-\cos.(m-1)x$,

let $2\cos.x=v+\frac{1}{v}$;

then $2\cos.2x=4\cos.x\cos.x-2\cos.0x=v^2+\frac{1}{v^2}$,

$$2\cos.3x=4\cos.x\cos.2x-2\cos.x=v^3+\frac{1}{v^3},$$

$$2\cos.4x=4\cos.x\cos.3x-2\cos.2x=v^4+\frac{1}{v^4},$$

&c.

and in general, $2\cos.mx=v^m+\frac{1}{v^m}$;

hence we get

$$v^{2m}-2v^m\cos.mx+1=0.$$

The equation $v+\frac{1}{v}=2\cos.x$ gives

$$v^2-2v\cos.x+1=0.$$

Now, since the two equations

$$v^{2m}-2v^m\cos.mx+1=0,$$
$$v^2-2v\cos.x+1=0,$$

require to be both satisfied at the same time, they must have at least one common root. Let $a$ be that root, then $\frac{1}{a}$ will also be a root of both; for putting them under the form

$$v^m+\frac{1}{v^m}-2\cos.mx=0,$$

$$v+\frac{1}{v}-2\cos.x=0,$$

the results will be the very same whether we substitute $a$ or $\frac{1}{a}$ for $v$.

Now the quadratic equation

$$v^2-2v\cos.x+1=0$$

can only have two roots, therefore these must also be roots of the equation

$$v^{2m}-2v^m\cos.mx+1=0;$$

hence it follows that the trinomial

$$v^{2m}-2v^m\cos.mx+1$$

must be divisible by this other expression,

$$v^2-2v\cos.x+1;$$

or, putting $mx=\varphi$, and therefore $x=\frac{\varphi}{m}$, that

$$v^{2m}-2v^m\cos.\varphi+1$$

must have for a divisor

$$v^2-2v^m\cos.\frac{\varphi}{m}+1.$$

Now we found, sect. 232, that $\pi$ being put for half the circumference,

$$\text{Cos.}\,\varphi=\cos.(2n\pi+\varphi);$$

hence it follows, that instead of $\frac{\varphi}{m}$, we may take any one of this series of arcs,

$$\frac{2\pi}{m}+\frac{\varphi}{m},\ \frac{4\pi}{m}+\frac{\varphi}{m},\ \frac{6\pi}{m}+\frac{\varphi}{m}\ldots\ldots\text{to}\left\{\frac{2(m-1)\pi}{m}+\frac{\varphi}{m}\right\},$$

for the cosine of $m$ times any one of these is the very same quantity; we may therefore infer that the trinomial

$$v^{2m}-2v^m\cos.\varphi+1$$

is divisible by each of these trinomial expressions of the second degree, viz.

$$v^2-2v\cos.\frac{\varphi}{m}+1,$$

$$v^2-2v\cos.\left(\frac{2\pi}{m}+\frac{\varphi}{m}\right)+1,$$

$$v^2-2v\cos.\left(\frac{4\pi}{m}+\frac{\varphi}{m}\right)+1,$$

$$\ldots\ldots$$

$$v^2-2v\cos.\left\{\frac{2(m-1)}{m}\pi+\frac{\varphi}{m}\right\}+1.$$

It is needless to carry the series farther, because the next divisor would involve $\cos.\left(\frac{2m}{m}\pi+\frac{\varphi}{m}\right)$, which is the same as $\cos.\left(2\pi+\frac{\varphi}{m}\right)=\cos.\frac{\varphi}{m}$, a repetition of the first, and so on. As the number of divisors which differ from one another is $m$, and the trinomial is of the $2m^{\text{th}}$ degree, it follows from the theory of equations, that the trinomial is the continual product of all the divisors.

This elegant theorem is due to De Moivre, as appears from his *Miscellanea Analytica*.

275. If we suppose $\varphi=0$, then $\cos.\varphi=1$, and the trinomial $v^{2m}-2v^m\cos.\varphi+1$ becomes in this case $v^{2m}-2v^m+1=(v^m-1)^2$, and the factors are

$$v^2-2v+1=(v-1)^2,$$

$$v^2-2v\cos.\frac{2\pi}{m}+1,$$

$$v^2-2v\cos.\frac{4\pi}{m}+1,$$

$$\ldots\ldots$$

$$v^2-2v\cos.\frac{2(m-1)}{m}\pi+1.$$

If, again, $\varphi=\pi$, then $\cos.\varphi=-1$, and the trinomial $v^{2m}-2v^m\cos.\varphi+1=v^{2m}+2v^m+1=(v^m+1)^2$; therefore the factors of this quantity are

$$v^2-2v\cos.\frac{\pi}{m}+1,$$

$$v^2-2v\cos.\frac{3\pi}{m}+1,$$

$$v^2-2v\cos.\frac{5\pi}{m}+1,$$

$$\ldots\ldots$$

$$v^2-2v\cos.\frac{(2m-1)\pi}{m}+1.$$

276. The two last formulæ are the analytic expressions of a very remarkable property of the circle discovered by Cotes, the friend and contemporary of Newton, and called the *Cotesian Theorem*. It consists of two parts, and may be thus enunciated (see Plate XVIII. fig. 25 and 26): Let the circumference of any circle be divided into $2m$ equal parts (for example ten), at the points $A_0$, $A_1$, $A_2$, $A_3$, $A_4$, ... $A_9$; and let $A_0C$ be a diameter drawn through $A_0$, one of the points of division; and from any point P in the diameter (fig. 25), or the diameter produced (fig. 26), let straight lines $PA_1$, $PA_3$, $PA_5$, $PA_7$, $PA_9$, be drawn to the points in the circumference which are the first, third, fifth, &c. from $A_0$; and also straight lines $PA_2$, $PA_4$, $PA_6$, $PA_8$, to the points which are the second, fourth,

sixth, &c.: then, putting $v = CP$, the distance of P from the centre, and $r = CA_0$, the radius.

I. The continual product of the lines drawn from P to $A_1$, $A_3$, $A_5$, $A_7$, &c. (the points marked with the odd numbers), is equal to $r^m + v^m$.

II. The continual product of the lines drawn from P to $A_0$, $A_2$, $A_4$, $A_6$, &c. (the points marked with even numbers), is equal to $r^m - v^m$, when the point is within the circle (fig. 25), or to $v^m - r^m$, when it is without (fig. 26).

Join $CA_1$, and, to simplify, let $r = 1$; because the whole circumference is divided into $2m$ parts, the arcs $A_0 A_1 = \frac{\pi}{m}$, $A_0 A_2 = \frac{2\pi}{m}$, $A_0 A_3 = \frac{3\pi}{m}$, and so on. Now by the elements of Geometry,

$$PA_1^2 = PC^2 - 2PC \times CA_1 \cos.\frac{\pi}{m} + CA^2 = v^2 - 2v \cos. \frac{\pi}{m} + 1.$$

In like manner, it will appear that

$$PA_2^2 = v^2 - 2v \cos. \frac{2\pi}{m} + 1,$$

$$PA_3^2 = v^2 - 2v \cos. \frac{3\pi}{m} + 1,$$

and so on, with respect to the lines drawn to the remaining points $PA_4$, $PA_5$.

Now, remarking that $PA_0 = v - 1$, from what has been proved, it appears that the product

$$PA_1^2 \times PA_3^2 \times PA_5^2 \ldots \text{to } PA_{2m-1}^2$$

is equal to the product of the trinomials

$$v^2 - 2v \cos. \frac{\pi}{m} + 1,$$

$$v^2 - 2v \cos. \frac{3\pi}{m} + 1,$$

$$v^2 - 2v \cos. \frac{5\pi}{m} + 1,$$

$$\cdot \; \cdot \; \cdot \; \cdot \; \cdot$$

$$v^2 - 2v \cos. \frac{(2m-1)}{m}\pi + 1;$$

and that the product

$$PA_0^2 \times PA_2^2 \times PA_4^2 \ldots \text{to } PA_{2m-2}^2$$

is equal to the product of the trinomials,

$$(v-1)^2 \text{ or } (1-v)^2,$$

$$v^2 - 2v \cos. \frac{2\pi}{m} + 1,$$

$$v^2 - 2v \cos. \frac{4\pi}{m} + 1,$$

$$\cdot \; \cdot \; \cdot \; \cdot \; \cdot \; \cdot$$

$$v^2 - 2v \cos. \frac{2(m-1)}{m}\pi + 1.$$

But we have proved that the first of these products is equal to $(v^m+1)^2$, and the second to $(1-v^m)^2 = (v^m-1)^2$; therefore, taking the square roots, we have

$$PA_1 \times PA_3 \times PA_5 \times PA_7, \text{ \&c.} = v^m + 1,$$
$$PA_0 \times PA_2 \times PA_4 \times PA_6, \text{ \&c.} = 1 - v^m \text{ or} = v^m - 1.$$

Thus both parts of the theorem are demonstrated.

This elegant geometrical theorem was found among the papers of Mr Cotes after his death. It had no demonstration, but that was soon supplied by his contemporaries, particularly De Moivre, who gave it the more general form which is expressed analytically in last article. At the time of its discovery, it was greatly esteemed; but now, analytical formulæ are found by experience more convenient than geometrical diagrams, and therefore are employed instead of them.

277. If we consider that

$$\text{Cos.}\frac{2(m-n)}{m}\pi = \cos.(2\pi - \frac{2n}{m}\pi) = \cos.\frac{2n}{m}\pi,$$

it will readily appear that the factors of the quantity $(v^m-1)^2$, which have been given in sect. 275, may be written thus:

$$v^2 - 2v + 1 = (v-1)^2,$$

$$v^2 - 2v \cos. \frac{2\pi}{m} + 1,$$

$$v^2 - 2v \cos. \frac{4\pi}{m} + 1,$$

$$\cdot \; \cdot \; \cdot \; \cdot$$

$$\cdot \; \cdot \; \cdot \; \cdot \; \cdot$$

$$v^2 - 2v \cos. \frac{4\pi}{m} + 1,$$

$$v^2 - 2v \cos. \frac{2\pi}{m} + 1,$$

where the second and last are identical; and the same is true of the third and last but two, the fourth and last but three, and so on, until, in the case of $m$ an even number, we come to two equal factors, one on each side of the $(\frac{1}{2}m+1)$th factor, which being $v^2 - 2v \cos. \frac{m\pi}{m} + 1$, will be $v^2 + 2v + 1 = (v+1)^2$; but in the case of $m$ an odd number, we come to two adjoining equal factors, the first of which is $v^2 - 2v \cos.\frac{m-1}{m}\pi + 1$; therefore, taking the square root of $(v^m-1)^2$, and at the same time rejecting one of each pair of equal factors, we find that when $m$ is an even number, $v^m - 1$ is equal to the product of these quantities,

$$v - 1,$$

$$v + 1,$$

$$v^2 - 2v \cos.\frac{2\pi}{m} + 1,$$

$$v^2 - 2v \cos.\frac{4\pi}{m} + 1,$$

$$\cdot \; \cdot \; \cdot \; \cdot \; \cdot \; \cdot$$

$$v^2 - 2v \cos.\frac{m-2}{m}\pi + 1.$$

But when $m$ is an odd number, the factors are

$$v - 1,$$

$$v^2 - 2v \cos.\frac{2\pi}{m} + 1,$$

$$v^2 - 2v \cos.\frac{4\pi}{m} + 1,$$

$$\cdot \; \cdot \; \cdot \; \cdot \; \cdot \; \cdot$$

$$v^2 - 2v \cos.\frac{m-1}{m}\pi + 1.$$

278. Next let us consider the expression $(v^m+1)^2$ and its factors, as given sect. 275. We have for this case

$$\text{Cos. } \frac{2m-n}{m}\pi = \cos. (2\pi - \frac{n}{m}\pi) = \cos.\frac{n}{m}\pi.$$

The factors are therefore

$$v^2 - 2v \cos. \frac{\pi}{m} + 1,$$

$$v^2 - 2v\cos.\frac{3\pi}{m} + 1,$$

. . . . . .

. . . . . .

$$v^2 - 2v\cos.\frac{3\pi}{m} + 1,$$

$$v^2 - 2v\cos.\frac{\pi}{m} + 1.$$

Here it appears that the first and last factors are identical, also the second and last but one, and so on, until in the case of $m$ an even number, we come to two adjoining equal factors, the first of which is $v^2 - 2v\cos.\frac{m-1}{m}\pi + 1$. But if $m$ be an odd number, there are two equal factors, and a single one between them, viz. $v^2 - 2v\cos.\frac{m}{m}\pi + 1 = v^2 + 2v + 1 = (v+1)^2$; therefore, taking the square roots of $(v^m + 1)^2$ and $(v+1)^2$, and rejecting one of each pair of equal factors, we obtain, in the case of $m$ an even number, $v^m + 1$, equal to the product of these factors:

$$v^2 - 2v\cos.\frac{\pi}{m} + 1,$$

$$v^2 - 2v\cos.\frac{3\pi}{m} + 1,$$

$$v^2 - 2v\cos.\frac{5\pi}{m} + 1,$$

. . . . . .

$$v^2 - 2v\cos.\frac{m-1}{m}\pi + 1.$$

But when $m$ is an odd number, the factors are,

$$v + 1,$$

$$v^2 - 2v\cos.\frac{\pi}{m} + 1,$$

$$v^2 - 2v\cos.\frac{3\pi}{m} + 1,$$

. . . . . .

$$v^2 - 2v\cos.\frac{m-2}{m}\pi + 1.$$

These formulæ, exhibiting the decomposition of the expressions $v^{2m} - 2v^m\cos.\varphi + 1$ and $v^m \pm 1$, are of great importance in the Differential Calculus or doctrine of Fluxions, and in the more recondite theories of Analysis.

279. In concluding the calculus of sines, we shall yet give three other examples of its application: the first shall be to the resolution of quadratic equations.

(1.) Let the equation be

$$x^2 + px = q,$$

where $p$ and $q$ are both positive numbers. This equation has two roots, a positive and a negative, of which $-p$ is the sum, and $-q$ the product. (Sect. 93.) Let $\tan.\frac{1}{2}v\sqrt{q}$ be the positive root, where $v$ is an angle to be determined; then $-\text{cotan}.\frac{1}{2}v\sqrt{q}$ will be the negative root, because $\tan.\frac{1}{2}v\sqrt{q} \times -\cot.\frac{1}{2}v\sqrt{q} = -q$. To determine $v$, we have this equation,

$$\sqrt{q}\,(\cot.\tfrac{1}{2}v - \tan.\tfrac{1}{2}v) = p:$$

but by (3) and (4) of (Q),

$$\cot.\tfrac{1}{2}v - \tan.\tfrac{1}{2}v = 2\cot.v = \frac{2}{\tan.v};$$

therefore, $\tan.v = \frac{\sqrt{q}}{\frac{1}{2}p}$. Hence we have this rule:

To resolve the equation $x^2 + px = q$, find an angle $v$, such, that $\tan.v = \frac{\sqrt{q}}{\frac{1}{2}p} \times$ *radius;* then the roots of the equation are,

$$x = +\tan.\tfrac{1}{2}v\sqrt{q}, \text{ and } x = -\frac{\sqrt{q}}{\tan.\frac{1}{2}v}.$$

(2.) In like manner we find that in the equation

$$x^2 - px = q,$$

the angle $v$ being found as before, the roots of the equation are,

$$x = +\frac{\sqrt{q}}{\tan.\frac{1}{2}v}; \text{ and } x = -\sqrt{q}\tan.\tfrac{1}{2}v.$$

(3.) When the equation is

$$x^2 - px = -q,$$

which has two positive roots whose sum is $p$, and product $q$ (sect. 93), these may be expressed by $\tan.\frac{1}{2}v\sqrt{q}$, and $\cot.\frac{1}{2}v\sqrt{q}$. In this case,

$$\sqrt{q}\,(\cot.\tfrac{1}{2}v + \tan.\tfrac{1}{2}v) = p:$$

but by (3) and (4) of formulæ (Q),

$$\cot.\tfrac{1}{2}v + \tan.\tfrac{1}{2}v = 2\,\text{cosec}.v = \frac{2}{\sin.v};$$

therefore, $\sin.v = \frac{\sqrt{q}}{\frac{1}{2}p}$. Hence, to resolve this case, find an angle $v$, such, that

$$\text{Sin}.v = \frac{\sqrt{q}}{\frac{1}{2}p} \times \textit{radius};$$

$$\text{then } x = +\sqrt{q}\tan.\tfrac{1}{2}v, \quad x = +\frac{\sqrt{q}}{\tan.\frac{1}{2}v}.$$

280. The second example is the resolution of a problem in pure algebra, said to have been proposed by the late Professor Porson.

Find $u, x, y, z$, from these equations,

$$uxyz = a, \quad . \quad . \quad . \quad (A)$$
$$uz + xy = b, \quad . \quad . \quad . \quad (B)$$
$$uy + xz = c, \quad . \quad . \quad . \quad (C)$$
$$ux + yz = d \quad . \quad . \quad . \quad (D)$$

*Solution.*

Let $p, q, r$, be such angles that

$$uz = \sqrt{a}\tan.p, \quad . \quad . \quad . \quad 1$$
$$uy = \sqrt{a}\tan.q, \quad . \quad . \quad . \quad 2$$
$$ux = \sqrt{a}\tan.r; \quad . \quad . \quad . \quad 3$$

then from the equation (A),

$$xy = \sqrt{a}\cot.p, \quad . \quad . \quad 4$$
$$xz = \sqrt{a}\cot.q, \quad . \quad . \quad . \quad 5$$
$$yz = \sqrt{a}\cot.r; \quad . \quad . \quad 6$$

and hence by substitution in the other equations

$$\sqrt{a}(\tan.p + \cot.p) = b,$$
$$\sqrt{a}(\tan.q + \cot.q) = c,$$
$$\sqrt{a}(\tan.r + \cot.r) = d;$$

and from these again (because A being any arc,

$$\tan.A + \cot.A = 2\,\text{cosec}.A = \frac{2}{\sin.2A}, \text{ sect. } 250);$$

$$\frac{2\sqrt{a}}{\sin.2p} = b, \quad \frac{2\sqrt{a}}{\sin.2q} = c, \quad \frac{2\sqrt{a}}{\sin.2r} = d,$$

$$\text{and } \sin.2p = \frac{2\sqrt{a}}{b}, \quad . \quad . \quad 7$$

$$\sin.2q = \frac{2\sqrt{a}}{c}, \quad . \quad . \quad 8$$

$$\sin.2r = \frac{2\sqrt{a}}{d}. \quad . \quad . \quad 9$$

By these equations the angles $p, q, r$ are determined.

By multiplying the corresponding sides of (1) (2) (3) we get

$$u^3xyz = (\sqrt{a})^3 \tan. p \tan. q \tan. r : \qquad 10$$

and, dividing this by Eq. (A),

$$u^2 = \sqrt{a} \tan. p \tan. q \tan. r. \quad . \quad . \quad 11$$

From this and equations 3, 2, and 1,

$$x^2 = \sqrt{a}\frac{\tan. r}{\tan. p \tan. q} = \sqrt{a} \cot. p \cot. q \tan. r,$$

$$y^2 = \sqrt{a}\frac{\tan. q}{\tan. p \tan. r} = \sqrt{a} \cot. p \tan. q \cot. r,$$

$$z^2 = \sqrt{a}\frac{\tan. p}{\tan. q \tan. r} = \sqrt{a} \tan. p \cot. q \cot. r :$$

so that, on the whole, to determine $u, x, y, z$, we first find the angles $p, q, r$, from these formulæ,

$$\sin. 2p = \frac{2\sqrt{a}}{b},$$

$$\sin. 2q = \frac{2\sqrt{a}}{c},$$

$$\sin. 2r = \frac{2\sqrt{a}}{d};$$

and then

$$u = \sqrt[4]{a}\sqrt{\tan. p \tan. q \tan. r},$$

$$x = \sqrt[4]{a}\sqrt{\cot. p \cot. q \tan. r},$$

$$y = \sqrt[4]{a}\sqrt{\cot. p \tan. q \cot. r},$$

$$z = \sqrt[4]{a}\sqrt{\tan. p \cot. q \cot. r}.$$

281. The last example shall be the manner of inscribing a regular polygon of 17 sides in a circle,—a discovery due to Mr Gauss of Brunswick, and one of the most remarkable that has been made in geometry. We take it as given in the excellent *Treatise on Geometry* by Legendre.

Let the arc $\frac{\pi}{17} = \varphi$; in the first place we have this equation,

$$\left.\begin{array}{l}\text{Cos. } \varphi + \cos. 3\varphi + \cos. 5\varphi + \cos. 7\varphi \\ + \cos. 9\varphi + \cos. 11\varphi + \cos. 13\varphi + \cos. 15\varphi\end{array}\right\} = \tfrac{1}{2}.$$

For, putting P for the first member, and multiplying all the terms by 2 cos. $\varphi$, and transforming the results by the formula 2 cos. $a$ cos. $b$ = cos. $(a-b)$ + cos. $(a+b)$ (sect. 238), we shall have 2 P cos. $\varphi$

$$= \left\{\begin{array}{l}1 + 2\cos. 2\varphi + 2\cos. 4\varphi + 2\cos. 6\varphi + 2\cos. 8\varphi \\ + 2\cos. 10\varphi + 2\cos. 12\varphi + 2\cos. 14\varphi + \cos. 16\varphi.\end{array}\right.$$

But since $17\varphi = \pi$, therefore cos. $2\varphi$ = cos. $(\pi - 15\varphi)$ = — cos. $15\varphi$; cos. $4\varphi$ = cos. $(\pi - 13\varphi)$ = — cos. $13\varphi$, and so on, to cos. $16\varphi$ = — cos. $\varphi$; therefore

$$2 \text{P} \cos. \varphi = 1 - 2\cos. 15\varphi - 2\cos. 13\varphi \ldots - 2\cos. 3\varphi - \cos. \varphi;$$

$$\text{or } 2 \text{P} \cos. \varphi = 1 + \cos. \varphi - 2 \text{P},$$

$$\text{or } 2 \text{P} (1 + \cos. \varphi) = 1 + \cos. \varphi, \text{ hence } \text{P} = \tfrac{1}{2}.$$

This being proved, we now divide the terms which compose P into two parts,

$$x = \cos. 3\varphi + \cos. 5\varphi + \cos. 7\varphi + \cos. 11\varphi,$$

$$y = \cos. \varphi + \cos. 9\varphi + \cos. 13\varphi + \cos. 15\varphi.$$

We have therefore $x + y = \frac{1}{2}$. We next multiply the four terms of $x$ by the four terms of $y$, and changing the products of cosines into the cosines of simple arcs, we obtain, all reductions being made,

$$xy = \phantom{-}2 (\cos. 2\varphi + \cos. 4\varphi + \cos. 6\varphi \ldots + \cos. 16\varphi),$$

$$\text{or } xy = -2 (\cos. 15\varphi + \cos. 13\varphi + \cos. 11\varphi \ldots + \cos. \varphi),$$

or at last $xy = -1$.

By these equations we obtain

$$x = \tfrac{1}{4} + \tfrac{1}{4}\sqrt{17}, \qquad y = \tfrac{1}{4} - \tfrac{1}{4}\sqrt{17}.$$

Now, if we divide anew the sums $x$ and $y$ into two parts, viz.

$$x = s + t, \qquad y = u + z,$$

$$s = \cos. 3\varphi + \cos. 5\varphi, \quad u = \cos. \varphi + \cos. 13\varphi,$$

$$t = \cos. 7\varphi + \cos. 11\varphi, \quad z = \cos. 9\varphi + \cos. 15\varphi.$$

We obtain in like manner,

$$st = -\tfrac{1}{4}, \qquad uz = -\tfrac{1}{4}:$$

so that we may now determine the four numbers $s, t, u, z$, by means of two new equations of the second degree.

Lastly, knowing cos. $\varphi$ + cos. $13\varphi = u$, and cos. $\varphi$ cos. $13\varphi$ $= \frac{1}{2}(\cos. 12\varphi + \cos. 14\varphi) = -\frac{1}{2}(\cos. 3\varphi + \cos. 5\varphi) = -\frac{1}{2}s$, we may obtain by a fourth equation of the second degree the value of cos. $\varphi$, and thence the side of the polygon, which is 2 sin. $\varphi = 2\sqrt{1 - \cos.^2 \varphi}$.

As to the method which has guided us in forming these equations, it depends on a very delicate theory, founded on the Indeterminate Analysis. For this we must refer to the work of Gauss, *Disquisitiones Arithmeticæ;* or the French translation, *Recherches Arithmétiques.* (W. W.)

---

ALGEMESI, a town of Spain, in the province of Valencia, on the river Jucar, 21 miles S.S.W. of Valencia. Its chief products are rice and silk. Pop. 4492.

ALGENIB, or $\gamma$ *Pegasi*, a star of 2·3 magnitude, in the wing of Pegasus: R.A. January 1. 1853, 0 h. 5 m. 40·25 sec.; N. Decl. 75° 38′ 1·85″.

ALGER, a learned French priest, who lived between the eleventh and twelfth centuries. He was first a deacon of the church of St Bartholomew at Liége, his native town; he was afterwards translated to the cathedral church of St Lambert, and finally retired to the monastery of Cluny, where he died in 1131. His History of the Church of Liége, and many others of his works, are lost, but there still exist of his: 1. *De Misericordia et Justitia*, a collection of extracts from Fathers, with reflections. It is to be found in the *Anecdota* of Martene, vol. v. 2. *De Sacramento Corporis et Sanguinis Domini;* a treatise in three books, against the Berengerian heresy, highly commended by Peter of Cluny and Erasmus. 3. *De libero arbitrio;* given in Pezius' *Anecdota*, vol. iv. 4. *De Sacrificio Missae;* given in the *Collectio Scriptor. Vet.* of Angelo Mai, vol. ix.

ALGEZIRAS, a city of Andalucia in Spain, on the western side of the bay of Gibraltar, and opposite to that fortress. It is situated at the foot of a high mountain called the Trocha, over which there is only one line of road, which is excessively bad. Algeziras derives its name from the Arabic *al-ghezeirah* (the island), on account of Isla Verde, a small islet that forms one side of its harbour. It was founded by Tarik, the moorish general who invaded Spain in 713; and was a place of note in the wars of the Moors and Christians of Spain. It was taken from the Moors in 1344 by Alphonso XI. of Castile, surnamed *The Avenger*, after an obstinate siege, in which Mariana says gunpowder was first used by the Moors in the wars of Europe. "The Earls of Derby and Salisbury were there from England:" this Earl of Derby was John of Gaunt, son of Edward III.

Alghalib-Billah || Alghisi.

During the famous siege of Gibraltar, in 1780–81–82, Algeziras was the station of the Spanish fleet and floating batteries. It is now a place of far less importance, and its fortifications have entirely gone to decay. It has a few manufactures of coarse linen, cotton, paper, leather, and culinary utensils, and exports charcoal made in the mountains around. The chief occupations of its inhabitants are fishing and smuggling. An aqueduct supplies the place with water. Pop. 11,000. Long. 5. 26. 4. W. Lat. 36. 8. N.

ALGHALIB-BILLAH, or THE CONQUEROR FOR THE CAUSE OF GOD, also called ALAHMAR, or *the Red Man*, the surname of Mohammed-ben-Yusuf-ben-Nasr, the first Moorish sovereign of Granada. He was born in the province of Jaen in Spain, A.D. 1195, and died in 1273, after a reign of forty-two years. On the decline of the empire of the Almohades in Spain, the governors of the several provinces declared themselves independent. Mohammed, following the general example, caused himself to be proclaimed sultan of Mahometan Spain; and after subduing various towns, established himself at Granada as the capital of his dominions. He was long the ally, and afterwards the vassal of the king of Castile. He encouraged learning, arts, and manufactures among his subjects; Granada was by him adorned as became the capital of a powerful sovereign; and in his reign the famous palace of the Alhambra was begun. The dynasty of which he was the founder reigned in Granada for two centuries, and ended with Boabdil, who was dethroned by Ferdinand and Isabella in 1492.

ALGHAZZALI, ABU HAMED MOHAMMED EBN MOHAMMED, commonly called ALGAZEL, a celebrated Arabian divine and philosopher, born at Tús in Khorassan, A.D. 1058. After studying at Nisapur and elsewhere, he settled at Baghdad, as a teacher of theology in the college of that city. After four years he embraced the monastic life, and retired to Mecca, where he spent many years in the study of philosophy and theology. Thence he travelled through Syria, Palestine, and Egypt, visiting Damascus, Jerusalem, Cairo, and Alexandria. He finally returned to Tús, and after some years retired to Baghdad, where he died, A.D. 1111.

Algazel was one of the most eminent and voluminous of Arabian writers. In his attempt to establish Mahometan theology on a philosophical foundation, he made himself obnoxious on the one hand to the orthodox Mahometans, and on the other to the followers of Aristotle. To the one he appeared as a heretic; to the other as a philosophical sceptic in the garb of a divine. In his celebrated treatise, entitled the *Destruction of the Philosophers*, he attacks the doctrines of Aristotle and the other Greek philosophers, attempting to show from their mutual want of agreement the uncertainty of philosophical principles, and the necessity of a refuge in religious faith. This was replied to by Averroes in his *Destruction of the Destruction*. A list of Algazel's numerous works on metaphysics, morals, and religion, is given in Casiri's *Bibl. Arab. Hisp. Escur*.

ALGHERI, or AGHUER, a strongly-fortified city on the island of Sardinia, in the district called Capo di Sassari. It is the see of a bishop, has a cathedral, seven monasteries, and 8000 inhabitants, who speak the Catalan language. Their chief occupation is cultivating vineyards. About a league from the city is the fine roadstead or open bay, Porto Conte, where a fleet can anchor securely and be defended by a strong fort.

ALGHISI, or ALGISI, FRANCESCO, an Italian musical composer, was born at Brescia in 1666, and died there in 1733. He was organist of the cathedral in his native city, and composed, during a residence at Venice, two operas, which had great success. In his latter years, his severe abstinence procured him the reputation of a saint.

ALGHISI, *Galeazzo*, an eminent Italian architect, of the latter end of the sixteenth century. He was a native of Carpi, in Modena, and held the office of architect to the Duke of Ferrara, for whom he designed a magnificent palace. His work, *Della Fortificazione*, on military architecture, published at Venice in 1570, was the best architectural production that had then appeared.—*Tiraboschi, Storia.*

Alghisi || Algiers.

ALGHISI, *Tomasso*, an eminent Italian surgeon, especially celebrated as a lithotomist. He was born at Florence in 1669, and died in 1713. He studied anatomy under Lorenzo Bellini, and surgery under his father, who was surgeon to the hospital of Sta Maria Nuova, at Florence. In 1703, he received his degree of Doctor at Padua, from the celebrated Vallisnieri. He afterwards became professor of surgery in his native town. His work, entitled *Litotomia, ovvero del cavar la Pietra*, published at Florence in 1707, and at Venice in 1708, with plates by himself, describes his treatment of lithotomy.—*Mazzuchelli Scritt. d'Italia.*

ALGIABARII, a Mahometan sect of predestinarians, who attribute all the actions of men, good or evil, to the agency of God. They stand opposed to the ALKADARII.

ALGIDUS, a mountain range of Latium in Italy, between Præneste and the Mons Albanus. On the top of one of these mountains was erected a temple of Diana, to which Horace refers, lib. i. ode 21, "*Quæcunque aut gelido prominet Algido;*" and lib. iii. ode 23, "*Quæ nivali pascitur Algido,*" &c.

ALGIERS, or ALGERIA, an extensive country of northern Africa bordering on the Mediterranean, formerly an independent kingdom, but now a dependency of France. It extends from Long. 2. 20. W. to 8. 45. E., and is bounded on the north by the Mediterranean, on the west by Marocco, on the south by the great desert of the Sahara, and on the east by Tunis; but, indeed, except along the coast, the exact boundaries of the country are very undefined. Boundaries

Algiers is traversed by lofty ranges of the Atlas mountains, running nearly parallel to the coast, and rising in some places to the height of upwards of 7000 feet, with deep valleys and extensive plains. Some of the mountains rise abruptly from the sea, and the coast generally is steep and rocky, abounding in capes and gulfs: but it is very deficient in good harbours, and even in secure roadsteads, in consequence of its exposure to the north winds. Mountains.

The rivers of Algiers are numerous, and generally assume the character of mountain torrents, rushing with great impetuosity from the elevations through deep and rocky channels. During the rainy season they are much swollen, which, from the present deficiency of sufficient bridges, renders communication with the different parts of the country extremely difficult. The most important river, both from the length of its course, and the volume of its waters, is the Chelif. It rises in the Djebel Amûr, takes first a northern, and afterwards a western direction, flows through Lake Titterie, and finally empties itself into the Mediterranean, near Mostagan, after a course of nearly 300 miles; during which it receives numerous tributary streams. The Seibouse is formed by the union of several small brooks in the interior of the province of Constantine, south of the town of that name, and after a course of about 120 miles reaches the Mediterranean at Bona. The Oued-el-Kebir or Rummel rises west of Constantine, passes that town, and then pursues a north-westerly course to the sea. Among the less important rivers which empty themselves into the Mediterranean are the Harrach, Isser, Mazafran, Tafna, and Macta. Besides these there are a number of streams in the interior; but they are less known, and are generally dry except in the rainy season. Rivers.

Algiers abounds in extensive lakes and marshes. Of the lakes in the northern part of the country, near the coast, are the Fezara, fourteen miles south-west of Bona; the two Lakes.

Algiers. lakes Sebgha and El-Melah, south of Oran; three small lakes in the immediate vicinity of the Calle, and several others. In the southern parts of the country are the extensive lakes of Chott-el-Harbi or Western Chott; the Chott-el-Chergui or Eastern Chott; the Zarhez Gherbi; and the Zarhez Chergui; the Grand Sebkha-el-Chott, and a number of others. They are mostly dried up in summer, leaving a thick stratum of salt. Many of the marshes, especially in the neighbourhood of the larger towns, have been drained by the French, thus improving considerably the salubrity of the climate. There are also a number of warm mineral springs, principally containing salts of lime, which are used with success by the Arabs in several kinds of diseases. Some of these are in the vicinity of the Calle, Bougie, Miliana, &c.

Plains. It has several fertile and well-watered plains; the principal, that of Metidja, immediately south of Algiers, is about 50 miles long by 20 broad.

Minerals. The mineral wealth of the country is considerable. Iron is very plentiful, and mines of copper, lead, silver, antimony, and coal, are wrought. Salt is obtained in great abundance from many of the lakes and marshes.

Climate. The nature of the climate varies considerably with the elevation. In the northern parts of the country it very much resembles that of the south of Spain, while in the Sahara the heat is frequently excessive. In the more elevated parts the winter is frequently severe; but along the coast it is mild, though often attended with heavy rain, and sometimes in such torrents as in a few hours to exceed the quantity falling at Paris in a whole year. The hottest month is August. In general, with the exception of places in the vicinity of the marshes, it is not unhealthy for Europeans. At Algiers the mean temperature is from 70° to 75° Fahr.; in summer averaging 86°, and in winter from 55° to 65°.

Productions. The vegetation generally resembles that of southern Europe. It has extensive forests of various species of oak, pine, cedar, elm, olive, &c. The trees are frequently of gigantic size, especially the cedars and oaks; but great injury is often done to the forests, by the inhabitants annually burning up the grass of their fields; and thus sometimes the most beautiful forests are consumed. The want of roads and navigable rivers, has, as yet, prevented the French from deriving much benefit from the forests. Among the fruits are oranges, lemons, pomegranates, dates, peaches, melons, &c.: wheat, barley, cotton, sugar-cane, and tobacco, are also extensively cultivated. In the animal kingdom, there is little particularly deserving of notice. Lions were formerly very plentiful, but they are now nearly extirpated; leopards are still common, and in the south are many jackals and hyænas. The chief wealth of most of the Arab tribes consists in their sheep, of which they frequently possess immense flocks; horses, mules, and camels, are also abundant, and of superior quality. Coral and sponge fishing is extensively prosecuted along the coast.

Divisions. Algiers was formerly divided into four provinces, viz., Constantine, Algiers, Oran, and Tittcrie: at present it is divided into three, Algiers, Oran, and Constantine. These provinces are divided into districts, and each district is subdivided into one or more circles. By the natives it is divided into the *Tell* or green country, in the north, and the *Date country*, in the south.

Population The population of Algiers is estimated at about 3,000,000. At the close of 1850, the European population was 125,963; and in the preceding year 112,607; of whom 58,005 were French, 6943 Anglo-Maltese, 33,659 Spaniards, 6986 Italians, 2515 Germans, 1253 Swiss, and 3246 of other nations. The increase of the European population is caused by immigration, as for several years the deaths have exceeded the births. In 1847, 1848, 1849, the deaths were 5163, 4835, 10,493; the births in the same years were 4283, 4347, 5206. The great mortality of 1849 was occasioned by cholera. The indigenous population residing in the towns in 1849, amounted to 84,133, being 60,928 Turks, 4177 Negroes, and 19,028 Jews.

Races. Besides the Europeans there are eight distinct races inhabiting Algiers. *1st*, The Arabs, the most numerous race in Algiers, inhabit the southern part of the country, and lead a pastoral life. They are the most unsettled and turbulent of the Algerine population, but are at the same time sprightly and intelligent. *2d*, The Kabyles or Berbers are next to the Arabs in point of numbers, and are descendants of the aboriginal inhabitants of the country. They occupy chiefly the more elevated and mountainous parts, but numbers of them also inhabit the plains and valleys: they are an active, industrious race, and principally engaged in husbandry. *3d*, The Moors, a mixed race, inhabiting principally the towns. *4th*, The Jews, also inhabiting the towns, and engaged in mercantile pursuits. They are supposed to amount to about 80,000. *5th*, Negroes, originally brought from the interior, and sold as slaves. They were declared free in 1848, and are estimated at 80,000. *6th*, The Turks, the former dominant race, are now decreasing rapidly. A great number of them left the country when it came into the hands of the French. *7th*, The Kolouglis, who are the descendants of Turks by native women, are also decreasing, and at present are about 20,000. *8th*, The Mozabites, an African race now principally inhabiting the coast towns. They are a peaceable, honest, and industrious race, chiefly engaged in manual labour.

History. The Algerine kingdom made formerly a considerable part of the Mauritania Tingitana, which was reduced to a Roman province by Julius Cæsar, and from him also called *Mauritania Cæsariensis*. The Romans were driven out of that continent by the Vandals; these by Belisarius, the Greek emperor Justinian's general; and the Greeks in their turn by the Saracens. This last revolution happened about the middle of the seventh century; and the Arabs continued masters of the country, divided into a great number of petty kingdoms or states, under chiefs of their own choosing, till the year 1051. In this year Abubeker-ben-Omar, or, as the Spanish authors call him, Abu-Texefien, an Arab of the Zinhagian tribe, gathered, by the help of his marabouts or saints, a most powerful army of malcontents, in the southern provinces of Numidia and Libya. His followers were named Marabites or Morabites, by the Spaniards Almoravides, probably from their being assembled principally by the saints, who were also called Morabites. The caliph's forces were at this time employed in quelling other revolts in Syria, Mesopotamia, &c.; and the Arabs in Spain were engaged in the most bloody wars; so that Texefien having nothing to fear from them had all the success he could wish against the Arabian sheiks or petty tyrants, whom he defeated in many battles, and at last drove not only out of Numidia and Libya, but out of all the western districts, reducing the whole province of Tingitania under his dominion. Texefien was succeeded by his son Yusef or Joseph, a brave and warlike prince. He founded the city of Marocco; and engaging in war with the Zeneti, a powerful tribe who inhabited Tremecen, defeated them in repeated engagements, and finally almost exterminated them. He then extended his conquests over almost all Barbary. Thus was founded the empire of the Morabites, which, however, was of no long duration, that race being in the twelfth century driven out by Mohavedin, a marabout. This race of priests was expelled by Abdulac, governor of Fez; and he in the thirteenth century was stripped of his new conquests by the Scherifs of Hascen, the descendants of those Arabian princes whom Abu-Texefien had formerly expelled.

Algiers.

The better to secure their new dominions, the Scherifs divided them into several little kingdoms or provinces; and among the rest, the present kingdom of Algiers was divided into four, namely, Tremecen, Tenez, Algiers Proper, and Bujeiah. The first four princes laid so good a foundation for a lasting balance of power between their little kingdoms, that they continued for some centuries in mutual peace and amity; but at length the king of Tremecen having ventured to violate some of their articles, Abul-Farez, king of Tenez, declared war against him, and obliged him to become his tributary. This king dying soon after, and having divided his kingdom among his three sons, new discords arose, which Spain taking advantage of, sent a powerful fleet and army against Barbary, under the count of Navarre, in 1505. This commander soon made himself master of the important cities of Oran, Bujeiah, and some others. Finally, he landed a number of forces near Algiers, and obliged that metropolis to become tributary to Spain.

Barbarossa.

To this galling yoke the Algerines were obliged to submit till the year 1516, when, hearing of the death of Ferdinand, king of Spain, they sent an embassy to Aruch Barbarossa, who was at that time on a cruise with a squadron of galleys and barks, spreading terror wherever he appeared by his valour and success. The purport of the embassy was, that he should come and free them from the Spanish yoke; for which they agreed to pay him a gratuity answerable to so great a service. Upon this Barbarossa immediately despatched 18 galleys and 30 barks to the assistance of the Algerines, while he himself advanced towards the city with 800 Turks, 3000 Jegelites, and 2000 Moorish volunteers. Instead of taking the nearest road to Algiers, he directed his course towards Shershel, where Hassan, another famed corsair, had established himself. Him he surprised, and obliged to surrender, not without a previous promise of friendship; but no sooner had Barbarossa got him in his power, than he beheaded him, and obliged all Hassan's Turkish adherents to follow him in his new expedition.

On Barbarossa's approach to Algiers, he was welcomed by all the people of that metropolis, who looked for deliverance from this daring bandit, whom they accounted invincible. Elated beyond measure with this kind reception, Barbarossa formed a design of becoming king of Algiers; and fearing some opposition from the inhabitants, on account of the excesses he suffered his soldiers to commit, he murdered their prince Eutemi, and caused himself to be proclaimed king; his Turks and Moors crying out as he rode along the streets, "Long live King Aruch Barbarossa, the invincible king of Algiers, the *chosen of God* to deliver the people from the oppression of the Christians; and destruction to all that shall oppose or refuse to own him as their lawful sovereign." These threatening words so intimidated the inhabitants, already apprehensive of a general massacre, that he was immediately acknowledged as king.

Barbarossa was no sooner seated on the throne, than he treated his subjects with such cruelty, that they used to shut up their houses and hide themselves when he appeared in public. In consequence of this, a plot was soon formed against him; but having discovered it, he caused twenty of the principal conspirators to be beheaded, and their bodies to be buried in a dunghill, and laid a heavy fine on those who survived. This so terrified the Algerines, that they never afterwards dared to attempt anything against either Barbarossa or his successors.

In the mean time the son of Prince Eutemi, having fled to Oran, and put himself under the protection of the marquis of Gomarez, laid before that nobleman a plan for putting the city of Algiers into the hands of the king of Spain. Cardinal Ximenes, having approved of it, sent a fleet with 10,000 land forces, under the command of Don Francisco, or, as others call him, Don Diego de Vera, to drive out the Turks, and restore the young prince; but the fleet no sooner came within sight of land than it was dispersed by a storm, and the greater part of the ships dashed against the rocks. Most of the Spaniards were drowned, and the few who escaped to the shore were either killed by the Turks or made slaves.

Though Barbarossa had nothing to boast on this occasion, his pride and insolence had now risen to such a pitch, that he imagined himself invincible. He found little difficulty in conquering the kingdoms of Tenez and Tremecen. Abuchen Men, however, the exiled sovereign of Tremecen, had recourse to Charles V. then lately arrived in Spain with a powerful fleet and army. That monarch immediately ordered the young king a succour of 10,000 men, under the command of the governor of Oran, who, under the guidance of Abuchen Men, began his march towards Tremecen; and in their way they were joined by Prince Selim, with a great number of Arabs and Moors. The tyrant kept close in his capital, being embarrassed by his fears of a revolt, and the politic delays of the king of Fez, who had not sent the auxiliaries he promised. Being now informed that Abuchen Men and his Arabs, accompanied by the Spaniards, were in full march to lay siege to Tremecen, he thought proper to come out at the head of 1500 Turks and 5000 Moorish horse, in order to break his way through the enemy; but he had not proceeded far from the city before his council advised him to return and fortify himself in it. This advice was now too late, the inhabitants being resolved to shut him out, and open their gates to their own lawful prince as soon as he appeared. In this distress Barbarossa saw no resource but to retire to the citadel. Here he defended himself vigorously; but his provisions failing, he took advantage of a subterraneous path, which he had caused to be dug, and, taking his immense treasure with him, stole away as secretly as possible. His flight, however, was soon discovered; and he was so closely pursued, that to amuse, as he hoped, the enemy, he caused a great part of his money, plate, jewels, &c. to be scattered on the way, thinking they would delay their pursuit in gathering it up. This stratagem, however, failed through the vigilance of the Spanish commander, who being himself at the head of the pursuers, obliged them to march on, till he came up close to him on the banks of the Huexda, about eight leagues from Tremecen. Barbarossa had just crossed the river with his vanguard, when the Spaniards came up with his rear on the other side, and cut them all off; and then crossing the water, overtook him at a small distance from it. Here a bloody engagement ensued, in which the Turks fought like lions; but being at length overpowered by numbers, they were all cut in pieces, and Barbarossa among the rest, in the 44th year of his age, and four years after he had raised himself to the royal title of *Jigel*.

Succeeded by Hayradin.

The news of Barbarossa's death spread the utmost consternation among the Turks at Algiers; however, they caused his brother Hayradin to be immediately proclaimed king. The Spanish commander now sent back the emperor's forces, without making any attempt upon Algiers, by which he lost the opportunity of driving the Turks out of that country; while Hayradin, justly dreading the consequences of the tyranny of his officers, sought the protection of the grand signior. This was readily granted, and he himself appointed bashaw or viceroy of Algiers; by which means he received such considerable re-

Algiers.

inforcements, that the unhappy Algerines could attempt no resistance; and such numbers of Turks resorted to him, that he was able not only to keep the Moors and Arabs in subjection at home, but to annoy the Christians at sea.

Hayradin next undertook to build a strong mole for the protection of his ships. In this he employed 30,000 Christian slaves, whom he obliged to labour without intermission for three years, in which time the work was completed. Hayradin soon became dreaded, not only by the Arabs and Moors, but also by the maritime Christian powers, especially the Spaniards. The viceroy failed not to acquaint the grand signior with his success, and obtained from him a fresh supply of money, by which he was enabled to build a strong fort, and to erect batteries on all places that might favour the landing of an enemy. All these have since received greater improvements from time to time.

Succeeded by Hassan Aga.

In the mean time the sultan, either out of a sense of the great services Hayradin had rendered, or perhaps out of jealousy lest he should make himself independent, raised him to the dignity of bashaw of the empire, and appointed Hassan Aga, a Sardinian renegado, an intrepid warrior, and an experienced officer, to succeed him as bashaw of Algiers. Hassan had no sooner taken possession of his new government, than he began to pursue his ravages on the Spanish coast with greater fury than ever, extending them to the Ecclesiastical State, and other parts of Italy. Pope Paul III. exhorted the emperor Charles V. to send a powerful fleet to suppress these frequent and cruel piracies; and, that nothing might be wanting to render the enterprise successful, a bull was published by his holiness, in which a plenary absolution of sins, and the crown of martyrdom, were promised to all those who either fell in battle or were made slaves. The emperor accordingly set sail at the head of a powerful fleet, consisting of 120 ships and 20 gallcys, having on board 26,000 chosen troops, and an immense quantity of money, arms, ammunition, &c. In this expedition many young noblemen and gentlemen attended as volunteers, and among these many knights of Malta, so remarkable for their valour against the enemies of Christianity. Even ladies of birth and character attended Charles in his expedition; and the wives and daughters of the officers and soldiers followed them with a design to settle in Barbary after the conquest should be completed. The expedition meeting with a favourable wind, soon appeared before Algiers; every ship displaying the Spanish colours on the stern, and another at the head, with a crucifix to serve for a pilot.

Charles V.'s expedition against Algiers.

By this prodigious armament the Algerines were thrown into the utmost consternation. The city was surrounded only by a wall, with scarcely any outworks. The whole garrison consisted of 800 Turks and 5000 Moors, without firearms, and poorly disciplined and accoutred; the rest of their forces being dispersed in the other provinces of the kingdom, to levy the usual tribute on the Arabs and Moors. The Spaniards landed without opposition, and immediately built a fort, under the cannon of which they encamped, and diverted the course of a spring which supplied the city with water. Being now reduced to the utmost distress, Hassan received a summons to surrender at discretion, on pain of being put to the sword with all the garrison. He was on the point of surrendering the city, when advice was brought to him that the forces belonging to the western government were in full march towards the place; upon which it was resolved to defend it to the utmost. Charles, in the mean time, resolving upon a general assault, kept up a constant firing upon the town; which, from the weak defence made by the garrison, he looked upon as already in his hands. But while the douwan, or Algerine senate, were deliberating on the most proper means of obtaining an honourable capitulation, a mad prophet, attended by a multitude of people, entered the assembly, and foretold the speedy destruction of the Spaniards before the end of the moon, exhorting the inhabitants to hold out till that time. This prediction was soon accomplished in a very surprising and unexpected manner; for on the 28th of October 1541 a dreadful storm of wind, rain, and hail, arose from the north, accompanied with violent shocks of earthquake, and a dismal and universal darkness both by sea and land; so that the sun, moon, and elements seemed to combine together for the destruction of the Spaniards. In that one night, some say in less than half an hour, 86 ships and 15 galleys were destroyed, with all their crews and military stores, by which the army on shore was deprived of all means of subsistence. Their camp also, which spread itself along the plain under the fort, was laid quite under water by the torrents which descended from the neighbouring hills. Many of the troops, in endeavouring to remove into some better situation, were cut in pieces by the Moors and Arabs; while several galleys and other vessels, seeking to gain some neighbouring creeks along the coasts, were immediately plundered, and their crews massacred, by the inhabitants.

The next morning Charles beheld the sea covered with the fragments of his numerous ships, and the bodies of men and horses floating on the waves. Seeing his affairs desperate, he abandoned his tents, artillery, and all his heavy baggage, and marched in great disorder towards Cape Metafuz, in order to re-embark his troops in the few vessels which had survived the tempest. But Hassan, who had caused his motions to be watched, allowed him just time to get to the shore, when he sallied out and attacked the Spaniards in the midst of their confused and hasty embarkation, killing great numbers, and bringing away a still greater number of captives; after which he returned in triumph to Algiers, where he celebrated with great rejoicings his happy deliverance.

Its failure.

Charles having reached the port of Bujeiah on the 2d of December, was detained there by contrary winds for several weeks, whence he set sail for Carthagena, which he reached without further disasters. In this unfortunate expedition upwards of 120 ships and galleys were lost, with above 300 colonels and other land and sea officers, 8000 soldiers and marines, besides those destroyed by the enemy on the re-embarkation, or drowned in the last storm. The number of prisoners was so great that the Algerines sold some of them, by way of contempt, for an onion per head.

Hassan, elated with this victory, in which he had very little share, undertook an expedition against the king of Tremecen, who, being now deprived of the assistance of the Spaniards, was forced to procure a peace by paying a large sum of money, and becoming tributary to him. The bashaw returned to Algiers laden with riches, and soon after died of a fever, in the 66th year of his age.

From this time the Spaniards were never able to annoy the Algerines in any considerable degree. In 1555 they lost the city of Bujeiah, which was taken by Salha Rais, Hassan's successor, who next year set out on a new expedition, which was suspected to be intended against Oran; but he had scarcely got four leagues from Algiers, when the plague, which at that time raged violently in the city, carried him off in 24 hours.

Bashaws.

The dignity of bashaw passed through several hands, when it was occupied by Hassan, the son of Hayradin. Immediately on his arrival, he engaged in a war with the Arabs, by whom he was defeated with great loss. Next year the Spaniards undertook an expedition against

Algiers.

Mostagan, under the command of the count d'Alcandela; but were utterly defeated, the commander himself killed, and 12,000 men taken prisoners.

Hassan engaged in the siege of Marsalquiver, situated near the city Oran, which he designed to invest immediately after. The army employed in this siege consisted of 26,000 foot and 10,000 horse, besides which he had a fleet consisting of 32 galleys and galliots, together with three French vessels laden with biscuit, oil, and other provisions. The city was defended by Don Martin de Cordova, brother of the count d'Alcandela, who had been taken prisoner in the battle where that nobleman was killed, but had obtained his liberty from the Algerines with immense sums, and now made a most gallant defence against the Turks. The city was attacked with the utmost fury by sea and land, so that several breaches were made in the walls. The Turkish standards were several times planted on the walls, and as often dislodged; but the place must have in the end submitted, had not Hassan been obliged to raise the siege in haste, on the news that the famed Genoese admiral Doria was approaching with considerable succours from Italy.

In 1567 Hassan was recalled to Constantinople, where he died three years after. He was succeeded by Mahomet, who gained the love of the Algerines by several public-spirited actions. He incorporated the janizaries and Levantine Turks together, and by that means put an end to their dissensions, which paved the way for making Algiers independent of the Porte. He likewise added some considerable fortifications to the city and castle, which he designed to render impregnable. At this time one John Gascon, a bold Spanish adventurer, formed a design of surprising the whole piratical navy in the bay, and setting them on fire in the night-time. For this he not only had the permission of King Philip II., but was furnished by him with proper vessels, mariners, and fire-works, for the execution of his plot. He came accordingly, unperceived by any, to the very mole-gate, and dispersed his men with their fire-works; but, to their great surprise, they found these so ill mixed, that all their art could not make them take fire. In the mean time Gascon took it into his head, by way of bravado, to go to the mole-gate, and give three loud knocks with the pommel of his dagger. This he had the good fortune to do without meeting with any disturbance or opposition; but it was not so with his men; for on finding their endeavours unsuccessful, they made such a noise as quickly alarmed the guard posted on the adjacent bastion, from which the alarm quickly spread through the whole garrison. Gascon now finding himself in the utmost danger, sailed off with all possible haste; but he was pursued, overtaken, and brought back a prisoner to Mahomet, who no sooner got him into his power than he immediately caused a gibbet of considerable height to be erected on the spot where Gascon had landed, ordering him to be hoisted up, and hung by the feet to a hook, so that he died in exquisite torture.

Mahomet, being soon after recalled, was succeeded by the renegado Ochali, who reduced the kingdom of Tunis, which, however, remained subject to the viceroy of Algiers only till the year 1586, when a bashaw of Tunis was appointed by the Porte.

The kingdom of Algiers continued to be governed, till the beginning of the 17th century, by viceroys or bashaws appointed by the Porte, whose avarice and tyranny were intolerable both to the Algerines and the Turks themselves. At last the Turkish janizaries and militia became powerful enough to depose these petty tyrants, and set up officers of their own. They sent a deputation of some of their chief members to the Porte, to complain of the avarice and oppression of these bashaws, and represent how much more honourable, as well as more economical, it would be for the grand signior to permit them to choose from among themselves their own dey or governor, whose interest it would be to see that the revenue of the kingdom was duly employed in keeping up its forces complete, and in supplying all other exigencies of the state, without any further charge or trouble to the Porte than that of allowing them its protection. On their part, they engaged always to acknowledge the grand signior as their sovereign, to pay him their usual allegiance and tribute, to respect his bashaws, and to lodge and maintain them and their retinue. All concerns which related to the government of Algiers were to be left under the direction of the dey and his douwan.

Algerines choose their own dey.

These proposals having been accepted by the Porte, the deputies returned highly satisfied; and having notified their new privileges, the great douwan immediately proceeded to the election of a dey from among themselves. Altercations, however, frequently happened between the bashaws and deys, the one endeavouring to recover their former power, and the other to reduce it.

In the year 1601 the Spaniards, under the command of Doria, the Genoese admiral, made another attempt upon Algiers, in which they were more fortunate than usual, their fleet being only driven back by contrary winds, so that they came off without loss. In 1609 the Moors, being expelled from Spain, flocked in great numbers to Algiers; and as many of them were very able sailors, they undoubtedly contributed to raise the Algerine fleet to that formidable condition which it soon after reached; though it is probable the frequent attempts made on their city would also induce them to increase their fleet. In 1616 it consisted of 40 sail of ships between 200 and 400 tons, their flag-ship having 500 tons. It was divided into two squadrons, one of 18 sail, stationed before the port of Malaga, and the other at the cape of Santa Maria, between Lisbon and Seville, both of which attacked all Christian ships, both English and French, with whom they pretended to be in friendship, as well as Spaniards and Portuguese, with whom they were at war.

The Algerines were now become very formidable to the European powers. The Spaniards, who were most in danger, and least able to cope with them, solicited the assistance of England and other states, and of the pope. The French, however, were the first who dared to show their resentment of these outrages; and in 1617 M. Beaulieu was sent against the Algerines with a fleet of 50 men of war, who defeated their fleet and took two of their vessels, while their admiral sunk his own ship and crew rather than fall into his enemies' hands.

In 1620 a squadron of English men of war was sent against Algiers, under the conduct of Sir Robert Mansel; but of this expedition we have no other account than that it returned without effecting any thing; and the Algerines, becoming more and more insolent, openly defied all the European powers, the Dutch only excepted, to whom, in 1625, they sent a proposal directed to the prince of Orange, that in case they would fit out 20 sail of ships the following year, upon any good service against the Spaniards, they would join them with 60 sail of their own.

The next year the *Coulolies* or *Cologlies* (the children of such Turks as had been permitted to marry at Algiers), who were enrolled in the militia, having seized on the citadel, had nearly made themselves masters of the city, but were attacked by the Turks and renegadoes, who defeated them with terrible slaughter. Many of them were put to death, and their heads thrown in heaps

Algiers.

upon the city-walls, without the eastern gate. Part of the citadel was blown up; and the remaining Coulolies were dismissed from the militia, to which they were not again admitted till long after.

Throw off their dependence on the Porte.

In the year 1623 Algiers and the other states of Barbary threw off altogether their dependence on the Porte. No sooner was this resolution taken, than the Algerines began to make prizes of several merchant ships belonging to powers at peace with the Porte. Having seizéd a Dutch ship and polacre at Scanderoon, they ventured on shore; and finding the town abandoned by the Turkish aga and inhabitants, they plundered all the magazines and warehouses, and set them on fire. About this time Louis XIII. undertook to build a fort on their coasts, in the room of one formerly built by the Marsilians, which they had demolished. This, after some difficulty, he accomplished, and it was called the *Bastion of France;* but the situation being afterwards found inconvenient, the French purchased the port of La Calle, and obtained liberty to trade with the Arabians and Moors. The Ottoman court, in the mean time, was so much embarrassed with the Persian war, that there was no leisure to check the Algerine piracies. This gave an opportunity to the vizier and other courtiers to compound with the Algerines, and to share their prizes, which were very considerable. However, for form's sake, a severe reprimand, accompanied with threats, was sent them; to which they replied, that "these depredations deserved to be indulged to them, seeing they were the only bulwark against the Christian powers, especially against the Spaniards, the sworn enemies of the Moslem name;" adding, that "if they should pay a punctilious regard to all that could purchase peace, or liberty to trade with the Ottoman empire, they would have nothing to do but set fire to all their shipping, and turn camel-drivers for a livelihood."

In the year 1635 four younger brothers of a good family in France entered into an undertaking so desperate, that perhaps the annals of knight-errantry can scarcely furnish its equal. This was no less than to retort the piracies of the Algerines upon themselves, and this with a small frigate of ten guns! In this ridiculous undertaking 100 volunteers embarked: a Maltese commission was procured, together with an able master and 36 mariners. They had the good fortune, on their first setting out, to take a ship laden with wine on the Spanish coast, with which they were so much elated, that three days after they madly encountered two large Algerine corsairs, one of 20 and the other of 24 guns, both well manned, and commanded by able officers. These vessels attacked the frigate so furiously that she soon lost her main-mast; notwithstanding which, the French made so desperate a resistance, that the pirates were not able to take them, till the noise of their fire brought up five more Algerines, when the French vessel, being almost torn in pieces, was boarded and taken. The young knights-errant were punished for their temerity by a dreadful captivity, from which they redeemed themselves in 1642 at the price of 6000 dollars.

Various expeditions.

The Algerines prosecuted their piracies with impunity, to the terror and disgrace of the Europeans, till the year 1652, when a French fleet being accidentally driven to Algiers, the admiral took it into his head to demand a release of all the captives of his nation, without exception. This being refused, the Frenchman without ceremony carried off the Turkish viceroy, and his cadi or judge, who had just arrived from the Porte, with all their equipage and retinue. The Algerines, by way of reprisal, surprised the Bastion of France already mentioned, and carried off the inhabitants to the number of 600, with all their effects; which so provoked the admiral, that he sent them word that he would pay them another visit the next year with his whole fleet.

The Algerines, undismayed by the threats of the French admiral, fitted out a fleet of 16 galleys and galliots, well manned and equipped, under the command of Admiral Hali Pinchinin. The chief design of this armament was to capture the treasure of Loretto, which, however, they were prevented by contrary winds from reaching. They then made a descent on Puglia, in the kingdom of Naples, where they ravaged the whole territory of Necotra, carrying off a vast number of captives. Thence steering towards Dalmatia, they scoured the Adriatic; and, having collected immense plunder, left these coasts in the utmost consternation and resentment.

At last the Venetians, alarmed at such terrible depredations, equipped a fleet of 28 sail, under the command of Admiral Capello, with express orders to burn, sink, or take, all the Barbary corsairs he should meet. An engagement ensued, in which the Algerines were defeated, and five of their vessels disabled, with the loss of 1500 men, Turks and Christian slaves, besides 1600 galley-slaves who regained their liberty. Pinchinin, after this defeat, returned to Valona, where he was again watched by Capello; but the latter had not lain long at his old anchorage before he received a letter from the senate, desiring him to make no further attempt on the pirates at that time, for fear of a rupture with the Porte. The brave Venetian was forced to comply; but resolving to take such a leave of the Algerines as he thought they deserved, attacked them with such bravery, that, without any great loss, his men towed out their 16 galleys, with all their cannon, stores, &c. To conceal this, Capello was ordered to sink all the Algerine ships he had taken, except the admiral's, which was to be conducted to Venice, and laid up as a trophy. Capello came off with a severe reprimand; but the Venetians were obliged to purchase, with 500,000 ducats, a peace from the Porte.

The news of this defeat and loss filled Algiers with the utmost grief and confusion. The whole city was on the point of a general insurrection, when the bashaw and douwan issued a proclamation, forbidding complaints and outcries, under the severest penalties. In the mean time they applied to the Porte for an order that the Venetians settled in the Levant should make up their loss. But with this the grand signior refused to comply, and left them to repair their losses, as well as build new ships, in the best manner they could.

Our pirates did not long continue in their weak and defenceless state; being able, at the end of two years, to appear at sea with a fleet of 65 sail. Admiral Pinchinin equipped four galliots at his own expense, with which, in conjunction with the chiayah, or secretary of the bashaw of Tripoli, he made a second excursion. This small squadron, consisting of five galleys and two brigantines, fell in with an English ship of 40 guns, which, however, Pinchinin's captains refused to engage; but being afterwards reproached by him for their cowardice, they swore to attack the next Christian ship that should come in their way. This happened to be a Dutch merchantman of 28 guns, which, however, beat them off with great loss. But though Pinchinin thus returned in disgrace, the rest of the fleet quickly returned with vast numbers of slaves, and an immense quantity of rich spoils; insomuch that the English, French, and Dutch, were obliged to court the mighty Algerines, who sometimes vouchsafed to be at peace with them, but swore eternal war against Spain, Portugal, and Italy, whom they looked upon as the greatest enemies to the Mahometan name. At last

Algiers.

Louis XIV., provoked by the grievous outrages committed by the Algerines on the coasts of Provence and Languedoc, ordered, in 1681, a considerable fleet to be fitted out against them, under the marquis du Quesne, vice-admiral of France. His first expedition was against a number of Tripolitan corsairs, who had the good fortune to escape him, and shelter themselves in the island of Scio, belonging to the Turks. This did not, however, prevent him from pursuing them thither, and making such a terrible fire upon them as quickly destroyed fourteen of their vessels, besides battering the walls of the castle.

Algiers bombarded and set on fire by the French.

This severity seemed only to be designed as a check to the piracies of the Algerines; but, finding they still continued their outrages on the French coast, he sailed to Algiers in August 1682, cannonading and bombarding it so furiously, that the whole town was in flames in a very short time. The great mosque was battered down, and most of the houses laid in ruins, insomuch that the inhabitants were on the point of abandoning the place; when on a sudden the wind changed, and obliged Du Quesne to return to Toulon. The Algerines immediately made reprisals, by sending a number of galleys and galliots to the coast of Provence, where they committed the most dreadful ravages, and brought away a vast number of captives; upon which a new armament was ordered to be prepared at Toulon and Marseilles against the next year; and the Algerines, having received timely notice, put themselves in as good a state of defence as the time would allow.

In May 1683, Du Quesne, with his squadron, cast anchor before Algiers; where, being joined by the marquis d'Affranville at the head of five stout vessels, he resolved to bombard the town next day. Accordingly, 100 bombs were thrown into it the first day, which did terrible execution; while the besieged made some hundred discharges of their cannon without doing any considerable damage. The following nights the bombs were again thrown into the city in such numbers, that the dey's palace and other great edifices were almost destroyed; some of their batteries were dismounted, and several vessels sunk in the port. The dey and Turkish bashaw, as well as the whole soldiery, alarmed at this dreadful devastation, sued for peace. As a preliminary, the immediate surrender of all Christian captives who had been taken fighting under the French flag was demanded; which being granted, 142 of them were immediately delivered up, with a promise of sending the remainder as soon as they could be got from the different quarters of the country. Accordingly Du Quesne sent his commissary-general, and one of his engineers, into the town; but with express orders to insist upon the delivery of all the French captives without exception, together with the effects taken from the French; and that Mezomorto, the admiral, and Hali Rais, one of their captains, should be given as hostages.

This last demand having embarrassed the dey, he assembled the douwan, and acquainted them with it; upon which Mezomorto broke out into a violent passion, and told the assembly that the cowardice of those who sat at the helm had occasioned the ruin of Algiers; but that, for his part, he would never consent to deliver up any thing that had been taken from the French. He immediately acquainted the soldiery with what had passed; which so exasperated them, that they murdered the dey that very night, and next day chose Mezomorto in his place. The new dey immediately cancelled all the articles of peace, and hostilities were renewed with greater fury than ever.

The French admiral now kept pouring in such volleys of bombs, that in less than three days the greater part of the city was reduced to ashes; and the fire burnt with such vehemence, that the sea was illumined by it for more than two leagues around. Mezomorto, unmoved at all these disasters, and the vast number of the slain, whose blood ran in rivulets along the streets, or rather growing furious and desperate, sought only revenge; and, not content with causing all the French in the city to be cruelly murdered, ordered their consul to be tied hand and foot, and fastened alive to the mouth of a mortar, whence he was shot away. By this piece of inhumanity Du Quesne was so exasperated, that he did not leave Algiers till he had utterly destroyed their fortifications, shipping, almost all the lower, and above two-thirds of the upper part of the city, by which means it became little else than a heap of ruins.

Treaty with England.

The haughty Algerines were now thoroughly convinced that they were not invincible; they therefore immediately sent an embassy into France, begging in the most abject terms for peace, which Louis immediately granted, to their inexpressible joy. They now began to pay some regard to other nations, and to be a little cautious how they wantonly incurred their displeasure. The first bombardment by the French had so far humbled the Algerines, that they condescended to enter into a treaty with England, which was renewed upon terms very advantageous to the latter in 1686. It is not to be supposed, however, that the rooted perfidy of the Algerines would at once disappear. Notwithstanding this treaty, they lost no opportunity of making prizes of the English ships which they could conveniently reach. Upon some outrage of this kind, Captain Beach drove ashore and burnt seven of their frigates in 1695, which produced a renewal of the treaty five years after; but it was not till the taking of Gibraltar and Port Mahon that Britain could have a sufficient check upon them to enforce the observation of treaties, and they have since paid a greater deference to the English than to any other European power.

The eighteenth century furnishes no very remarkable events with regard to Algiers, except the taking of the city of Oran from the Spaniards in 1708 (which, however, they regained in 1737), and the expulsion of the Turkish bashaw, and uniting his office to that of dey, in 1710.

The increasing naval power of the great European states, in this century, made the Barbary corsairs more cautious in their attacks, which were now chiefly confined to the weaker states in the vicinity of the Mediterranean, particularly those of Naples and Sardinia;—not only attacking their vessels, but making descents upon their shores, and carrying off not only property but also persons of every age, sex, and rank, and disposing of them as slaves. Europe, engrossed by the mightier evils in which it was involved during thirty years of war, bestowed comparatively little attention on this partial distress. At the Congress of Vienna, however, when the peace of the Continent appeared to be established on a permanent basis, the attention of the sovereigns was laudably drawn to every quarter from which it could suffer disturbance. The evil in question, by which numerous individuals, often of a respectable place in society, were torn from their homes, immured in dungeons, and exposed to every outrage, could not fail to appear of the first magnitude. The Congress, having been unexpectedly broken up, did not come to any final decision. The subject, however, continued to be agitated in the councils of Britain, and her gallant officers who had been employed in the Mediterranean strongly represented the propriety of interference. The Dutch, at the same time, her now friendly neighbours, cordially concurred in promoting this common interest of humanity.

The first step taken was to send squadrons under Lord Exmouth to Algiers, and Sir Thomas Maitland to Tunis,

Algiers.

with a demand for the general liberation of the slaves actually in bondage, and the entire discontinuance, for the future, of this detestable trade. Overawed by the immense power with which they knew these demands to be supported, they returned a conciliatory answer. They dismissed a number of slaves actually in their hands, and engaged that only the final sanction of the Porte should be wanting to abolish for ever the system of Christian slavery. The British commanders then returned to England with their fleets, which were immediately laid up.

Tunis, which had imbibed some portion of European humanity and civilisation, and was better aware of its real interests and position, adhered very tolerably to the terms stipulated. But Algiers, bred in rapine, furiously repelled a system which opened to its rovers the fearful prospect of being obliged to earn a subsistence by honest industry. So dreadful was the ferment, that a plan, it is said, had been formed to assassinate Lord Exmouth on his way to the ship. The dey, raised from the dregs of the soldiery, and sharing all their barbarism, allowed full scope to their violence, and sought only to secure himself against its effects. He formed alliances with the Porte, the emperor of Marocco, and other leading Mussulman potentates; he strengthened Algiers with new works, and prepared to brave the utmost fury of the Christian powers. Under these precautions, the system of Christian piracy was commenced with redoubled activity, to compensate for the late suspension, and to repair the loss of the slaves who had been given up. The Algerine soldiery, in their blind fury, had recourse to an outrage still more terrible. A number of vessels, belonging to Naples and other Mediterranean states, had been in the practice of assembling at Bona to carry on the pearl fishery, in which, upon payment of an annual tribute, they were protected by the Algerine state. Suddenly these peaceful and industrious fishermen were surrounded by a band of Moors, who commenced an indiscriminate massacre, which could not be justified on any ground or pretence, and seems to have had no object but to show their implacable hatred to the Christian name.

Lord Exmouth's expedition.

As soon as the tidings of this dreadful outrage arrived in England, they kindled at once a just indignation, and a determination to follow up to the utmost the measures projected against this common pest of the civilized world. Lord Exmouth's fleet was re-equipped with almost incredible dispatch. Early in July 1816 he sailed with five ships of the line and eight smaller vessels, and arrived at Gibraltar in the beginning of August, when he was joined by a Dutch fleet of six frigates under Admiral Capellen. Having remained at Gibraltar a short time, to make some necessary preparations, Lord Exmouth sent forward Captain Dashwood, of the Prometheus, to bring away, if possible, the consul and his family. Captain Dashwood was strictly interrogated as to Lord Exmouth's armament, of which the dey had received information from a French vessel, and from other quarters. He contrived to evade the questions; and, though he found it impossible to obtain the consul's release, managed to bring off his wife and daughter, disguised in the uniform of naval officers. An attempt was also made to carry off his infant child in a basket, but it betrayed itself by its cries; however, the dey, with unusual humanity, allowed the child to follow its mother. The consul himself was thrown into close confinement. The dey, meantime, was exerting himself in the most extraordinary manner to put the place in a posture of defence. The batteries on the mole, and all other points commanding the harbour, were strengthened and enlarged; and armed men, to the number of forty thousand, were brought in from the surrounding country.

Algiers.

Lord Exmouth, being detained by calms and contrary winds, did not anchor in front of Algiers till the 26th, when he sent in a flag of truce under cover of the Severn gun-brig, with a peremptory demand of certain conditions, which, however, were extremely moderate. They consisted in the final abolition of Christian slavery—the immediate liberation of all slaves now within the territory of Algiers—the repayment of all ransoms obtained since the commencement of the year—the liberation of the consul and all British subjects now in confinement. On the Severn arriving in front of the mole, the captain of the port came out to meet the English, and invited them to enter the city. Salame, the interpreter, declined, but presented the conditions, demanding that an answer should be sent within an hour. The captain, not without some reason, replied that this was a period wholly inadequate to decide on so important a demand. Hereupon two or three hours were allowed; and two were declared by the captain to be sufficient. Meantime, a favourable breeze having sprung up, Lord Exmouth moved forward his ships to within a mile of the harbour, where he held himself ready for action. Salame waited three hours and a half, when no boat appearing from the land, he steered for the fleet, making signals of the failure of his mission; after which, steps were immediately taken for commencing operations.

Algiers was fortified in the strongest manner, and by all the resources of nature and art. The mole, considered a masterpiece of defensive architecture, was encircled by four batteries, respectively of 44, 48, 66, and 60 guns. All the range of steeps facing the sea, on which the city was built, were covered with batteries, which could keep up a united fire on an assailing fleet. Lord Exmouth, undismayed, bore up into the centre of this mighty line of defence, and placed the Queen Charlotte within fifty yards of the mole,—a bold and happy position, where her own fire was more effective than elsewhere, and many of the principal Turkish guns could not bear upon her. The other ships took their stations in line; while the Dutch squadron, which could not find room in front of the mole, was detached to the flanks, to occupy the fire of batteries which might otherwise have borne on the English. The fleets were placed in this formidable array, yet all was still silent, and the surrounding heights were crowded with spectators, who came as to a show. Lord Exmouth began to hope that the dey was yet to yield, when three shots were fired from the batteries. They were instantly returned, and a fire commenced, as animated and well supported as was ever witnessed. The British navy, pitched against these iron walls, underwent as hard and doubtful a struggle as it had ever maintained against the strongest array of hostile fleets. The atmosphere was filled with so thick a smoke, as to render it impossible for one ship to discern the position of another. About sunset Admiral Milne communicated that his vessel, the Impregnable, had lost 150 killed and wounded, and that he stood in urgent need of a frigate to divert some part of the fire now directed against them. Soon, however, the enemy's efforts began to slacken; the principal batteries were successively silenced; ship after ship caught fire, till the flame spread over the whole fleet, and reached the arsenal; the harbour and bay were illumined by one mighty and united blaze. At ten o'clock, seven hours after the commencement of this hard combat, the destruction of the Algerine naval force was complete; but as some distant batteries still kept up a harassing fire, Lord Exmouth gave the signal to steer out into the bay, which was speedily accomplished.

Next morning Lord Exmouth, confident that the dey was now sufficiently humbled, sent a letter, in which, after enumerating the heavy wrongs which had called forth this signal chastisement, he repeated the moderate terms already offered, adding, that in the event of their being now accepted, three guns should be fired as a signal. This letter was sent in the same boat as the day before, with instructions to wait three hours. As soon as the English boat was seen, another came out having on board the captain of a frigate, who received the letter, and intimated that there was no doubt of its terms being complied with; pretending even that, had a little longer time been allowed the day before, the conflict would have been unnecessary. Accordingly, in an hour and a half three shots were fired, and a boat immediately came out, on board of which were the captain of the port and the Swedish consul. All the demands were granted; and the dey in vain attempted, on various pretexts, to evade or delay their execution. The captives, to the number of 1083, were set at liberty; ransoms amounting to 382,500 dollars were repaid to Sicily and Sardinia; the consul was liberated, and received a compensation for the insults he had endured: in fine, a treaty was signed, by which the dey bound himself to discontinue the practice of Christian slavery, and hereafter to treat prisoners of war according to the established practice of civilized nations.

In this desperate contest the English lost 128 killed and 690 wounded, the Dutch 13 killed and 52 wounded. Lord Exmouth received two slight hurts, and his clothes were cut with several balls. The enemy lost four frigates, five large corvettes, and 30 gun-boats. All their arsenals were consumed, and their principal batteries reduced to a state of ruin. The city also was greatly injured, Salame having counted no less than thirty shots which had passed through the walls of the consul's house.

The Algerines, notwithstanding this severe and merited chastisement, did not long adhere to sentiments of moderation. No time was lost, and no effort spared to place the city in a more formidable state of defence than ever; and they considered themselves again in a condition to set even the great powers at defiance. Annoyances were begun against the French trade; and the consul having made remonstrances on the subject, was grossly insulted. France then declared war, and sent a fleet against Algiers; but the fortifications on the sea-side were so strong, that for more than a year her ships could only prolong an ineffective blockade. At length war on a great scale was resolved on. A large fleet under Admiral Duperre, and a land force of upwards of 30,000 men under General Bourmont, then minister at war, sailed from Toulon in the end of May 1830. After some delay in the bay of Palma in Majorca, this armament reached the coast of Africa, and the troops began to land on the morning of the 14th June, upon the western side of the peninsula of Sidi Ferruch, in the bay of Torre Chica. The disembarkation began at a quarter past four, and continued till twelve. The Algerines at first showed only flying parties of horse, which retreated before the fire of two steam-vessels. Afterwards they opened a somewhat brisk fire from several batteries, which having kept up for several hours, not without some loss on the part of the French, they retreated.

The army continued for some days landing their provisions and stores, with only slight annoyance from flying troops of cavalry. On the 19th, however, the Turkish troops in Algiers being reinforced by the contingents of the beys of Constantine, Oran, and Titterie, a general attack was made with a force of 40,000 or 50,000 men. They advanced, outflanking the French army, and charged with such impetuosity as to penetrate the line at several points. After a very obstinate conflict they were compelled to retreat, and their camp was taken and plundered. The French admit a loss of 60 killed and 450 wounded; and the son of the commander-in-chief died of his wounds.

The Algerine troops renewed their attacks on the 24th and 25th, when, after hard combats, they were again repulsed. The French then advanced upon Algiers; on the 29th the trenches were opened, and at four in the morning of the 4th July the batteries began their fire, which was returned with much vigour. At ten the fort called Emperor, being no longer defensible, was blown up by the enemy, with a tremendous explosion. The French commander took possession of its ruins, where he received a flag of truce: before the close of the day a treaty was concluded for the entire surrender of Algiers; and next day, 5th July, the French flag waved on its forts. Twelve ships of war, 1500 brass cannon, and L.2,028,500 sterling, came into the hands of the conquerors. The Turkish troops were permitted to go wherever they pleased, provided they left Algiers; and the dey chose Naples for his place of retirement, while most of the soldiers desired to be landed in Asia Minor.

The capture of Algiers was celebrated in France with great demonstrations of joy. This was the first military exploit of any brilliancy of which France could boast since the downfall of Napoleon. General Bourmont was raised to the rank of marshal, and Admiral Duperre was promoted to the peerage. The ministry had hoped by this war to render themselves popular with a people so enthusiastically fond of military glory, and to divert the public attention from their mal-administration. But three weeks after the capture of Algiers, the revolution of 1830 dethroned the elder branch of the house of Bourbon, and placed the crown on the head of the Duke of Orleans. On receiving intelligence of this event, the army in Algiers declared in favour of the revolutionists. General Clausel was appointed to succeed Marshal Bourmont, with instructions to reduce to obedience all the provinces dependent on Algiers, and to promote commerce and agriculture by encouraging the settlement of European emigrants. The new governor found himself placed in circumstances requiring the greatest prudence, both in his intercourse with the natives, and in his military operations. The French army, which had not been there three months, was already reduced, by the loss of 15,000 men, killed, wounded, or sick; and from the unsettled state of the country at home, the French government was unable to render him any efficient assistance. The conquerors, instead of attempting to gain the good will of the natives, had destroyed a number of their mosques, seized upon lands set apart for religious purposes, and attempted to introduce their own forms and usages in the place of those of the country,—the consequence of which was that the natives imbibed the greatest abhorrence of their oppressors, whom they looked upon as the enemies of God and their prophet. General Clausel incensed them still more by seizing upon the possessions of the dey, the beys, and the expelled Turks, in direct violation of the conditions on which the capital had been surrendered. Colonists, however, now began to arrive from Europe, particularly from France and Germany, and a model farm was laid out in the vicinity of Algiers for the purpose of instructing the inhabitants in the arts of cultivation. Bona was taken possession of, and an incursion made into the southern province of Titterie, when the troops of the bey were defeated, and Mediah taken. The beys of Titterie and Oran were deposed; the former being sent to France, and a pension of 12,000 francs granted him; and the latter to Alexandria. Clausel established tributary rulers in the provinces, and actively assisted them when attacked by the hostile Arabs, while he severely punished those who were faithless in their engagements to him. Still the war continued. Mediah was evacuated, and Oran abandoned. The French were incessantly harassed by irruptions of hordes of the

Arabs, so that no Frenchman was safe even in the vicinity of the town, and little reliance could be placed on the fidelity of the beys who governed the provinces. In these circumstances a corps of irregular Arab troops was organised; and Clausel entered into an agreement with the bey of Tunis, by which the provinces of Constantine and Oran were transferred to two brothers of the latter, on condition of their paying an annual tribute of a million of francs, and of their doing all in their power to promote the settlement of the French in the country. The French government, however, refused to sanction this treaty, on the ground that the governor had exceeded his powers. General Berthezene was now appointed commander-in-chief of the troops, although Clausel was still allowed to retain the title of governor of the colony. The warlike operations were continued during the ensuing spring and summer (1831), and several expeditions were made into the interior, to chastise the hostile tribes; but on the approach of the French troops, these wild hordes deserted their villages, dispersed themselves over the country, and again collecting, hung upon the rear of the army on its return.

In one of these expeditions (in June 1836) the French having gone to assist the new bey of Mediah whom the inhabitants refused to acknowledge, were attacked in their retreat by a numerous army of nomad tribes, which engaged them in incessant skirmishes, in which a great number of the French were slain. It was no longer possible to keep Belida and Mediah in subjection, and the newly-installed bey was obliged to take refuge in Algiers. In October Bona was surrounded and taken by the Kabyles. There was now no safety but in the town of Algiers; and the government found itself compelled, at the same time, to support the emigrants who had settled there. Agriculture was consequently neglected; and it was necessary to send to France for a supply of provisions, and for fresh troops.

The French government now determined to try the effect of a change in the administration of the colony, and entrusted the civil and military jurisdictions to distinct officers. Accordingly, in the end of the year 1831, Savary, Duke of Rovigo, was sent out as governor with an additional force of 16,000 men, and Baron Pichon was placed at the head of the civil administration of the colony; but in consequence of the conflicts between the two powers, they were both afterwards united in the hands of the governor. The determination of the French government to retain permanent possession of Algiers was now no longer doubtful.[1] The new governor, the Duke of Rovigo, did not disdain to have recourse to fraud and cruelty for the accomplishment of his purpose. Among his exploits was the extirpation of an Arab tribe, on account of a robbery committed by them, when not only the men, but the women and children were massacred in the night time; as were also two Arab chiefs, whom he had enticed into his power by a written assurance of safety. These proceedings still farther exasperated the natives, and those tribes which had hitherto remained quiet now embraced the cause of their countrymen.

About this time Abd-el-Kader first appears as an opponent to the French. For fourteen years, this chief, with a few nomadic Arab tribes, kept in check the forces of one of the most powerful nations of the world. His father, a marabout of the tribe of Hachem, had collected a few of the hostile tribes, and attacked and taken possession of Oran. On this the tribes wished to acknowledge him as their chief: but this, on account of his great age, he declined in favour of his son Abd-el-Kader, who, he said, united in himself all the qualities of intelligence, activity, valour, and piety, necessary to ensure success; farther adding, that in his journey to Mecca, an old *fakir* had predicted that his son would one day become sultan of the Arabs. Abd-el-Kader was born about the beginning of 1807, at the *ghetna* of his father, in the vicinity of Mascara. The *Ghetna* is a seminary where the marabouts instruct the young Arabs in literature, theology, and jurisprudence. Abd-el-Kader early distinguished himself in these branches, and soon acquired great reputation among his countrymen for his learning. Nor did he neglect those manly exercises for which the Arabs are distinguished, but was remarkable for his skill in horsemanship, and in throwing the lance and wielding the yatagan. He made two pilgrimages to Mecca in company with his father, once when only a child, and again in 1828, by which he obtained the title of *Hadji*. On his return he married a female whom he tenderly loved, and by whom he has two sons. He also visited Egypt, for the purpose of observing the civilisation which had been introduced there under Mahomet Ali. At the time that his father was proclaimed emir, he was living in obscurity, distinguished by the austerity of his manners, his piety, and his zeal in observing all the precepts of the Koran. Having resolved to devote himself to the defence of his country, he, by great exertions, collected an army of 10,000 horsemen, with whom, accompanied by his father, he marched to attack the town of Oran, which had been taken possession of by the French. They arrived before the town about the middle of May 1832; but after continuing their attack for three days with great bravery, they were repulsed with considerable loss.

Algiers.

In this first essay of Abd-el-Kader as a soldier, he is said to have conducted himself with extraordinary bravery. He several times threw himself into the thickest of the fight, to teach the Arabs not to dread the fire of the artillery. This enterprise was followed by a series of contests more or less severe between the parties, without any permanent or decided advantage being gained by either. In March 1833, the Duke of Rovigo was obliged, on account of his declining health, to return to France, and General Avizard was appointed interim governor; but the latter dying shortly afterwards, General Voirol was nominated his successor. Abd-el-Kader was still extending his influence more and more widely among the Arab tribes, and now resolved to subdue the whole province of Mascara. He accordingly marched to Tlemecen, which at that time was in the possession of two separate factions; the Turks occupying the citadel and the Moors the rest of the town. Abd-el-Kader began by attacking the Moors, whose chief soon took to flight, and the inhabitants surrendered the town. He treated them with great kindness, and set a new chief over them; but he was not equally successful with the Turks, who refused to surrender; and not having been able to force the citadel, he returned to Mascara, where he heard with great grief of the death of his father. The French now considered it their interest to offer the emir conditions of peace. A treaty was accordingly concluded with him by General Desmichels, governor of Oran; one of the conditions of

[1] When the French undertook the Algerine expedition, the Duke of Wellington's Ministry insisted upon and obtained from the French court pledges that France did not aim at the permanent possession of Algiers, but only to obtain satisfaction for the injuries and insults she had received, and to put down that system of piracy with which Europe had been so long outraged. The French Ministry engaged that these objects being accomplished, the final settlement and government of the country should be arranged in concert with the other European powers for the general advantage; and the Wellington Cabinet obtained a repetition of these assurances from Louis Philippe and his ministry immediately after their accession. Nevertheless, in the session of 1833, the French Ministry declared that it was the intention of their government to retain possession of Algiers and to colonise it.

Algiers.

which was, that the emir was to have a monopoly of the trade with the French in corn. This part of the treaty General Desmichels at first endeavoured to keep secret from the government; but they soon heard of it, from the disputes which arose, and the general was consequently removed from his post. Towards the end of 1834, Drouet Count d'Erlon was appointed governor-general of the colony; and under him were appointed a commander of the troops, a commander of the naval forces, and several other officers. Tribunals of justice were also established, by which both French and natives were allowed to enjoy their respective laws. From the tranquil state of the country at this time, the new governor was enabled to devote his attention to its improvement. The French soon became jealous of the power of the emir; and on the pretence that he had been encroaching on their territory, General Trezel, who had succeeded Desmichels in the governorship of Oran, was sent out against him with a considerable force. The two armies met at the River Macta, where the French army was routed with great slaughter on the 28th of June 1835. On the news of this defeat the government resolved effectually to humble Abd-el-Kader, and sent Marshal Clausel to Algiers for that purpose, where he arrived in August 1835. On the 26th November following, he set out, at the head of 11,000 men, for Mascara, which he reached on the 6th of the following month. On his arrival, finding the town totally deserted, he destroyed it, and afterwards returned to Algiers, persuading himself, if we may judge from his bulletins, that he had extirpated the Arab power. Some time after this the emir attacked General d'Arlanges and a company of 3000 men, on the Tafna. The contest was continued for some time with great vigour, but the French troops were at length put to flight. On this General Bugeaud was commissioned to put down the emir either by hostile or pacific measures. Conciliatory means having failed, he attacked the Arabs at the pass of Sikak, on the 6th of July 1836, and gained a complete victory over them; but not having sufficiently followed up this advantage, the emir in a few months had so far recovered himself that the French were fain to conclude a treaty with him, even on terms very advantageous to the Arabs. By the terms of this treaty, Abd-el-Kader was allowed to retain possession of those parts of the country that were already in subjection to him, with liberty to purchase from the French such military stores as he required; while on his side he was bound to acknowledge the sovereignty of France, and to deliver for the use of the French army a stipulated quantity of provisions. This treaty was concluded on the 30th of May 1837. Previous to this, however, Marshal Clausel made an unsuccessful attack upon Constantine. He arrived before the town after a very fatiguing march on the 21st of November 1836, with a force of about 9000 men. After several unsuccessful attacks upon the town, he was obliged to retreat. In this expedition he lost a great number of his soldiers through exhaustion and disease; and this failure occasioned his recal from his government. His successor, general Damremont, arrived on the 3d of April 1837; and after subjecting some tribes of the Kabyles who had revolted, he directed his attention to the capture of Constantine;—for which purpose he collected a force of 12,000 men, partly Europeans and partly natives. With this army he arrived before the town on the 6th of October without encountering any opposition on his march. The town was defended by 6000 or 7000 men, chiefly Kabyles, under the command of Ben Aissa, the deputy of the bey. After a very gallant defence, the town was taken by storm on the 13th of that month by General Vallée, General Damremont having been killed by a cannon ball on the preceding day. On the capture of the city, the neighbouring tribes hastened to make their submission to the conquerors; and a strong garrison being left to defend the town, the army retraced its steps to Bona, where it arrived on the 3d of November. As a reward for his services, General Vallée was made a marshal, and appointed governor-general of the colony. Disputes with the emir as to the boundaries of his territory were very frequent, until at length war was again declared between the parties. The French have endeavoured to fix upon the emir the infringement of both these treaties; but the truth seems to be, that it was occasioned by their jealousy of his growing power; and even some of themselves admit, that he can be accused of no breach of faith, and that, in both instances, the formal violation of the treaties was by the French. The emir, like a good general, had employed those intervals of peace in extending his influence among his subjects, chastising those tribes that refused to acknowledge him, and treating those who submitted to his authority with the greatest kindness. He set rulers and chiefs on whom he could depend over the divisions and subdivisions of his territory, and bestowed the greatest attention on the military training of his subjects.

The immediate cause of the war on this occasion was the marching of an armed force of French troops through the emir's territory. This the latter looked upon as an infringement of the treaty, and consequently declared war. On the 14th of December 1839, he fell upon the French troops in the plain of Metidja, and routing them with great slaughter, took and destroyed their settlements. He even advanced as far as the very walls of Algiers, and soon reduced their possessions to the fortified places which they occupied. On this the French army in Africa was augmented, and numerous skirmishes took place, without any decisive results to either party; the only thing worthy of notice being the gallant and successful defence, for four days, of Fort Mazagran, near Mostagan, by a garrison of 123 men, against from 12,000 to 13,000 of the enemy. The campaign was opened on the part of the French on the 25th of April 1840, when they set out with a considerable force to take possession of the towns of Mediah and Milianah. Although successful, the permanent results of this expedition were comparatively trifling. The garrisons left behind found themselves so surrounded by enemies that they could not trust themselves without their walls; and even when the French arms were successful at a distance, no one could consider himself secure immediately without the walls of Algiers. The French government being dissatisfied with Marshal Vallée's want of success, appointed General Bugeaud as his successor. The new governor-general arrived at Algiers on the 22d of February 1841. On opening the campaign, his first object was to provision Mediah and Milianah. Having accomplished this, he next marched at the head of 11,000 men to Jekedemt, the principal stronghold of Abd-el-Kader. When he arrived there on the 25th of May, he found it abandoned by its inhabitants; on which he ordered it to be destroyed, and the citadel, which had been built by the emir, to be blown up. From hence the general went to Mascara, which he entered on the 30th of the month. In October following, he set out for Laida, the only remaining stronghold in the possession of the emir, which he took, and entirely demolished. These misfortunes of the emir caused numerous defections among his subjects;—none of them now offered any opposition to the French, and several of them became their allies. The region towards the borders of Marocco being still unsubdued, an expedition was sent into that territory in January 1842. On the 30th of that month, they took the town of Tlemecen; and ten days afterwards the fort of Tafrua, which they demolished. The troops of Abd-el-Kader having been almost entirely destroyed by so many misfortunes, he was

Algiers.

obliged to take refuge in Marocco, and most of his subject tribes now submitted to the French. But Abd-el-Kader was not yet overcome: he appeared again with a small force, and going from tribe to tribe exhorted them, by all they held dear and sacred, to bestir themselves, and by one vigorous effort, to drive the invaders out of their country. By these means he was able to raise a considerable force; and he made up for the want of troops by the rapidity of his movements. He suddenly made an attack upon one part of the French territories, when he was supposed to be in quite a contrary direction, and even advanced to within a short distance of Mascara. An army was accordingly sent out against him, which advanced south as far as the sources of the Taguin, but without coming up to the enemy. On their retreat, however, a conflict took place at Isna, in which the Arabs were defeated, and the emir himself narrowly escaped being taken prisoner. On this the French troops returned to Mascara, in the end of November 1842. The emir now stirred up the Kabyles of Bougie to make an attack upon Cherchell. In this however they were baffled by the energetic proceedings of General Bugeaud, who did not hesitate to go in the middle of winter to the mountainous regions of the Jurjura to quell this insurrection. Though the colony was now in a comparatively quiet and secure state, this had only been accomplished at a vast expenditure of money, amounting to not less than L.60,000,000 sterling, and at a great sacrifice of human life, of which we may in some measure judge from the fact that, in the month of September, independently of the lives lost, out of 80,000 men, as many as 24,000 were lying in the hospitals. It is unnecessary to follow out the remaining struggles of the emir in Algiers. His forces were now so reduced, that he could not cope with the French in the open field, though he did not cease to harass them by incursions into their territories.

The emir was at length reduced to such straits, that he agreed to deliver himself up to the French, on receiving a promise of safety, and of being allowed to retire to Alexandria or to St Jean d'Acre. Notwithstanding this promise, which was given by General Lamoriciere, and ratified by the governor of the colony, the Duke d'Aumale, son of Louis Philippe, he and his suite were embarked at Oran for Toulon, where he arrived on the 29th of January 1848. From Toulon the emir was removed first to the chateau of Paris, and afterwards (in November) to the chateau of Amboise near Boise, where, till very recently, he was detained a prisoner. The emir, in December 1852, left France for Broussa, where he now lives in retirement, and is said to be devoting his time chiefly to reading the Koran, and religious exercises.

Since the removal of Abd-el-Kader from Algiers, the French power may be said to be established in the country; but even now skirmishes are not unfrequent with some of the more unsettled tribes. This possession has as yet turned out to be anything but a profitable speculation for France; and although it has been lately much improved, it is doubtful if, for many years to come, it will compensate for the immense sums of money and the loss of life that it has occasioned to that country.

Government.

Before giving an account of the present government of Algiers, it may be interesting to take some notice of it under the Turks. The bey or pasha, although nominally under the Porte, to whom he annually transmitted some presents, was in reality an absolute monarch. The first Beys were elected by the militia, who were then called the *douwan* or "common council." This body was at first composed of 800 militia officers, but was afterwards reduced to thirty *chiah-bashaws* or colonels, with the *mufti* or high priest, and *cadi*, or chief judge, upon some emergencies; and on the election of a dey the whole militia was allowed to vote. Latterly the power of this court was merely nominal, and it had only to sanction the measures of the dey. The dey rose from the army, and indeed any bold and aspiring soldier might attain that honour, if he succeeded in getting rid of the existing ruler. Thus the dey was continually exposed to attacks, and few of them had the good fortune to die in office. The new dey frequently established his power by causing to be strangled all the officers of the douwan who had opposed his election. Each of the three provinces, exclusive of Algiers, was governed by a bey nominated by the dey. The corsairs or pirates formed a number of small republics, of each of which the *rais* or captain was the supreme bashaw; who, with the officers under him, composed a kind of douwan, in which every question relating to the vessel was decided. These corsairs carried on likewise the commerce of Algiers, importing whatever commodities were brought into the kingdom either as merchandise or as prizes.

At present the country is under a governor-general, who is invested with the chief power in all the civil and military affairs. Each of the provinces has a prefect, under whom are sub-prefects for each of the districts, and under these, a number of native rulers over smaller divisions. Various courts of justice have been established, with a court of appeal in the capital, composed of two chambers—the one for civil, and the other for criminal cases. The natives are also still allowed their own courts and laws; and among the Jews, justice is administered by the rabbis.

Religion.

The Roman Catholic religion was established here in 1838. There is a cathedral in Algiers, and the Catholic worship is performed in almost every town, either in edifices built for the purpose, or in mosques which have been appropriated to that end. The Bishop of Algiers is assisted by four vicars-general, and eight canons, with a number of curates and vicars, amounting in 1849 to 114. There are four Protestant pastors in the country, established at the towns of Algiers, Douera, Blidah, and Oran. The Jews and Turks are also allowed the free exercise of their religious worship.

Education

Considerable attention is paid to education by the establishment of schools and other means. In 1850 there were 68 public, 39 private, and eight infant schools, attended by 9679 scholars, besides Mussulman and Jewish schools. There is also a college at Algiers, the capital; and in 1848 an academy was established there, at the head of which is a rector, who, assisted by an inspector, has the general superintendence of the public instruction.

Medical board.

The medical knowledge of the Arabs is in a very rude state, but latterly the French surgeons have been in great request among them. A medical board has been established near each Arab bureau; and the inhabitants come in great numbers to consult the physicians. Some tribes less subject to national prejudice even bring their wives, and consent that they should be visited by the French practitioners. The patients most seriously affected are received into the military hospitals, when they can surmount the repugnance to enter them. The officers of health likewise make frequent tours to visit the sick in their tents. Vaccination has spread with unexpected success. At first the Arabs refused to present their infants, because they believed that the object of the French was to fix a mark upon them by which they might afterwards recognise them and carry them into France as slaves or as soldiers. This distrust has now been overcome.

The Arab markets were always objects of vigilant surveillance, for it was there that all the reports hostile to the French originated and were propagated. To meet these fomenters of disorder, and to circulate intelligence of the administrative measures of the government, a journal is printed in the Arabic character, and distributed gratis among

Algiers. the chiefs. It is published every fortnight, and is sought after with great avidity; and has already produced the most beneficial effects.

Commerce. From the unsettled state of the country, the restrictions and heavy duties of the French tariff, and the poverty of the people, Algiers has as yet attained little commercial importance. The principal exports of the country are horses and cattle, skins of animals, leeches, wool, wax, coral, tobacco, and minerals. The exports of 1848 amounted in value to L.281,863, of which L.138,484 was the produce of the country, and L.143,379, was the re-exportation of French and foreign merchandise. The following were the proportions of the principal of its exports:—to France, 48·5 per cent.; Spain, 22·8; the Two Sicilies, 7·6; Sardinia, 6·8; England, 5·8; Tuscany, 5·5. The imports of the same year amounted to L.3,419,858, of which nearly a third consisted of cotton and woollen goods, and a fifth of grain. The following countries contributed to its imports as follows, viz.—France, 77·5 per cent.; Tuscany, 5·7; Turkey, 5·7; Spain, 4·9; England, 4·1. Army. The French troops in Algiers in 1850 amounted to 70,771 infantry, and 13,189 cavalry, 6437 native infantry, and 3422 cavalry, with a militia force of 16,407 men.—See *Tableaux de la situation des etablissements Français dans l'Algerie*, 1851.

ALGIERS, the capital of the above territory, is probably the ancient *Icosium;* by the Arabians called *Algezair*, or rather *Al-Jezier* or *Al-Jezerah*, i.e. *the island*, because there was an island before the city, to which it has since been joined by a mole. It is built of white stone, on the declivity of a hill fronting the sea, in the form of an amphitheatre; and from the sea resembles a ship under sail. The houses rise above each other in such a manner that each from its flat roof commands a view of the sea. The streets are so narrow as scarcely to admit two persons to walk abreast. But since the French conquest, about a fourth part of the old town has been superseded by new streets, lined with fine houses, shops, and hotels; and in the centre of the city is the *Place du Gouvernement*, a large and handsome square in the European style. The streets have all received French names; and in a population amounting in 1849 to 97,389, including the garrison, 72,393 were French or other Europeans, the rest Moors, Kabyles, Jews, &c. The town is the seat of a court of appeal and two courts of primary jurisdiction, has a public hospital, a chamber of commerce, library, and museum, a cathedral, and a Protestant church. Many shops have been opened by Europeans, but business is still mostly transacted in the bazaars; which, with barbers' shops and cafés, are the chief places of resort for the natives. Algiers is the residence of the governor-general of the French possessions in Africa, and of the principal functionaries, and courts of justice. It has been newly fortified, and is strongly garrisoned. It is well supplied with water: provisions are generally cheap, except bread, which is dear. Long. 3. 30. E. Lat. 36. 49. N. The harbour of Algiers, at the time of the capture, was rather small, and incapable of accommodating any vessel larger than a middle-sized frigate; but a plan was definitively adopted in 1848, which, when carried out, will render the harbour very capacious. It will be surrounded on the northern side by a breakwater 700 yards long, on the south by one 1200 yards long, and the entrance will be 350 yards wide. Each side of the entrance is to be defended by a strong battery. These improvements are now being effected, and experiments were recently made (1852) to ascertain how far they were satisfactory. Five men-of-war towed by steamers severally entered the port, and cast anchor at a cable's length from each other: a sixth man-of-war and several steamers also entered and anchored; and all these vessels did not encroach upon the space set apart for merchant vessels. It is said that three men-of-war and three steam frigates in addition might have anchored there without inconvenience. It is calculated that the removal of a rock called "Roche sans nom," situated about the middle of the port, will allow a fleet of at least twelve men-of-war and as many frigates to anchor, in addition to the merchant vessels. Orders have been given to have this rock removed forthwith.

Algoa ‖ Alhambra.

ALGOA BAY, or ZWART-KOPS, in Southern Africa, is situated in Long. 26. 53. E. Lat. 33. 56. S. and 425 miles east from the Cape of Good Hope. It lies between Capes Woody and Recife, which are 33½ miles apart; but it is only in the west and north-east parts of the bay that ships may anchor and find shelter. The anchorage of Port Elizabeth on the west side is perfectly secure for six months in the year, during the prevalence of the north-east winds. The bay is much frequented by black whales and seals. There is a lighthouse on Cape Recife.

ALGOL, or $\beta$ *Persei*, a variable fixed star of the second or third magnitude, called *Medusa's Head.* Its position, according to the catalogue of the London Astronomical Society, was, on January 1. 1853, 2 h. 58 m. 37·16 sec.; N. Decl. 49° 36′ 51·76″.

ALGOR is used to signify an unusual coldness in any part of the body.

ALGORITHM, an Arabic word expressive of numerical computation.

ALGUAZIL, in the Spanish polity, an officer whose business it is to see the decrees of a judge executed.

ALHAMA, a city of Spain, in the province of Granada, in Andalucia. It is in a fine valley, enjoys a most salubrious climate, and is surrounded by fields most abundantly productive of wheat and barley. Near it are some medicinal baths of ancient celebrity, to which invalids still resort. Dr Traill found their temperature equal to 118° F. It was a most important fortress when the Moors ruled Granada, and its capture by the Christians was the most decisive step in the reduction of their power. It contains 6500 inhabitants, and is situated in Lat. 37. N. Long. 4. 10. W.

ALHAMBRA, the ancient fortress and residence of the Moorish monarchs of Granada. It derives its name from the red colour of the materials with which it was originally built, Alhambra signifying a red house. It appears to a traveller a huge heap of as ugly buildings as can well be seen, all huddled together, seemingly without the least intention of forming *one* habitation out of them. The walls are entirely unornamented, all of *tapia* or *pisé*, a mixture of fine gravel and clay, formed into huge sun-dried bricks; yet this is the palace of the Moorish kings of Granada, indisputably the most curious place within that exists in Spain, perhaps in the world. In many countries may be seen excellent modern as well as ancient architecture, both entire and in ruins; but nothing to be met with anywhere else can convey an idea of this edifice, except the decorations of an opera, or the tales of the genii.

Passing round the corner of the emperor's palace, one is admitted at a plain unornamented door in a corner. "On my first visit," says Mr Swinburne (*Travels in Spain*), "I confess I was struck with amazement, as I stept over the threshold, to find myself on a sudden transported into a species of fairy land. The first place you come to is the court called the *communa* or *del mesucar*, that is, the *common baths;* an oblong of 165 by 25 feet, with a deep basin of clear water in the middle; two flights of marble steps leading down to the bottom; on each side a parterre of flowers, and a row of orange trees. Round the court runs a peristyle paved with marble: the arches bear upon very slight pillars, in proportions and style different from all the regular orders of architecture. The ceilings and walls are incrustated with fretwork in stucco, so minute and intricate that the most patient draughtsman would find it difficult to follow it, unless he made himself master of the general plan. This would facilitate the operation exceedingly; for all this work is frequently and regularly repeated at certain distances, and has been executed by means of square moulds applied successively, and the parts joined together with the utmost nicety. In every division are Arabic sentences of different lengths, most of them expressive of the following meanings: 'There is no conqueror but God;' or, 'Obedience and honour to our lord Abouabdoulah.' The ceilings are gilt or painted, and time has caused no diminution in the freshness of their colours, though constantly exposed to the air. The lower part of the walls is mosaic, disposed in fantastic knots and festoons. A work so novel, so exquisitely finished, and so different from all that he has ever seen, must afford a stranger the most agreeable sensations while he treads this magic ground. The porches at the ends are more like grotto-work than any thing else to which they can be compared. That on the right hand opens into an octagon vault, under the emperor's palace, and forms a perfect whispering gallery, meant to be a communication between the offices of both houses: at its north end is the most magnificent hall of this palace, *Sala de Gomarez*, intended for the court receptions, and giving audience to ambassadors." Dr Traill found it a square of 456 with a height of between 50 and 60 feet; the walls exquisitely ornamented with costly fretwork of stucco enriched with gilding; and to the height of six feet from the floor, covered with glazed porcelain tiles.

"Opposite to the door of the communa through which you enter, is another leading into the *corte de los leones*, or court of the lions, which is an oblong court, 100 feet in length and 50 in breadth, environed with a colonnade seven feet broad on the sides, and 10 at the end. Two porticoes or cabinets, about 15 feet square, project into the court at the two extremities. The square is paved with coloured tiles, the colonnade with white marble. The walls are covered five feet up from the ground with blue and yellow tiles, disposed checquerwise. Above and below is a border of small escutcheons, enamelled blue and gold, with an Arabic motto on a bend, signifying, 'No conqueror but God.' The columns that support the roof and gallery are of white marble, very slender, and fantastically adorned. They are nine feet high, including base and capital, and eight inches and a half in diameter. They are very irregularly placed; sometimes singly, at others in groups of three, but more frequently two together. The width of the horse-shoe arches above them is four feet two inches for the large ones, and three for the smaller. The ceiling of the portico is finished in a much finer and more complicated manner than that of the communa, and the stucco is laid on the walls with inimitable delicacy: in the ceiling it is so artfully frosted and handled as to exceed belief. The capitals are of various designs, though each design is repeated several times in the circumference of the court; but not the least attention has been paid to placing them regularly or opposite to each other. Not the smallest representation of animal life can be discovered amidst the varieties of foliages, grotesques, and strange ornaments. About each arch is a large square of arabesques, surrounded with a rim of characters, generally consisting of quotations from the Koran. Over the pillars is another square of exquisite filigree work. Higher up is a wooden rim, or kind of cornice, as much enriched with carving as the stucco that covers the part underneath. Over this projects a roof of red tiles, the only thing that disfigures this beautiful square. This ugly covering is a modern addition made by a late prime minister, who a few years ago gave the Alhambra a thorough repair. In Moorish times the building was covered with large painted and glazed tiles, of which a few are still to be seen. In the centre of the court are twelve ill-made marble lions, their fore parts smooth, their hind parts rough, which bear upon their backs a polygonal basin, $15\frac{1}{2}$ feet in diameter, out of which rises a lesser basin. While the pipes were kept in good order, a great volume of water was thrown up, which, falling down into the basins, passed through the lions, and issued out of their mouths into a large reservoir, where it communicated by channels with the *jets d'eau* in the apartments. This fountain is of white marble, embellished with many festoons and Arabic distiches.

"Passing along the colonnade, and keeping on the south side, you come to a circular room occupied by the men as a place for drinking coffee, &c. A fountain in the middle refreshed the apartment in summer. The form of this hall, the elegance of its cupola, the cheerful distribution of light from above, and the exquisite manner in which the stucco is designed, painted, and finished, exceed all power of description. Every thing in it inspires the most pleasing, voluptuous ideas; yet in this sweet retreat, it is said that Abouabdoulah assembled the Abencerrages, and caused their heads to be struck off into the fountain. Continuing your walk round, you are next brought to a couple of rooms at the head of the court, which are supposed to have been tribunals, or audience-chambers.

"Opposite to the *sala de los Abencerrages* is the entrance into the *torre de las dos hermanas*, or the tower of the two sisters; so named from two very beautiful pieces of marble, laid as flags in the pavement. This gate exceeds all the rest in profusion of ornaments, and in the beauty of the prospect it affords through a range of apartments, where a multitude of arches terminate in a large window open to the country. In a gleam of sunshine, the variety of tints and lights thrown upon this enfilade are uncommonly rich. The first hall is the concert-room, where the women sat: the musicians played above in four balconies. In the middle is a *jet d'eau*. The marble pavement is equal to the finest existing, for the size of the flags and evenness of the colour. The *two sisters*, which give name to the room, are slabs that measure 15 feet by seven and a half, without flaw or stain. The walls, up to a certain height, are mosaic, and above are divided into very neat compartments of stucco, all of one design, which is also followed in many of the adjacent halls and galleries. The ceiling is a fretted cove. To preserve this vaulted roof, as well as some of the other principal cupolas, the outward walls of the towers are raised ten feet above the top of the dome, and support another roof over all, by which means no danger can ever be caused by wet weather or excessive heat and cold. From this hall you pass round the little myrtle garden of Lindaraxa, into an additional building made to the east end by Charles V. The rooms are small and low. His favourite motto, *Plus outre*, appears on every beam. This leads to a little tower projecting from the line of the north wall, called *el tocador*, or the dressing-room of the sultana. It is a small square cabinet, in the middle of an open gallery, from which it receives light by a door and three windows. The look-out is charming. In one corner is a large marble flag, drilled full of holes, through which the smoke of perfumes ascended from furnaces below; and here, it is presumed, the Moorish queen was wont to sit to perfume herself. The emperor caused this pretty room to be painted with representations of his wars, and a great variety of grotesques, which appear to be copies, or at least imitations, of those in the loggie of the Vatican. From hence you go through a long passage to the hall of ambassadors, which is magnificently decorated with innumerable varieties of mosaics, and the mottoes of all the kings of Granada. This long narrow antichamber opens into the communa on the left hand, and on the right into the great audience-hall in the tower of Comares; a noble apartment, 36 feet square, 36 high up to the cornice, and 18 from thence to the centre of the cupola. The walls on three sides are 15 feet thick, on the other nine; the lower range of windows 13 feet high. The whole wall is inlaid with mosaic of many colours, disposed in intricate knots, stars, and other figures. In every part various Arabic sentences are repeated.

"Having thus completed the tour of the upper apartments, which are upon a level with the offices of the new palace, you descend to the lower floor, which consisted of bed-chambers and summer-rooms: the back stairs and passages, that facilitated the intercourse between them, are without number. The most remarkable room below is the king's bed-chamber, which communicated by means of a gallery with the upper story. The beds were placed in two alcoves, upon a raised pavement of blue and white tiles; but as it was repaired by Philip V. who passed some time here, its former appearance can only be conjectured. A fountain played in the middle, to refresh the apartment in hot weather. Behind the alcoves are small doors that conduct to the royal baths. These consist of one small closet with marble cisterns for washing children, two rooms for grown-up persons, and vaults for boilers and furnaces that supplied the baths with water, and the stoves with vapours. The troughs are formed of large slabs of white marble; the walls are beautifully adorned with party-coloured earthen ware; and light is admitted by holes in the coved ceiling.

"Hard by is a whispering gallery, and a kind of labyrinth, said to have been made for the diversion of the women and children. One of the passages of communication is fenced off with a strong iron grate, and called *the prison of the Sultana;* but it seems more probable that it was put up to prevent any body from climbing into the division allotted to the women.

"Under the council-room is a long slip, called *the king's study;* and adjoining to it are several vaults, said to be the place of burial of the royal family. In the year 1574 four sepulchres were opened; but as they contained nothing but bones and ashes, they were immediately closed again."

This description of the Alhambra may be finished by observing how admirably every thing was planned and calculated for rendering this palace the most voluptuous of all retirements; what plentiful supplies of water were brought to refresh it in the hot months of summer; what a free circulation of air was contrived, by the judicious disposition of doors and windows; what shady gardens of aromatic trees; what noble views over the beautiful hills and fertile plains. "Alhambram," said the Italian, Peter Martyr, when he entered it in the train of the Gothic conquerors, "proh dii immortales! qualem regiam! unicam in orbe terrarum crede!" No wonder the Moors regretted Granada! no wonder that they still offer up prayers to God every Friday for the recovery of this city, which they regard as a terrestrial paradise!

ALHAURIN EL GRANDE, so called to distinguish it from a neighbouring village of the same name, a town of Spain, in the province of Malaga, 12 miles south-west of the town of that name. It is a favourite summer resort of the inhabitants of Malaga. Pop. 5514.

ALHAZEN, an Arabian author of the eleventh century, who is better entitled to the appellation of philosopher than most of those of his countrymen by whom it has been obtained. The place of his birth was Bassora; the year uncertain; but his death took place at Cairo in 1038. There was another author of the same name, who translated the *Almagest* of Ptolemy; but that writer lived during the reign of the caliph Almamun. In some accounts of Alhazen we find it said that he lived chiefly in Spain; but it appears from Casiri (*Bibl. Arabico-Hispana Escurialensis*), that after he had left his native city, Egypt was his place of residence. It also appears that he was invited to that country by one of the Fatemite caliphs, on account of some boasts which he had made of being able to obviate the evils attendant upon the alternate overflowing and decrease of the waters of the Nile. He surveyed the country with a view to this project, to aid which, every thing that he asked was liberally furnished by the caliph; but finding that his imagination had seduced him into a wild and impracticable scheme, he feigned madness, thereby to avoid the punishment which he dreaded; and he continued to play this humiliating part till the caliph's death relieved him from his apprehensions.

But, whatever figure he may have made as a projector, there can be no doubt that he was a skilful geometrician, and that his name deserves a conspicuous place among the improvers of the science of optics. He was not a mere compiler from the ancients, or commentator upon their works: he followed the bent of his own genius; and, striking into the right path of experiment and observation, his inquiries were productive of a real accession to the stock of knowledge, in regard to some of the most interesting phenomena of nature. He refuted the error of the ancient philosophers that vision was produced by rays emitted from the eye. He gave the first sensible explanation of the cause of the apparent increase of the sun and moon when seen near the horizon; showing that this is occasioned by their being then supposed, owing to the number of intermediate objects, to be at a greater distance from the spectator. He was the first who applied the laws of refraction to show how the heavenly bodies are sometimes seen as if above the horizon when still below it; and who, in the same way, explained the cause of the morning and evening twilight;—of that beneficent provision of nature by which the glories of day are made gradually to approach, and gradually to withdraw. These dioptrical discoveries of the Arabian philosopher have furnished M. Bailly with one of the many fine passages which embellish his celebrated work on the history of Astronomy. —*Astron. Moderne*, liv. vi., sec. 20.

As a writer, Alhazan is censurable for unmeaning prolixity and scholastic subtilty. It appears from Casiri that his works were numerous; but only two of them have been printed, namely his treatise on *Optics*, and that on the *Twilight*. They were both published in Latin in 1572, by Frederic Risner, under the title of *Opticæ Thesaurus.*

ALHUCEMAS. See Alucemas.

ALI, the son of Abu Taleb, is one of the most celebrated characters in Mahometan history. He was cousin to Mahomet, and at the age of fourteen engaged with youthful ardour in his cause. When Mahomet first revealed his prophetic character to his friends, and inquired who among them would undertake to be his companion, Ali exclaimed, "O prophet, I will be thy attendant; the man who dares to rise against thee I will break his legs, pluck out his eyes, dash out his teeth, and even rip up his belly." Mahomet accepted his services, and honoured him with the titles of brother, vicegerent, and Aaron to a new Moses. He was remarkable both for eloquence and valour; and the latter obtained him the surname of "*the Lion of God, always victorious.*" He succeeded to the chief dignity of the renowned house of Hashem, and was also hereditary guardian of the temple and city of Mecca. Mahomet gave him his daughter Fatimah in marriage, and the grandfather lived to embrace the children of his daughter. These advantages induced Ali to cast a wistful eye towards the regal succession: however, Abubeker, Omar, and Othman, reigned before him. But after the death of the latter he was saluted caliph by the chiefs of the tribes, and companions of the prophet, when he was repairing to the mosque of Medina at the hour of prayer, A.D. 656, Hegira 35.

Ayesha, the widow of the prophet, strenuously opposed his succession; and under her influence two powerful chiefs soon raised the standard of rebellion. Ali greatly increased his difficulties by the imprudent removal of all the governors of provinces from their stations. Telha and Zobeir, two chiefs of great influence, collected a numerous army, and induced Ayesha to attend them to the field of battle; but Ali gained a complete victory, and took Ayesha prisoner. Telha fell on the field, and Zobeir was assassinated after surrendering upon promise of quarter. This dastardly action was severely reprehended by Ali. He likewise kindly treated the captive widow, and sent her back to the tomb of the prophet.

Ali next attacked Moawiyah, who had been proclaimed caliph, and was strongly supported by a powerful and numerous party. When the two armies approached each other, Ali proposed to decide the matter by single combat; but to this his opponent would not agree. Several skirmishes were fought with considerable loss on both sides; but at length a "pious fraud" produced a division of sentiment in the army of Ali. They fixed to the points of lances a number of copies of the Koran, carried them before the troops, and exclaimed, "This is the book which forbids Mussulmans to shed each other's blood, and ought therefore to decide our disputes." Ali was constrained to yield, and umpires were mutually chosen; on the side of Ali, Abu Moussa; Amrou, the conqueror of Egypt, on the part of Moawiyah. The day of final decision arrived. Abu Moussa ascended the pulpit, and cried, "As I draw this ring from my finger, so I depose both Ali and Moawiyah from the caliphate." When Amrou ascended, he cried, "As I put on this ring, so I invest Moawiyah with the caliphate, and also depose Ali." He also added, that Othman, the former caliph, had declared Moawiyah both his successor and avenger. Thus began that memorable contest among the Mahometans which was long agitated with considerable violence by both parties.

Ali was highly enraged at this injustice, but, constrained for the present to yield, he retired to Kufa. A sect of enthusiasts, called the *Kharejites*, revolted against Ali; but he quickly reduced them to subjection, and again obtained possession of Arabia. But Syria, Persia, and Egypt, fell to the share of his rival.

An unexpected event terminated the existing disputes. Three Kharejites one day conversing together concerning the blood which had been shed, and the impending calamities, resolved to assassinate Ali, Moawiyah, and Amrou, the three authors of the present disasters. They provided themselves with poisoned swords, and hastened to accomplish their purpose. Moawiyah was wounded, but the wound did not prove fatal. A friend of Amrou fell in his stead. Ali was fatally wounded at the door of the mosque; and in the 63d year of his age, he expired on the fifth day after his wound, A.D. 661.

Ali had eight wives besides Fatimah, and left a numerous family, who were very remarkable for their valour. He also rose to high eminence for learning and wisdom; and of his works there are still extant a hundred maxims, a collection of verses, and a prophecy of all the great events which are to happen to the end of time.

The Mussulmans term Ali *the heir of Mohomet and the accepted of God;* and his particular followers have possessed various states in Africa and Asia, and the Persian part of the Usbek Tartars; and some sovereigns of India are at present of the sect of Ali. A monument is raised upon his tomb near Kufa, which the kings of Persia have successively decorated and religiously revered. Near the ruins of Kufa, a city named Meshed Ali has been built to his memory. Some of his deluded followers imagine that he is still alive, and that he will revisit the earth and fill it again with justice. A green turban still continues to distinguish the descendants of Ali.

Ali, a town of Sicily, at the mouth of the river of the same name, 15 miles S.S.W. of Messina. It has sulphurous baths of some celebrity, and contains 1300 inhabitants.

Ali *Bey*, an eastern adventurer, is said to have been a native of the Caucasus, and about the age of twelve or fourteen to have been sold for a slave in Cairo. The two Jews who became his masters presented him to Ibrahim, then one of the most influential men in the kingdom. In the family of Ibrahim, he received the rudiments of literature, and was also instructed in the military art. Both in letters and military skill he made rapid improvement. He gradually gained the affection of his patron to such a degree that he gave him his freedom, permitted him to marry, and promoted him to the rank of governor of a district. Afterwards he was elected to the elevated station of one of the governors of provinces. Deprived of his protector by death, and engaging in the dangerous intrigues that pave the way to power in that unstable government, he procured his own banishment to Upper Egypt. Here he spent two years in maturing his schemes for future greatness; and in 1766, returning to Cairo, he either slew or expelled the beys, and seized the reins of government.

Emboldened by success, he rescued himself from the power of the Porte, coined money in his own name, and assumed the rank of sultan of Egypt. Occupied in more important concerns, the Porte made no vigorous opposition to his measures, and Ali seized this opportunity to recover a part of the Said, or Upper Egypt, which had been taken possession of by an Arab sheik. He next sent out a fleet from Suez, which seizing upon Djedda, entered the port of Mecca; while a body of cavalry, commanded by Mohammed Bey, his favourite, took and plundered Mecca itself. Having formed an alliance in 1770 with one Sheik Daher, a rebel against the Porte in Syria, he aimed at the conquest of all Syria and Palestine. He first endeavoured to secure Gaza: then his army, forming a junction with that of Daher at Acre, advanced to Damascus. There on the 6th of June 1771 a battle was fought with the Turkish pashas, and Mohammed and Daher, Ali's generals, routed them with great slaughter. They instantly took possession of Damascus, and the castle itself had also capitulated, when all on a sudden Mohammed hastened back to Egypt with all his Mamelukes. Some ascribe this strange conduct to an impression made upon Mohammed by the Turkish agents, and others to a report of the death of Ali Bey.

Although unsuccessful, Ali never lost sight of his favourite object; and Mohammed, losing his confidence, was forced to save his life by exile. Mohammed, however, quickly returned with an army, and drove Ali Bey from Cairo. In this unfortunate state of affairs Ali fled to Daher, and, combining their forces, they attacked the Turkish commander at Sidon, and came off victorious, although the Turkish army was three times their number. After a siege of eight months, they next took the town of Jaffa. Deceived by letters from Cairo, which were only intended to ensnare him, and stimulated with recent victories, he returned to Cairo. Entering the deserts which divide Gaza from Egypt, he was furiously attacked by a thousand chosen Mamelukes led on by Murad Bey, who was enamoured with the beauty of Ali's wife, and had obtained the promise of her, provided that he could take Ali captive. Murad wounded and made Ali prisoner, and carried him up to Mohammed, who received him with affected respect; but in three days, either from the effects of poison or of his wounds, Ali breathed his last.

ALI PACHA. See Albania.

ALIAS, signifying *at another time*, is used in judicial proceedings to connect the several names of a person who attempts to conceal his true name, or to pass under a feigned one; as Smith alias Jones, James alias John.

ALIBI, in *Law*, denotes the absence of the accused from the place where he is charged with having committed a crime; or his being *elsewhere*, as the word imports, at the time specified.

ALICANTE, a city of Spain, in the new province of the same name, with a port on the Mediterranean Sea. The city forms a half moon on the sea-shore, and is defended by a castle built on a rock about 400 feet in height; and the bay in which vessels are anchored is well protected by various batteries. The commerce of this port, though still considerable, has much declined during the last eight or ten years. Two lakes on the coast furnish a large supply of salt made by spontaneous evaporation, which is shipped chiefly to England and Sweden. A fertile plain called the Huerta, near the city, which has been furnished with the means of irrigation at a vast expense, is covered with vines which produce excellent wines and raisins; with mulberry trees, which rear silk-worms; and with great quantities of almonds, olives, and figs, that supply articles for foreign commerce. On the coast near this city, the island of Plana, a barren rock, supplies the most beautiful marbles in great variety. The coast furnishes large quantities of barilla, which is one of the most important branches of the commerce of the city. As the exportable commodities engage the principal attention of the agriculturists, the quantity of corn grown is insufficient for the consumption of the city and its vicinity, though rice might be raised in great quantity; and the wheat is brought partly from La Mancha, and partly by sea from Africa and from Italy. The castle of Alicante is in Long. 0. 30. 51. W. and in Lat. 38. 20. 41. N. This city contains 1 cathedral, 3 parish churches, 6 hot springs, and 19,000 inhabitants. It is the seat of a bishop, and has manufactories of linen and woollen cloths, and of esparto matting. The harbour is but a road-stead in a deep bay, and only small vessels approach the quay. English and other European consuls reside here.

ALICATA, a city of Sicily, in the intendancy of Calatanisera. It is a seaport and a parliamentary city at the mouth of the river Salso, from which corn, fruit, and sulphur are exported. There is a roadstead, but no harbour. It contains 13,465 inhabitants. Near it are vestiges of the ancient city of Gela.

ALICUDI, one of the Lipari Isles.

ALIEN, obviously derived from the Latin *Alienus*, is the technical term applied by British constitutional law to any one who does not enjoy the privileges of a British subject. In all powerful and independent nations the right of citizenship has been restricted and guarded with more or less jealousy. Fears have been entertained that foreigners would obtain it for the purpose of undermining the institutions of the state receiving them, or of bringing it under the subjection of the government to which they originally belonged. But, generally, the jealousy against communicating the privileges of citizenship to foreigners has its foundation in mistaken views of political economy. It arose from the impression that the produce of the energy and enterprise of any community is a limited quantity, of which each man's share will be the less the more competitors there are; superseding the just view that the riches of a state depends on the number and energy of the producers. Thus the skilled workmen who would increase its riches have often been jealously kept out of a country. But, on the other hand, special temptations, including the gift of citizenship, have often been offered to skilled foreigners, by states desiring to acquire them as citizens. Britain has occasionally received industrious and valuable citizens driven forth by the folly or tyranny of other powers, as in the memorable instance of the revocation of the edict of Nantes which sent the Spitalfield colony, and many other Frenchmen, to this country. Looking on the full benefit of British citizenship as a transcendent boon, the principle of our older legislation on the subject has been to allow foreigners to possess at least a portion of it. There never existed in Britain a law so harsh as the *Droit d'Aubaine* of France, which confiscated to the crown all the property of a deceased alien. The courts of justice have ever been opened to them, and they have thus been entitled to protect themselves from any inequalities which do not apply to them by special law. Whether an alien can be sent furth of the realm by exercise of the crown's prerogative, is questioned. Though this is often spoken of as a power of the crown, subsidiary to that of declaring war against foreign nations, yet there is no known writ or form by which it could be enforced, against which a foreigner might not seek the protection of the law. On this ground it was felt that there would have been difficulty in dealing with the person of Napoleon, could his friends have brought him on British soil. The prerogative has been so far practically doubted, that whenever it has seemed necessary to extrude foreigners, a special act of Parliament has been obtained for the purpose. Thus, during the continental convulsions of 1848, a temporary act was passed for the removal of any foreigners whose presence might be dangerous to the peace of the country. A return to parliament in 1850 showed that this act had not been enforced in a single instance.

Our law, save with the special exceptions mentioned afterwards, admits to the privileges of subjects all who are born within the British dominions. In the celebrated question of the *post-nati* in the reign of James I. of England, it was found, after solemn trial, that natives of Scotland born before the union of the crowns were aliens in England, but that those born subsequently enjoyed the privileges of English subjects. A child born abroad, whose father or whose grandfather on the father's side was a British subject, may claim the same privilege, unless at the time of his birth his father was a traitor or felon, or engaged in war against the British empire (4th Geo. II. c. 22). Owing to this exceptional provision, some sons of Jacobite refugees born abroad, who joined in the rebellion of 1745, were admitted to the privilege of prisoners of war, because as the conduct of their fathers deprived them of the privileges of citizenship, they were not to be liable to its burdens. The main characteristic disabilities to which aliens have been subjected have been, incompetency to exercise political privileges, such as that of electing or being elected to sit in Parliament, and incapacity to hold landed property. The privilege of sitting in a jury has been counted among the political rights from which they are excluded; but when a foreigner is on trial, he has, in England, the privilege of the jury *medietatæ linguæ*, in which half the panel consists of foreigners. In Scotland it seems to be questioned if aliens are excluded from the privilege of voting on occupancy. The application of the restriction against holding property, to land and not to moveable effects, is the natural progeny of the feudal system, which attributed allegiance or fealty to land tenures.

Many of the special disabilities to which aliens were subject under the Navigation Act and other laws connected with our old restrictive commercial policy, have been removed or neutralised by the free trade measures of later years. Some of the disabilities of aliens have been by special laws applied to natural born subjects, as in the instance of Jews and Catholics. It was long a question in England whether a Jew could by the common law hold landed property. On the other hand, some of the privileges of citizenship have been specially communicated to persons coming naturally within the classification of aliens. As, for instance, to foreign seamen, on their serving two years in time of war on board a British ship under proclamation, and to foreign Protestants serving two years in the army in an American colony, or being three years employed there in the whale fishery, and not absenting themselves from the British dominions for more than a year (13th Geo. II. c. 3, 20th Geo. II. c. 44). Acts have, from time to time, been passed for regulating the manner in which aliens are bound to conduct themselves, and defining the extent of their privileges. The latest of these was passed in 1836, and amended in 1844 (6th and 7th Will. IV. c. 11, and 7th and 8th Vict. c. 66). By the former act masters of vessels required to intimate the arrival of all aliens, who were bound to have their names registered and to obtain certificates of registration. It is believed that these conditions, of a similar character to those contained in previous acts, have seldom been complied with or enforced. The act of 1844 was a considerable relaxation of the alien law. It communicated to the children born abroad of a British mother the privilege of acquiring land by purchase or succession. It gives friendly aliens the privilege of holding leases for any time not exceeding twenty-one years. Before this act the rights of citizenship could only be conferred on aliens by statute; and it was enacted at the commencement of the Hanover succession, that no private naturalisation bill should be brought in unless it contained a clause disqualifying the person it applied to from being a privy councillor or a member of Parliament, and from holding any office, civil or military, and from being a freeholder; but this restriction is repealed by the Act of 1844. Limited privileges could formerly be given by the sovereign's letters of denization; but by the act of 1844, an alien intending to reside and settle in Britain, may on application by memorial to the Home Secretary, obtain a certificate, giving him all the rights of a natural born subject, except those of eligibility as a privy councillor or a member of Parliament, along with any other exceptions specially set forth in the certificate. See farther, ALLEGIANCE; INTERNATIONAL LAW. (J. H. B.)

*ALIEN Priories*, a kind of inferior monasteries, formerly very numerous in England, and so called from their belonging to foreign abbeys.

ALIENATION, in *Law*, denotes the act of making over a man's property in lands, &c., to another person.

*ALIENATION in Mortmain*, is the making over of lands, &c., to a body politic, or to a religious house.

ALIMENT, in the *Law of Scotland*, is the reciprocal obligation of parents and children to contribute to each others' maintenance. It also indicated a similar obligation of other parties, as of creditors to imprisoned debtors, &c.

ALIMENTARIA LEX, was an old Roman law, whereby children were obliged to find sustenance for their parents.

ALIMENTARII PUERI, &c., were certain children publicly maintained and educated by the munificence of the Roman emperors. This was first done by Nerva, and afterwards by Trajan and Adrian. Antoninus Pius did the same for a number of girls, at the solicitation of Faustina; and hence, in some medals of that empress, we read PVELLAE FAVSTINIANAE.—Alexander Severus did the like at the request of Mammæa; and the maids thus educated were called *Mammæanæ*.

*ALIMENTARY Duct* or *Canal*. See ANATOMY.

ALIMENTS. See DIETETICS.

ALIMONY is usually applied in law to the proportion of allowance for maintenance that a wife is entitled to out of her husband's estate, on a legal separation, when not occasioned by her elopement or adultery.

ALIPILARIUS, or ALIPILUS, in *Roman Antiquity*, a servant belonging to the baths, whose business it was, by means of waxen plasters, and an instrument called *volsella*, to take off the hair from the arm-pits, arms, legs, &c., this being deemed a point of cleanliness.

ALIPTERIUM, ἀλειπτήριον, in *Antiquity*, a place in the ancient *palestræ*, where the *athletæ* were anointed before their exercises.

ALIQUANT PART, in *Arithmetic*, is that number which cannot measure any other without some remainder. Thus, 7 is an aliquant part of 16; for twice 7 wants two of 16, and three times 7 exceeds 16 by 5.

ALIQUOT PART, is that part of a number or quantity which will exactly measure it without any remainder. Thus, 2 is an aliquot part of 4, 3 of 9, 4 of 16, &c.

ALISON, REV. ARCHIBALD, author of essays on the Nature and Principles of Taste, was born at Edinburgh on the 13th November 1757. His father was the second son of Alexander Alison, Esq. of Newhall, an ancient family near Cupar in Forfarshire, and who having come to reside in Edinburgh, was for two years Lord Provost. Alison Square, near Nicolson Street, was called after him. The future essayist on taste, who was his third son, evinced an early and decided turn for literary pursuits, which led to his being sent at the early age of twelve to Glasgow College, where his talents procured for him a presentation to one of the bursaries from that university to Baliol College, Oxford, which determined his choice of the Church of England as a profession. There also he formed a friendship with Dugald Stewart, who afterwards became so celebrated as a metaphysician, which continued unbroken through the whole of life.

At Oxford he soon distinguished himself, and gained high honours. He there formed an intimacy with several men who afterwards became remarkable, particularly Mr, afterwards Sir William Jones, and Dr Matthew Baillie. There also he became acquainted with Mr William Gregory, son of Dr John Gregory, professor of the theory of medicine in the university of Edinburgh, who was also studying for the English Church; and this induced a friendship with his family, which led to the most important event in Mr Alison's life—his marriage in 1780 to Dorothea, youngest daughter of Dr Gregory, professor of the theory of physic in the university of Edinburgh, and sister of the Dr James Gregory whose talents afterwards rendered him so celebrated in that university.

Mr Alison's first ecclesiastical preferment was the curacy of Brancepeth near Durham, which he held from 1778 to 1780. His marriage with Miss Gregory, however, introduced him to Sir William Pulteney, of whose only daughter and heiress, Lady Bath, she was an intimate friend; and Sir William in consequence bestowed on him first the curacy of Sudbury in Northamptonshire, and afterwards the livings of High Ercall, Roddington, and Kenley, in Shropshire; at the last of which he lived in tranquillity and happiness, in the enjoyment of the highest domestic felicity, till 1800, when he removed for the education of his family to Edinburgh. In 1798 he was made a dignitary of the Church as one of the prebendaries of Sarum. The first edition of of his *Essays on Taste* was published in 1784; but though admired in the highest degree by a limited circle of men of taste and refinement, it did not, from being printed in quarto, in an expensive form, obtain, in the first instance, the general circulation which it ultimately attained.

In May 1800 he moved from Shropshire to the vicinity of Edinburgh, and obtained the situation of senior incumbent of St Paul's Chapel, Cowgate, there. There his great talents and eloquence as a preacher soon attracted universal attention, and caused that chapel, which held 1500 persons, speedily to overflow in every quarter with a congregation of the very highest caste which the metropolis could boast. On the days of national fast and thanksgiving, in particular, which occurred annually, and often more frequently at that period, the chapel was always crowded to suffocation with the *elite* of rank and talent in the city who flocked to listen to the highest specimens of pulpit oratory which the country could boast.

In 1809 a new edition of the *Essays on Taste*, in octavo, was published with considerable additions, which elicited a very able and flattering review from the pen of Lord Jeffrey, one of the ablest he ever wrote, in the Edinburgh Review, which at once brought it in into general notice. Since that period it has gone through five editions, and the copyright having expired, it has received the most unequivocal proof of general popularity in having been published in a cheap form, at the moderate price of 2s. 6d., which has brought it within the reach of all classes of readers. Whatever opinions philosophers may entertain on the abstract principles this work contains, whether beauty is to be resolved, as Mr Alison thinks, into the expression by material objects of the qualities of mind, or is itself an inherent quality of certain combinations of matter, as others suppose; all must agree in the beauty of its ideas, and the eloquence with which it is written, and join in the wish of its gifted author, with which it concludes, "that the world we inhabit is to be regarded, not as the abode merely of human passions or human joys, but as the temples of the living God, in which praise is due, and where service is to be performed."

Mr Alison's celebrity as a preacher led his friends, in 1814, to join in an earnest request that he would give some of his discourses in a durable form to the world; and to this he at length, with much reluctance, consented. They appeared, and at first met with eminent success. The first edition of 6000 copies was sold in a few weeks, and four subsequent editions of them, nearly of equal magnitude, speedily followed. The author, ere long, had the gratification of receiving the most decisive proof of the wide spread of their popularity, by receiving copies of two editions of them printed beyond the Allegany Mountains. Their subsequent reputation, however, has not kept pace with this early celebrity, chiefly from their relating to matters of transient and historical interest, and speaking more to the feelings and the heart rather than the intellect or the conscience. The most competent judges, however, among whom may be named Lord Brougham, have pronounced several of them, especially the one on autumn, as among the most finished models of composition in the English language; and Lord Jeffrey concluded his eloquent review of them with the words, "We cannot help envying Mr Alison the power of uniting so much wisdom to so much eloquence, and giving us in this same work the highest gratifications of taste, and the noblest lessons of virtue."

The success of Mr Alison in the pulpit enabled the directors of St Paul's chapel to pay off nearly the whole debt with which that building was charged, and to erect the new and beautiful structure in York Place, to the completion of which Mr Alison's numerous friends and admirers largely contributed. There he continued to do duty regularly till increasing years compelled him, in 1834, to retire from active life. In 1830 he was severed by death from Mrs Alison, with whom he had lived in happiness for eight and forty years; but he continued in the full enjoyment of his faculties; and his powers of imagination increased rather than the reverse till his death, which happened on May 17. 1839, at the advanced age of eighty-two. His latter years were chiefly spent at a beautiful villa he had purchased near Colinton, where he enjoyed, in the very highest degree, the society of his family and friends, and the beauties of nature, to which through life he had been passionately attached.

Mr Alison transmitted his literary tastes and habits to his sons. The eldest, who, after the example of a long line of ancestors by the mother's side, embraced the medical profession, rose to its very highest grade. He was successively made professor of medical jurisprudence and of the theory and practice of physic in the university of Edinburgh, once held by his uncle and grandfather; and in 1845, on the death of the lamented Dr Abercrombie, was appointed first physician to the queen in Scotland. He rose to the highest eminence as a consulting physician, and published a most valuable work on medical science. But he is more generally known as an unwearied and active philanthropist, and as having mainly contributed, by his strenuous exertions, and the startling facts he revealed in his pamphlets on the subject, to the great reformation in the management of the poor in Scotland, which was effected by the Act of 1845. His youngest son, Sir Archibald Alison, Bart., was bred to the bar, at which he rapidly rose, and was successively appointed advocate-depute in 1823, and sheriff of Lanarkshire, the highest judicial situation in Scotland next to the bench, in 1835, which office he still holds. He is the author of the History of Europe during the French Revolution, its continuation to 1852, the Principles of Population, the Life of Marlborough, a voluminous treatise on Criminal Law, and a variety of essays, chiefly in Blackwood's Magazine, a selection of which have been published in a collected form. In November 1850, he was, by a singular coincidence, elected Lord Rector of Glasgow College, where his father had commenced his career eighty years before; and in June 1852, under the administration of Lord Derby, he was created a baronet; but this dignity has not lessened his literary tastes, which still continue to be exerted in historic literature.

ALISONTIA, or Alisuntia, in *Ancient Geography*, a river of Belgic Gaul, now *Alsitz;* which, rising on the borders of Lorraine, and running through that duchy, waters the city of Luxemburg, and, swelled by other rivulets, falls into the Sour.

ALIWAL, in northern India, a village on the left bank of the Sutlej, 18 miles west of the town of Loodiana. The place, though in itself insignificant, is associated with historical recollections of interesting character. At the commencement of the year 1848, a large body of Sikhs crossed the river from the Punjaub for the purpose of intercepting the communications of the British army of the Sutlej. They were met at Aliwal by Major-General Sir Harry Smith, who, on the 28th January, attacked and routed them with great slaughter. The tactics displayed by the British officer commanding in this action were deemed by the best military judges of the day deserving of the highest praise. Lat. 30. 58. Long. 75. 37. (E. T.)

ALJAMEIA was the Moorish name for the Spanish language.

ALKADARII, a sect among the Mahometans who deny any eternal, fixed, divine decrees, and are assertors of free-will. The word is formed from the Arabic *alkadar*, which signifies "decree." The Alkadarii are a branch of Motazalites, and stand opposed to the Algiabarii.

ALKAHEST, or Alcahest, among alchemists, derived from a word which signifies *spirit of salt* or *all spirit*, was supposed to be a universal menstruum, capable of resolving all bodies into their principles. It is likewise used for all fixed salts volatilized.

ALKALI, in *Chemistry*, denotes a particular class of salts. The word *alkali* is of Arabian origin, and was introduced into chemistry after it had been applied to a plant which still retains the name of *kali*. When this plant is burnt, the ashes washed in water, and the water evaporated to dryness, a white substance remains, which is called *alkali*. See Chemistry.

ALKALIMETER, a name given to a small instrument, invented by M. Descroizilles for ascertaining the value of the alkalies in commerce. There is an account of it in the 28th vol. of Tilloch's *Philosophical Magazine*.

ALKALOID, the name given to the alkaline bases of organic compounds that appear to exist in certain vegetables combined with organic acid; such as *morphia* in opium, *strychnia* in nux vomica, &c. See CHEMISTRY.

ALKINDI, a celebrated Arabian physician and philosopher who flourished at Baghdad, and died about A.D. 880. From the extent of his knowledge, he has been styled the Thales and Pythagoras of Mahometans. He was the author of various excellent works on medicine, general philosophy, logic, music, arithmetic, geometry, and astronomy; and this too at a period when Europe was involved in a cloud of the deepest ignorance.—*D'Herbelot Bibl. Orient. Bayle. Moreri.*

ALKMAAR. See ALCMAER.

ALKANET, the root of *Anchusa tinctoria*, much used to give a fine red colour to oils and other fatty matters. See ANCHUSA.

ALKORAN. See ALCORAN.

ALL-HALLOW, or *All-Saints*, a festival celebrated on the first of November, in commemoration of all the saints in general. The number of saints being so excessively multiplied, it was found too burdensome to dedicate a feast-day to each. In reality, there are not days enough, scarce hours enough, in the year, for this purpose. Hence it was found expedient to have an annual aggregate commemoration of such as had not special days for themselves. Pope Boniface IV., in the ninth century, introduced the feast of *All-Saints* in Italy, which was soon after adopted in the other churches.

*ALL-Saints*, islands near Guadaloupe, in the West Indies.

*ALL-Saints' Bay*, a captainship in the middle division of Brazil, so called from the harbour of that name; bounded on the north by the Rio Real, on the south by that of Ilheos, on the east by the ocean, and on the west by three unconquered nations of Indians. It is reckoned one of the richest and most fertile captainships in all Brazil, producing great quantities of cotton and sugar. The bay itself is about two and a half leagues wide, interspersed with a number of small but pleasant islands, and is of immense advantage to the whole country. It has several cities and towns, particularly St Salvador, which is its capital. All-Saints' Bay lies in Lat. 13. 10. S. Long. 38. 50. W.

*ALL-Souls*, in the *Calendar*, denotes a feast-day, held on the second of November, in commemoration of all the faithful deceased. The feast of All-Souls was first introduced in the eleventh century by Oidlon, abbot of Cluny, who enjoined it on his own order; but it was not long before it became adopted by the neighbouring churches.

ALLA, or ALLAH, the Mahometan name for the Supreme Being. It is an Arabic word, derived from the verb *alah*, to adore. It is the same with the Hebrew *Elohi*, which signifies the *Adorable Being*.

ALLAGNA, a town in the province of Val Sesia, in the principality of Piedmont, in Italy. It has some rich copper mines, with gold mixed in the same ore. It is on the river Sesia, and contains 1800 inhabitants.

ALLAHABAD, a fortified town of Hindustan, and the principal place of the province of the same name, is situated in a dry and healthy soil, on a triangle, at the junction of the two mighty streams, the Ganges and the Jumna. It has been occasionally the residence of royalty, and contains some fine ruins; but notwithstanding its advantageous commercial position, the benefit derived from numerous visitors for devotional purposes, and the support afforded by the civil and military establishments, it is still a small city, with mean houses and narrow and irregular streets, confined to the banks of the Jumna. Its population is however gradually improving, both in character and amount. Hodges, the artist, who visited the place in 1782, describes all the dwellings without the fort as thatched huts. In 1803, the native population was computed at 20,000; in 1834 it had increased to 38,000, and a later return brings it up to 45,000. The fort, which is placed at the distance of a quarter of a mile, on a tongue of land washed by the Jumna and the Ganges, is lofty and extensive, and completely commands the navigation of the two rivers. It is strong both by nature and art, and has been a noble castle; but although it has gained in strength, it has lost in appearance, by some modern improvements which it has undergone, by which its lofty towers have been lowered into bastions and ravelins, and its high stone ramparts covered with turf parapets, and obscured by a green sloping glacis. It is still, however, according to Bishop Heber, a striking place, and its principal gate, surmounted by a dome, with a wide hall beneath, surrounded by arcades and galleries, and ornamented with rude, but glowing paintings, forms a fine entrance to a place of arms. The barracks are handsome and neat. On one side is a large range of buildings, which are in the oriental style, and contain some noble vaulted rooms, chiefly occupied as officers' quarters, and overlooking from a considerable height the rapid stream and craggy banks of the Jumna. The principal mosque is in good repair. This building, which is solid and stately, but without much ornament, is advantageously situated on the banks of Jumna, adjoining the city on one side, and an esplanade before the glacis of the fort on the other. It was at one time the residence of the general of the station, but has since been restored to its original destination. Among the finest buildings in the neighbourhood is the Serai of Prince Khoosro, the ill-fated son of the Emperor Jehangir. The structure is a noble quadrangle, with four fine Gothic gateways, surrounded within an embattled wall, by a range of cloisters for the accommodation of travellers. Adjoining the Serai is a garden planted with fine old mangoe trees, in which are three beautiful tombs raised over two princes and a princess of the imperial family. The houses of the civil and military servants of the company, are at some distance both from the fort and the town. These villas are surrounded by gardens: they are described as handsome and richly fitted-up buildings, and as giving a grand appearance to the neighbourhood.

Allahabad is one of the most noted resorts of Hindu pilgrimage, and such visits are now perfectly free, the government pilgrim-tax formerly levied having been abolished since 1840. The place owes its celebrity in this respect to the reputed confluence of three sacred rivers, the Ganges, the Jumna, and the Sereswati; but the third is by no means obvious to the sight, being lost in the sands of Sirhind, upwards of 400 miles to the north-west. The Hindus, however, assert that it joins the other two under ground, and that consequently the same religious merit is acquired by bathing at this sacred confluence as by bathing in all the three separate rivers. In former years instances frequently occurred of devotees drowning themselves in the sacred stream at the great annual meeting of Allahabad; this mode of self-immolation being regarded by Hindus as the most acceptable of all offerings. At the present time this meeting has assumed rather a festive than a gloomy character; and is described as a pretty scene, the platforms for the bathers being covered with canopies as booths in an English fair, and the women dressed in holiday clothes, and shining in coloured scarfs among the crowd. Allahabad was taken in the year 1765 by the British, from the Vizier of Oude, and assigned as the residence of Shah Alum, the titular emperor of Delhi. But the emperor having thrown himself into the hands of the Mahrattas, the place was resumed by the donors in 1771, and again transferred to the Nabob of Oude, by whom it was finally ceded to the British in 1801, in commutation of the subsidy which the vizier had agreed to pay for British protection. Distance from Calcutta 496 miles;

from Benares 75; from Lucknow 128; from Delhi 391. Lat. 25. 26. Long. 81. 55.

The district of Allahabad forms one of the provinces under the jurisdiction of the lieutenant-governorship of Agra; it has an area of 2801 square miles, and a population, composed chiefly of Hindus and Mahometans, amounting to 710,000. The history of the district is included in that of the city of Allahabad. (E. T.)

ALLAN, David, a Scottish historical painter of considerable celebrity, was born at Alloa, on the 13th February 1744. At a very early age he showed such marks of genius as attracted the notice of some gentlemen living in the neighbourhood. In a remote part of the country, and deprived of the ordinary means of indulging his propensity to drawing, he betook himself, when a boy, to such implements and materials as he could readily procure; and the mechanical skill and taste which he displayed, particularly in the use of his knife, have been mentioned as remarkable for his years. Mr Stewart, then collector of the Customs at Alloa, having mentioned these proofs of natural talent to Mr Foulis the printer, who some time before had instituted an academy in Glasgow for painting and engraving, young Allan was invited to study under his care. Here he remained about seven years, studying the elementary principles of his art; and, by the proficiency which he attained, justified the opinion of his talents which had procured him admission to that ill-fated seminary. But although the public taste for the fine arts in Scotland was at that time so feeble as to leave his liberal and public-spirited preceptor without support, Allan, on leaving the academy, had the good fortune to gain the patronage of individuals whose generosity enabled him to prosecute his views, and to improve his taste, by studying the works of art abroad. He devoted himself with great zeal to his profession at Rome, where he remained sixteen years; during which time his subsistence chiefly depended on the copies which he made from the most celebrated pictures of the ancient masters. Among the original works which he then painted, was one which gained for him the gold medal given by the Academy of St Luke, in the year 1773, for the best specimen of historical composition. This picture represents the *Origin of Painting*, and is well known by the excellent engraving of it by Cunego. His design of the *Calabrian Shepherds* is also a composition of great merit; and his four views of the Carnivals at Rome, etched by Paul Sandby, are said likewise to have been very successful.

On his return to his native country, he took up his residence at Edinburgh; and soon after, on the death of Alexander Runciman, in 1786, was appointed director and master of the academy established by the Board of Trustees for Manufactures in Scotland. There he executed a great variety of works, of various degrees of merit; but perhaps none such as might have been expected from the author of the *Origin of Painting*. Those, indeed, by which he is most known, are of a cast altogether different, being remarkable for the comic humour which they display. The *Scotch Wedding*, the *Highland Dance*, the *Repentance Stool*, with his *Illustrations of the Gentle Shepherd*, are all of this class, and so generally known, from his own spirited etchings in aqua-tinta, as to need no description.

Mr Allan was long remembered and spoken of as an excellent private character. He died at Edinburgh on the 6th August 1796, in the 53d year of his age.

Allan, *Sir William*, R.A., and President of the Scottish Royal Academy for the Fine Arts, raised himself from obscurity, by the force of native genius and indefatigable perseverance, to a high rank among the painters of his age and country. A detail of the steps by which this eminent artist and excellent man overcame the difficulties of his first position, however valuable as an example to the young aspirant for distinction, would be here misplaced. We shall content ourselves with an outline of his professional career.

William Allan was born at Edinburgh, in 1782, of humble but respectable parents, who afforded him the elements of a classical education in the High School of his native city. He early showed a strong attachment to drawing; and it was intended that he should become an ornamental coach-painter. With this view he was entered as a pupil in the School of Design established by the Board of Trustees for Arts and Manufactures, then under the direction of Mr Graham as master. This able teacher had the good fortune to have among his first pupils *Allan* and *Wilkie*. The two youthful artists were placed at the same table, and for months studied the same designs. During this time they contracted a friendship which terminated only with their lives. In the Edinburgh school Allan remained for several years, and exhibited such proficiency that he aspired to the higher branches of painting. He subsequently was for some time a student in the Royal Academy of London; and afterwards attempted to practise his art in the vast field of the metropolis. But not meeting with the encouragement he had hoped to find, young Allan, with that decision which was one of his characteristics, speedily determined, with very scanty resources, to seek his fortunes abroad. Some circumstances made him think of Russia as a probable field; and having procured a few introductions, especially one to Sir Alexander Crichton, then the imperial family physician, our artist, in 1804, embarked for Riga; but was carried by a succession of storms to Memel in Prussia, where the state of his finances compelled him to remain for some time, supporting himself, as he best could, by the exercise of his pencil. At last he was enabled to set out for St Petersburg by land; and on his way he encountered the Russian army, then on its route for the campaign that terminated in the bloody field of Austerlitz. He soon arrived in the Russian capital, where the kindness of Crichton, and his other introductions, procured him abundant employment. Allan remained long in Petersburg, where the emoluments of his profession enabled him to indulge his eager desire to travel for improvement in his art; and for several years he made occasional excursions into Southern Russia, Turkey, the Crimea, and Circassia, where he stored his mind, and filled his portfolio, with those vivid sketches of Cossacks, Tartars, Turks, Circassians, and other orientals, of which he made such admirable use in his subsequent pictures.

After a ten years' residence abroad, Mr Allan, in 1814, took up his abode in his native place; where his talents, his unassuming manners, and his interesting conversation, won him the esteem and friendship of Walter Scott, and the other literary ornaments of the northern capital. At this time he produced his masterly picture, *The Circassian Captives*, which, after delighting the eyes of his fellow citizens, was exhibited at London in 1815. This beautiful composition, which united graceful forms and powerful expression with novel and picturesque costumes, established Allan's reputation as a master in the highest walk of art. But liberal collectors were then comparatively rare amongst us; and the picture remained in the studio of the artist, until some of his admiring friends resolved to subscribe what would be a remunerating price, and thus decide by lot who should obtain the picture. The fortunate possessor is the Earl of Wemyss, of whose collection it is a chief ornament. About the same time, the Grand Duke Nicolas, now emperor of Russia, visited Edinburgh, and purchased two of Allan's capital pictures, *Siberian Exiles*, and the Circassian prince *Haslan Gheray crossing the River Kuban with his followers*. This imperial patronage gave a very favourable turn to the fortunes of the painter, whose pictures were now sought for by collectors.

Mr Allan, however, had the misfortune to suffer from ophthalmia, which threatened him with total blindness. Obliged to suspend his loved profession, he was advised to spend the winter in the milder air of Italy. He went to Rome during that season, and to Naples in the hot weather, from whence he passed to Constantinople. With renovated health, he returned home by the classic shores of Asia Minor and Greece, and with rich stores of materials for future compositions, as appeared in his fine picture of the *Constantinopolitan Slave-Market*, and other productions of his pencil. For several years he uninterruptedly pursued his profession in Edinburgh; but in 1834, the care of his health, and his desire of further improvement in his art, induced him to visit the south of Spain; and he made a short excursion to the opposite coast of Marocco. In 1841 he went again to Petersburg; when he was employed by his imperial patron to paint *Peter the Great as a Naval Architect*, a fine composition, which is now in the winter palace of the emperor, after having been exhibited in London in 1845. The author of this memoir met him in Holland in 1847, on his return from a professional tour in Germany and Belgium; making, as was his custom, his relaxation from the pencil subservient to his love of his art.

Mr Allan had been elected an *Associate* of the Royal Academy of London in 1826, and an *Academician* in 1835. Honours now flowed in upon him. On the death of his early friend Sir David Wilkie, he was appointed *Limner to Her Majesty for Scotland.* On the decease of the president of the Scottish Academy in 1838, Allan was elected to that office, which he held till his death; in 1842 he received the honour of knighthood; and in 1849, he was appointed one of the commissioners of the Board of Arts and Manufactures; but the declining state of his health, which was but too obvious to his friends, induced him to decline the honourable office, to the sincere regret of the members of that Board.

Sir William Allan was now confined to the house by a chronic bronchitis. But his professional energy and love for his art remained unabated; and, till increasing debility interrupted his labours, he was assiduously engaged on a grand picture—the subject being *Bruce at Bannockburn*—which, though far advanced, remains unfinished. It exhibits no trace of impaired powers; and it is as conspicuous as his two fine pictures of the *Battle of Waterloo*, for the spirit of the composition, and the skill with which the artist has contrived to vary the formality of armies drawn up in battle array, by interesting episodes, all conducive to the main story.

Sir William Allan died on Friday, 22d of February 1850, unmarried, in the 68th year of his age, deeply regretted by numerous friends, and by the public, who justly considered him as an ornament to the country that gave him birth. The following is a chronological list of the principal works of this eminent artist:—

1. Circassian Captives. 2. Tartar Bandits. 3. Haslan Gheray crossing the Kuban. 4. Polish-Jewish Wedding. 5. Siberian Exiles with their Cossack Guards. 6. Slave-Market at Constantinople. 7. Lord Byron after crossing the Hellespont at Abydos. 8. Assassination of David Rizzio; by many considered his masterpiece. 9. Moorish Love-Letter. 10. Battle of Prestonpans. 11. Incident in the campaign of Robert Bruce in Ireland. 12. Peter the Great teaching Shipbuilding to his Subjects. 13. Polish Exiles on their route to Siberia. 14. Naval Battle. 15. Battle of Waterloo from the French position; purchased by the Duke of Wellington. 16. Napoleon and the English Sailors at Boulogne. 17. Battle of Waterloo from the English position. This picture was painted for the competition of artists in Westminster Hall in 1846; but though highly prized by the best judges, was not successful. 19. Several fine landscapes of Scottish scenery. 20. Battle of Bannockburn, left unfinished. (T. S. T.)

ALLAN, a river of Perthshire, in Scotland, which passes by Dunblane, and falls into the Forth near Stirling.

ALLAN, *Bridge of*, a beautiful village on the above river, three miles from Stirling, much frequented in summer on account of its mineral well. It has rapidly increased in size within the last few years.

ALLANTOIS, or ALLANTOIDES, a thin transparent bag investing the fœtus of quadrupeds, as cows, goats, sheep, &c., filled with a urinous liquor conveyed to it from the bladder of the young animals by means of the urachus.

ALLATIUS, LEO, keeper of the Vatican library, a native of Scio, and a celebrated writer of the seventeenth century. He was of great service to the Port Royalists in their controversy with M. Claude, touching the belief of the Greeks with regard to the eucharist. No Latin was ever more devoted to the See of Rome, or more inveterate against the Greek schismatics, than Allatius. He never was married, nor did he take orders; and when Pope Alexander VII. asked him one day why he did not enter into orders, he answered, "Because I would be free to marry." The pope rejoined, "If so, why do you not marry?" "Because," replied Allatius, "I would be at liberty to take orders." "Thus," as the sarcastic Bayle observes, "he passed his whole life, wavering between a parish and a wife; sorry, perhaps, at his death, for having chosen neither of them; when, if he had fixed upon one, he might have repented his choice for thirty or forty years." In his works he discovers more erudition and industry than sound judgment; and his style is perplexed and diffuse. He died at Rome in 1669, aged 83.

ALLECTUS, the prime minister and confidential friend of Carausius, emperor of Britain. In order to avoid the punishment due to the several enormous crimes with which he was chargeable, he fell upon the desperate expedient of murdering his master, and usurping the imperial dignity, which he maintained for three years. With the design of recovering Britain, the Cæsar Constantius despatched a portion of his fleet and army under the command of the prætorian præfect Asclepiodotus. The fleet of Allectus was stationed off the Isle of Wight to receive them; but under the cover of a thick fog, the invaders escaped their notice, and landed in safety on the western coast, and, according to Gibbon, convinced the Britons "that a superiority of naval strength will not always protect their country from a foreign invasion." In expectation of an attack from Constantius, who commanded the fleet off Boulogne, the usurper had taken his station in the vicinity of London; but informed of the descent of Asclepiodotus, he made forced marches to oppose his progress. In the battle which ensued Allectus was slain, and his forces received a total defeat; and thus Britain, after a separation of ten years, was restored to the Roman empire, A.D. 297.

ALLEGANY, the name of several counties in the United States of North America.—1. In the state of New York, with a population in 1850 of 37,880. 2. In Pennsylvania, Pop. 138,098. 3. In Maryland, Pop. 22,873. 4. In the valley district of Virginia, Pop. 3516.

ALLEGANY MOUNTAINS, situated between the Atlantic Ocean, the Mississippi River, and the Lakes, are a long and broad range of mountains, composed of several ridges, tending north-east and south-west, nearly parallel to the sea-coast, about 1100 miles in length, and from 50 to 200 miles in breadth. The ridges which compose this immense range of mountains have different names in the different states, viz., the *Blue Ridge*, the *North Mountain* or *North Ridge*, *Laurel Ridge*, *Jackson's Mountains*, and *Cumberland Mountains*. All these different and immense ridges are penetrated by rivers, which appear to have forced their way through solid rocks. The principal ridge is more especially called *Allegany*, and is descriptively named the *Back Bone of the United States.* The general name of the whole range, taken collectively, is the *Allegany Mountains.* Mr Evans calls them the *Endless Mountains;* others have called them the *Appalachian Mountains*, from a tribe of Indians who lived on a river which proceeds from this mountain, called the *Appalachicola ;* but the most common name is the *Allegany Mountains.*

They pass through the states eastward of the Mississippi like a spine or back-bone, and give rise to nearly all the rivers in that region. They approach the sea at the river Hudson, but take a direction inland from that point, and in Georgia are above 200 miles from the sea. They are generally covered with natural wood, and capable of cultivation, with some exceptions. The soil in the valleys between the ridges is found to be superior to that between the mountains and the sea, and is indeed among the best in the United States. Towards the northern extremity of the Alleganies, the primitive rocks cover a great breadth of country; but southward of New York they are chiefly confined to the eastern slope of the mountains. A zone of transition rocks from 20 to 40 miles in breadth extends nearly the whole length of the chain ; and beyond this to the westward the country is chiefly limestone. They are not confusedly scattered, but run along in ridges generally of a uniform height, estimated on an average at 3000 feet. The ground rises to them from the sea so gradually that their height does not much strike the eye. They contain a considerable variety of minerals, and on the western side great beds of coal.

*Allegany River*, in Pennsylvania, rises on the western side of the Allegany Mountains, and after running about 300 miles in a south-west direction, meets the Monongahela at Pittsburg, and both united form the Ohio. The lands on each side of this river, for 150 miles above Pittsburg, consist of white oak and chesnut ridges, and in many places of poor pitch pines, interspersed with tracts of good land and low meadows. It is navigable for boats of ten tons for 260 miles above Pittsburg.

ALLEGATA, a word anciently subscribed at the bottom of rescripts and constitutions of the emperors; as *signata* or *testata* was under other instruments.

ALLEGIANCE, either derived from the French *Allegeance*, or taken from the same Latin source, has been used to express that duty which a person possessing the privileges of a citizen owes to the state to which he belongs, and is technically applied in law to the duty which a British subject owes to the sovereign as representing the state. It has been divided by the English legal commentators into natural and local; the latter applying only to the deference which a foreigner must pay to the institutions of the country in which he happens to live; but it is in its wider sense that the word is important, as representing a condition attached to mankind, of which it is very difficult in theory, and still more in practice, to adjust the true character and limits. For a state to decide what persons are bound to it by allegiance may be easy, but for a man to know where his allegiance lies when two or more states claim him—and hence for jurists to decide what is the reasonable extent to which any state ought to make such a claim, is often involved in difficulty. In oriental nations caste and tribe seem to have been the barriers of nationality; and when these were once overcome, people seem to have been in general free to choose their allegiance. But in most ancient nations, including Greece and Rome, the absence of the courtesies of war, since introduced by chivalry and feudality, prevented an opening for the nice questions arising in later days, since the enemy overcome in war, whether he might have been alien or denizen according to our modern notions, was slain or enslaved. Nice as is the question, what should constitute the allegiance which makes war against a state high treason in the soldier, and renders him liable to be punished as a criminal instead of being received as a prisoner of war, British constitutional law has defined it in the broadest manner. By its doctrine every person born within the British dominions, though he should be removed in infancy to another country wherein his family resides, owes an allegiance to the British Crown, which he can never resign or lose. This was found in the case of Æneas Macdonald, tried for accession to the rebellion of 1745, who, though born in Britain, had been removed in childhood, and having been educated in France held a commission in the French army (Foster's Reports, 59). It will not apparently affect this broad principle, then, that the parents are foreigners. But further, according to the strict rule of the law, as the son or grandson of a British subject is entitled to the privilege of a natural born subject (see ALIEN) he must acquire it with its obligation, and commits high treason if he make war against Britain. The cause of so hard and irrational a principle is that the English law has taken the theory of allegiance entire from the feudal system, where it involved fidelity approaching to bondage due by the vassal to the lord. Hence the great English lawyers have exhausted their eloquence in describing the illimitable character of allegiance. In the celebrated case of the *Post-nati*, Bacon said, "Allegiance is of a greater extent and dimension than laws or kingdom, and cannot consist by the laws merely, because it began before all laws: it continueth after laws, and it is in vigour when laws are suspended and have not their force." Coke, on the same occasion, said "whatsoever is due by law or constitution of man may be altered: but natural ligeance or obedience of the subject to the sovereign cannot be altered."—(St. Tr. II. 596, 652), and in his Institutes he defines allegiance as "The greatest obligation and duty that can be." Though our law counts every one a liege subject who is not an alien, yet it permits aliens to acquire rights without exacting the burden of allegiance [ALIEN]. In other countries the same classification will be found more or less to apply—aliens will be able to obtain some rights of citizens without coming under the obligations of allegiance, and the rights and obligations of allegiance will be impartable to persons who have not lost a similar position in the country of birth. It would be interesting to possess an account, throughout the civilised world, of the way in which citizenship may be lost to a native and acquired by a stranger in each state. Any attempt to lay down such particulars from law books would incur the risk of making statements which have been superseded; and there is the farther difficulty, that while the practical extent of the law is often to be known only by practice, wherever its principles are invidious or oppressive there is a reluctance to carry it out. No man, for instance, would be put on trial for high treason, for taking service against Britain, because his grandfather was an Englishman. It may be maintained, however, that a great deal of information on the methods of acquiring citizenship in foreign states is to be found in the evidence taken by the select committee of 1843, on the laws affecting aliens (Parl. Pap. No. 307). It will be in questions between European governments and the United States, that the true rule by which citizenship should be lost or acquired will come out in its broadest shape, since it is the principle of that empire to receive and enrol among the citizens owing it allegiance, people from all parts of Europe, without inquiring whether they have lost or can give up their native allegiance. The enactment of naturalisation laws is reserved by the constitution for Congress, and it is a characteristic part of the system that only free white persons can acquire the privilege. The general tenor of the acts of Congress from 1802 to 1828, regulating naturalisation is, that the person received must be a native of a country at peace with the States, that he be qualified by a five years' residence, abjure any title or order of nobility he may have possessed, and take an oath of allegiance in which he obliges himself to support the constitution of the United States, and abjures his previous allegiance (Kent's Com. 3d edition. i. 63–4.) (J. H. B.)

Allegiance, *Oath of*, one of the oaths required of people in public office or trust, and which by laws either repealed or in virtual disuse might be tendered to any person. The oath having assumed a servile character was, at the Revolution, modified into a simple engagement to bear allegiance to the sovereign.

ALLEGORY, in *Composition*, consists in choosing a secondary subject, having all its properties and circumstances resembling those of the principal subject, and describing the former in such a manner as to represent the latter. The principal subject is thus kept out of view, and we are left to discover it by reflection.

Nothing gives greater pleasure than an allegory, when the representative subject bears a strong analogy, in all its circumstances, to that which is represented. But most writers are unlucky in their choice, the analogy being generally so faint and obscure, as rather to puzzle than to please; or on the other hand, so obvious as not to awaken our curiosity. As an example of a well-sustained allegory we may point to Bunyan's *Pilgrim's Progress*. Spenser's *Faëry Queen*, again, has both the defects we have mentioned. Allegories, as well as metaphors and similes, are unnatural in expressing any severe passion which totally occupies the mind. For this reason, the latter part of the following speech of Macbeth is justly condemned by the learned author of the *Elements of Criticism:*

Methought I heard a voice cry, Sleep no more!
Macbeth doth murder Sleep, the innocent sleep;
Sleep, that knits up the ravell'd sleeve of care,
The birth of each day's life, sore labour's bath,
Balm of hurt minds, great Nature's second course,
Chief nourisher in life's feast. *Act* ii. *sc.* 2.

ALLEGRI, Antonio, called *Coreggio*, from the place of his birth, a most celebrated historical painter, was born in the year 1494. It is a mistake to represent Coreggio as of mean descent. His family was respectable, and the place of his birth, a small, neat city. Of his studies we know little, except that he entered the school of Francesco Bianchi, and was an expert modeller. Even A. Caracci, his admirer, was ill-informed on his history, which is still obscure, notwithstanding the researches of Mengs, Tiraboschi, and Lanzi. He saw none of the statues of ancient Greece or Rome, nor any of the works of the established schools of Rome and Venice: but Nature was his guide; and Coreggio was one of her favourite pupils. To express the facility with which he painted, he used to say that he always had his thoughts at the end of his pencil.

The agreeable smile, and the profusion of graces, which he gave to his madonnas, saints, and children, have been taxed with being sometimes unnatural; but still they are lovely and attractive. An easy and flowing pencil, a union and harmony of colours, and a perfect intelligence of light and shade, give an astonishing relief to all his pictures, and have been the admiration both of his contemporaries and his successors. Annibale Caracci, who flourished fifty years after him, studied and adopted his manner in preference to that of any other master. In a letter to his cousin Lodovico, he expressed with great warmth the impression which was made on him by the first sight of Coreggio's paintings: "Every thing which I see here," says he, "astonishes me; particularly the colouring, and the beauty of the children. They live, they breathe, they smile with so much grace and so much reality, that it is impossible to refrain from smiling and partaking of their enjoyment. My heart is ready to break with grief when I think on the unhappy fate of poor Coreggio—that so wonderful a man (if he ought not rather to be called an angel) should finish his days so miserably, in a country where his talents were never known!"

From want of curiosity or of patronage, Coreggio never visited Rome, but remained during his whole life at Parma, where the art of painting was little esteemed, and of consequence poorly rewarded. This concurrence of unfavourable circumstances at last occasioned his premature death at the age of forty. He was employed to paint the cupola of the cathedral at Parma, the subject of which is the Assumption of the Virgin, which he executed in a manner that has long been the admiration of every person of good taste, for the grandeur of the design, and especially for the boldness of the fore-shortenings; an art which he first, and at once, brought to the utmost perfection. When he went to receive his payment, the canons of the church, either through ignorance or baseness, found fault with his work; and although the price originally agreed upon had been very moderate, they alleged that it was far above the merit of the artist, and forced him to accept of the paltry sum of 200 livres; which, to add to the indignity, they paid him in copper money. To carry home this unworthy load to his wife and children, poor Coreggio had to travel six or eight miles from Parma. The weight of his burden, the heat of the weather, and his chagrin at his villanous treatment, immediately threw him into a pleurisy, which in three days put an end to his life and his misfortunes. The story of the extreme poverty and sufferings of Coreggio is, it seems, untrue; for we are told by Lanzi that he left his family not in indigence, though probably not in affluence.

For the preservation of this magnificent work, the world is indebted to Titian. As he passed through Parma, in the suite of Charles V., he ran instantly to see the *chef d'œuvre* of Coreggio. While he was attentively viewing it, one of the principal canons of the church told him that such a grotesque performance did not merit his notice, and that they intended soon to have the whole defaced. "Have a care of what you do," replied the other; "if I were not Titian, I should certainly wish to be Coreggio."

Coreggio's exclamation upon viewing a picture by Raphael is well known. Having long been accustomed to hear the most unbounded applause bestowed on the works of that divine painter, he by degrees became less desirous than afraid of seeing any of them. One, however, he at last had occasion to see. He examined it attentively for some minutes in profound silence; and then, with an air of satisfaction, exclaimed, *I am still a painter*. Giulio Romano, on seeing some of Coreggio's pictures at Parma, declared they were superior to anything in painting he had yet beheld. One of these, no doubt, was the famous Virgin and Child, with Mary Magdalene and St Jerome. The no less famous *Notte*, or Night, of Coreggio, was sold for a great sum of money to Augustus II. the king of Poland, and is now in his *family* gallery at Dresden.

When speaking of his more finished works, Mengs, a most able critic, places Coreggio second in the triad with Raphael and Titian. He considers him inferior to the former in exquisite delineation of the affections of the soul, but before him in the expression of external character, from his unrivalled colouring and admirable chiaroscuro, which clothe his compositions with a very natural species of ideal beauty. This praise has chiefly been bestowed on his St Jerome and his *Notte* by Annibale Caracci, by Mengs, and Algarotti. His design, indeed, exhibits not the daring depth of Buonarotti; but he is at once so grand and judicious in this

Allegri.

respect, that the two Caracci adopted him as their model of excellence. True, his compositions have not the varied outline of Raphael, or of the ancients, because his principle was to avoid angles and straight lines; and he studied a softly undulating outline, to which Mengs attributes his grace. His draperies are much commended for the fine disposition of their general masses, rather than for his attention to particular folds. His infantine and youthful heads are beaming with nature and simplicity. But the variety of his daring fore-shortenings is truly astonishing; and by introducing them freely in his ceilings, which Raphael rather avoided, he overcomes difficulties in that species of painting till his time never conquered. His greatest charm, however, lies in the exquisite harmony of his lucid colouring, which must be acknowledged by all who have ever attentively examined his magnificent 'Communion of St Jerome,' his 'Notte,' his 'Reposing Magdalen,' or the 'Ecce Homo,' and 'Mercury teaching Cupid in the presence of Venus,' of the British National Gallery.

The principle of Coreggio's design is the soft transition from the convex to the concave outline, combining power with grace. The principle of his harmonious lights and shadows is a central globe of light, softly passing through clear semitones into rich reflex shadows. This is the keynote to his compositions, to which every other quality is made subordinate, and gives a mellowness to his colouring which no other artist ever obtained. This great painter's death happened in 1534.—Lanzi, *Stor. Pittor.* iv.; Mengs, *Opere;* Tiraboschi, *Storia della Lit. Italiana.* (T. S. T.)

Allegri, *Gregorio*, an ecclesiastic by profession, and a celebrated composer of music of the seventeenth century, was a native of Rome. He was the disciple of Nanini, the intimate friend and contemporary of Palestrina. His abilities as a singer were not remarkable, but he was deemed an excellent master of harmony, and so much respected by all the musical professors of his time that the pope, in the year 1629, appointed him to be one of the singers in his chapel. To his uncommon merit as a composer of church music, he united an excellent moral character, exhibiting in his actions the devotion and benevolence of his heart. The poor crowded daily to his door, and were relieved to the utmost of his ability; and not content with these beneficent actions, he daily visited the prisons of Rome, in order to relieve the most deserving and afflicted objects immured in these dreary mansions. With such exquisite simplicity and purity of harmony did he compose many parts of the church service, that his loss was severely felt, and sincerely was it lamented by the whole college of singers in the papal service. He died on the 18th February 1650, and was interred in the Chiesa Nuova, in a vault destined for the reception of deceased singers of the pope's chapel, before the chapel of S. Filippo Neri, near the altar of the annunciation.

Among his other musical works preserved in the pontifical chapel, is the celebrated *Miserere*, which is still annually performed at that chapel on Wednesday and Good Friday in Passion Week, by the choral band and the best singers in Italy. It is, however, generally believed that it owes its reputation more to the manner in which it is performed than to the composition itself. The beauty and effect of the music is not discernible upon paper, but the singers have by tradition certain customs, expressions, and graces of conventions, which produce wonderful effects. Some of the effects produced may be justly attributed to the time, the place, and the solemnity of the ceremonials observed during the performance. "The pope and conclave are all prostrated on the ground, the candles of the chapel and the torches of the balustrade are extinguished one by one, and the last verse of this psalm is terminated by two choirs; the *maestro di cappella* beating time slower and slower, and the singers diminishing or rather extinguishing the harmony by little and little, to a perfect point." Padre Martini says that there never were more than three copies made by authority, "one of which was for the emperor Leopold, one for the late king of Portugal, and the other for himself;" but a very complete one was presented by the pope to King George III. as an inestimable curiosity.

Allegro || Alleluiah.

ALLEGRO, in *Music*. See Music.

ALLEIN, Joseph, the son of Tobias Allein, was born at Devizes, in Wiltshire, in 1633, and educated at Oxford. In 1655 he became assistant to Mr Newton, in Taunton-Magdalen, in Somersetshire; but was ejected for nonconformity. He died in 1668, aged 35. He was a man of great learning and greater charity; preserving, though a nonconformist, and a severe sufferer on that account, great respect for the church, and loyalty to his sovereign. He wrote several books of piety, which are highly esteemed,—especially his *Alarm to Unconverted Sinners.* There have been many editions of this pious little work, the sale of which has been very great.

Allein, *Richard*, an English nonconformist divine, was born at Ditchet, in Somersetshire, in 1611. His father was rector of Ditchet, and conducted the education of his son until he was prepared for the Oxford university. There he soon obtained the degree of master of arts; and after he entered into holy orders, first as an assistant to his father, and afterwards as rector of Batcomb, in Somersetshire, he discharged the duties of a clergyman with great industry, and singular fidelity. He was a zealous puritan, and was appointed assistant to the parliamentary commissioners whose business it was to eject "scandalous ministers;" in which office his father also bore a part. At the Restoration he in his turn was ejected from the rectory of Batcomb, which he had creditably held for twenty years, because he could not conscientiously accede to the terms of the act of conformity. But in the house of Mr More, who had been a member of the long parliament, he continued to exercise his ministerial functions in defiance of the penalties imposed by that act. Although frequently reprimanded for his conduct in this matter, his piety and exemplary conduct procured him a mitigation of the punishment. No dangers could deter him from duty; for although constrained to remove from Batcomb, in consequence of the "five-mile act," he continued in the discharge of his ministerial office at Frome-Selwood. Here he remained until his labours were terminated by death, in 1691.

His most celebrated work is called *Vindiciæ Pietatis*, which is still esteemed by theologians of the nonconformist school; another is *Heaven Opened*, and a third *The World Conquered;* all giving proof of his fervent piety.

ALLELUIAH, or Halleluiah, a Hebrew word signifying *Praise the Lord*, to be met with either at the beginning or end of some psalms; such as psalm cxlvi. and those that follow to the end. Alleluiah was sung upon solemn days of rejoicing, Tobit xiii. 18. St John in the Revelation (xix. 1, 3, 4, 6) says, that he "heard a great voice of much people in heaven, saying, Alleluiah: . . . and the four and twenty elders and the four beasts fell down and worshipped God that sat on the throne, saying, Amen, Alleluiah." This hymn of joy and praises was transferred from the synagogue to the church. So much energy has been observed in this term, that the ancient church thought proper to preserve it, without translating it either into Greek or Latin, for fear of impairing its softness and expression. The fourth council of Toledo has prohibited the use of it in time of Lent, or other days of fasting, and in the ceremonies of mourning; and, according to the present practice of the Romish Church, this word is never repeated in Lent, nor in the obsequies of the dead: notwithstanding which, it is used in the mass for the dead, according to the Mosarabic ritual, at the introit, when they sing, *Tu es portio mea, Domine, Alleluiah, in terra viventium, Alleluiah, Alleluiah.*

ALLEMOND, a town of Upper Dauphiny, in the arrondissement of Grenoble, in France. In the mountains of Chalanches, near it, a lead mine with silver was discovered in 1767, which yielded by smelting, in somewhat less than twenty years, upwards of 300,000 ounces of silver.

ALLEN, John, archbishop of Dublin in the reign of King Henry VIII., was born in 1476, and educated in the university of Oxford. From thence he removed to Cambridge, where he took the degree of bachelor of laws. He was sent by Dr Warham, archbishop of Canterbury, to the pope, on certain business relating to the church. He continued at Rome nine years, and was created doctor of laws, either there or in some other university of Italy. After his return he was appointed chaplain to Cardinal Wolsey, and was commissary or judge of his court as legate *a latere;* in the execution of which office he was suspected of great dishonesty, and even perjury. He assisted the cardinal in visiting, and afterwards suppressing, forty of the smaller monasteries, for the erection of his college at Oxford and that at Ipswich. In 1528 he was consecrated archbishop of Dublin; and about the same time was made chancellor of Ireland. He was cruelly murdered in July 1534, by Thomas Fitzgerald, eldest son of the earl of Kildare.

Allen, *John*, M.D., was born near Edinburgh in 1770, and educated at the university of that city, where he took the degree of M.D. in 1791. With youthful enthusiasm, Allen joined the Scottish movement of that period for parliamentary reform; and this circumstance, according to the policy of the day, probably being an impediment to professional employment, induced him to become a lecturer on physiology in Edinburgh, where he was distinguished by the precise philosophical views and clearness of his prelections.

Some years afterwards, he took up his abode in Holland House, as the friend and private secretary of the late Lord Holland. In 1811 he was elected warden of Dulwich College; and in 1820 obtained the comfortable sinecure of master of that institution, where he died in 1843.

Allen's detached publications, though well-written, are not very important, if we except his valuable "*Inquiry into the growth of the Royal Prerogative*," which appeared in 1830; but he was an able contributor to the *Edinburgh Review*, of not less, it is said, than forty articles, chiefly on physiological, metaphysical, and political subjects; and some of his contributions on French and Spanish history are very interesting. To this last department he was probably directed by his intimacy with Lord Holland. Dr Allen was a man of vigorous mind, and extensive information. (T. S. T.)

Allen, *Thomas*, a famous English mathematician, was born at Uttoxeter, in Staffordshire, on the 21st of December 1542. He was admitted scholar of Trinity College, Oxford, on the 4th of June 1561; and in 1567 took his degree of master of arts. In 1580 he quitted his college and fellowship, and retired to Gloucester Hall; where he studied very closely, and became famous for his knowledge in antiquity, philosophy, and mathematics. Having received an invitation from Henry, earl of Northumberland, a great friend and patron of mathematicians, he spent some time at the earl's house, where he became acquainted with those celebrated mathematicians, Thomas Harriot, John Dee, Walter Warner, and Nathaniel Torporley. Robert, earl of Leicester, had a particular esteem for Allen, and would have conferred a bishopric upon him; but his love of solitude and retirement made him decline the offer. His great skill in the mathematics earned him, as was usual in those times, the credit of being a magician; and the sagacious author of a book entitled *Leicester's Commonwealth*, accuses him of employing the art of "figuring" to further the earl of Leicester's unlawful designs, and of endeavouring by the black art to bring about a match between him and Queen Elizabeth. Allen was indefatigable in collecting scattered manuscripts relating to history, antiquity, astronomy, philosophy, and mathematics. A considerable part of his collection was bestowed on the Bodleian Library by Sir Kenelm Digby. He published in Latin the second and third books of Claudius Ptolemy of Pelusium, *Concerning the Judgment of the Stars*, or, as it is commonly called, of the *Quadripartite Construction*, with an exposition. He wrote also notes on many of Lilly's books, and some on John Bale's work *De Scriptoribus M. Britanniæ*. He died at Gloucester Hall on the 30th September 1632, at the great age of 90.

Allen, *William*, an eminent pharmaceutical chemist, and chemical lecturer in London, was born in 1770. He early showed a predilection for experimental investigations, and was placed in a respectable pharmaco-chemical establishment in Plough Court, in which he afterwards became a partner with Luke Howard. While successfully pursuing his business Allen engaged in various important experimental investigations. In 1804, he was appointed lecturer on chemistry at Guy's Hospital, an office from which he did not finally retire till 1827. He became a fellow of the Royal Society in 1807; and several of his communications appear in the *Philosophical Transactions*, especially the important experimental researches by him and Mr Pepys on *Respiration*. He was a zealous member and a president of the pharmaceutical society. But along with his scientific occupations, he was an active promoter of various schemes of benevolence. He had purchased an estate near Lindfield in Sussex, to which he retired several years before his death. There he devoted himself to the establishment of schools, to which workshops for the children, a library, and experimental laboratory were attached, and where he himself gave occasional instruction to the young experimentalists. He was highly esteemed in private life, and died, much regretted, at his house near Lindfield, in 1843. (T. S. T.)

ALLENDORF, a city, capital of the bailiwick of the same name in Hesse-Cassel. It contains 3935 inhabitants. In the suburb is a salt-spring of great strength, and works for granulating and drying the salt.

ALLER, a river which rises in the district of Magdeburg in Prussia, and passing through the duchy of Luneburg falls into the Weser a little below Verden.

Aller, sometimes written *alder*, an old Saxon form of superlative. Thus *aller-good* signifies the greatest good.

ALLERION, or Alerion, in *Heraldry*, a sort of eagle without beak or feet, having nothing perfect but the wings. They differ from marlets in having their wings expanded; and denote imperialists vanquished and disarmed; for which reason they are more common in French than in German coats of arms.

ALLESTREE, or ALLESTRY, Richard, D.D., was born at Uppington in Shropshire in 1619, and educated in the grammar school of Coventry, and afterwards at Christ Church in Oxford. His natural talents, which were uncommonly vigorous, were carefully improved by unwearied application to study. Accordingly, his promotion was rapid. After passing as bachelor of arts, he was made successively moderator in philosophy, canon of Christ Church, doctor of divinity, chaplain in ordinary to the king, and regius professor of divinity. His early studies, however, were interrupted by the hostilities of the times. In the year 1641 he and many other students of Oxford entered the royal service, and gave eminent proofs of their courage and loyalty. A short interval of hostilities permitted Allestry to return to his literary pursuits; but soon after he again took up arms, and was present at the battle of Keinton-field. On his way to Oxford to prepare for the reception of the king he was taken prisoner, but was released by the king's forces. A violent disease which then prevailed in the garrison of Oxford brought Allestry to the brink of the grave; but recovering, he again joined a regiment of volunteers, chiefly consisting of Oxford students. Here he served as a common soldier, and was often seen with the musket in one hand and a book in the other. At the close of the revolutionary struggle, he returned to his favourite studies, but still continued true to his party. This occasioned his expulsion from the college; but he was provided with a comfortable retreat in the families of the Honourable Francis Newport and Sir Anthony Cope.

Such was the confidence reposed in him, that when the friends of Charles II. were secretly preparing the way for his restoration, they intrusted him with personal messages to the king. In returning from one of these interviews he was seized at Dover, and upon examination committed a prisoner to Lambeth House. The Earl of Shaftesbury obtained his release in a few weeks. Returning to visit his friends, and among others the learned Dr Hammond, he met his corpse at the gate of his house, on its way to the grave. This melancholy occurrence deeply affected his mind. The doctor left him his library, assigning as a reason that "he well knew that his books in his hands would be useful weapons for the defence of that cause he had so vigorously supported." This valuable library, along with his own, Allestry bequeathed at his death to the university. He died in January 1681.

Allestry erected at his own private expense the west side of the outward court of Eton College, and the grammar school in Christ Church College; besides settling several liberal pensions upon individual persons and families. A volume of sermons, printed at Oxford in 1684, is all by which posterity can judge of his literary abilities.

Allestry, *Jacob*, an English poet of the seventeenth century, was the son of James Allestry, a bookseller of London. He was educated at Westminster School, entered at Christ Church, Oxford, in the act-term 1671, at the age of 18, and was elected student in 1672. He died young on the 15th October 1686. Some of his poems are to be found in a collection of "Miscellany Poems," published in 1721.

ALLEY, William, bishop of Exeter in the reign of Queen Elizabeth, was born at Great Wycomb in Buckinghamshire. From Eton School, in the year 1528 he removed to King's College, Cambridge, where he took the degree of bachelor of arts. He also studied some time at Oxford: afterwards he married, was presented with a living, and became a zealous reformer. Upon Queen Mary's accession he left his cure and retired into the north of England, where he maintained himself and his wife by teaching a school, and practising physic. When Elizabeth came to the throne, he went to London, where he acquired great reputation by reading the divinity lecture at St Paul's; and in July 1660 was consecrated bishop of Exeter. He died on the 15th of April 1570, and was buried at Exeter, in the cathedral. He wrote, among other things, The Poor Man's Library, 2 vols. folio, London 1571, containing twelve lectures on the first epistle of St Peter, read at St Paul's; and a Hebrew Grammar. He also translated the Pentateuch, in the version of the Scriptures known as *the Bishop's Bible*.

ALLEYN, Edward, a celebrated English actor in the reigns of Queen Elizabeth and King James, and founder of the college of Dulwich in Surrey, was born at London, in the parish of St Botolph, on the 1st of September 1566, as appears from a memorandum of his own writing. Dr Fuller says that he was bred a stage-player, and that his father would have given him a liberal education, but that he was not turned for a serious course of life. He was, however, a youth of excellent capacity, cheerful temper, tenacious memory, graceful elocution, and stately aspect, advantages that might probably have induced their possessor to adopt the theatrical profession. By several authorities we find he must have been on the stage some time before 1592; for at that time he was in high favour with the town, and greatly applauded by the best judges, particularly by Ben Jonson.

Heywood, in his prologue to Marlowe's *Jew of Malta*, calls him

Proteus for shapes, and Roscius for a tongue.

He usually played the capital parts, and was one of the original actors in Shakspeare's plays: in some of Ben Jonson's he was also a principal performer; but what characters he personated in any of their plays, it is difficult now to determine. This is owing to the inaccuracy of their editors, who did not print the names of the players opposite to the characters they performed, as the modern custom is; but gave one general list of actors to the whole set of plays, as in the old folio edition of Shakspeare; or divided one from the other, setting the dramatis personæ before the plays, and the catalogue of performers after them, as in Jonson's.

It may appear surprising that one of Alleyn's profession should be enabled to erect such an edifice as Dulwich College, and liberally endow it for the maintenance of so many persons. But it must be observed that he had some paternal fortune, which, though small, might lay a foundation for his future affluence; and it is to be presumed that the profits he received from acting must have considerably improved his fortune: besides, he was not only actor, but proprietor of a playhouse built at his own expense, by which he is said to have amassed considerable wealth. He was also master of the royal bear-garden, which was frequented by vast crowds of spectators; and the profits arising from these sports are said to have amounted to L.500 per annum. He was thrice married; and the portions of his first two wives, they leaving him no issue, would probably increase his wealth. Aubrey mentions a tradition, that when Alleyn was personating a demon, with six others, in one of Shakspeare's plays, in the midst of the play he was surprised by an apparition of the devil; which so worked on his fancy, that he made a vow, which he performed by building Dulwich College. The foundation of this college was begun under the direction of Inigo Jones, in 1614; and the buildings, gardens, &c., on which he is said to have expended about L.10,000, were finished in 1617. After the college was built, he met with some difficulty in obtaining a charter for settling his lands in mortmain; for he proposed to endow it with L.800 per annum, for the maintenance of one master, one warden, and four fellows, three whereof were to be clergymen, and the fourth a skilful organist; also six poor men and as many women; besides twelve poor boys to be educated till the age of fourteen or sixteen, and then put out to some trade or calling. The obstruction he met with arose from the Lord Chancellor Bacon, who wished King James to settle part of those lands for support of two academical lectures, and wrote a letter to the Marquis of Buckingham, dated August 18, 1618, entreating him to use his interest with his Majesty for that purpose. Alleyn's solicitation was, however, at last complied with, and he obtained the royal license, giving him full power to lay his foundation, by his Majesty's letters-patent, bearing date the 21st of June 1619. He was himself the first master of his college; so that, to make use of the words of Heywood, one of his contemporaries, "He was so mingled with humility and charity, that he became his own pensioner, humbly submitting himself to that proportion of diet and clothes which he had bestowed on others." We have no reason to think he ever repented of this distribution of his substance; but, on the contrary, that he was entirely satisfied, as appears from the following memorial in his own writing, found amongst his papers:—"May 26. 1620. My wife and I acknowledged the fine at the common pleas bar, of all our lands to the college: blessed be God that hath given us life to do it." His wife died in the year 1623; and about two years afterwards he married Constance Hinchtoe, who survived him. He died on the 25th of November 1626, in the 61st year of his age, and was buried in the chapel of his new college, where there is a tombstone over his grave, with an inscription. His original diary is also there preserved.

Alleyn lived on the most friendly terms with both Shakspeare and Ben Jonson. They used frequently to spend their evenings together at the sign of the Globe, somewhere near Blackfriars, where the playhouse then was. The following letter gives a small but interesting glimpse of these *noctes cœnæque Deorum.* The writer was a student of Christ Church, Oxford, a dramatic poet, who belonged to the Club.

"Friend Marle,

"I must desyr that my syster hyr watch, and the cookerie book you promysed, may be sente bye the man. I never longed for thy company more than last night: we were all very merrye at the Globe, when Ned Alleyn did not scruple to affyrme pleasauntly to thy Friende Will, that he had stolen his speech about thee Qualityes of an actor's excellencye in Hamlet hys Tragedye, from conversations manyfold which had passed betweene them, and opinyons given by Alleyn touching the subjecte. Shakspeare did not take this talke in good sorte: but Jonson put an ende to the strife with wittylye remarkinge, *This affaire needeth no Contentione; you stole it from Ned, no doubte; do not marvel: Have you not seen him act tymes out of number?*—Believe me most syncerilie yours, G. Peele."

ALLIA, a small river of Italy, in the Sabine territory, which joins the Tiber eleven miles from Rome; famous for the great slaughter of the Romans by the Gauls under Brennus, when 40,000 were killed or put to flight; hence *Alliensis dies*, an unlucky day (Virgil, Ovid, Lucan).

ALLIANCE in the *Civil* and *Canon Law*, the relation contracted between two persons or two families by marriage.

Alliance is also used for a treaty entered into by sovereign princes and states, for their mutual safety and defence. In this sense, alliances may be distinguished into such as are offensive, whereby the contracting parties oblige themselves jointly to attack some other power; and into defensive ones, whereby they bind themselves to stand by and defend each other in case they are attacked by others. The forms or ceremonies of alliances have been various in different ages and countries. In ancient times eating and drinking together, chiefly offering sacrifices together, were the customary mode of ratifying an alliance. Among the Jews and Chaldeans, heifers or calves, among the Greeks, bulls or goats, and among the Romans, hogs were sacrificed on this occasion. Among the ancient Arabs, alliances were confirmed by drawing blood out of the palms of the hands of the two contracting princes with a sharp stone, dipping therein a piece of their garments, and therewith smearing seven stones, at the same time invoking the gods Vrotalt and Alilat, *i. e.*, according to Herodotus, Bacchus, and Uranius. Among the people of Colchis, the confirmation of alliances was said to be effected by one of the princes offering his wife's breasts to the other to suck, which he was obliged to do till the blood flowed.

ALLIER, a department of France, on a river of the same name, which runs at the foot of a branch of the Cevennes Mountains. It extends over 2828 square miles, and in 1851 contained 336,758 inhabitants. It is composed of a part of the ancient province of Bourbonnois, and is divided into four arrondissements, viz., Mount Luçon, Moulins, Gannat, and La Palisse.

Allier, *Louis*, who afterwards assumed the name of Hauteroche, was a famous French antiquary and numismatist, and the author of several very erudite archæological and numismatical essays. He died in 1827 at the age of 61.

ALLIGATI, in *Roman Antiquity*, the basest kind of slaves. The Romans had three degrees or orders of slaves or servants; the first employed in the management of their estates; the second in the menial or lower functions of the family; and the third, the *alligati*, who worked in fetters, whence their name.

ALLIGATION, the name of a method of solving all questions that relate to the mixture of one ingredient with another. Though writers on arithmetic generally make alligation a branch of that science, yet as it is plainly nothing more than an application of the common properties of numbers, in order to solve a few questions that occur in particular branches of business, we choose rather to keep it distinct from the science of arithmetic.

Alligation is generally divided into *medial* and *alternate*.

Alligation *Medial*, from the rates and quantities of the simples given, discovers the rate of the mixture.

*Rule.* As the total quantity of the simples,
To their price or value;
So any quantity of the mixture,
To the rate.

*Example.* A grocer mixes 30 lb. of currants, at 4d. per lb., with 10 lb. of other currants, at 6d per lb.: What is the value of 1 lb. of the mixture? *Ans.* $4\frac{1}{2}$d.

| *lb.* | | *d.* | | *d.* |
|---|---|---|---|---|
| 30 | at | 4 | amounts to | 120 |
| 10 | at | 6 | ——— | 60 |
| — | | | | —— |
| 40 | | | | 180 |

*lb.* *d.* *lb.* *d.*
If 40 : 180 : : 1 : $4\frac{1}{2}$.

Alligation *Alternate*, being the converse of alligation medial, from the rates of the simples, and rate of the mixture given, finds the quantities of the simples.

*Rules.* I. Place the rate of the mixture on the left side of a brace, as the root; and on the right side of the brace set the rates of the several simples, under one another, as the branches. II. Link or alligate the branches, so as one greater and another less than the root may be linked or yoked together. III. Set the difference between the root and the several branches right against their respective yoke-fellows. These alternate differences are the quantities required. *Note* 1. If any branch happen to have two or more yoke-fellows, the difference between the root and these yoke-fellows must be placed right against the said branch, one after another, and added into one sum. 2. In some questions the branches may be alligated more ways than one; and a question will always admit of so many answers as there are different ways of linking the branches.

Alligation alternate admits of three varieties, viz., 1. The question may be unlimited, with respect both to the quantity of the simples and that of the mixture. 2. The question may be limited to a certain quantity of one or more of the simples. 3. The question may be limited to a certain quantity of the mixture.

*Variety* I. When the question is unlimited, with respect both to the quantity of the simples and that of the mixture, this is called *Alligation Simple.*

*Example.* A grocer would mix sugars at 5d., 7d., and 10d. per lb., so as to sell the mixture or compound at 8d. per lb.: What quantity of each must he take?

| | | | *lb.* |
|---|---|---|---|
| 8 | 5 | 2 | 2 |
| | 7 | 2 | 2 |
| | 10 | 3,1 | 4. |

Here the rate of the mixture 8 is placed on the left side of the brace as the root; and on the right side of the same brace are set the rates of the several simples, viz., 5, 7, 10, under one another, as the branches; according to Rule I.

The branch 10 being greater than the root, is alligated or linked with 7 and 5, both these being less than the root, as directed in Rule II.

The difference between the root 8 and the branch 5, viz., 3, is set right against this branch's yoke-fellow 10; the difference between 8 and 7 is likewise set right against the yoke-fellow 10; and the difference between 8 and 10, viz., 2, is set right against the two yoke-fellows 7 and 5, as prescribed by Rule III.

As the branch 10 has two differences on the right, viz., 3 and 1, they are added; and the answer to the question is, that 2 lb. at 5d., 2 lb. at 7d., and 4 lb. at 10d., will make the mixture required.

The truth and reason of the rules will appear by considering, that whatever is lost upon any one branch is gained upon its yoke-fellow. Thus, in the above example, by selling 4 lb. of 10d. sugar at 8d. per lb. there is 8d. lost: but the like sum is gained upon its two yoke-fellows, for by selling 2 lb. of 5d. sugar at 8d. per lb., there is 6d. gained; and by selling 2 lb. of 7d. sugar at 8d. there is 2d. gained; and 6d. and 2d. make 8d.

Hence it follows, that the rate of the mixture must always be mean or middle with respect to the rates of the simples; that is, it must be less than the greatest, and greater than the least; otherwise a solution would be impossible. And the price of the total quantity mixed, computed at the rate of the mixture, will always be equal to the sum of the prices of the several quantities cast up at the respective rates of the simples.

*Variety* II. When the question is limited to a certain quantity of one or more of the simples, this is called *Alligation Partial.*

If the quantity of one of the simples only be limited, alligate the branches, and take their differences, as if there had been no such limitation; and then work by the following proportion:—

As the difference right against the rate of the simple whose quantity is given,
To the other differences respectively;
So the quantity given,
To the several quantities sought.

*Example.* A distiller would, with 40 gallons of brandy at 12s. per gallon, mix rum at 7s. per gallon, and gin at 4s. per gallon: How much of the rum and gin must he take, to sell the mixture at 8s. per gallon?

$$\begin{array}{c} \\ 8\left\{\begin{array}{l}12\\7\\4\end{array}\right. \end{array}\begin{array}{c}\\ \begin{array}{r}1,4\\4\\4\end{array}\end{array}\begin{array}{c}\\ \left|\begin{array}{c}5\\4\\4\end{array}\right.\end{array}\begin{array}{l}\textit{Galls.}\\ \left|\begin{array}{l}\text{40 of brandy,}\\\text{32 of rum,}\\\text{32 of gin.}\end{array}\right\}\end{array}\textit{Ans.}$$

The operation gives for answer, 5 gallons of brandy, 4 of rum, and 4 of gin. But the question limits the quantity of brandy to 40 gallons; therefore say,

If 5 : 4 : : 40 : 32.

The quantity of gin, by the operation, being also 4, the proportion needs not be repeated.

*Variety* III. When the question is limited to a certain quantity of the mixture, this is called *Alligation Total.*

After linking the branches, and taking the differences, work by the proportion following:—

As the sum of the differences,
To each particular difference;
So the given total of the mixture,
To the respective quantities required.

*Example.* A vintner has wine at 3s. per gallon, and would mix it with water, so as to make a composition of 144 gallons, worth 2s. 6d. per gallon: How much wine, and how much water, must he take?

$$\begin{array}{l}\quad\textit{Galls.}\\ 30\left\{\begin{array}{l}36\\0\end{array}\right.\begin{array}{r}30\\6\\\hline 36\end{array}\left|\begin{array}{l}\text{120 of wine,}\\\text{24 of water.}\\\hline \text{144 total.}\end{array}\right.\end{array}\Big\}\ \textit{Ans.}$$

$$120 \times 36 = 4320$$
$$24 \times 0 = 0$$

Proof 144)4320(30

As 36 : 30 : : 144 : 120

As 36 : 6 : : 144 : 24.

There being here only two simples, and the total of the mixture limited, the question admits but of one answer.

ALLIGATOR (a corruption of the Spanish *el lagarta, i.e. the lizard*), the common name of the American crocodile, called *Cayman* by the Indians. See REPTILIA, *Index.*

ALLIOTH, a star in the tail of the Greater Bear, of much use for finding the latitude at sea.

ALLITERATION, an ornament of language chiefly used in poetry, and consisting in the repetition of the same letter at certain intervals.

We apprehend the principal operation of this ornament to be quite mechanical. It is easier for the organs of speech to resume, at short intervals, one certain conformation, than to throw themselves into a number of different ones, unconnected and discordant. For example, a succession of labials, interspersed at regular distances with dentals and gutturals, will be more easily pronounced than the succession of all the three at random. Sounds of which the articulation is easiest are most completely in the power of the speaker. He can pronounce them slowly or rapidly, softly or with force, at pleasure. In this, we imagine, the power and advantage of alliteration are founded; for we would not lay any stress on the pleasure which can result to the ear from the repetition of the same letter. It has been compared to the frequent returns of the key-note in a musical strain; but that analogy is extremely faint. The ear. we presume, can be pleased with alliteration only in so far as it contributes to the superior easiness of recitation; for what is recited with ease must naturally be more pleasing.

It is true, however, as is remarked by Dr Thomas Brown (Lect. 36), that though the alliteration itself consist only in the similarity of sounds, it is not indifferent on what words of the sentence the alliteration is made to fall. That ingenious writer mentions *resemblance* and *contrast* as the qualities which give particular point to alliterative expression, and cites as an example the line of Pope,

Puffs, powders, patches, *bibles, billets-doux;*

the first words indicating objects naturally connected, and the last deriving their point from the contrast of ideas.

These remarks might be confirmed and illustrated by numberless passages from the best poets. Some few lines will suffice, taken from Gray, who seems to have paid particular attention to this grace. He professed to have learned his versification from Dryden, as Dryden did from Spenser; and these three abound in alliteration above all the English poets. We choose Gray for another reason, that alliteration contributes not only to the *sweetness*, but also to the *energy*, of versification; for he uses it chiefly when he aims at strength and boldness. In the *Sister Odes*, as Dr Johnson styles them, almost every strophe commences and concludes with an alliterative line. The poet, we suppose, wished to begin with force, and end with dignity.

"*R*uin seize thee *r*uthless king."
"To *h*igh-born *H*oel's *h*arp, or soft *L*lewellyn's *l*ay."
"*W*eave the *w*arp, and *w*eave the *w*oof."

"Stamp we our vengeance *d*eep, and ratify his *d*oom."
"Regardless of the *s*weeping whirlwind's *s*way."
"That hush'd in grim re*p*ose, ex*p*ects his ev'ning *p*rey."

It must be observed here, that we hold a verse alliterative which has a letter repeated on its accented parts, although those parts do not begin words; the repeated letter bearing a strong analogy to the bars in a musical phrase. Gray seems to have had a particular liking to those sorts of balanced verses which divide equally, and of which the opposite sides have an alliterative resemblance.

"Eyes that *g*low, and fangs that *g*rin."
"Thoughts that *b*reathe, and words that *b*urn."
"*H*auberk crash, and *h*elmet ring."

All these lines have a force and energy, arising from alliteration, which renders them easy to be recited. For the same reason the following passage appears sad and solemn, by the repetition of the labial liquid.

"*M*ountains, ye *m*ourn in vain."
"*M*odred, whose *m*agic song."—&c.

If alliteration thus contribute to enforce the expression of a poetical sentiment, its advantages in poetry must be considerable. An epithet should not be selected merely for its initial letters, unless it suit the purpose well in every other respect; for the beauty of alliteration, when happy, is not greater than its deformity when affected. A couplet from Pope will exemplify both; the first line being bad, and the second good;

"Eternal beauties grace the shining scene,
*F*ields ever *f*resh, and *g*roves for ever *g*reen."

In the dearth of poetical talent in the middle ages, alliterative composition was cultivated as a distinct poetical exercise. As a specimen of these ridiculous feats of poetical legerdemain, we give three lines from the performance entitled *Pugna Porcorum per Publium Porcium, Poetam*, a *poem* in which every word began with the letter *P*.

Propterea properans Proconsul, poplite prono,
Præcipitem Plebem, pro Patrum pace poposcit.
Persta paulisper, Pubes preciosa! precamur, &c., &c.

ALLIUM, a genus of plants of the natural order of *Asphodeleæ*, including garlic, the onion, the leek, &c.

ALLIX, Pierre, a French Protestant divine, was born at Alençon in France, in the year 1641. At the time when the edict of Nantes tolerated and protected the Protestants of France, he entered upon the clerical profession, and remained minister of Rouen until the 35th year of his age. During this period he wrote several pieces upon the controversy between the Papists and the Protestants, by which he obtained great fame among his own party. The unwise revocation of the edict of Nantes drove Allix and many others to seek refuge in England. Three years after his arrival in England, he had made himself so perfectly master of the English language as to be able to write very correctly a *Defence of the Christian Religion*. This work he dedicated to James II. in testimony of gratitude for his kind reception of the distressed refugees of France. Not long after his arrival in England, he was honoured with the title of doctor of divinity, and also received the more substantial honour of being appointed treasurer of the church of Salisbury.

After having exercised his talents with much industry and learning in defence of Protestantism, he employed his pen to support the doctrine of the Trinity against the Unitarians, who contended that the idea of Christ's divinity could be traced up no higher than the time of Justin Martyr. With a great display of erudition, he attempted to prove that the Trinitarian doctrine was believed by the Jewish church. But the reputation which he had acquired for learning and ability was somewhat diminished by the ridicule he brought on himself in attempting to prove that Christ should again appear upon earth in the year 1720, or, at the latest, in 1736. This able divine died at London in 1717, at the age of 76.

ALLOA, a seaport town of Scotland, in the county of Clackmannan. It is situated on the north shore of the Firth of Forth, 27 miles from Edinburgh, 6 from Stirling by land and 12 by water. It has a safe and commodious harbour, having 16 feet of water in neap, and 22 in spring tides. The town is irregularly built. The chief public building is the church, which was first opened in 1819. It is a fine building, in the pointed style of architecture, with a handsome spire. Alloa has several distilleries in its neighbourhood, from which large quantities of spirits are shipped for England; and its breweries are noted for producing a very fine quality of ale, which is in great repute. Among the principal manufactories of this place are extensive brick and tile works; a copper work, at which are made most of the implements or apparatus for distilleries; the Devon iron-works; and a glass-work, where, in addition to the ordinary green glass bottles, they now manufacture all sorts of finer glass. There are extensive collieries in the immediate vicinity, from which abundant supplies of fuel are brought by a waggon-way direct to these works from the mouth of the pit. The exports from Alloa consist of pig-iron, ale, spirits, glass, and coals; and the imports are timber, oak, bark, hides, and great quantities of grain for malting. Adjoining the harbour is an excellent dry dock, capable of receiving ships of the greatest burden; and to the west is a ferry across the Forth, which is there 500 yards broad, with piers projecting down to low water-mark. A daily communication is maintained with Edinburgh and other towns along the Forth by means of steam-boats. It has a custom-house, which comprehends under the port of Alloa the creeks on both sides of the Forth from Kincardine to Stirling inclusive. In the immediate vicinity of the town there is an ancient tower 89 feet high, with walls 11 feet in thickness, which was built about the year 1315. This was the residence of the Erskines, the descendants of the Earls of Mar, once a powerful family; and here many of the Scottish princes received their education, having been for more than two centuries the wards of the Lords Erskine and the Earls of Mar. The last heir of the Scottish monarchy educated here was Henry Prince of Wales. Pop. in 1851, 6676. Long. 3. 46. W. Lat. 56. 7. N.

ALLOCATION denotes the admitting or allowing of an article of an account, especially in the exchequer. Hence

*Allocatione Facienda* is a writ directed to the lord treasurer, or barons of the exchequer, commanding them to allow an accountant such sums as he has lawfully expended in the execution of his office.

ALLOCUTIO, an oration addressed by a Roman general to his soldiers, to animate them to fight, to appease sedition, or to keep them to their duty.

ALLODIUM, or Alleud, denotes lands which are the absolute property of their owner, without being obliged to pay any service or acknowledgment whatever to a superior lord. This tenure of land was common in the north of Europe, is the *udal* tenure of the Scandinavians, and still exists, in a few instances, in the county of Orkney. What existed of it in England was destroyed by William I., who introduced the stringent *feudal* tenure, by which all lands are held of the crown.

ALLORI, Alessandro, a Florentine painter of the third epoch of the school, who introduced fine anatomy into his pictures. He also wrote an essay on painting, of considerable merit. Born 1535, died 1607. He was a nephew of Bronzino, whose name he assumed.

Allori, *Cristofano*, the son of the former, was a superior colourist and excellent painter of portraits, and some reckon him among the best painters of the fourth epoch of the Florentine school. Born 1577, died 1621.—*Lanzi*, I.

ALLOXAN, a crystallised substance, formed by the action of nitric on uric acid. It forms oblique four-sided prisms. It is capable of further oxidation, and becomes alloxanic acid.

ALLOY, or ALLAY, properly signifies a proportion of a baser metal mixed with a finer one. The alloy of gold is estimated by carats, that of silver by pennyweights. In different nations different proportions of alloy are used; whence their moneys are said to be of different degrees of fineness or baseness, and are valued accordingly in foreign exchanges. The chief reasons alleged for the alloying of coin are, 1. the mixture of the metals, which, when smelted from the mine, are not perfectly pure; 2. the saving of the expense it must otherwise cost if they were to be refined; 3. the necessity of rendering them harder, by mixing some parts of other metals with them, to prevent the diminution of weight by wearing in passing from hand to hand; 4. the melting of foreign gold or coin which is alloyed; 5. the charges of coinage, which must be made good by the profit arising from the money coined; 6. and lastly, the duty belonging to the sovereign, on account of the power he has to cause money to be coined in his dominions.

ALLSTADT, a bailiwick in the grand duchy of Saxe-Weimar, containing one city and eleven villages. Its capital, of the same name, is on the Rhone, 22 miles W.S.W. of Halle, and 26 north of Weimar. This city is of considerable antiquity; and as early as 974, an imperial diet was held there under Otho II. A ducal castle crowns an adjoining eminence. It has some manufactures of cloth, saltpetre, and potash. Pop. 2550.

ALLSTON, WASHINGTON, an American historical painter, distinguished for his excellence in colouring. His picture of "The Dead Man resuscitated by Elisha's Bones," obtained the L.220 prize of the British Institution in 1811. His first wife was a sister of Dr Channing. He was born in South Carolina in 1779, and died in Massachusetts in 1843.

ALLUMEE, an *Heraldic* term, applied to indicate eyes of animals depicted sparkling, or of a red hue.

ALLUMINOR, from the French *allumer*, to lighten, an old term for one who coloured or painted upon paper or parchment; because he gave light and ornament by his colours to the letters or other figures. Such ornaments are styled *illuminations*. The term is used in statute 1 Richard III. cap. 9; and is still traceable in the word *limner*.

ALLUSION, in *Rhetoric*, a figure by which something is applied to, or understood of, another, on account of some similitude between them.

ALLUVION, in *Law*, denotes the gradual increase of land along the sea-shore, or on banks of rivers.

ALLUVIUM, or ALLUVIAL, is used in *Geology* to denote those deposits of sand, gravel, stone, &c., which are brought down by streams and rivers, and spread over lower lands. See GEOLOGY.

ALLYGHUR, in the East Indies, a fort in the British district of the same name, within the territory of the lieutenant-governorship of Agra. Its site is an elevated plain, skirted by swamps and morasses. The fort is now dismantled; and it was proposed some years since to convert it into a provincial jail, but the undertaking was abandoned in consequence of the alleged insalubrity of the locality. Towards the close of the year 1802, the Peishwa, driven from his capital by Holcar, fled to Bassein, and there concluded the treaty whereby he secured the co-operation of the British in re-establishing his sovereignty. This alliance excited the jealousy of the principal Mahratta chiefs, who shortly after confederated for the purpose of defeating the objects of the treaty. Among the operations planned by the British for the destruction of this confederacy, was an attack upon General Perron the French adventurer, who held a large force in readiness in the Dooab to co-operate with the Mahrattas. In furtherance of this measure, General Lord Lake, in August 1803, marched from Cawnpore towards the Mahratta territory, and on the 29th of that month, came up with Perron, who was strongly posted in the vicinity of Allyghur. Perron, however, retreated upon the advance of the English, leaving the fort of Allyghur in charge of a French officer, with injunctions to defend it to the last extremity. In addressing this commander, Perron observed, "You will have received the answer you are to make to the propositions of General Lake. I never could have believed that, for an instant, you could have thought of a capitulation. Remember you are a Frenchman; and let no action of yours tarnish the character of your nation. I hope in a few days to send back the English general as fast or faster than he came. Make yourself perfectly easy on this subject. Either the Mogul emperor's army, or that of General Lake, shall find a grave before the Fort of Allyghur. Do your duty and defend the fort while one stone remains upon another. Once more, remember your nation. The eyes of millions are fixed upon you." Upon being summoned to surrender, the commandant declared his resolution to defend the fort. It was obvious to the British general that delay could only render the conquest more difficult, and preparations were ordered for the assault. On the morning of the 4th September, Lieutenant-Colonel Monson led the attack: the defence was obstinate and vigorous, and continued for nearly an hour, when the fortress, hitherto deemed impregnable, fell before the spirit and intrepidity of the assailants. Its acquisition transferred to the captors a large proportion of the military stores of the French party who had constituted it their grand depôt. The loss of the British amounted to 59 killed and 206 wounded; that of the enemy exceeded 2000.

The value of the conquest was duly appreciated at the time, and its memory has not been suffered to pass away. So late as the year 1851, a medal was struck in commemoration of the event, and presented under the sanction of Her Majesty to the surviving officers and soldiers who took part in the capture. Elevation above the sea, 740 feet. Distance from Delhi, S.E. 84 miles; from Calcutta N.W. 803. Lat. 27. 56. Long. 78. 8. (E. T.)

ALMACANTARS. See ALMUCANTARS.

ALMADA, a Portuguese town upon the Tagus, opposite Lisbon, in the province of Estremadura, with one monastery, 900 houses, and 4000 inhabitants. Not far from this place is one of the entrances to the Tagus, defended by the tower of St Sebastian. Lat. 38. 37. 20. N.

ALMADEN, a town in Spain, in the province of Ciudad Real, with 9000 inhabitants. It is distinguished by the rich mines of quicksilver in its vicinity. Formerly these mines were wrought partly by convicts, but now wholly by free labourers. The government of late years has leased these mines to private speculators. In 1848 they yielded 40,000 quintals of mercury. The principal mines are at Almaden, and at Almadenejos, two leagues from the former, with some less important in Valencia. The whole amount of quicksilver obtained in Spain in 1848 was 48,868 quintals, or about 40,578 cwt. Lat. 38. 41. N. Long. 4. 49. W.

ALMADIE, a kind of canoe or small vessel, about four fathoms long, commonly made of bark, and used by the negroes of Africa. At Calicut the same name is applied to a kind of long boats, 80 feet in length and six or seven in breadth. They are exceedingly swift, and are otherwise called *cathuri*.

ALMAGEST, compounded of the Arabic *al* and μεγιστη, an epithet of distinction conferred on a collection or book composed by Claudius Ptolemy, containing various problems of the ancients both in geometry and astronomy. Other collections have received the same name. Thus, Riccioli has published a book of astronomy, which he calls the *New Almagest;* and Plukenet, a book which he calls *Almagestum Botanicum.*

ALMAGRE, a fine, deep red ochre, very heavy, and of a dense yet friable structure, and rough, dusty surface. It adheres very firmly to the tongue, has scarcely any taste, and seems analogous to the ore of iron called in England *Red Reddle.* It is the *Sil Atticum* of the ancients. It is found in immense quantities in many parts of Spain, and is used at Seville to colour snuff.

ALMAGRO, a city of Spain, the capital of one of the districts of Ciudad Real. It was built by the Archbishop Roderic of Toledo, who finished it in 1214, and put a considerable garrison into it, to restrain the incursions of the Moors. They soon afterwards besieged it, but were obliged to retire with loss. The town is now celebrated for its lace manufacture. Pop. 12,605.

Almagro, *Diego de*, a Spanish commander, was of such obscure birth and mean parentage that he derived his name from the village where he was born in 1463. Deprived of the means of early instruction, he could neither read nor write; but nevertheless, in consequence of his improvements in the military art, he formed an association with Francisco Pizarro and Hernando de Luque, for the purpose of discovery and conquest upon the Peruvian coast. The governor of Panama having sanctioned their enterprise, they devoted their united exertions to that undertaking. Pizarro directed the conquest, and Almagro was appointed to conduct the supplies of provisions and reinforcements. In the first two unsuccessful attempts he performed this office with persevering fidelity and uncommon activity. His perseverance was followed with complete success; for they at last discovered the coast of Peru, and landed at Tumbez, situated about three degrees south of the line, and distinguished by its temple and a palace of the incas or sovereigns. Pizarro was sent over to Spain to solicit further powers, after the three adventurers had previously adjusted their future preferments, and agreed that Pizarro should be governor, Almagro lieutenant-governor, and Luque bishop. In this negotiation Pizarro obtained the clerical dignity for Luque, but chiefly concerned for his own interest, he neglected the preferment of Almagro. On his return, Almagro was so enraged that he refused to act with such a perfidious companion, and resolved to form a new association. Pizarro, for the present, artfully endeavoured to avert the indignation of Almagro, and gradually soothed the rage and disappointment of the soldier. The union was renewed upon the former terms; and it was solemnly stipulated that they should mutually share the expenses and the advantages.

In February 1531, leaving Almagro at Panama to supply provisions and reinforcements, Pizarro set sail for Peru. He attacked a principal settlement of the natives in the province of Coaque, obtained immense spoil, and made such ample remittances to Almagro as enabled him to complete his reinforcement; and, in the close of the year 1532, Almagro arrived at St Michael, with a body of men nearly double the number of those whom Pizarro had with him. The Spaniards about this time took captive the unfortunate Inca Atahualpa, and, after they had received an immense sum for his ransom, they barbarously put him to death. Ferdinand Pizarro sailed for Spain with the news of their success, and with remittances to a great amount; and consequently Almagro gained that elevated station he had so long and so eagerly desired. But no sooner did he receive the intelligence of his promotion by the royal grant than he attempted to seize Cuzco, the imperial residence of the Incas, under pretence that it lay within his destined territory. This produced a new quarrel; but peace was restored upon condition that Almagro should attempt the conquest of Chili, and, if he did not find in that province an establishment adequate to his merit, that Pizarro should yield up to him a part of Peru.

In 1535 he accordingly set out at the head of 570 Europeans. In crossing the mountains he suffered great hardships and losses by mistaking the route; but at length he descended into the plains of that devoted region. Here he met with a more vigorous resistance from the natives than the Spaniards had ever experienced in other countries. He had, however, made some progress, when he was recalled to Peru by the news of the natives having risen in great numbers, and attacked Lima and Cuzco. He pursued a new route, and marching through the sandy plains on the coast, he suffered, by heat and drought, calamities not inferior to those which he had endured from cold and famine on the summits of the Andes. Arriving at a favourable moment, he resolved to hold the place, both against the Indians and his Spanish rivals. He attacked the Peruvian army with great vigour, and, making a great slaughter, proceeded to the gates of Cuzco without any further interruption. The open, affable, and generous temper of Almagro, gained over to his side many of the adherents of the Pizarros, who were disgusted with their harsh and oppressive conduct. With the aid of these he advanced towards the city by night, surprised the sentinels, and surrounding the house where the two brothers Ferdinand and Gonzalo Pizarro resided, compelled them, after an obstinate resistance, to surrender at discretion. A form of government was settled in the name of Almagro, and his jurisdiction over Cuzco was universally acknowledged. This was the origin of a civil war, the beginning of which was very advantageous to Almagro, who, by skilful manœuvres, entirely routed a body of Spanish troops advancing to the relief of Cuzco, and made Alvarado, their commander, prisoner. But instead of improving these advantages, he unwisely marched back to Cuzco, and there awaited the arrival of Pizarro, who, convinced of his own feeble resources, proposed an accommodation, and, with his usual art, protracted the negotiation till he found himself in a condition to meet his antagonist in the field of battle. Meanwhile Alvarado and one of the Pizarros, by bribing their keepers, found means to escape, and persuaded sixty of the men who guarded them to attend them in their flight; and the governor released the other. When Pizarro thought himself sufficiently prepared to settle the dominion of Peru, he marched with an army of 500 men to Cuzco. Almagro, worn out with age and infirmity, had previously resigned the command to Orgognez. A fierce and bloody battle ensued, in which Almagro's army was defeated, and the commander wounded. About 140 soldiers fell in the field, and Orgognez, along with several officers of distinction, was massacred in cold blood. During that fatal day, Almagro, placed in a litter which was stationed on an eminence, beheld from thence the total discomfiture of his troops, and felt all the indignation of a soldier who had seldom experienced defeat. He was taken prisoner, remained several months in confinement, and was afterwards tried and condemned to death. In the view of an ignominious death, the courage of the veteran forsook him, and he unsuccessfully supplicated for life in a manner unworthy of his former character. All the arguments he could employ were ineffectual. The Pizarros remained unmoved by all his entreaties. As soon, however, as Almagro saw that his fate was inevitable, he resumed his courage, and exhibited all his usual dignity and fortitude. In the year 1538, and in the 75th year of his age, he was strangled in prison, and afterwards beheaded. He left one son by an Indian woman of Panama; and, in consequence of a power which the emperor had granted him, he declared his son his successor in the government, although he was then a prisoner in Lima.

Almagro, the Younger, by his courage, generosity, and other accomplishments, was placed at the head of the party after the death of his father. The father, conscious of his own inferiority from the total want of education, used every possible means to improve the mind and embellish the manners of his son; so that he soon acquired those accomplishments which rendered him respected by illiterate adventurers, who cheerfully ranged round his standard, and, in his dexterity and skill, sought deliverance from the oppressions of Pizarro. Juan de Herrada, an officer of great abilities, continued still to direct his councils, and to regulate his enterprises; and while Pizarro confided in his own security, a conspiracy was formed against him which terminated in his death. The assassins, exulting in their success, and waving their bloody swords, hastened to the street, proclaimed the death of the tyrant, and compelled the magistrates and principal citizens of Lima to acknowledge Almagro as lawful successor of his father. But his reign was of short duration; for, in 1541, Vaca de Castro, arriving at Quito, produced the royal commission appointing him governor of Peru, together with all the privileges and authority of Pizarro. The talents and influence of the new governor soon overpowered the interest of Almagro, who, perceiving the rapid decline of his influence, hastened with his troops to Cuzco, where his opponents had erected the royal standard under the command of Pedro Alvarez Holguin. Herrada, the guide of his councils, died during this march; and from that time his measures were conspicuous for their violence, concerted with little ingenuity, and executed with little address. At length, on September 16. 1542, the forces of Almagro and Vaca de Castro met, and victory long remained doubtful, till at last it declared for the new governor. Almagro conducted the military operations of that fatal day with a gallant spirit, worthy of a better cause, and deserving of a better fate; and his followers displayed uncommon valour. In proportion to the number of combatants, the carnage was very great. Of 1400 men, 500 fell in the field, and many more were wounded. Almagro escaped, but being betrayed by some of his own officers, he was publicly beheaded at Cuzco; and in him the name and spirit of the party of Almagro became extinct.

ALMAMUN, or the *Trustworthy*, the surname of Abu l'Abbas Abdallah, eldest son of the caliph Haroun Alraschid, who was born at Baghdad A.D. 785. By the will of his father, the younger brother Al Amin, as the son of his favourite wife, succeeded to the caliphate, while the elder Almamun was left second in the order of succession. He was at that time governor of Khorassan, and in obedience to his father's will acknowledged the supremacy of his brother. He, however, repaid his good-will with open hatred, and unjust attempts to exclude him from the succession. Almamun was thus forced to consult measures for his own safety and promotion, and caused himself to be proclaimed caliph. After various struggles, his general Thaher, in the year 813, took possession of Baghdad, pursued Al Amin to his retreat, and caused him to be assassinated, so that Almamun remained without a competitor. Various rebellions disturbed the tranquillity of the first years of his reign; but, by his prudent administration and vigorous exertions, these were at length extinguished. Instigated by the advice of his vizier, he soon after raised greater commotions, and exposed his dignity to greater dangers, by countenancing the sect of Ali. He invited to court Iman Rizza, gave him his daughter in marriage, and even declared him his successor in the empire. He assumed the green turban, the colour of the house of Ali, and obliged his courtiers and soldiers to imitate his example. Alarmed at these proceedings, the orthodox Mussulmans, and the house of Abbas, excited a great revolt in Baghdad, and proclaimed Ibrahim, Almamun's uncle, caliph. A civil war was just about to commence, when Fadel the vizier was assassinated, and Rizza died. The people of Baghdad then deposed Ibrahim, and returned to their former allegiance. Taking advantage of Almamun's absence, Thaher seized upon the government of Khorassan, where he founded a dynasty which existed but sixteen years.

Almamun employed the period of tranquillity that followed, in introducing literature into his dominions, and in its improvement; which constitutes the greatest glory of his reign. During the days of his father he discovered an ardent thirst after knowledge, by forming a college in Khorassan, adorned by the most eminent men of various countries; and appointed Mesue, a famous Christian physician of Damascus, for their president. When his father remonstrated against conferring such an honour upon a Christian, he reminded him that the most learned men and most skilful artists in his dominions were Jews and Christians; and added, that he had chosen Mesue as a preceptor in science and useful arts, and not as a teacher of religion. Under his auspices Baghdad became the seat of literature, of private and academical instruction, and the habitation of men of eminence from all quarters. Many valuable books in the Greek, Persian, Chaldean, and Coptic languages, among which were the works of Aristotle and Galen, were translated into the Arabic at his own expense. This caliph himself deemed it an honour to set an example to others of the becoming respect due to mental cultivation, by visiting the schools, and treating the professors with great regard. In mathematics, astronomy, and philosophy, he made a rapid and extensive progress. He was the author of astronomical tables, which, on account of their accuracy, have been much admired. By these various exertions the character of the Saracens was suddenly changed from rudeness and ferocity to politeness and civilisation, while the most powerful and extensive of the European states were involved in ignorance and barbarism. Literature has sustained some irreparable losses from his too great partiality to the Arabic writers, which induced him to destroy the originals of the translated manuscripts. He is represented by the Sonnites, or orthodox Mahometans, as little better than an infidel, because of his attention to philosophy and letters. His conduct, however, shows that he was not sufficiently careful to preserve a philosophical mean between the different religious parties during the time of his administration, as he openly manifested a predilection for the doctrines of the Motazeli, who asserted the free-will of man, and denied the eternity of the Koran. Some allege that, on account of the murmurs which arose against him, he was induced to exhibit too great a zeal, by establishing a kind of inquisition, to compel all his subjects to profess Islamism. The experiment, however, soon terminated in the better and juster expedient of universal toleration; and it is abundantly evident that the Christains in his dominions never felt the power of his inquisition.

The public transactions of his reign are in themselves important. In the years 822 he sent a body of his troops to the assistance of Thomas, a Greek, who made war on Michael the Stammerer, the emperor of Constantinople, and besieged his capital. This expedition, which on the part of the caliph seems to have been founded in justice, proved unsuccessful; Thomas was taken prisoner, and suffered death. In the years 829 and 830 he commenced hostilities upon the Greeks, rendered himself master of many places, and carried devastation into their territories. He was successful in supressing a revolt in Egypt in the year 831. In this country he was led to discover a treasure buried under

Almanack. two columns by Merwan, the last caliph of the house of Ommijah. In repairing a decayed *mikias* or measuring pillar, and erecting a new one for determining the gradation of the increase of the Nile, Almamun displayed his love of science. In the year 833 he again visited Egypt: on his return he penetrated into the territories of the Greek emperor, even into Cilicia. Returning home, he encamped on the banks of a river, and, excited by thirst, drank too freely of the water, and at the same time indulged himself immoderately in eating a particular kind of dates, which brought on a complaint in his stomach, and reduced him to the most imminent danger. Sensible of his approaching dissolution, he sent letters into all the provinces, declaring his brother Motassem his successor, and then patiently waited the event. After a tedious struggle under the pressure of his disease, and while uttering this ejaculation, "O thou who never diest, have mercy on me, a dying man!" he expired at the age of 48 or 49 years, after a reign of 27 years and some months.

ALMANACK, a book or table, containing a calendar of days and months, the rising and setting of the sun, the age of the moon, the eclipses of both luminaries, &c.—Authors are divided with regard to the etymology of the word; some deriving it from the Arabic particle *al*, and *manach*, to count; some from *almanach*, new-year's gifts, because the Arabian astrologers used at the beginning of the year to make presents of their ephemerides; and others from the Teutonic *almaen achte*, observations on all the months. Dr Johnson derives it from the Arabic particle *al*, and the Greek *μην*, a month. But the most simple etymology appears from the common spelling; the word being composed of two Arabic ones, *Al Manack*, which signify *the Diary*. All classes of the Arabs are commonly much given to the study of astronomy and astrology; to both of which they are inclined by their belief in fate, and by their pastoral life, which affords time and opportunity to cultivate them. They neither sow, reap, plant, nor undertake any expedition or business, without previously consulting the stars, or, in other words, their almanacks, or some of the makers of them. From these people, by their vicinity to Europe, this art, no less useful in one sense than trifling and ridiculous in another, has passed over to us; and those astronomical compositions have still everywhere not only retained their old Arabic name, but were, like theirs, for a long while, and still are among many European nations, interspersed with a great number of astrological rules for planting, sowing, bleeding, purging, &c., down to the cutting of the hair and paring of the nails. Regiomontanus appears to have been the first in Europe, however, who reduced almanacks into their present form and method, gave the characters of each year and month, foretold the eclipses and other phases, calculated the motions of the planets, &c. His first almanack was published in 1474.

The essential part of an almanack is the calendar of months and days, with the risings and settings of the sun, age of the moon, &c. To these are added lists of posts, offices, dignities, public institutions, with many other articles, political as well as local, and differing in different countries.

England has abounded in almanacks, some of them of no very creditable description, though widely circulated among the people for a long period of years. Such, in particular, were *Moore's Almanack*, and *Poor Robin's Almanack*, now happily, with several others of the same class, either extinct or about to become so. This change has been mainly owing to the publication of an entirely new almanack by the Society for the Diffusion of Useful Knowledge. The following statement is extracted from a curious article upon *English Almanacks*, in the *London Magazine*, third series, vol. ii. p. 591. "For a century and a half, the two universities and the Stationers' Company held the monopoly of them, by letters-patent of James I. During this period, according to the condition of the patent, almanacks received the *imprimatur* of the Archbishop of Canterbury and the bishops of London; and yet it would be difficult to find, in so small a compass, an equal quantity of ignorance, profligacy, and imposture, as was condensed in these publications. By the persevering exertions of one individual, the monopoly was overthrown about 1779; and the parties claiming the patent-right then applied to parliament for an act to confirm it. That bill was introduced by the minister of the day; but Erskine, then first coming into repute, appeared at the bar to oppose it,—and the monopoly was destroyed for ever, by a solemn vote of the House of Commons. From that time the Stationers' Company proceeded upon a different course. They secured their monopoly by buying up all rival almanacks; and they rendered the attempts of individuals to oppose them perfectly hopeless, by those arts of trade which a powerful corporation knew how to exercise. For the last fifty years they have rioted, as of old, in every abomination that could delude the vulgar to the purchase of their commodity. On a sudden a new almanack started up, under the superintendence and authority of a society distinguished for its great and successful labours to improve the intellectual condition of the people. For the first time in the memory of man, an almanack at once rational and popular was produced. From that hour the empire of astrology was at an end. The public press, infinitely to their honour, took up the cause. The blasphemy of Francis Moore, and the obscenity of Poor Robin, were denounced and ridiculed through all quarters of the kingdom. In one little year the obscene book was discontinued, the blasphemous book retreated into pure stupidity, and the publishers of the blasphemy and the obscenity applied themselves, in imitation of the first powerful rival they had ever encountered, to make a rational and useful almanack." The almanack of the Society for the Diffusion of Useful Knowledge is entitled the *British Almanack;* the improved one published in imitation of it by the Stationers' Company, is called the *Englishman's Almanack.* Of other British Almanacks, the most deserving of mention are *Oliver and Boyd's Edinburgh Almanack*, and *Thom's Irish Almanack and Official Directory;* of foreign almanacks, the *Almanach Royal de Belgique*, and the small but excellent *Almanach de Gotha*, now in its 89th year.

The French *Almanach Royal* is one of the most extensive publications of this class, the volume generally extending to about a thousand octavo pages.

*Almanack, Nautical.* This, which in some respects is a national almanack, is published under the sanction of the Board of Longitude, and is designed chiefly to facilitate the use of Mayer's Lunar Tables, by superseding the necessity of making calculations to determine the longitude at sea. It commenced with the year 1767, and has ever since been continued annually, but two or three years in advance. The late Dr Maskelyne was the originator of this very valuable publication. It is now published under the immediate superintendence of the secretary to the Board. Similar to this almanack is the French publication entitled *Connoissance des Tems*, directed by the *Bureau de Longitude*, and which commenced so early as the year 1698. At Berlin, the celebrated Bode for about 50 years conducted the excellent astronomical almanack, *Astronomisches Jahrbuch*, which is still continued.

Almanack, among *Antiquaries*, is also the name given to a kind of instrument, usually of wood, inscribed with various figures and Runic characters, and representing the order of the feasts, dominical letters, days of the week, and golden number, with other matters necessary to be known throughout the year; used by the ancient northern nations in their computations of time, both civil and ecclesiastical. Almanacks of this kind are known by various names among the different nations in which they have been used, as rimstocks, primstaries, runstocks, runstaffs, clogs, *Scipiones Runici, Bacculi Annales*, &c. They appear to have been used only by the Swedes, Danes, and Norwegians. From the second of these people their use was introduced into England, whence divers remains of them in the counties. Dr Plot has given the description and figure of one of these clogs, found in Staffordshire, under the title of *The Perpetual Staffordshire Almanack*. The external figure and matter of these calendars appear to have been various. Sometimes they were cut on one or more wooden leaves, bound together after the manner of books; sometimes on the scabbards of swords, or even daggers; sometimes on tools and implements, as portable steelyards, hammers, the helves of hatchets, flails, &c. Sometimes they were made of brass or horn; sometimes of the skins of eels, which being drawn over a stick properly inscribed, retained the impressions of it. But the most usual form was that of walking staves, or sticks, which they carried about with them to church, market, &c. Each of these staves is divided into three regions; whereof the first indicates the signs, the second the days of the week and year, and the third the golden number. The characters engraven on them are, in some, the ancient Runic; in others, the later Gothic characters of Ulfilas. The saints' days are expressed in hieroglyphics, significative either of some endowment of the saint, the manner of his martyrdom, or the like. Thus, against the notch for the 1st of March, or St David's day, is represented a harp; against the 25th of October, or Crispin's day, a pair of shoes; against the 10th of August, or St Lawrence's day, a gridiron; and, lastly, against New-year's day, a horn, the symbol of liberal potations, which our ancestors indulged in at that period.

ALMANSA, a small city of Spain, in the province of Albacete, to the north of the river Segura. A pyramid erected near it commemorates the decisive battle fought here in 1707, when the French and Spaniards, under the Duke of Berwick, gained a complete victory over the united forces in the interest of the Archduke Charles. It now contains 8700 inhabitants.

ALMANSUR, *i. e., the Victorious*, the second caliph of the house of Al Abbas, succeeded his brother Abul Abbas Al Saffah in the year 753, of the Hegira 136, and in the following year was inaugurated at Al Hashemiyah. Although Al Saffah had declared him presumptive heir of the crown, and he had been proclaimed caliph in the imperial city of Anbar, yet immediately upon his inauguration his uncle Abdallah ebn Ali had sufficient interest to cause himself to be proclaimed caliph at Damascus. In Arabia, Syria, and Mesopotamia, he collected a numerous army, and arrived at the banks of the Masius, near Nisibis, where he encamped, ready to dispute his royal accession by arms. Almansur collected an immense army in Persia, Khorassan, and Irak, and gave the command of it to Abu Moslem, who harassed his uncle's troops for five months, and at last totally defeated him, A.D. 754. Notwithstanding the services which Abu Moslem had rendered to the family of Al Abbas, after this victory he became an object of jealousy, and was assassinated in the presence of Almansur himself, by his express order. After the death of Abu Moslem, the standard of rebellion was raised by Simon, a Magian, who seized on the treasures of the deceased governor of Khorassan, and excited the people of that country to a general revolt; but this insurrection was suddenly quelled by the general of Almansur, Jamhur ebn Morad. The caliph avariciously seized the spoils of this victory, which so incensed Jamhur that he immediately turned his arms against his royal master; but he was soon defeated by the caliph's forces. The patriarch of Antioch was about this time detected in an illicit correspondence with the Grecian emperor, and consequently was banished into an obscure part of Palestine; and in the mean time the Christians in the dominions of the caliph were prohibited from building or repairing any churches, and also were laid under several other severe restraints.

Almansur sent a large army into Cappadocia in the year 757, fortified the city of Malatia or Melitene, and deposited in it a great part of his treasures. But in this year he was attacked by a sect of believers in the metempsychosis, called the *Rawandians*. This sect assembled at Al Hashemiyah, the residence of the caliph, and, by the ceremony of going in procession round his palace, intimated their purpose of invoking him as a deity, and paying him divine homage. Incensed by their impiety, the caliph ordered several of these sectaries to be imprisoned, which roused their resentment, and led them to form the design of his assassination. The generous interposition, however, of Maan ebn Zaidet, an Ommiyan chief, who had been under the necessity of concealing himself from the caliph's resentment, defeated their intention. This insult, received in his capital, induced him to build the city of Baghdad, and to fix his residence there, A.D. 762. In the preceding year a plan was formed to dethrone him; but it being discovered, he severely punished all who were either directly or indirectly concerned in it. He set out on a pilgrimage to Mecca in the year 774, and being seized on the road with a dangerous disease, he sent for his son and intended successor Al Mohdi, and gave him some salutary advice. "I command you," said he, "to treat publicly your relations with the greatest marks of distinction, since this conduct will reflect no small degree of honour and glory upon yourself. Increase the number of your freedmen, and treat them with all kindness, as they will be of great service to you in your adversity; but neither this nor the other injunction will you fulfil. Enlarge not that part of your capital erected on the eastern bank of the Tigris, as you will never be able to finish it; but this work I know you will attempt. Never permit any of your women to intermeddle in affairs of state, or to have any influence over your councils; but this advice I know you will not take. These are my last commands; or, if you please, my dying advice; and to God I now recommend you." In parting they both gave vent to their feelings in a flood of tears. He pursued his journey to Bir-Maimun, *i. e.*, the well of Maimun, where he died in the 63d year of his age and 20th of his reign. His remains were interred at Mecca.

ALMARAZ, a small town of Estremadura in Spain. About two miles south of the town flows the Tagus, which is here crossed by a bridge built by Charles V. in 1552. The defeat of the French here by Lord Hill on 18th May 1812, was one of the most brilliant actions of the peninsular war.

ALMARIC, the name of a tenet introduced in France by one Almaric, in the thirteenth century. It consisted in holding that every Christian was actually a member of Christ, and that without this faith no one could be saved. His followers went farther, and affirmed that every one is to be saved by the internal operation of the Holy Spirit alone, without any external act of religion. Their morals were as infamous as their doctrine was absurd. Their tenets were condemned by a public decree of the council of Sens, in the year 1209.

ALMAZARRON. See MAZARRON.

ALMAZORA, a Spanish town on the sea-shore, in the province of Castellon de la Plana, remarkable for a grand tunnelled aqueduct, executed in the year 1640, for conducting the waters of the Mijares to irrigate the fine plain of Castellon. Lat. 39. 53. N. Pop. 3636.

ALME, or ALMA, singing and dancing girls in Egypt, who, like the Italian *Improvisatori*, can occasionally pour forth "unpremeditated verse." They are called *Almé*, from having received a better education than other women. They form a celebrated society in that country. To be received into it, according to M. Savary, it is necessary to have a good voice, to understand the language well, to know the rules of poetry, and be able to compose and sing couplets on the spot, adapted to the circumstances. The Almé know by heart all the new songs. Their memory is furnished with the most beautiful tales. There is no festival without them, no entertainment of which they do not constitute the ornament. They are placed in a rostrum, from whence they sing during the repast. They then descend into the saloon, and form dances which have no resemblance to ours. They are pantomime ballets, in which they represent the usual occurrences of life. The mysteries of love, too, generally furnish them with scenes. The suppleness of their bodies is inconceivable; and the mobility of their features gives at pleasure the impression suited to the characters they play. The indecency of their attitudes is often carried to excess. The common people have also their Almé. They are girls of the second class, who try to imitate the former; but have neither their grace nor their intelligence.

ALMEHRAB, a niche in the Mahometan mosques, pointing towards the kabba or temple of Mecca, to which they are obliged to bow in praying.

ALMEIDA, a strong fortress of Portugal, in the province of Beira. It is situated between the rivers Coa and the Duas Casas, which forms a branch of the Agueda. The capture of it by the duke of Wellington in 1811, after it had fallen into the hands of the French, was deemed one of the most brilliant exploits of the peninsular war. It is about four leagues from the Spanish fortress of Ciudad Rodrigo. It is well fortified, though till the late war it was not considered so important as it was then deemed. The Spanish engineers did not estimate it as a defence to Lisbon, but merely as covering the province of Beira, into which, according to their judgment, a Spanish army ought never to attempt to penetrate. This place contains 6200 inhabitants, an hospital, one monastery, one church, and a poor-house. Lat. 40. 37. N. Long. 6. 52. W.

ALMEISAR, a celebrated game among the ancient Arabs, performed by a kind of casting of lots with arrows, and strictly forbidden by the law of Mahomet, on account of the frequent quarrels occasioned by it.

ALMELO, an arrondissement in the province of Overyssel, in the Netherlands, containing five cantons and 62,000 inhabitants. Its capital, of the same name, contains 3200 inhabitants, chiefly engaged in the linen manufacture.

ALMERIA, a modern province of Spain, comprehending the eastern portion of the ancient kingdom of Granada. It is bounded on the north by Jaen and Murcia, on the east and south by Murcia and the Mediterranean, and on the west by Granada. It embraces an area of about 3800 square miles; with a population in 1849 of 292,234. Its whole extent is traversed by mountain-ridges, some of them of considerable elevation; with corresponding valleys and plains of great fertility. This province is one of the richest in minerals of all Spain; the mountains yielding silver, mercury, lead, antimony, copper, and iron. The silver mines of the Sierra de Almagrera, opened in 1839, produced in 1843 nearly 1,700,000 ounces; while the lead mines of the Sierra de Gador, a branch of the Alpujarras, are computed to have yielded, from 1795 to 1841 inclusive, 11,000,000 quintals of lead. The principal rivers are the Almanzora, running from west to east, with a course of about 50 miles; the Almeria north-west to south-east; and the Adra from north to south, watering the fertile district between the Sierra de Gador and the Alpujarra proper. The climate is mild, except in the interior, where the winter is cold. On the coast rain seldom falls, and south-west winds prevail. The inhabitants are principally engaged in mining and in agriculture. All kinds of grain are raised in abundance. The common fruits are plentiful, as well as oranges, lemons, and vines. Much excellent silk is produced in the western districts. Cattle are extensively bred; those of the valley of the Almeria are especially remarkable for their size and beauty. The manufactures consist chiefly of esparto cordage, white-lead, shot, soap, saltpetre, and leather. The principal exports are lead, esparto, barilla, and soap. The imports consist of woollen and cotton stuffs from Catalonia; silk from Valencia and Malaga, and linen from Marseilles and Gibraltar. Education in this province is in a backward state; the means of instruction not extending to half the population. The ratio of crime is consequently high, being to the population as 1 to 355.

ALMERIA, the capital of the above province, is situated on a rocky promontory near the Cabo de Gata, and from the strength of the port was deemed by the Moorish kings of Granada the most valuable of their fortresses and commercial ports; from whence their cruisers overawed the Catalans and Italians, and the merchants conveyed their various merchandise to Africa, Egypt, and Syria. Almeria is the see of a bishop, and has a splendid cathedral. Its exports consist chiefly of lead, esparto, and barilla; its imports of woollen, cotton, linen, silk, and hardware. Pop. 18,000. Long. 2. 32. 54. W. Lat. 36. 51. N.

ALMEYDA, DON FRANCISCO, was the son of the count d'Abrantes, a grandee of Portugal, who served with great distinction in the war of Ferdinand of Castile with Granada. His important services gained him high esteem in the court of his sovereign. Without any solicitation on his part he was nominated the first viceroy of the newly conquered countries in the East Indies, and set sail from Lisbon in March 1505 with a powerful fleet. He touched at the Cape Verde islands, doubled the cape at a considerable distance to the south, and arrived at Guiloa. From thence he proceeded to Mombaza, a well-fortified city in an island, which he reduced, and proceeded to the Angediva islands, not far from Goa, where he built a fort: he likewise erected and garrisoned another fort at Cananore, and arriving at Cochin, he secured it to the Portuguese interest. The island of Madagascar was discovered during his government; and his son Don Lorenzo first surveyed the Maldive islands, and about the same time discovered the island of Ceylon, the principal sovereign of which he brought under submission to the crown of Portugal. Returning from this expedition, while employed in the fleet destined against Calicut, he lost his life in a sea-fight against the Zamorin. His father sustained his loss with an heroic firmness, saying that "Lorenzo could not die better than in the service of his country." On the arrival of Alphonso d'Albuquerque, who was destined to be his successor, Almeyda yielded to the impressions of jealousy; and under the pretence of misconduct he confined him to the citadel of Cananore. He engaged in 1508 the whole force of the Mahometans in the port of Diu; and, gaining a complete victory, facilitated the enterprises of Albuquerque his successor, by contributing to break that formidable league by which the Zamorin was in hopes of being able to compel the Portuguese to abandon their Indian conquests. Returning home with the great riches which he had acquired, he unfortunately touched at Saldanha Point, on the coast of Africa, where some of the sailors, in quest of water, quarrelled with the natives, who attacked and drove them to their ships. With a view to revenge this pretended affront, they persuaded Almeyda himself to go ashore, with a body of 150 men, armed only with swords and lances.

While stepping into the boat, Almeyda exclaimed, "Whither do you carry my sixty years?" The Portuguese furiously rushed on to attack the natives, whose numbers were greatly augmented; and Almeyda, with fifty-seven of his men, was killed in this rash and unprovoked attempt.

ALMIGGIM. See ALMUGGIM.

ALMISSA, a small but strong town at the mouth of the Cetina, in Dalmatia, famous for its piracies; 16 miles south-east of Spalatro. Long. 16. 40. E. Lat. 43. 30. N.

ALMOHEDES, or ALMOHADES, a Mahometan dynasty that flourished in Africa and in Spain during the twelfth and thirteenth centuries. This title was derived from the religious sect of *Al-Mou-ah-hedi*, which in Arabic signifies Unitarians. Mohammed-ben-Toumert, the founder of this sect, was the son of a lamp-lighter in the great mosque at Sous-el-Aksa, and was a person of bold, subtle, and ambitious character. He prepared himself for the part he intended to play by travelling in the East; and at Baghdad he became the disciple of the famous philosopher Algazeli, from whom he acquired a knowledge of those abstruse mysteries by which he hoped to impose on his superstitious countrymen. For this purpose he connected himself with Abdelmoumen, a young Mussulman of great abilities, whom he sent forth as his apostle to propagate the new doctrine; while in his own person he affected an unusual degree of piety and mortification, appearing in tattered garments, and interdicting the use of wine, music, and every gratification of the senses. His fame spread rapidly among the mountain tribes of Mahgreb, and the ignorant multitude adopted his opinions with eager zeal. Entering the city of Marocco, this new prophet foretold the downfall of the existing dynasty, and mocked the authority of the reigning prince Ali-ben-Yusseff. Ali, lulled in security, despised his predictions as the mere ravings of a fanatic; and it was not without some difficulty that he was at length prevailed on to banish him from the city. Mohammed retired to the mountains, and fortified the town of Tinmal, which he defended against every assault of his enemies. Here throwing off the mask, he gave out that he was the Imam Mahdi, who had miraculously disappeared, and now was come as the vicegerent of Mahomet, invested with all temporal and spiritual authority for the purpose of restoring the true religion. His retreat became the rendezvous of a numerous sect, who assumed the title of Almouahhedi, or Almohedes, and asserted that they alone of all the Mussulmans maintained the religion of Islam in its original purity. Many Arab and Berber tribes acknowledged this impostor as their political chief, and 20,000 soldiers rallied around his standard. Ali only perceived the error he had committed when it was too late: his armies, at each encounter, were panic-struck, and fled. Yet notwithstanding the great success of the Almohedes, the vast empire of the Almoravides was not all at once subdued: and Mohammed, after an ineffectual attempt to reduce the city of Marocco, died in the year 1130, having failed to accomplish the object of his ambition, the possession of a throne. He was succeeded by Abdelmoumen, who assumed the title of *Emir-el-Moumenin*, or commander of the Faithful. During the thirty years that he reigned, and under his descendants, Yusseff, and Yacoub called Almanzor-Billah, the dynasty of the Almohedes was exceedingly illustrious, and the arts flourished greatly. They rendered themselves masters of the provinces of Fez, Marocco, Tremcen, Oran, and Tunis; and passing into Spain, they overran Andalucia, Valencia, and a part of Aragon and of Portugal, as far as the Ebro on one side, and the Tagus on the other. But this vast empire was not of long continuance: for in the year 1212, when the Moslems under Mohammed were defeated by the Christian princes of Spain in the great battle of Las Navas, near Tolosa, the governors of the several provinces took advantage of that disaster to throw off their allegiance, and declared themselves independent; an example that was the signal for a general revolt. The dynasty of the Almohedes became extinct in Spain in the year 1257, and in Africa in 1269. The last sovereign of this race, who had with difficulty maintained a shadow of power in the city of Marocco, was assassinated by a slave. They were succeeded by the dynasties of the Hassides, the Meyanides, and the Merinides. See ALMORAVIDES.

ALMOND (*Amygdalus communis*), a tree belonging to the natural order Rosaceæ, a native of Asia and Northern Africa, but also acclimated and cultivated in the milder parts of Europe. On account of its beautiful vernal flowers and ornamental appearance it is much grown in England; but in this climate the fruit seldom arrives at maturity. It attains the height of 12 or 14 feet; the flowers are of a pink colour, growing in pairs, and pentapetalous; the leaves oval, pointed, and delicately serrated. The covering of the fruit is a thick-set down on a thin coriaceous pericarp, enclosing a hard shell which contains an emulsive kernel. The bitter almond is produced by a variety of the same species: it yields a yellowish volatile oil when distilled from contact with water, and is heavier than that fluid. The oil obtained by expression from either kind is bland and tasteless. The flavour of the bitter almond is not derived from hydrocyanic acid alone, but from an essential oil, which, however, is only produced when water comes into contact with the vegetable albumen of bitter almond; for the dry kernel has no flavour, and the essential oil is only generated when water is added to the bruised kernel. Some individuals are highly susceptible of the poison of bitter almonds; and instances have occurred where even death has ensued from eating them in no great quantity. The leaves also of this tree contain the hydrocyanic or prussic acid.

Valencia was long famous for its almonds, but the best now come from Malaga, and the bitter kind chiefly from Mogadore in Barbary. The quantity imported into Britain in 1849 was as follows:—sweet almonds, 25,897 cwt.; bitter almonds, 6141 cwt. The quantity exported was—sweet almonds, 14,087 cwt.; bitter almonds, 2866 cwt. (T. S. T–L.)

ALMOND *Furnace*, among refiners, that in which the slags of litharge, left in refining silver, are reduced to lead again by the help of charcoal.

ALMONDBURY, a township of the wapentake of Agbrigg, in the west riding of the county of York. It is situated on the river Calder, and had formerly a cathedral and a strong castle. It is 186 miles distant from London, in a manufacturing district near Huddersfield, and is noted for its extensive manufactures of woollens. It has a good grammar-school. The population in 1841 was 8828; in 1851, 9749.

ALMONDS, in *Anatomy*, a name sometimes given to two glands, generally called the *tonsils*.

ALMONDS, among lapidaries, signify pieces of rock-crystal, used in adorning branch-candlesticks, &c., so called from the resemblance they bear to the fruit of that name.

ALMONER, in its primitive sense, denotes an officer in religious houses, to whom belonged the management and distribution of the alms of the house. By the ancient canons, all monasteries were to spend at least a tenth part of their income in alms to the poor. The almoner of St Paul's is to dispose of the moneys left for charity, according to the appointment of the donors, to bury the poor who die in the neighbourhood, and to breed up eight boys to singing, for the use of the choir. By an ancient canon, all bishops are required to keep almoners.

*Lord* ALMONER, or *Lord High* ALMONER *of England*, is an ecclesiastical officer, generally a bishop, who has the forfeiture of all deodands, and the goods of a *felo de se*, which he is to distribute among the poor. He has also, by virtue of an ancient custom, the power of giving the first dish from the king's table to whatever poor person he pleases, or, instead of it, an alms in money.

ALMORAH, in Northern India, the chief town of the British province of Kumaon, in the territories of the lieutenant-government of Agra. It is built on a ridge of the Himalaya Mountains, 5337 feet above the level of the sea, and consists chiefly of a single street, about three fourths of a mile long, and about 50 feet wide, which runs along the ridge of the mountain, with scattered dwellings, chiefly inhabited by Europeans, to the right and left hand on the descent of the hill. The main street has a gate at each end; and Bishop Heber mentions that it reminded him, on a small scale, of Chester. The houses all stand on a lower story of stone, where the shops are. This is open in front, while the upper stories are faced with a framework of wood, occasionally carved and painted, supported on the projecting side-walls below, and surmounted by a sloping roof of heavy gray slate, on which many of the inhabitants pile up their hay in small stacks, as winter provender for their cattle. The town is very neat, and the street has a natural pavement of slaty rock, which is kept beautifully clean. It is very strongly situated, and is approached by a long, steep, and winding road, which a handful of men might defend against an army. From Almorah the vast range of the Himalaya Mountains bounds the prospect to the north. Nundidevi, one of the highest peaks in the world, being 25,689 feet above the level of the sea, is within 40 miles from Almorah in a direct line, though it is a nine days' journey by the only accessible road through the mountains. There is an old Ghorkha citadel, which stands on a commanding point of the ridge, at the eastern extremity; and several martello towers have been erected. A citadel, named Fort Moira, has been constructed on a small eminence at the western extremity of the town. It is, according to Bishop Heber, very ill contrived, and incapable of defence against a resolute enemy. The surrounding country is of a bleak and desolate character, and there is scarcely a tree within a circuit of four miles from the walls. Almorah was conquered in 1790 by the Ghorkhas. It subsequently attained some celebrity as the scene of the British victory which terminated the war with Nepaul. The attack of the heights and town by Colonel (now Sir Jasper) Nicolls, on the 25th April 1815, was crowned with complete success. The breastworks of the enemy were carried in rapid succession, and before the evening the British had established themselves in the occupation of a considerable section of the town. On the succeeding day preparations were commenced for an assault upon the fort, but while these were in progress, the Ghorkha commander proposed a suspension of hostilities preparatory to a permanent pacification. The result was the conclusion of a convention under which the Nepaulese evacuated Kumaon, and the province was forthwith incorporated with the British dominions. Distant north-west from Calcutta by Lucknow and Bareilly 910 miles. Lat. 29. 35. Long. 79. 42. (E. T.)

ALMORAVIDES, a family of Mahometan princes who reigned in Africa and in Spain in the eleventh and twelfth centuries. This appellation was derived from the sect of *Al-Morabethin*, which in Arabic signifies 'dedicated to the service of God.' The sect which assumed this title arose about the middle of the eleventh century, among a poor ignorant tribe of Berbers inhabiting the Mountains of Atlas on the shores of the Atlantic Ocean, and at a time when all Western Africa was in the possession of strangers, and a prey to anarchy. At the request of a sheik of Lamtouna, who had acquired some taste for learning by travelling in the East, Abdallah-ben-Yazim, an Arabian of extraordinary erudition, consented to instruct the people in the truths of Islam. The enthusiasm of Abdallah created a like zeal in the hearts of his ignorant hearers. All the chief persons were filled with admiration at his wisdom; and by the energy and novelty of his discourses he so inflamed the minds of his disciples, that they compelled those whom persuasion could not move to embrace the new religion. Thus Abdallah found himself at the head of a numerous sect, who soon began to regard him as their leader, both in temporal and spiritual matters. A wide field was opened to his ambition; and by fostering the fanatical zeal of his adherents, he spread the terror of his arms far and wide. Under the name of Almorabethin or Almoravides, they overran the country of Daza, lying between the desert of Sahara and the ancient Getulia; and ultimately extended their conquests from the shores of the Mediterranean to the frontiers of Nigritia. This extraordinary man died on the field of battle in the year 1058. He was succeeded by Abou-Bekr-ben-Omar, a man whose abilities were scarcely equal to the difficulties of the position in which he was placed. The commencement of his career, indeed, was prosperous; for he seized upon the province of Fez, conquered Mequinez and Lewata, and founded the city of Marocco: but, when an insurrection among the Berbers required his presence in Atlas, he had the imprudence to entrust the government to the ambitious Yusseff-ben-Taxefien, a person whose abilities were superior to his own; and on his return he accordingly found himself supplanted by his rival. Yusseff possessed every requisite of a conqueror and a legislator; and when he was firmly established in power, he resolved to turn his arms against Spain. He passed the straits, and after receiving re-inforcements from all the emirs who had partitioned among themselves the empire of the Ommiades, he marched against Alonzo VI., the most potent prince in Christendom. They met in the plains of Zalaca, and Alonzo was defeated with terrible slaughter. The news of Yusseff's success induced many of the Arabs of Spain to enlist under his victorious banner. He then attacked Mohammed, king of Andalucia; and after a protracted siege he became master of Seville. This conquest was followed by the subjugation of Almeria, Denia, Xativa, and Valencia. The acquisition of the Balearic Isles was the completion of this vast empire, which extended from the Ebro and the Tagus to the frontiers of Soudan. Although Marocco was his capital, he frequently visited his Spanish dominions; and on the last occasion, having assembled the governors of the provinces at Cordova, he appointed Ali, the youngest of his sons, as his successor. He then returned to Marocco, where he died at a very advanced age, A.D. 1106 (of the Hegira 500), after a reign of forty years.

Few kings have received so noble a heritage as that to which Ali succeeded. The first years of his reign were prosperous, though disturbed by the Almohedes, who were preparing the way for the destruction of the Almoravides. Ali was at last obliged to recal from Spain his son Taxefien, who was using his utmost endeavours to oppose the victorious career of Alonzo of Aragon, surnamed the Fighter. But the valour of Taxefien was of little avail against the rising power of the Almohedes: disaster followed disaster; and when, in 1143, he succeeded to the throne, but a moiety of the kingdom remained. It was in vain that he received succours from Spain, the troops from that soft climate being little fitted for service in the wild regions of Atlas. Driven from Tlemecen, he sought refuge in Oran; but Abdelmoumen appeared before its walls, and by threats so intimidated the inhabitants that Taxefien was compelled to provide for his safety by flight. Concealed by the darkness of night he escaped on horseback, with his favourite wife behind him; but being closely pursued, he urged his horse over a precipice, and with his wife was dashed to pieces. Such was the end of this prince; and with him expired the domination of the Almoravides: for although they still remained in possession of the city of Marocco, their power was completely broken. Ishak-Ibrahim, the son of Taxefien was taken and put to death at Alcazar in 1146, on the surrender of Marocco by treachery, after a siege which was attended with all the horrors of famine and disease; and with him the dynasty of the Almoravides became extinct. (*For the history of the Arabians in Spain, see the works of Cartas, Cardonne, Condé, Dombay, St Hilaire, and D'Herbelot.*)

ALMS, a general term for what is given out of charity to the poor. In the early ages of Christianity, the alms of the charitable were divided into four parts; one of which was allotted to the bishop, another to the priests, and a third to the deacons and subdeacons, which formed their whole means of subsistence: the fourth part was employed in relieving the poor, and in repairing the churches. No religious system is more frequent or warm in its exhortations to almsgiving than the Mahometan. The Koran represents alms as a necessary means to make prayer be heard. Hence that saying of one of their caliphs: "Prayer carries us halfway to God, fasting brings us to the door of his palace, and alms introduce us into the presence-chamber." Hence many illustrious examples of this virtue among the Mahometans.

ALMS also denotes lands or other effects left to churches or religious houses, on condition of praying for the soul of the donor, a tenure by which many of the old monasteries and religious houses in Britain held their lands. Lands thus held were free of all rent or service. Hence

*Free ALMS, Frank Almoign*, that which is liable to no rent or service.

*Reasonable ALMS*, a certain portion of the estates of intestate persons, allotted to the poor.

*ALMS Box* or *Chest*, a small chest or coffer, called by the Greeks Κιβωτιον, wherein anciently the alms were collected, both at church and at private houses.

The alms-chest, in English churches, is a strong box, with a hole in the upper part, having three keys, one to be kept by the parson or curate, the other two by the church-wardens. The erecting of such alms-chest in every church is enjoined by the book of canons, as also the manner of distributing what is thus collected among the poor of the parish.

ALMUCANTARS, in *Astronomy*, an Arabic word, denoting circles of the sphere passing through the centre of the sun or a star, parallel to the horizon, being the same as *PARALLELS of Altitude*.

*ALMUCANTAR's Staff* is an instrument usually made of pear-tree or box, having an arch of 15 degrees; used to take observations of the sun, about the time of its rising and setting, in order to find the amplitude, and consequently the variation of the compass.

ALMUCIUM, denotes a kind of cover for the head, worn chiefly by monks and ecclesiastics. It was of a square form, and seems to have given rise to the bonnets of the same shape still retained in universities and cathedrals.

ALMUDE, a liquid measure in Portugal. At Lisbon, 26 almudes make a pipe. It is applied also to a corn measure in Spain and Barbary.

ALMUGGIM, ALMIGGIM, or ALMUG TREE, a certain kind of wood mentioned in the First Book of Kings (x. 11), which the Vulgate translates *ligna thyina*, and the Septuagint *wrought wood*. The Rabbins generally render it *coral;* others, *ebony, brazil*, or *pine*. But it is observed, that the almug tree can by no means be coral, because that is not fit for the purposes for which the Scripture tells us the almug tree was used, such as musical instruments, staircases, &c. The word *thyinum* is a name for the citron tree, known to the ancients, and very much esteemed for its sweet odour and great beauty. It came from Mauritania. The almug tree, or almuggim, or simply gummim, taking *al* for a kind of article, is, therefore, by the best commentators, understood to be an oily and gummy sort of wood, and particularly that sort of tree which produces the gum ammoniac; which is also thought to be the same with the shittim wood so frequently mentioned by Moses.

ALMUNECAR, a small city of the province of Granada, in Spain. The soil around it is productive of all the tropical vegetables. Sugar-canes grow as large and as juicy as in the West Indies, the cotton is of excellent quality, and the rum made here is deemed equal to that of Jamaica. The anchorage is fit for small vessels only, and its exposure to gales from the east, which are frequent, renders it insecure. It contains 5000 inhabitants. Long. 3. 54. W. Lat. 36. 42. N.

ALNAGE, or AULNAGE, the measuring of woollen manufactures with an ell. It was at first intended as a proof of the goodness of that commodity; and accordingly a seal was invented as a mark that the commodity was made according to statute.

ALNAGER, ALNEGER, or AULNEGER, signifies a sworn public officer, who, by himself or deputy, was to look to the assize of woollen cloth made throughout the land, *i. e.*, the length, width, and work thereof; and to the seals for that purpose ordained. The office of king's alnager seems to have been derived from the statute of Richard I., A.D. 1197, which ordained that there should be only one weight and one measure throughout the kingdom; and that the custody of the assize or standard of weights and measures should be committed to certain persons in every city and borough. His business was, for a certain fee, to measure all cloths made for sale. The office was abolished by stat. 11th & 12th Gul. III., cap. 20.

ALNUS, a botanical genus to which our common alder belongs.

ALNWICK, a thoroughfare town in Northumberland, on the road to Scotland. Here, in 1093, Malcolm king of Scotland, making an inroad into Northumberland, was killed, with Edward his son, and his army defeated, by Robert Moubray, earl of this county. Here also William king of Scotland, in 1174, invading England with an army of 80,000 men, was encountered, his army routed, and himself made prisoner. The town is in general well built; and has a large town-house, where the quarter-sessions and county-courts are held, and members of parliament elected. It has a spacious square, in which a market is held every Saturday. From the vestiges of a wall still visible in many parts, and three gates which remain almost entire, Alnwick appears to have been formerly fortified. This borough is governed by four chamberlains, and 24 common council men. It is ornamented by a stately old Gothic castle, the seat of the noble family of Percy, dukes of Northumberland. The manner of making freemen is peculiar to this place, and is indeed as ridiculous as singular. The persons who are to be made free, or, as the phrase is, "leap the well," assemble in the market-place, very early in the morning, on the 25th of April, being St Mark's day. They appear on horseback, with every man his sword by his side, dressed in white, and with white nightcaps, attended by the four chamberlains and the castle bailiff, mounted and armed in the same manner. From hence they proceed, with music playing before them, to a large pool called *Freeman's Well*, where they dismount, and draw up in a body, at some distance from the water; and then rush into it all at once, and scramble through the mud as fast as they can. As the water is generally very foul, they come out in a dirty condition; but they put on dry clothes, remount their horses, and ride at full gallop round the confines of the district; then re-enter the town, sword in hand, and are met by women dressed in ribbons, with bells and garlands, dancing and singing. They are called *timber-wasts*. The houses of the new freemen are on this day distinguished by a great holly bush, as a signal for their friends to assemble and make merry with them after their return. The establishment of this singular ceremony is traditionally referred to King John, who was mired in this well, and, as a punishment for not mending the road, made this a part of their charter. Alnwick is 310 miles north by west from London, 33 north of Newcastle, and 29 south of Berwick. Long. 1. 42. W. Lat. 55. 24. N. Pop. in 1851, 6231.

ALOA, in *Grecian Antiquity*, a festival kept in honour of Demeter and Dionysius by the husbandmen, and resembling our harvest-home.

ALOE or ALOES, the name of a genus of plants of the natural order of *Asphodeleæ*. See BOTANY. But the name is also applied to an extract obtained from several species, and employed in medicine as a cathartic. The most valued kind is named Socotrine aloes; although the small island in the Arabian seas from which it has obtained its name, produces but a small part of the drug that goes under its name. Six kinds are known in commerce. 1. Clear garnet red aloes, a very rare variety. 2. Socotrine aloes, now chiefly brought from India. 3. Common East Indian aloes. 4. Barbados, or Hepatic aloes, much used in farriery. 5. Cape aloes, often sold as the Socotrine variety. 6. Caballine aloes, a soft inferior sort, formerly much used by farriers, but now superseded by the Barbados aloes. The active principle in this drug is a peculiar extractive matter soluble in water and in proof spirit, but not in strong alcohol; from which it was considered as allied to gum resins; but it is now believed to be a highly oxidated extract. This substance, called *Aloesine*, varies in quantity in each species, from 52 to 80 per cent.—See *Christison's Dispensatory*.

ALOGI (α, privative, and λογος), in *Church History*, a sect of ancient heretics, towards the close of the second century, so called because they denied that Jesus Christ was the Logos. They likewise denied the continuance of the *charismata*, or special spiritual gifts, in the Christian church, and accordingly rejected the prophetical portions of the New Testament, besides the Gospel of John. They were particularly opposed to the Montanists; but our information regarding them is very scanty. They are first mentioned by Epiphanius.

ALOGOTROPHIA, among *Physicians*, a term signifying the unequal growth or nourishment of any part of the body, as in the rickets.

ALOPECIA, a term used among physicians to denote a total falling off of the hair from certain parts.

ALOPECURUS, a genus of the natural order of grasses or gramineæ. *A. pratensis* is our meadow foxtail: *A. arvensis*, field foxtail: *A. geniculatus*, float foxtail.

ALORA, a Spanish town, in the judicial district of the same name, and province of Malaga. Pop. 6794. This is the ancient *Iluro* or *Lauro*, where Cn. Pompeius the younger was slain after the battle of Munda.—Florus, Hirtius (*De Bell. Hispan.*)

ALOSA, a fossil genus of fishes of the Cycloïd order. It is also the trivial name of a living *Clupea*, our herring.

ALOST or AALST, a town of Belgium, in the province of East Flanders, and chief town of the arrondissement of the same name. It is situated on the Dender, about half way between Brussels and Ghent; and vessels of small size come up to the town. It is clean and well built; has a college and other educational establishments; and carries on a considerable trade in corn, hops, beer, and the produce of its linen, cotton, and lace manufactories. By the census of October 1846, it had 3010 houses, and 17,226 inhabitants. The arrondissement of the same name is divided into 11 cantons, 81 communes, and, by the same census, had a population of 138,251. Lat. 50. 57. N. Long. 4. E.

ALP ARSLAN, or AXAN, the second sultan of the dynasty of Seljuk, in Persia, and great-grandson of Seljuk the founder of the dynasty. He was born in the year 1030, of the Hegira 421. In place of Israel, which was his original name, he assumed that of Mohammed when he embraced the Mussulman faith; and, on account of his military prowess, he obtained the surname *Alp Arslan*, which in the Turkish language signifies *a valiant lion*. Having held the chief command in Khorassan for ten years as lieutenant of his uncle Togrul Beg, he succeeded him in the year 1063, and, at the commencement of his reign, saw himself sole monarch of Persia, from the river Amu to the Tigris. When he assumed the reins of government, faction and open rebellion prevailed in his dominions; in subduing which he was ably assisted by Nadham al Molk, his vizier, one of the most distinguished characters of his time, whose prudence and integrity in the administration of the affairs of the kingdom proved of most essential service to this prince and to his successor. Peace and security being established in his dominions, he convoked an assembly of the states; and having declared his son Malek Shah his heir and successor, he exacted an oath of fidelity to him from the principal officers of the empire. With the hope of acquiring immense booty in the rich temple of St Basil in Cæsarea, the capital of Cappadocia, he placed himself at the head of the Turkish cavalry, crossed the Euphrates, and entered and plundered that city. He then marched into Armenia and Georgia, which, in the year 1065, he finally conquered. In the former country the very name of a kingdom and the spirit of a nation were totally extinguished; but the native Georgians, who had retired to the woods and valleys of Mount Caucasus, made a more vigorous resistance. They too, however, overpowered by the arms of the sultan and his son Malek, were forced to submission, and reduced to slavery. To punish them for the brave defence which they had made, and as a badge of their humiliating condition, Alp Arslan obliged them to wear at their ears horse-shoes of iron. Some, to escape this mark of cruelty and ignominy, professed to embrace the religion of Mahomet.

In the year 1068 Alp Arslan invaded the Roman empire, the seat of which was then at Constantinople. Romanus Diogenes, the Greek emperor, assuming in person the command of his forces, met the invaders in Cilicia. In three several campaigns his arms were victorious; and the Turks were forced to retreat beyond the Euphrates. In the fourth he advanced with an army of 100,000 men into the Armenian territory, for the relief of that country. Here he was met by Alp Arslan, with 40,000 cavalry, or, according to some authors, a much smaller number; and the sultan having proposed terms of peace, which were insultingly rejected by the emperor, a bloody and decisive engagement took place, in which the Greeks, after a terrible slaughter, were totally routed. Romanus, deserted by the main body of his army, with unshaken courage kept his station, till he was recognised by a slave, taken prisoner, and conducted into the presence of Alp Arslan. When the terms of his ransom were about to be settled, Romanus was asked by Alp Arslan what treatment he expected to receive. To this question the emperor, with seeming indifference, replied, "If you are cruel, you will take my life; if you follow the dictates of pride, you will drag me at your chariot wheels; if you consult your interest, you will accept a ransom, and restore me to my country." "But what," says the sultan, "would you have done in such circumstances?" "Had I been victorious," said the insolent Romanus, "I would have inflicted on thy body many stripes." The conqueror smiled at the fierce and unsubdued spirit of his captive; observed that the Christian precepts strongly inculcated the love of enemies and the forgiveness of injuries; and, with a noble greatness of mind, declared that he would never imitate an example which he disapproved. A ransom of a million, an annual tribute of 3000 pieces of gold, an intermarriage between the families, and the deliverance of all the captive Mussulmans in the power of the Greeks, were at last agreed to as the terms of peace and the liberty of the emperor. Romanus was now dismissed loaded with presents, and respectfully attended by a military guard. But the distracted state of his dominions, the consequence of a revolt of his subjects, precluded him from fulfilling the terms of the treaty, and remitting the stipulated price of his ransom. The sultan seemed disposed to favour and support the declining fortunes of his ally; but the defeat, imprisonment, and death of Romanus interrupted the accomplishment of his generous, or rather ambitious, design.

At this time the dominion of Alp Arslan extended over the fairest part of Asia: 1200 princes, or sons of princes, surrounded his throne; and 200,000 soldiers were ready to execute his commands. He now meditated a greater enterprise, and declared his purpose of attempting the conquest of Turkistan, the original seat of his ancestors. After great preparations for the expedition, he marched with a powerful army, and arrived at the banks of the Oxus. Before he could pass the river with safety, it was necessary to gain possession of some fortresses in its vicinity, one of which was for several days vigorously defended by the governor, Yúsuf Cothual, a Carizmian. He was, however, obliged to surrender, and was carried a prisoner before the sultan, who, enraged at his obstinacy and presumption, addressed him in very reproachful terms. Yúsuf replied with so much spirit, that he roused the resentment of Alp Arslan, and was commanded instantly to be fastened by the hands and feet to four stakes, to suffer a painful and cruel death. Yúsuf, on hearing this sentence, became furious and desperate; and drawing a dagger which he had concealed in his boots, rushed towards the throne to stab the sultan. The guards raised their battle-axes, and moved forward to defend their sovereign; but Alp Arslan, the most expert archer of his age, checking their zeal, forbade them to advance, and drew his bow: his foot slipped, and the arrow missed Yúsuf, who rushed forward, and plunging his dagger in the breast of the sultan, was himself instantly cut in pieces. The wound proved mortal, and the sultan expired a few hours after he received it, in the year 1072.

ALPACA, a species of the South American family of quadrupeds called *Llama*, the soft hairy wool of which is now largely employed in the fabrication of cloths of different sorts. There would appear to be three species of this family, the *Guanaco* or wild Llama; the *Alpaca*, which was domesticated as a beast of burden by the ancient Peruvians, and hence considered as the camel of the new world; and the *Vicuña*, a small species, chiefly valued for the softness of its fine wool. Some consider the *paco* a fourth species: but the descriptions of travellers are too indefinite to enable us to decide this point. The fleece of the alpaca is fine, long, and shaggy; and the animal exceeds much in size the other two.

ALPARGATES, sandals made of the *Esparto* rush or *matweed*, *Stipa tenacissima*, which the Spanish peasantry also manufacture into mats and thread.

ALPHA, the name of the first letter of the Greek alphabet, answe ing to our A. As a numeral, it stands for one, or the first of anything. It is particularly used among ancient writers to denote the chief or first man of his class or rank. In this sense the word stands contradistinguished from *beta*, which denotes the second person. Plato was called the *Alpha* of the wits. Eratosthenes, keeper of the Alexandrian library, whom some call a *Second Plato*, is frequently named *Beta*.

Alpha is also used to denote the beginning of anything; in which sense it stands opposed to *omega*, which denotes the end. (Rev. i. 8.) These two letters were made the symbol of Christianity, and accordingly were engraven on the tombs of the ancient Christians, to distinguish them from those of idolaters. It was the opinion of Morales that this custom only commenced since the rise of Arianism, and that it was peculiar to the orthodox, who hereby made confession of the eternity of Christ; but there are tombs prior to the age of Constantine whereon the two letters were found, besides that the emperor just mentioned bore them on his labarum before Arius appeared.

# ALPHABET.

We have received the word *Alphabet* immediately from the Latin, *alphabetum*, for which substantive, however, there is no better authority in that language than the writings of Tertullian and St Jerome. The more classical Juvenal writes, "*Hoc discunt omnes ante alpha et beta puellæ*," which is literally, "girls learn this before their A, B, C." We do not find the word in Greek. Athenæus uses the adjective αναλφαβητος to signify a man who does not know the first two letters; and it is from these two letters that our word *alphabet* is evidently derived. Whatever the subsequent arrangement may be, the letters A and B stand at the beginning of a great number of alphabets. The ordinary definition of the word is a table or list of characters, which are the signs of particular sounds. Mathematicians have amused themselves by calculating the number of combinations which may be made of these signs or sounds. Tacquet, according to Harris, writes thus: "*Mille milliones scriptorum mille annorum millionibus non scribent omnes* 24 *litterarum alphabeti permutationes, licet singuli quotidie absolverent* 40 *paginas, quarum unaquæque contineret diversos ordines litterarum* 24." We may doubt, perhaps, whether this pomp of numbers will give any very clear notion even to a mathematician; but the passage shows, that for any practical purpose the combinations of elementary sounds, and consequently the number of words, may well be considered infinite. The consideration of the peculiar sets of combinations which constitute, at least in part, what is called the genius of a language, would be a curious inquiry, that has received but little attention; but it does not belong to this head. It has been asserted that the words of no two languages are respectively so unlike as the words in the same language are to themselves, and to one another when read backwards; but this consideration also, of whatever value it be, rather appertains to language itself than to the elements of which it is composed.

When we read the volumes of Lord Monboddo on the origin of language, we know not whether to laugh more at his countless absurdities and boundless credulity, or to wonder at his ingenuity and learning. Many other works have been composed on the same subject, less ridiculous and less admirable, but equally unsuccessful in clearing up the difficulties which they sought to solve. The attempt which is sometimes made to illustrate the invention of writing by that of language, proves invariably to be an impotent effort to explain one unknown thing by another. The invention of alphabetic writing is in truth an inexplicable mystery; we cannot touch it in any way, or approach it on any side. As this opinion is contrary to the commonly received notions, we will briefly state our reasons for adopting it.

It is generally believed that certain steps may be observed, by means of which we are able to trace the gradual progress of the invention. These are the songs and rude drawings of savages, and some simple contrivances for preserving the memory of numbers by beads and similar devices; but especially the Egyptian hieroglyphics, the Chinese characters, and certain alphabets that are said to be syllabic. Learned men have thought fit to assert that there once was a time when no nation was able to write; but they are unable to bring any proof of this assertion, and the evidence of history seems to contradict it. They tell us that men composed songs and ballads to preserve the remembrance of past events, and used paintings and knots to assist the memory. We know that some nations who are unacquainted with letters use these artifices; and we can readily believe that five beads on a string may represent five men, or five days, or five years, but such a memorial has no connection with writing. We know, moreover, that in times when writing is universal, ballads are made and sung, and paintings are produced; and a person who is unwilling to forget an engagement sometimes ties a knot on his pocket-handkerchief. Those who can write often avail themselves of other aids; and those who cannot, have been obliged in all ages to do as well as they can without. It is manifest that we shall not be able to find any firm ground for placing the first step amongst the operations of savages. In common with their civilized brethren, they have the desire to remember certain events; but they have not done any thing to advance the peculiar means of which we treat.

The learned president Goguet, in his instructive and popular work, *De l' Origine des Loix, des Arts, et des Sciences*, discourses at some length and with much ability of the invention of writing. Having mentioned the substitutes which are adopted by savages, he brings forward the Egyptian hieroglyphics thus: "We have been a long time in error as to the first use of hieroglyphics: men believed that the Egyptian priests invented them for the purpose of hiding their knowledge from the vulgar, but it is through want of attention that they have been thus deceived. We may easily satisfy ourselves, that at the beginning they only employed hieroglyphics to hand down and make known their laws, their usages, and their history. Nature and necessity, not choice, have produced the different kinds of hieroglyphic writing. It is an imperfect and defective invention, suitable to the ignorance of the first ages: it was through want of the knowledge of letters that the Egyptians had recourse to them. If this nation had found out alphabetic writing before, they would have been too sensible of its advantages to employ any other. The mistake concerning hieroglyphics has come from the Greeks. They were only acquainted with the Egyptians in much later times. This people had then the use of alphabetic characters. The ancient method of writing in hieroglyphics had been neglected by the mass of the nation; but the Egyptian priests, who, according to the custom of all the learned men of antiquity, were only concerned about the means of hiding their learning, retained the hieroglyphic writing as a fit veil to hide the knowledge of what they did not choose to divulge. It is thus that, after the discovery of alphabetic writing, hieroglyphics became in Egypt a secret and mysterious kind of writing." It is plain that a sensible and learned man here speaks too positively about matters which no one can know. If the Greeks, who were acquainted with the Egyptians, although in later times, are mistaken, how can we, who only know the Egyptians through their report, venture to correct them? "But how did they arrive at this discovery?" The president afterwards candidly asks, "how did they pass from hieroglyphics, and even from syllabic writing, to alphabetic characters?" (It would not have been difficult to have passed from syllabic writing if it had ever existed.) "This is not easy to imagine. Hieroglyphics and syllabic writing certainly have no connection with the letters of the alphabet." (The latter undoubtedly has, for it represents sounds.) "It was necessary, then, to change entirely the nature of the signs which were used. In vain shall we have recourse to the writers of antiquity to clear up this question. They do not show us in what manner these singular transitions could have been made. We may conjecture that the abridged marks of hieroglyphic writing, of which I have spoken above, conducted to the still more abridged method of alphabetic letters, which by their different combinations express all the articulations of the voice in a simple and easy manner. This conjecture becomes very probable. When we cast our eyes upon the alphabets of some ancient nations, the letters which compose them appear, both by their forms and their names, to have been taken from hieroglyphic signs. If we compare with attention what remains of the Egyptians with the hieroglyphic figures engraved on the obelisks and other monuments, we shall perceive that the Egyptian letters derive their origin from the hieroglyphics." "The Ethiopic alphabet, and the majuscule letters of the Armenians, also supply proofs of what I advance: we find there very distinct traces of the ancient hieroglyphic character." We know not what he means by "the ancient Egyptian characters," unless it be the Coptic alphabet, which is posterior to and derived from the Greek, as Plate XXI. demonstrates. It shows also the Ethiopic letters, and the ordinary Armenian, which are not ancient: still less are the majuscules or capitals: the latter are undoubtedly formed in the shape of animals, &c.; but they are like the illuminated letters that were used as initials in the middle ages. These certainly were not taken from hieroglyphics, but were designed for ornament; and so is it likewise with the majuscules of the Armenians, which were a very late invention; and it is matter of history, and not of conjecture, that they were taught them by the Greeks. It is very doubtful whether the paintings of the Mexicans, of which some writers have treated largely, had any connection with writing, or were intended for any thing but pictures; in truth nothing is known about them, and we may at once dismiss them as having no relation to the subject.

The hieroglyphics appear to be related to the alphabet; and as they are very extraordinary in themselves, and have received much attention from the learned, we must speak somewhat fully of them; although they will not enable us to trace any transition or progress towards alphabetic writing, which is perfect and complete wherever it exists, the instances usually adduced of imperfect and incipient writing being in our opinion entirely unfounded; and it is an unwarranted assumption, that the Egyptian hieroglyphics preceded the use of the letters of the alphabet, of which there is no proof, whatever testimony exists being to the contrary. In every generation there have been a few gifted interpreters, who have professed that they were able to read the hieroglyphics; nor have these been wanting in our own times. The expedition of the French to Egypt, and especially the discovery of the famous Rosetta stone, which, the late Dr Young declares, was an ample compensation for all that the two armies suffered, gave a powerful impulse to these studies. It had been observed on the Egyptian monuments, that clusters of figures were often included in a ring, scroll, or cartouch; and it was deemed expedient that these should represent proper names. To meet the exigency of the case the *Phonetic* system was devised, which is briefly this: if we suppose that the scroll contains a dog, an ass, and a yew-tree, the initials of the three words are taken, and they form the word Day; and this by the hypothesis is a proper name; and we may infer, if we please, that Potiphar had read Sandford and Merton, and was greatly delighted with that excellent work. The language, however, in which the objects that supply the initials are to be named, is not English, but Coptic; but the results, we shall see, are precisely the same. Let us assume that the figure of a bird denotes A; since the engraving is not executed with the exquisite accuracy of a Bewick, it may be an albatross, a buzzard, a crow, a duck, an eagle—any bird, in short, in the Coptic vocabulary, and any letter in the alphabet; and so with the tree, which stands for B: it may be an apple, a beech, a cedar, or any arborescent vegetable whatever: and, as if this were not loose enough, each letter has several visible objects, each of which may be made to run the gauntlet of the alphabet. The number of figures contained in the scroll, we should have imagined, would control the length of the word, and indicate the number of the letters; but they are relieved from that slight responsibility thus: since every allowance ought to be made for a scribe who writes upon granite, ΠΤΟΛΜ. will stand for Πτολεμαιος; or, if there be a redundancy of objects, the superfluous letters are disposed of as symbolical, and are classed with the goose and globe, or the goose and grid-iron, and some other favourite emblems. Although there be figures enough to complete the name Πτολεμαιος, that monarch, if it be not his turn, may be desired to stand aside: any three may be chosen to spell Day, and the other seven may be explained symbolically to signify the author of Sandford and Merton, or any thing any body pleases. Such is the Phonetic system, and its results are such also as might have been expected. Dr Young, an ingenious and learned person, founding himself on certain notions entertained by Warburton, proceeded with singular zeal and activity to compass and imagine discoveries which we are not able to relate. We will only observe briefly, that any conjecture of that prelate may safely be presumed to be wrong; for although his energy, learning, and acuteness, were undoubtedly great, experience has shown, that from haste or some other cause his views are commonly erroneous. Dr Young, being in that vein, of course went on from discovery to discovery, being guided by that warm fancy which usually attends real talent; and, as is ever the case on such occasions, every person who took the pains to investigate the matter found precisely what he was looking for and most desired: no one was ever disappointed. MM. Champollion-Figéac, Sylvestre de Sacy, D'Akerblad, and many other foreigners, learned to read,—to run and read. The hieroglyphics were as legible when they rode by the obelisks as the names over our shops. Our own countrymen ran a bright career of glory. Mr W. J. Bankes, Mr Salt, and others saw immediately strong confirmations. Even Mr George Grey, a very estimable young gentleman, who took a little trip to Egypt in the season, according to the fashion, crept into the great pyramid and out again, saw every thing, bought a charming pair of mummies, a cock and a hen, cut them open, and found, without knowing it, the "ring of Polycrates," as Dr Young says, and perhaps also that of Hans Carvel. He found a Greek translation, it is said, of a manuscript, which had recently been brought from Egypt to Paris. The original was in the Enchorial character, and the translation showed that it was a sale of land. It was, moreover, duly registered and probably stamped; but that we are not told. That a landowner should go to bed with his title-deeds in his stomach, that the muniments of the deceased should be buried with him, ought to astonish us, even in an age of discovery. It shows, however, the perfection of the enchorial registration in Egypt, that the settlement was buried with the first tenant for life who died; and it will be a wholesome example to our law-commissioners, who are about to introduce registration in England, and an admonition to make the public title so complete, that all private securities may safely be dispensed with. The papyrus which Mr George Grey brought from Egypt refers, however, not to the hieroglyphics, but to the characters called enchorial, which are the second in order of the three inscriptions on the Rosetta stone. They seem to be alphabetic, although no one has been able hitherto to make out the alphabet. It is hard indeed to imagine, that there ever was any writing which was not alphabetic. Efforts have been made to interpret these also, but after turning over a few pages of the interpretation, the reader is disposed to say to the interpreter, "if you are permitted to read an inscription either backwards or forwards, to consider the letters as imperfectly formed, to select them from any alphabet that will suit your purpose, to turn them round or invert them, to supply, and amend, and reject at pleasure, to take any form of any word in any language you choose, and to make great allowances for barbarism, ignorance, foreign spelling, and so forth,—if you may do all these things, and cannot find your own name, your mother's, and mine, in any writing whatever, you certainly are not fit to decipher enchorial characters." The hieroglyphics which the accomplished Dr Young and his admiring disciples, whether foreign or domestic, were unable to read or to reconcile with their hypotheses, they boldly declared, after the usage of interpreters, to be spurious, and said that they had been negligently and unskilfully sculptured at Rome, in imitation of the Egyptian manner. They speak with as much confidence about a good and a bad style in hieroglyphic inscriptions, as if they were critics writing in the *Egyptian Review*, if we can fancy that such a periodical existed under the Pharaohs or Ptolemies, and deciding, in a summary manner and without appeal, on the literary merits of the new obelisks and pyramids as they appeared. So intolerant were they of the claims of what Dr Young in his first zeal termed "an exorbitant antiquity," that they condemned as forgeries some of the finest and most admired of the Egyptian monuments. But such aggressions upon the reverential feelings of mankind being likely to provoke retaliation, and to endanger the theory, they devised an ingenious expedient, and found, under the more modern scrolls, containing the names of Ptolemies or Roman emperors, the vestiges of more ancient scrolls comprehending those of older and native princes which had been erased to make way for the usurpers. Some ef these, it is said, have been deciphered. And since it has been the fashion to discover the

Alphabet.

names of the ancient kings of Egypt, many buildings have been restored to their original rank, and almost every scroll decided to stand in the place of one that had been obliterated. We would recommend some of the most sharp-sighted of these antiquaries to look well if there be not a third and older name under the second, that even "exorbitant antiquity" may once more be taken into favour. Mr Salt, in his *Essay on the Phonetic System of Hieroglyphics*, shows, that even in the symbolical department, which of course must be the most lax, it is necessary to humour the theory a good deal. This zealous convert speaks thus of Horapollo: "Having so often quoted this author, I may here state, that though I am convinced, for numerous reasons, that the first book and part of the second are written by a person perfectly acquainted with Egyptian hieroglyphics, yet so am I perfectly persuaded that the remainder is a vile interpolation, excepting perhaps the three or four last hieroglyphics, which seem to have been reserved from the original work, and placed at the end, more effectually to deceive the reader." This is very like choosing so much of a writer as will serve a favourite purpose, and rejecting the rest. It is unnecessary, however, to pursue this part of the subject farther. If we admit that the discovery of the phonetic system was very admirable; that it is demonstrated clearly, it may be mathematically; that the examples have been adduced with perfect candour and fairness; that it will afford much valuable illustration to the history of Egypt; and that it is madness, or even a crime, to doubt its truth and importance: if we concede all this, and more, it will not assist us in discovering the origin of the alphabet. The phonetic system is essentially alphabetic; the bird, and the tree, and the other figures within the scroll, are not hieroglyphics, but letters: they represent sounds. It is not a transition from hieroglyphics to letters: it is not a step in advance; but, if it be a step, it is assuredly a step backwards; for it is merely the substitution of clumsy and ambiguous letters for others that were simple and certain. The dog, the ass, and the yew-tree do not represent the author of Sandford and Merton symbolically or hieroglyphically. That ingenious person had not any of the properties peculiar to these objects. The three figures are an awkward manner of writing the three letters that compose his name, and any other object might be agreed upon to denote the same letters without reference to the initials, which could only have been chosen to assist the memory. A man, a woman, and a child would of course spell Day, if it were understood that a man was in the place of *d*, and the other figures of the other letters. Thus every one might compose at pleasure innumerable phonetic systems.

There is no foundation for the assertion of the president Goguet, and of other learned men, that the Egyptian hieroglyphics preceded the invention of alphabetic writing: whatever testimony exists is to the contrary. It is vain to argue that it is improbable any persons would use such cumbrous and inconvenient writing after they had experienced the advantages of a simple and convenient method; for there is abundant evidence, as the learned president admits, that it was practised long after they had become acquainted with the excellent alphabet of the Greeks. It is not easy to understand and to reconcile the passages in which the various sorts of writing that prevailed in Egypt are mentioned; the enchorial, the hieratic, the sacred, the demotic, the Ethiopic, &c. Our limits will not permit us to comment upon, or even to extract, the statements of Herodotus, Clemens Alexandrinus, Porphyry, Heliodorus, and others. The first author tells us that, unlike the Greeks, they wrote from the right to the left; and Clement and Porphyry affirm that the hieroglyphics were the invention of the priests, for the purpose of mystery and religious secrecy. Our physicians write their prescriptions in an uncouth character, and with barbarous abbreviations, not because they are unacquainted with the ordinary writing, but through quackery and for concealment; and for the same reasons the record in a court of law is made up in the form of a carpet, or the sail of a ship; and many similar devices, not unworthy of Tartars or Laplanders, are practised there, and in the composition of deeds, not through ignorance, but of design. If the hieroglyphics be in truth writing, and history seems to declare that they are, it is most probable that they are alphabetic; not only because we are told that they were invented when letters were in use, but because it is impossible to conceive any writing which is not such. Whether we shall ever obtain the alphabet, is very doubtful. It is easy to imagine many systems, but it is perhaps impossible to fix upon any. An animal or other object might represent a letter; and the representations might be varied according to fixed rules; or the parts of an animal might be the letters, and the animal itself would then be a word. There is no end of conjectures. It is not impossible, although the supposition has never been hazarded, that the priests wrote in initials only, like the Roman lawyers, who, partly for the sake of brevity, and partly and principally for concealment, entered their forms in that manner. A Roman notary would begin a will thus: T. I. T. L. W. A. T. &c. "This is the last will and testament," &c. Apuleius supplies a curious passage, which seems to imply that the sacred books were partly secured against profane readers by abbreviations. "Et injecta dextera senex comissimus ducit me protinus ad ipsas fores ædis amplissimæ; rituque solemni apertionis celebrato ministerio, ac matutino peracto sacrificio, de opertis adyti profert quosdam libros, literis ignorabilibus prænotatos: partim figuris cujuscemodi animalium, concepti sermonis compendiosa verba suggerentes; partim nodosis et in modum rotæ tortuosis, capreolatimque condensis apicibus, a curiosa profanorum lectione munita." (*Metamorph.* lib. 11.) We know not whence the Roman lawyers derived this kind of cipher or abbreviation, of which they made much use. It was a favourite practice likewise of the Rabbins to compose memorial words of initials. We are told that the hieroglyphics were the invention of the priests, and were connected with religion: it is probable therefore that they contain rituals, perhaps in an abbreviated form. The frequent repetitions of the same characters, and the perpetual recurrence of the same sets of characters, favour this supposition. The frequent repetitions of the services of the church of Rome furnished cause of complaint at the Reformation. In the liturgies of the Greek church they are far more remarkable. If we open any book of Greek offices, we shall find such directions as, "here make 60 kyries, then 30 doxas, then 30 χαιρες, and then 60 more kyries." The tedious ceremonies are infinitely protracted by such wholesale orders. The ancient Egyptians surpassed all people, even the Hindoos, in their addiction to religious exercises. We may read copious details of the prodigious exertions of the early Egyptian monks, who brought, with the common zeal of converts, the peculiar sentiments and habits of their nation, amongst whom all was prayer and rite, every thing was sacred, the whole land swarmed with gods. If we could translate a hieroglyphic inscription, we should probably find that it comprehended the rites to be observed in consecrating a punt. It would direct the faithful waterman to find the day and hour for the ceremony by certain rules, and to prepare himself and his boat for so many days in such a manner. At the proper hour, having made all previous preparations, he would be enjoined to turn his face to the north, and to say such and such and such prayers so many times, making certain gesticulations; and then to turn to the south, and to say the same, and this, that, and another, ten times as often, with the same gestures and some others. It is easy to imagine that the shortest epitome of the formula, although the boat was not to be used for fishing, or in a part of the Nile where crocodiles abounded, would cover the walls of a building as large as Westminster Hall; for if such folly be once permitted to begin, it is perfectly impossible to assign a reason why it should ever terminate. If such be the treasures which are locked up in the sacred characters, as it is most likely they are, we need not repine if we are never permitted to find the key; for it is plain that an authentic and faithful report of the precise words which have been uttered in all the masses that have been said for the repose of the souls of the departed, would be neither an amusing nor an instructive, although a very voluminous, pile of writing.

We have shown, we trust, that no assistance can be derived from the hieroglyphics towards discovering the origin of the alphabet. We will next examine, more briefly it is true than we would, the nature of the Chinese characters, which it is pretended afford much light, and indeed are an infallible guide to the invention of the alphabet. Let us suppose that the tradition as to the sound of the Greek letters, and all that has been written on the subject, were lost, but that we retained all the other materials for learning Greek which we still possess: if it were deemed expedient to study that divine language, we might still acquire it with pain and difficulty, as we learn the Chinese; and considering the word αλλος as a symbol, we should call it *another;* πολυς, βους, βιος, and ποταμος, would be regarded as pictures, and remembered as such; and, without reference to their original sound, would be named *many*, an *ox*, *life*, and a *river.* In copying these and other words, not as sounds composed of simple elements, but as drawings of objects, they would doubtless be much disfigured in the course of ages; it would even be desirable to vary their forms designedly, and to make them as grotesque and striking as possible, to assist the memory, which would surely deserve the aid of the compassionate. They would, moreover, be divided into classes, according to some clumsy calculation of the number of strokes by which they are formed, like the Chinese characters, that they might be arranged in dictionaries. Some mythic story of the invention of the Greek symbols would be current in Europe, as similar fables are received in China. The ingenious persons who occupy themselves in finding reasons to account for every thing just as it exists, or is supposed to exist, and lavish their admiration upon it, would indulge in raptures at contemplating the living, moving pictures which these symbols present. Not Cuyp himself, they would declare, could paint such a spirited ox as is sketched out by the image βους; and if the sign ποταμος were drawn large and black, so that the memory might seize on it through the eye and hold it fast, it would be refreshing, they would swear, on a sultry day to sit beside it and gaze on it; for no stream would be so lovely as that gentle Greek river,

Qui fluit illimis, nitidis argenteus undis.

It is no light matter to learn Greek now; what would it be under the circumstances we have supposed! When mankind were at last quite weary of admiring the Greek symbols, and of weeping over myriads of schoolboys who had been fairly flogged to death, some great man would at last arise, who, considering that all written language must of necessity be alphabetic, although the alphabet may have been lost in some cases amidst national convulsions, would proceed patiently to analyze the characters, not as a logician to seek for genera and species, nor as an artist to look for exquisite touches of art, but simply as a grammarian, to make out the letters. He would carefully dissect a character into parts, and assign arbitrarily to each part its sound, taking due care to make those parts or letters vowels which occur in words in such a manner as to render it necessary or convenient so to consider them for the purpose of articulation. He might, for example, call αλλος *uttak*, and πολυς *gatek:* the harmony of the language would be deteriorated or improved by the change, according to the taste of the age. But when the supposed symbols were once more restored to an alphabetic form, although entirely different sounds might have been substituted for the ancient, it would not be more difficult to acquire the language, than if the original alphabet had never been lost. "The Chinese characters, taken in general, are, as every body knows, images and symbols, designed to represent directly material objects, by an imitation more or less exact, and other objects by metaphors more or less ingenious. They are consequently entirely unconnected with pronunciation, and do not stand for any sounds. As it is necessary, however, that books should be read aloud, they attach by convention to each character a simple or complex syllable, which brings to the mind, in the spoken language, the same idea as the character in writing; but nothing in the latter denotes the sound or the syllable, and it is very possible to understand the one without knowing the other, and *vice versa.*" We quote these words from the excellent work of M. Abel Remusat, entitled *Recherches sur les Langues Tartares.* M. Freret, who tells the strange tale in his sensible reflections on the Chinese writing, in the sixth volume of the *Memoirs of the Academy of Inscriptions*, makes this lively remark—"*On diroit que cette écriture auroit été inventée pour des muets, qui ignorent l'usage de la parole;*" and we may add, that when we believe that the whole population of China are dumb, then will it seem worthy of belief, which is utterly incredible, that any kind of writing was ever devised that was not alphabetic. A person who gives from a Greek book, without naming the words in the original tongue, a literal translation in English, is like the man who reads aloud Chinese writing in the spoken language of China. He renders one language by another, and of two languages it is possible to know the one and not the other. Some understand English who are ignorant of Greek, and *vice versa.* "It was necessary sometimes," M. Abel Remusat continues, "for the Chinese to represent in writing the proper names of persons and of places, and of new objects and ideas. When their knowledge extended, they found that it was impossible to invent figures sufficiently exact, or to compose symbols sufficiently characteristic, to denote, in such a manner that they should be recognised, different natural objects,—quadrupeds, birds, fishes, trees, &c. Many expedients occurred, and were successively employed. They might take a symbol which was already known, and make it the sign of an individual. All proper names in China are characters of this sort. Most commonly there is nothing in these characters to mark this kind of alteration. Sometimes, however, they add to the symbol which has been thus stripped of its original meaning, the sign of the mouth, to show the change it has undergone." The sign of the mouth is precisely equivalent to the use of the capital letter, which with us marks a proper name, and shows that Mead signifies, not a liquor, but a physician, and Rose a man, and not a flower. Why one man should ever have been called Mead and another Rose, is as much a mystery as any thing in Chinese literature, although the question has not yet provoked an elaborate disquisition concerning the first Mead or the origin of Roses. "The second method is of so much consequence in Chinese writing, that from the most ancient times it has been accounted one of the six rules for forming characters. It consists in taking, as in the former case, a simple or complex symbol, and adding another, which denotes that it signifies a tree, a bird, &c. Almost all the names of natural objects are thus represented by two characters, one of which represents the genus, and the other the species." There is nothing peculiar in this method—it is common to all languages. We make compound words by the union of two simple, as tea-pot, coffee-pot; the latter word denoting the genus pot, and the former, or rather the two together, the species. These and similar contrivances, therefore, do not prove that there was a transition or gradual passage from symbolic to alphabetic writing. It is urged that tradesmen and ignorant persons in China frequently use those signs indifferently which have the same names but a different signification, for all the several purposes of the various characters; but this is not a step. In like manner, a boy has been known, in endeavouring to translate "thou shalt till" into Latin, to have found in his dictionary "till, *donec*," and to have written down "*donecabis*." If a foreigner arrives in China, and it is necessary to give him a name in writing, they usually assign to him some new combination of characters, which has no reference to the sound of his name. It is asserted, however, that they sometimes seek to express by their characters the sound of his name. If it be Har-ri-son, for instance, they take the three characters the names of which most resemble in sound the three syllables of the proper name. This would certainly be syllabic writing; but there is no satisfactory proof that it was ever devised by the Chinese themselves. It would occur very naturally to a foreigner who was familiar with alphabetic writing, and knew something of the language of the country. The spoken language of China consists entirely of monosyllables; consequently the necessity for such an expedient could never arise, except in conjunction with foreigners who are used to the alphabet. They could have no idea of a syllable, as distinct from and forming part of a word; and the name Harrison would not be to their ears one word of three syllables, but three separate words, each a monosyllable. We do not wonder if the Chinese have picked up from strangers a little instruction in reading; we are rather astonished that, in consequence of their addiction to old customs, they have not learned more. It has been said that the Japanese have adopted an alphabet of syllables of this kind, consisting of as many of the Chinese characters as are necessary to furnish it. We must withhold our assent to the existence of syllabic alphabets, until we have actually examined one that is not manifestly composed of letters. We read also that some nations of Tartars use an alphabet constructed of Chinese characters, either entire or mutilated. If we were to select 26 of these characters, we might of course write our own language in the same cipher; and the only consequence would be, that we should adopt very incommodious letters. Musical sounds, numbers, the signs of the Zodiac, and a few other matters of peculiar simplicity, are marked by arbitrary symbols, which have no reference to sound, and are understood by many nations. These examples, however, do not prove that it is possible to contrive a universal character, or to invent such a language, as the written Chinese is alleged to be. It would no doubt be a work of considerable difficulty, but not insuperable, to analyze the Chinese characters, and to reduce them to an alphabetic form. It would probably be necessary to assign several figures to the same letter—but this is common in other languages—and other expedients might be needed; but the result would facilitate immensely the acquisition of a language rich in a prodigious number of finely printed books. Hyde and others maintained that the language of the Manchou Tartars, in which there exist translations of most of the Chinese books, was, like the written language of China, symbolic; yet by the labours of MM. Amyot and Langlés it has been dissected into very comfortable and legible alphabetic letters. The spoken language of China is a vulgar, barbarous, and most imperfect jargon, that has never been reduced into writing, and has essentially no more connection with the written language than the Welsh or the Basque. If we must concede, contrary to reason and probability, that the Chinese characters contain a symbolic writing which is not alphabetic, they do not afford any assistance towards tracing the invention of the alphabet; for there is no proof that the Chinese, by their own means, and without foreign aid, have advanced a single step.

The uses of the alphabet are sweet and marvellous, and its origin, like the signification of the Egyptian hieroglyphics, undiscovered; but its structure is usually imperfect. It is commonly at once deficient and redundant, and the arrangement immethodical. In our own language, for example, although we have the sounds of the long and short vowels, we have only one character for each vowel; and it is left doubtful which sound is intended, or it is pointed out by the addition of other letters. In ben the *e* is short; in bean, been, bene, it is long, and the syllable might be spelled thus, bēn. The Greeks have a distinct character for the long and the short *e*, and two for *o* likewise; but their alphabet is as deficient as our own with respect to the other three vowels. If the Romans had used ten signs for vowels instead of five, all that difficult department of grammar which teaches the quantity of syllables would have been superseded by a simple and mechanical contrivance. Our alphabet is said to be redundant, because the one sound of *c* is expressed by *k*, and the other by *s*. It is true that *ch* is a peculiar sound, differing from that of *sh*, as cherry differs from sherry: it is true, however, that it might be represented by *kh*, if our orthographers had thought fit to ordain it. *F* is said to be redundant, because we might spell fig, phig: for we write philosopher, whilst the Italians use *filosofo*; and so with some other letters. As the Greek is pronounced in England, the $\chi$ is superfluous for the purposes of speech, and its place might always be supplied by $\kappa$. It distinguishes nevertheless many words to the eye, and is useful in etymology, on account of which, letters that would be redundant if they were to be tried by the verdict of the ear alone, have been retained in many alphabets. If the number of our own letters be too small, the deficiency is not very great. Those who affirm that there is the largest amount of simple sounds in our language, would not extend it beyond 32 or 33 characters, and their opponents would cut it down to about half the number: 26, therefore, is a tolerably fair mean between these extremes.

The lovers of method complain grievously that the arrangement of the letters is most unphilosophical. There is no reason, they truly affirm, why *b* should succeed to *a*, or *c* to *b* in the Latin and English, or *g* in the Greek and Hebrew alphabets. The vowels, they maintain, ought to walk first, and to be marshalled precisely according to the aperture that each demands from the mouth to give it due utterance; and the consonants ought to be arranged with reference to the organ to which they are chiefly indebted,—the lips, the teeth, the tongue, the throat. If we were about to compose an alphabet for the first time, such precision might be permitted; but this change, like most others, would be attended with many inconveniences. The next generation, for example, could not use our dictionaries and encyclopædias; and as the letters are sorted on the next page of the primer, although not in the alphabet itself, the advantage would be very trifling. An extreme and rigid regularity does not suit mankind; men love anomalies, exceptions, and varieties. In some languages, as in the Italian, and very probably, if we can judge of the pronunciation of the ancient Romans, in the Latin, each letter performs its office with great constancy and uniformity, and indicates the sound according to a few simple and well-observed rules; in others, as in some of the Celtic tongues, the only use of letters seems to be to mislead, and to show what is not the true pronunciation. The English orthography torments foreigners, and presents difficulties that appear at first to be insuperable: by perseverance, however, they find the clue to the labyrinth, and acknowledge that the maze is not always without a plan. The mode of spelling that was observed in the middle ages, especially in English and French, was to admit into words every letter that could possibly claim a shadow of right to be there. It resembles the style of law proceedings, the grand canon of composition and construction therein being, so that all is there that ought to be, it matters little how much is there that ought not: the excess may help, but cannot hurt, and may be rejected as surplusage. The French, after their peculiar manner, by means of the Roman letters, have cooked up strange kickshaws of words; their pronunciation, however, whimsical as it is, being practically, and especially amongst those who speak soberly and moderately, less absurd than the extraordinary persons who compose grammars of that language would have us believe.

The forms of letters in different systems are of course very various. It is curious to contrast the complicated characters of the Gothic, or of German text, or of some languages that are less generally known, with more simple alphabets, especially with those used in modern systems of short-hand. These extremely simple letters, however, are not so favourable to rapidity in reading as in writing: plainness and distinctness, a certain form that fills the eye, giving to each its proper individuality, are essential to give facility to the reader's office. If there were no other books but manuscripts, it would certainly be of great importance that such characters only should be used as the transcriber could execute with the utmost celerity: but as copies are now multiplied by printing, it matters little whether the letters are simple or complex; for although it may be more difficult to make the punches, and more troublesome to cast the types, these considerations cannot greatly influence the price of books. The manner of arranging letters and words is also various. The Chinese, and a few other people, dispose the words in perpendicular lines, one word below another; but most nations conform to the general practice of placing them in horizontal rows: and the world is nearly equally divided on the question, whether it be expedient to begin to write at the right or the left side of the page. The people of the East usually adopt the former, and those of the West the latter method. There are some exceptions, however: the Sanscrit is written, like the English, from the left to the right; and the Etruscans seem to have committed a similar error in longitude, for they proceeded, like the Arabs, from the right towards the left. The one arrangement is quite as convenient as the other. Persons who are prejudiced in favour of every thing to which they have been accustomed, have imagined reasons in support of the superiority of our method: daily practice convinces us that it is very excellent; but we must acknowledge, notwithstanding, that the best writers are to be found amongst the people who write from the right hand to the left. The Chinese, it is said, in their peculiar way, attain to great skill and excellence.

There is one kind of arrangement that was anciently in use among the Greeks, which is very remarkable: the letters proceed from the left to the right, and back again from the right to the left, or *vice versa*, alternately, like the course of an ox in ploughing, whence it has received the name βουστροφηδον. We can imagine that a person writing running-hand very rapidly might be tempted to adopt this alternate path for the sake of dispatch—although such perhaps would not be the result—in order to save the time that is wasted in carrying the hand back from the end of one line to the beginning of the next; but this could not be the motive that suggested its use in the inscriptions that are now in existence. It was probably esteemed sacred from its connection with ploughing, which was always a holy thing. A treaty written thus was more likely therefore to be observed. If a bill of exchange had a better chance of being accepted or paid were it sped like the plough, the sacred arrangement would no doubt be adopted by the drawers of these instruments.

The inconveniences of a diversity of characters have induced some speculative persons to endeavour to devise a universal character, and even to remedy the curse of Babel by a universal language. The great Leibnitz employed himself much, it is said, on these speculations, but without success. John Wilkins, bishop of Chester, a less able man, composed *An Essay towards a Real Character and an Universal Language*, which was printed by the Royal Society in 1668. Whoever will open this thick folio, will not be surprised that the husband of Oliver Cromwell's sister had but few disciples, or, whatever learning and ingenuity the book may display, that it has long been forgotten. It has rarely happened that men of distinguished ability have sought to introduce a severe uniformity into any science. Speculators who propose to furnish characters that will faithfully represent all the sounds of all the letters of all languages, only show that they have not accurate ears: sounds are infinite, and cannot be thus portrayed. Men have vainly discoursed also concerning a natural language: there is no language natural to man. It is not natural to call a horse a horse, or by any other name; but it is perfectly natural, for it is the universal practice, to call that animal by some name or other which is understood by those with whom we communicate. If there were a universal character to represent words, and it were generally received, so that the character for a horse should be read by an Englishman *horse*, by a Frenchman *cheval*, by a Spaniard *caballo*, and by a German *pferd*, as has been recommended, it would avail little. The syntax and construction of languages are so various, that although the characters might be understood, and every word intelligible by itself, the sense of a whole passage that had been written by a German would be utterly unintelligible to a Frenchman.

The Chinese is said to be a language of which the structure is remarkably easy and simple. As a proof that it is not enough to know the meaning of the words, but that it is necessary to be familiar with the collocation, in order to comprehend the sense of the author, let us take an example at hazard from the grammar of M. Abel Remusat. The following is a literal translation: "*Sicut amat sicut scit agit eam amat eam eam qui eam qui qui non qui non.*" Could Bishop Wilkins himself detect the meaning which lurks in these few and very plain words? They are rendered thus, having been re-arranged according to the rules of a system which is far more artificial, but with which, through habit, we are conversant: "*Celui qui la connoit* (*la vertu*) *ne vaut pas celui qui l'aime; celui qui l'aime ne vaut pas celui qui la pratique.*" If we are unable to interpret a short and easy sentence in an inartificial language, with the forms of which we are unacquainted, is it not certain, that if one of the long and rhetorical periods of Demosthenes, to say nothing of more obscure writers, were transcribed in the universal character, it would be as incomprehensible as a Babylonian brick covered with arrow-headed characters, to a person familiar with the universal writing, but who had not mastered the majestic but abstruse idiom of the Greek tongue? Nor is there a natural collocation of words. All collocation is artificial; and that to which the reader is most accustomed seems to him to be the most natural. He who speaks of the natural order of a sentence, and recommends that it should be observed in his projects for grammatical uniformity, commits the same error as the sailor who condemned the Spaniards with many oaths, as a most unnatural race, for calling a hat *sombrero*, and not, like men, by its natural name, a hat.

Having spoken as largely as our limits will permit of the alphabet in general, we will next call the attention of our readers to a few particular alphabets, not perhaps with so much minuteness as some might desire, nor certainly to all that are worthy of attention. The Greek alphabet is by far the most important to literature, not only because the most precious remains of antiquity have been preserved by its means, but because it is the parent of the Latin, which has been adopted by, and prevails amongst, the most civilized nations of the world. Plate XIX., which is the first of the three plates connected with this subject, is entirely devoted to elucidate its origin and history. The plate has been taken, except that part on the right hand which is headed "Greek," from Astle's work on the *Origin and Progress of Writing*, and was compiled from authorities which we regret that it would greatly exceed our limits to enumerate. It would be easy to extract the passages which would explain it; but as the book is generally accessible, we will content ourselves by referring to it; and as that admirable treasure of alphabetic lore, the *Nouveau Traité de Diplomatique* (6 tom. 4to, Paris, 1750–65), whence Astle has chiefly derived his authorities and the forms of the letters, may easily be consulted, we will not avail ourselves of the assistance it would afford. Joseph Scaliger was the first who endeavoured to show systematically, and with elaborate learning, the derivation of the Greek letters from the Phœnician. He has had many followers and imitators. A cursory inspection of the numerous specimens of Phœnician letters which this plate affords will prove, that if their forms are sometimes like those of the ancient Greek characters, they are often very dissimilar, at least if we may suppose that we have obtained from coins and inscriptions the true characters of the Phœnicians; and if the powers of the letters were the same as in the Hebrew, as the order appears to have been, there was a great dissimilarity in sound also. That portion of the plate which is headed "Greek" is taken from a plate inscribed *Variæ Alphabeti Græci per ætatis ordinem formæ*, published in the *Pœcilographia Græca* of Hodgkin, and in vol. ix. of the *Classical Journal.* The first column on the left consists of the ordinary letters, of which the number is increased to 27 by the insertion of the Fαυ επισημον, which marks the number 6, after E, of σανπι, 900, and of κοππα, 90, after Π. The second column is headed "Cadmi A. C. 1500," and is taken from Morton. The next column, standing immediately below "Greek," gives the various forms of the Sigean inscription, as published by Chishull, and is headed "Sigeum, circa 600 A. C." The third column is inscribed "Simonidis, A. C. 500," and is also from Morton. The remainder of the letters are of the date 450, A. C., and are given on the authority of Wachter, from W. Massey's *Essay on the Origin and Progress of Letters.* Mr Hodgkin has published in the same work a large and valuable collection of abbreviations and connections. The fac-similes of the Herculanean papyri present the Greek characters that were in ordinary use at the time when they were written. M. d'Agincourt, in his valuable *Histoire de l'Art par les Monumens*, has given many curious examples of Greek manuscripts of the middle ages, extracted from the unpublished treasures of the Vatican library; and Mr Rose has collected, with much care and accuracy, the various forms of letters from inscriptions at Athens and in Attica. It would be easy to multiply references to other volumes. Although the philologist may not accept all Mr Payne Knight's conclusions, as they are presented in his well-known *Analysis of the Greek Alphabet*, he cannot refuse him credit for much learning and ingenuity, for novelty sometimes amounting to paradox, and an energy often approaching to anger. The two learned dissertations of M. l'abbé Renaudot, in the second volume of the *Memoirs of the Academy of Inscriptions*, are well known. It is impossible not to remark, that, whenever a new inscription is discovered, archæologists instantly fly to it, and for a time, commonly until something else is turned up, endeavour to solve every phenomenon by means of it. This fickleness is undoubtedly suspicious, and resembles the conduct of men who are ill at ease in their theories. The letters which we find on coins and marbles of the earliest periods are only of certain peculiar forms; but it would be a rash deduction to infer, therefore, that they did not use letters of a different shape for other purposes. These have remained, because the materials on which they were impressed or engraven were durable; and the cursive writing, which probably existed and was inscribed on perishable substances, and for temporary purposes, has been lost. If all lettered monuments of the 19th century had disappeared except our money, the inference would be most erroneous, that the inhabitants of Great Britain knew no other characters save the Roman capitals, which are alone to be found on the sovereign; and will seem ridiculous to all who are aware that the bank-note that circulates with it presents, in evidence of its mercantile origin, specimens of every kind of hand which an ambitious schoolmaster, anxious to display his penmanship, could devise.

On the Greek alphabet, as on many others, the question arises, What is properly to be considered a letter? If we accept the ordinary definition, that it is a mark for a certain known sound, it is plain that *h* is entitled to the honourable appellation. The Romans include it in the alphabet, and, except perhaps in prosody, grant to it all its rights.

By most of the nations of the west it is duly recognised, and by the orientals it is usually had in great honour. The Greeks, however, have attenuated it into a spirit, and translated it, as such, out of the alphabet, and elevated it above the heads of its fellows. The practice of sending letters aloft, that were supposed to have a turn for climbing, exists indeed in many other languages. The two dots or lines, for instance, that sometimes hang over the vowels in the German, are the remains of *e*: thus *pökel* was formerly written *poekel*; and some grammarians have recommended that the old orthography should be resumed. It is unnecessary to multiply examples from other tongues. This letter was anciently marked by the sign H, as in the Latin and our own language. When that sign was applied to denote the η, it was cut in two, and one half was suspended in the air to mark the *spiritus asper*, the rough breathing, or the *h*, which, according to the definition, is a letter; the other half was hung up in the same manner for a very peculiar purpose, not to designate any letter, not as the mark of any known sound, but, under the name of the *spiritus lenis*, it signified the absence of a letter—it became a negative sign in grammatical algebra. Since the *spiritus lenis* merely imports the absence of the *spiritus asper*, or *h*, if a sign be used to show the absence of one letter, there ought equally to be a sign to denote that of every other letter in the alphabet; and on this principle there ought to be as many negative as positive signs. If it be supposed that the reader who sees the word *all* cannot understand that the word does not begin with *h*, and is not *hall*, unless a spirit tell him so, and a mark be prefixed to signify that the word *all* does not begin with *h*, he must need the like assistance to enable him to comprehend that every other letter also is wanting. He ought to be told that the word *all* does not begin with *b*, *c*, *d*, &c. and that it is not *ball*, nor *call*, nor *pall*, nor *tall*. Since the initial is not more intelligible than the remainder of the word, every other letter of every word ought on the same principle to be preceded by the negative signs of all the letters, to show that it is nothing more than itself. To such absurdities must we be reduced, if we abandon the plain rule, that the absence of a letter alone is sufficient to show that it is wanting. We should wonder the more that a people so intelligent as the Greeks should have fallen into such an error, if, as far as we know, Lanzi had not been the first to notice it. His *reductio ad absurdum* of the *spiritus lenis* has not hitherto received the attention which its acuteness merits. In Arabic, the mark *gesma*, unless we look upon it as representing the hyphen, is also a negative sign, importing, however, a more extensive negation. It has been conjectured that the Greek accentual marks were contrived to assist persons in reading aloud, before the practice of leaving a space at the end of each word was adopted. They certainly would be extremely useful in this respect, and they afford great help in perusing a manuscript written continuously. For this purpose the spirits are more useful than the accents; for they show that the vowels over which they are placed are initials,—ignorance whereof is a fertile source of ambiguity; and for this purpose the *spiritus lenis* is as necessary as the aspirate. The latter is a letter, and an orthographical mark besides; the former is only a mark that the Ε begins another word, as in the example ΚΑΙἘΓΩ, which is equivalent to ΚΑΙ ΕΓΩ, the sign ⊣ being equal to the space between the two words. It was afterwards usual to place a period after each word, as a spirit general affecting equally vowels and consonants, thus, ΚΑΙ.ΕΓΩ.ΛΕΓΩ; and this expedient is applicable to all words: and many manuscripts that were written continuously have received the convenient addition at a time long subsequent to the date of the writing. If we consider the *spiritus lenis* in this point of view, the inventors of it will be exculpated from the absurdity of which Lanzi sought to convict them, and it will attach to those grammarians only who retained the mark after the practice of leaving a space at the end of every word became prevalent. We must esteem the Greek accents and spirits, especially if we acquiesce in this theory of their invention, as venerable relics of antiquity—as contrivances which have been superseded. On this account, and from habit, it is difficult for a scholar to consent to abandon them, or to rest satisfied with a work, however well printed it may be in other respects, in which they are omitted.

Orthographical expedients to facilitate reading are numerous and ingenious, as spaces, punctuation, capitals for proper names and at the beginning of sentences, the apostrophe, and many others. It would be an interesting pursuit to trace their origin and history. Much attention has always been paid to reading and writing by the Christians, the Jews, the Mahometans, and, in short, by all nations whose religion is comprehended in ancient writings. Among the Greeks and Romans, little of their worship had been reduced into writing, nor did they profess to be in possession of a code of divine laws, like the Koran and similar volumes that are studied, transcribed, and venerated, by the orientals. The reverence that Alexander the Great displayed for the poems of Homer, remarkable as it appeared to his contemporaries, was but a faint shadow of the homage and adoration that the people of the East lavish on their sacred volumes. The treatment which the Sibylline books received at Rome was perhaps in some respects similar; but they were not publicly read; the grand object, indeed, of those in whose custody they were placed being, although they were not wanting in veneration for the prophetic volumes, to conceal, and not to publish, their mysterious contents. We cheerfully acknowledge that the religion of Greece and Rome, as a political institution, had many important advantages; but it is not to be denied that it was less favourable to the diffusion of reading and writing than Christianity and some of the religions of the East. The translations of the Scriptures have preserved for the philologer many curious fragments of languages, of which there are no other remains. In pagan Rome, as in Greece, public recitation and reading aloud were practised to a great extent; but these exercises were always performed by persons of some learning, and of considerable experience, who were comparatively few in number. When the Christians increased, public readers were greatly augmented: it became necessary to read the Scriptures, homilies, and other pious compositions, not only to learned men in cities, but to the poor and ignorant in the most obscure villages of the most remote provinces; and this office was commonly performed by men of extremely moderate attainments. It became expedient, therefore, to devise every contrivance that could facilitate the task of reading in public. The Biblical critic knows, that we owe to this cause many orthographical advantages, which are now commonly enjoyed, although the source of them is not generally understood. We are unable, however, to pursue this part of the subject at present; nor can we find leisure to trace our ordinary running-hand. It may be followed step by step from the Greek cursive, in such works as the *Palæographia Græca, sive de Ortu et Progressu Literarum Græcarum*, of Bern. de Montfaucon; in the curious publication of the Abate Marini, the principal librarian of the Vatican, entitled *I Pa-*

*piri Diplomatici raccolti ed illustrati;* in the specimens of D'Agincourt, and in similar publications. The Arabic alphabet, which, especially in the hands of the Persians, seems expressly designed to favour rapid writers, has six unconnectible letters; and when the Greek characters are written in running-hand, there are several letters which may not be joined, some with those that precede, others with those that follow. In our cursive every letter in every word may be united; but as it was first adapted to the Latin language, the school-boy who has written even a theme in that tongue must have remarked that the letters unite more easily and pleasantly than in English.

The second plate (No. XX.) presents a comparative table of hieroglyphic and alphabetic characters. We cannot dwell upon this very singular assemblage of signs and symbols, or point out in detail the absurdity of the theories which would deduce alphabetic writing from the Egyptian hieroglyphics; but it will manifest itself most strikingly and plainly, and without prejudice, to an intelligent person who will examine attentively this table, which has been arranged expressly for the purpose of presenting an untenable and unfounded hypothesis in the least unfavourable light. The first column on the left, headed "Chaldaic Letters," contains an alphabet which is so important in the history of literature, that we must not pass it over without some notice. The Chaldaic or Hebrew alphabet consists of 22 consonants, of which the forms are given on the extreme left of the comparative table, and their powers on the extreme right, and of 14 vowel points, making a total of 36 letters, if we may reckon the points, which are held to be less ancient than the consonants, and are often omitted in manuscripts and printed books, as letters. There are, besides, in a great number, accentual and other marks, designed to facilitate reading, and sometimes perhaps chanting or singing. Of some of these, however, the use is not at present understood; our business is with the 22 consonants only, and with their forms. The third letter, *g*, is called Gimel, which signifies the camel. *Camelus suo nomine Syriaco in Latium venit,* as Varro elegantly writes. There can be no doubt about the derivation of the animal's name, but the letter is as much like any other creature as a camel. Pe, the 17th letter, is called the mouth: it resembles the nose or the eyes equally. And the letter that immediately precedes it, as its name implies, is thought to be a picture of the eye; but it is as faithful a representation of any other feature, or even of the whole face. The ingenuity of the engraver could not humour the appearance of the teeth so as to make it remind us, as it ought, of the last letter but one—Shin. A very learned Rabbi, from whom we formerly received some instruction in Hebrew, gravely affirmed that the letter Pe, the mouth, is the true image of that organ; and that if it had not been the Sabbath, he would have written it, and shown, moreover, that there is a piece of pudding in it. Being offered a dry pen, that he might point it out in a book, he refused to do even that act. Such a severe observance of the day of rest appeared very surprising to persons unacquainted with the strict literal interpretation that prevails in the East. He consented indeed to explain by words that the piece of pudding is that mark which is inserted in the 17th letter, Pe, and serves to distinguish it from the 11th letter, Caph. The learned Jew, however, did not regard consistency in his explanation, nor do these ingenious people in general; for Caph is the palm of the hand; and by placing a piece of pudding in it, although it would probably be more welcome to the mouth, it would not be made to resemble it in form. Jod, which immediately precedes Caph, is the hand also; and these letters are equally unlike the hand and each other. We will not speak longer, however, of this miserable nonsense: the immense load of absurdity would soon become intolerable, if, in passing through several languages, we were to pick up in each some new extravagance. It is true that the names of the greater part, if not all, of the Hebrew letters, signify visible objects; but it does not follow that the letter ever resembled in form the object of which it bears the name. Nouns are used in the second intention without regard to shape; neither the horse for drying clothes, nor the dogs on which wood is burned, nor the cock of a barrel, nor a crow-bar, will remind us of any of the animals that lend them titles; nor do we ever see a boot-tree or a saddle-tree flourishing, like real trees, with leaves, flowers, and fruit. If we were to teach that our letter B derives its form and name from the insect, and that our alphabet, if considered in the same manner, would furnish a key to the Egyptian hieroglyphics, and would explain the origin of writing, we should not trifle more egregiously than certain expositors of the Hebrew characters.

Our third and last plate (No. XXI.) comprehends specimens of some remarkable alphabets. We will treat them in the order in which they stand. In the Syriac, the number and order of the letters are the same as in the Hebrew, and their names and powers are nearly the same also. The row of characters on the right is that square writing which is called Estrangelo. The letters in the next row are commonly termed Chaldee. Many of them resemble the former, and some are different. The open letters are the same as the first row, except that they are formed with greater regularity, and are more square. The remaining four columns consist of the ordinary Syriac letters, varying more or less in form from the Estranghelo, and arranged from the right to the left in order, as initial, medial, final, and solitary letters. Of these alphabets, the Estranghelo is the most ancient and solemn. Some maintain that the Hebrew Scriptures were originally written in this hand. It corresponds in its origin and use with the Roman capitals, which we esteem older than the small letters, and now use only for titles, inscriptions, and the like. The second column, or Chaldee, is called also the reformed Syriac, being a medium between the Estranghelo and the ordinary Syriac. Vowel points are added to these letters; but it is acknowledged that the use of them, in this language at least, is entirely modern. The Illyrian and Servian alphabets are evidently derived from the Greek: *Græco fonte cadunt;* we cannot add, however, *parce detorta:* the order of the letters is the same, many being inserted. The two rows of letters on the left, which are usually very like the Greek originals, are the Servian, and are commonly called the alphabet of St Cyril, being ascribed to that saint. The other two rows of letters, which are, as it were, double, and frequently of an extraordinary form, are the Illyrian, or Dalmatian, and are named the alphabet of St Jerome. We are apt to wonder why the good father should have taken so much trouble, if he was indeed the inventor, to disfigure the elements of speech. The appearance of the Illyrian, when we see an entire passage in this character, is still more strange: it is impossible indeed to judge of its effect from a mere table of letters. We regret, therefore, that our space will not suffer us to give a specimen of this whimsical and unusual writing. The Russian alphabets, both ancient and modern, are formed from the Greek by additions and alterations, the order of the letters being nearly the same. The Ethiopic alphabet, which occupies the middle of the plate, is extremely interesting, because it is said to be a great and important step in the history of writing; and it is expressly referred to by the very learned President Goguet, as a specimen of a syllabic alphabet: "rectius syllabarium quam alphabetum." Syllabic writing, if it ever existed, would not be a step from hieroglyphic to alphabetic writing: it would be a kind of alphabetic writing, in which the alphabet would be very numerous, and the sounds expressed by each letter complex; but it would have no connection with hieroglyphics; the pretended link would be united to the chain at one end, but not at the other. If we suppose *prosterner*, the word chosen by Goguet, to be represented by three letters only, each of which is a syllable, as πσν, the π, which stands for *pro*, would mark a complex sound, but it would not be in any respect hieroglyphic. It would not denote a sensible object or an idea, and so of the other two syllabic letters σ and ν, and of all the rest. The conjecture would appear probable in itself, that syllabic characters are compounded of other and less complex forms; nor is the aspect of the alphabets that are put forth as belonging to this class so simple as to exclude the supposition. It is easy in the Ethiopic to trace the vowel which is added with tolerable uniformity to the simple letter. There are a few anomalies, no doubt, as in the grammatical arrangements of all languages. The first column on the left, next to the name, shows the simple letter. It is not combined with the vowel *a*, as it would seem at first sight; for that union is effected in the fourth or middle column. A moment's inspection of this alphabet and table of syllables will satisfy any one that it is composed of 26 consonants—we must use the word in an eastern sense—combined with six vowels, precisely like the tables ba, be, bi, bo, bu, by, &c., in our spelling-books; and that it does not in any respect resemble the case which is put by Goguet, of the word *prosterner* being spelled by three letters. As the Sanscrit alphabet is not shown on our plates, we will not analyze it to prove that it is not to be considered as syllabic. The Persian is as much entitled to that appellation, because the junction of the letters being often difficult, they write, for the assistance of learners, books full of syllables. It is not by steps built of such materials as these that we can hope to ascend to the origin of that most wonderful invention, the alphabet. The Ethiopic is derived from the Arabic: it is a dead language, like the Latin, and it is called the language of study, or the language of books: the Abyssinian, or Amharic, so called from Amhar, the principal province of Abyssinia, and termed the royal language, has taken its place as a living speech; and seven letters have been added to the 26 of the Ethiopic alphabet, which we have given. These two languages may be studied in the grammars of Job Ludolphus, who tells us that they are of difficult acquisition, and declares the words to be exceedingly unutterable—"maxime esse ineffabilia." The aspect of the characters, when arranged in words and sentences, is uncouth and unsightly: they somewhat resemble the Tironian notes, which, although their appearance is unpromising, were written, as we are informed by positive testimony, with great rapidity. Contractions, abbreviations, and connections, far from indicating that writing is in an imperfect condition, evince that penmanship is far advanced.

The Armenian alphabet consists of 38 letters. They have several other kinds of writing. We have given that which is called the round hand, and is used in printed books. Like ourselves, they write from the left to the right. The appearance of their printed books is neat and agreeable. The leaning of the letters was perhaps learned from the Italic, which was chiefly used by the printers of Venice. The greatest benefactors to their literature and typography have been the congregation of Armenian monks, who resided at Methone in the Peloponnesus, and afterwards removed to Venice. This language possesses a few original works, but is chiefly rich in translations from the writings of St Chrysostom and other Greek fathers, which have improved and refined it. Those who are curious on the subject may consult the dissertation of Schröder, *De Antiquitate et Fatis Linguæ Armenaicæ;* and the historian of a nation, to whom it is said we owe the apricot, and who have always been renowned for skill in the ancient, delightful, and honourable art of gardening, Moses Chorenensis. The Iberian or Georgian letters, as expressed in types, are commonly somewhat lighter than our engraved alphabet of 36 letters. The Georgians write also from the left, and have several kinds of writing. The plate represents the ordinary hand. The Coptic language derives its name from Coptos, a city of Upper Egypt, where it was chiefly spoken. It is said to be a mixture of Greek with the ancient language of Egypt, Ethiopic, and the old Persian. The alphabet, which is borrowed from the Greek, superseded the use of the older letters in Egypt, as the characters introduced by Cadmus possibly took the place of those that were used by the Greeks before his time. The names, figures, and order of the letters, are the same as in Greek. Eight letters were added to express sounds unknown to the Greeks. Seven of these follow the omega; psi is put out of its place, being the last letter; and ϛ, under the name So, is duly inserted after the epsilon. This tongue has attracted some little attention, in consequence of the phonetic system, of which we have spoken. A full and handsome grammar was published at Rome in 1778, by the Society *de propaganda Fide.* The examples are given in Arabic, as well as Coptic. The Gothic alphabet of the patriarch Ulphilas, which is the last of our specimens, was formed in part from the Latin, and in part from the Greek: the letters are arranged in the order of the former language. We know not whether certain theorists will consider the double letters at the end as syllabic characters. The Runic alphabet is interesting from its connection with Scandinavian antiquities. It is nearly identical with the Icelandic: the letters are copied from the Greek and Roman, being a little varied for the sake of notching them more conveniently on sticks or staves; but the order of the sixteen letters is very different from both these alphabets. There are many specimens in Hickes's *Thesaurus.* These letters have afforded much scope for controversy. Those who are most favourable to the antiquity of the Runic inscriptions assign to them nearly 2000 years. Olaus Rudbechius teaches that the Greeks used these letters before the time of Cadmus. Those who are least so say that they are not older than the third century of our era.

The best kind of Anglo-Saxon writing was very elegant; the small round characters that we see in charters are neat and extremely legible. Domesday book is written in a hand less perfect, but somewhat similar. After the Norman conquest writing deteriorated in England, and became quaint, affected, and illegible. In proportion as a nation is civilized or barbarous, the pronunciation of its language, it has been maintained, varies from the orthography. In the Celtic languages the variation is prodigious; in our own tongue it is very considerable; in the Anglo-Saxon, so far as we are able to judge, it was much less. That language was assiduously cultivated before the conquest, especially in poetry; many poems were composed, and in extremely difficult and complicated metres. After that event French became the language of the aristocracy; and the Saxon or English was long neglected, and was spoken only by the vulgar, for a long period, during which the foundations of our present orthography were laid.

The Irish claim "an exorbitant antiquity" for their tree alphabet, in which the order of the letters is peculiar, and the name of each of them is borrowed from some tree. B, under the name Beith, which signifies a birch-tree, is the first of them: it is fit that the tree of knowledge should lead the band. This alphabet is commonly allowed to be a modern fabrication: a few antiquaries, however, are ready to maintain that it is many centuries older than the creation. In most languages words are pronounced in a manner somewhat different from that in which they are written; but in the Irish the aberration of the sound from the spelling is so great, that the only use of letters seems to be, to show how words are not pronounced by omitting all that are really wanted, and inserting all but the right. As straight lines placed in different positions will form most of the letters of the Roman alphabet, so the various arrangement of lines, shaped like wedges or the heads of arrows, would make a sufficient variety of characters not altogether dissimilar to the Roman. Two of them inclining towards each other at the bottom would be V, one wedge at right angles to another might represent L, and three might be so placed as to designate either F or H. It is not necessary to pursue the subject farther. The structure of the arrow-headed, cuneiform, or ancient Persian alphabet, must be already sufficiently intelligible. Inscriptions in this character, which perhaps was also esteemed sacred, closely resemble the Runic Ogham, represented in General Vallancey's *Irish Grammar.*

The twenty-five instructive and excellent plates in the second volume of the Collection of Plates, published with the French *Encyclopédie*, contain many curious specimens of alphabets. They are taken, however, almost entirely and without acknowledgement, after the manner of the French literati, from the valuable publications of the Society *de propaganda Fide* at Rome. M. du Marsais, the writer of the article on the alphabet in that *Encyclopédie*, evinces a passionate desire to regenerate the world—such was the taste of the age—and strenuously recommends a new alphabet: had it been adopted, according to his advice, we should undoubtedly be using the old one at the present day. The numerous publications of the Society we have mentioned well deserve attention; and many curious alphabets are given in Niebuhr's *Travels*, and in other works that we need not enumerate. We have spoken already of the advancement which the arts of reading and writing have received from religion: we will mention a very remarkable and important alphabet, which derived its origin and its general diffusion from the same source. The Arabic letters are said to be the invention of the unfortunate Vizier Moclah, who flourished at the beginning of the 10th century, and lost at different times, for political offences, his right hand, which had thrice copied the Koran, his left hand, and his tongue; cruel privations for a man of letters and an elegant penman. The Cuphic, a most grave and goodly character, appears to stand in the same venerable relation of paternity to the Arabic, as the Estranghelo to the vulgar Syriac. In the *Arabian Nights*, that faithful mirror of eastern manners, we find that the second Calender, who was a king's son, after describing his critical knowledge of the Koran, and of the commentaries on "that blessed book," boasts of his excellent penmanship thus: "But one thing, which I highly admired and succeeded in to admiration, was to form the characters of our Arabian language, wherein I surpassed all the writing-masters of our kingdom that had acquired the greatest reputation." The Arabic character, especially as it has been modified by the Persians, who have added to it much elegance, with some affectation, is not only favourable to the most daring flights of the pen, but in an eminent degree also to rapid execution. Wherever the Koran penetrated it was received, and it superseded the older and more tedious modes of writing. This alphabet consists of twenty-eight or twenty-nine letters, for it is a question whether *Lam-alif* is to be accounted a letter; but it has as much right to the title as ψ, and some others in the Greek alphabet, and it can plead a proverb in its favour, "from alif to lam-alif" being exactly equivalent to "from alpha to omega." For twenty-eight or twenty-nine letters there are only seventeen primary figures, and these perhaps may be reduced to fifteen; and the letters of which the figures are similar are distinguished by the number and position of certain dots, which are called diacritical or distinctive points. It is precisely as if a numeral were added, as a co-efficient, to a letter in order to change its power entirely (we refer to this alphabet without a plate, as being generally known): thus, 1b is b, but 2b perhaps is j, 3b is n, 4b is t, and 5b is th; again, 1f is f, but 2f is k, and so with the rest. It is impossible to conceive a more clumsy device, or one more fruitful in mistakes, especially as they are distinguished, not by numerals, but by dots, which are easily omitted or misapplied. The Persians have added four more letters, by means of additional dots, without introducing a new figure. They content themselves, nevertheless, with a smaller number than the Arabs, and the same as the Greeks, for the purposes of their own tongue; never using eight of the letters except in words adopted from the Arabic. Thus, with the Romans k, y, and z, held offices in the foreign department only. The Persians vary the character in many hands, some of which are very beautiful, others very legible, and others very rapid. The Indians, when they write in the Arabic character, increase the number by three more letters, which they distinguish by additional points. The order of the Arabic letters has been changed; for their numerical value is the same as that of the twenty-two equivalent letters in the Hebrew, the six letters that have been added differ in their points only, and not in figure. It is a remarkable difference, that in the languages of the East, at least in that family which is called Semitic, the vowels are not expressed, but only the consonants. On the contrary, in all the languages of the West, the vowels and consonants enter equally into the composition of the writing. Besides the twenty-eight or twenty-nine letters, eleven other marks are used in the Arabic. In the Semitic family the vowels are not of the essence of the word, the radical meaning resides entirely in the consonants, and so is it also in the Teutonic tongues. In our own we have, for example, *sang*, *sing*, *song*, and *sung*, and innumerable other instances. Whatever may have been, therefore, the parent of the Greek, it is impossible to agree with Colonel Vans Kennedy, who maintains in his late work *On the Origin of Languages*, that the Teutonic tongues are the offspring of the Sanscrit, in which the vowels are radicals.

It has been conjectured with some ingenuity, but without foundation, that the Arabic characters in which the vowels are not expressed were invented for the common use of several dialects, in which the consonants alone were determined in an invariable manner, and the pronunciation of the vowels varied. They have certainly been applied thus, but they were invented to facilitate those who transcribed the pure Arabic of the Koran, as the Hebrew letters were used without points to copy the Jewish law. Abbreviations and simple characters, that are of easy formation, are not merely advantageous to the reporter, but are useful also to the man of letters, for instantly catching the warm thought as it issues from the imagination; and perhaps also as a cipher, that the rash surmise, the first hasty impression, may not be exposed to the rude gaze of those who, never being original themselves, never give birth to errors, and accordingly are intolerant of them in others. Short-hand, therefore, independently of its ingenuity, is so useful, that it deserves notice in an essay on the alphabet; but we refer to it only to illustrate the Arabic. The use of an extremely simple character, which is very cursive, and joins easily, and of many contractions, and the total omission, in languages like our own, where they are not radical, of all the vowels, are the means by which the short-hand writer attains to expedition. These are the wings on which his pen flies; they are the characteristics also of the Arabic alphabet. Let us suppose that all Great Britain was smitten with an immense love of writing—printing being still unknown—and that it was deemed the chief good to copy as much as possible; that for this purpose all men learned short-hand, and, finding that it increased their powers, and the passion continuing, laid aside all the ordinary hands, so that they were forgotten. Such was the origin of the Arabic writing. When the short-hand writer would make his writing more legible, he adds the more important vowels by dots, and by various diacritical marks resolves ambiguities and clears up difficulties. If it were necessary to explain it to children and to strangers, and to interpret the abbreviations of distant times—and it would be were stenography universal—many orthographical signs would be required, whereby men would in truth return to the course which they had formerly quitted. Such was the origin of the vowel points and their adjuncts.

When we reflect that we have the very words of Socrates, as he spoke them, unless Plato and Xenophon have deceived us, we cannot wonder, since the power of letters is really so great, that men have sometimes attributed to them a little more influence than they possess. Hence originated the belief in magical spells, and charms, and characters; and certain mysterious properties were assigned to writing, not only amongst the Pagans, but by many of the Christians. It is somewhat remarkable that it has always been the practice from the earliest times, and it still prevails in Catholic countries, for the bishop, when he consecrates a church (the order of this ancient and venerable rite may be read in the *Pontificale*), to inscribe twice on the pavement, in the form of a cross, all the letters of the Roman alphabet. History assigns the highest antiquity to the most precious art of alphabetic writing. The author of the book of Job was familiar with it. Moses speaks of it constantly in the Pentateuch, and he acquired his human learning in Egypt, where it was necessarily well known at that time. The better opinion seems to be, that although Cadmus, the contemporary of Joshua, introduced an alphabet into Greece, which was accepted there, it was only taken in exchange for that which had been previously in use. Josephus, it is true, with his usual desire to exalt his own nation and its laws at the expense of the Gentiles, asserts, without hesitation, that letters were unknown in Greece even in the time of Homer, and to Homer himself; and some of the fathers of the church, who piously but unfairly endeavoured to degrade the learning of the Greeks, accepted the assertion as well founded. The startling paradox of the Jew, whose nationality has been less doubted than his veracity, has been maintained, at different periods, with much ingenuity: it is capable, however, of an easy refutation. The more diligently we inquire, the more ample and unequivocal shall we find the testimony of history to be in favour of the antiquity of alphabetic writing, and also, as reason alone teaches us, that no other ever existed.

The Egyptian hieroglyphics, the Chinese characters, and the supposed syllabic alphabets, have been examined, and they do not afford, as is commonly asserted, any clue to lead us to the invention of the alphabet. Since we are unable, either in history or even in imagination, to trace the origin of the alphabet, we must ascribe it, with the Rabbins, who are prepared with authenticated copies of the characters they used, and of those of Seth, Enoch, and Noah, to the first man, Adam; or we must say with Pliny, "ex quo apparet æternus literarum usus;" or we must admit that it was not a human, but a divine invention, and that the artist who made men, Prometheus, says truly,

Εξευρον αυτοις γραμματων τε συνθεσεις. (T. J. H.)

---

ALPHÆUS, or Cleophas, father of James the Less, and husband of Mary the sister of our Lord's mother; for which reason James is called "the Lord's brother." It would seem that Alphæus was his Greek, and Cleophas, or rather Clopas, his Hebrew, or Syriac name. Compare John xix. 25, with Luke xxiv. 10, and Matt. x. 3.

ALPHERY, Mikipher, or Nikephor, a clergyman of the English church, was descended from a branch of the imperial line of Russia. That country being distracted by intestine commotions in the latter end of the sixteenth century, he and his two brothers were sent over to England, and recommended to the care of Mr Joseph Bidell, a Russia merchant. Mr Bidell, when they were of age fit for the university, sent them to Oxford, where, during the prevalence of the small pox, two of the brothers died of that disease. The surviving brother entered into holy orders, and in the year 1618 was presented to the rectory of Wooley in Huntingdonshire, a living rated under L.10 in the king's books. Here he did his duty with great cheerfulness and alacrity; and although he was twice invited back to his native country by some who would have ventured their utmost to have set him on the throne of his ancestors, he chose rather to remain with his flock, and to serve God in the humble station of a parish priest. Yet in 1643 he underwent the severest trials from the rage of the fanatics, who, not satisfied with depriving him of his living, insulted him in the most barbarous manner. Having left Huntingdonshire, he went to Hammersmith, where he resided till the Restoration put him in possession of his living again. Being upwards of 80 years of age, and very infirm, he retired to his eldest son's house at Hammersmith, where soon after he died, much honoured and respected, and affording a remarkable instance of the vicissitudes of the world.

ALPHEUS, the chief river of Peloponnesus, now called *Alfeo*, *Rofeo*, or *Ryfo*. Its sources are in the mountains of Arcadia, in the east of Megalopolis. Being fed by a great number of small streams it becomes navigable, and traversing Elis, empties itself into the Ionian sea. In mythology, the Alpheus, or rather the river god of the same name, acts a very prominent part, especially as the lover of the nymph Arethusa.

ALPHONSE, two small rocky islands in the Indian Ocean.

ALPHONSIN, in *Surgery*, an instrument for extracting bullets out of gunshot wounds. This instrument derives its name from the inventor, Alphonso Ferri, a physician of Naples. It consists of three branches, which are closed by a ring. When closed and introduced into the wound, the operator draws back the ring towards the handle, upon which the branches opening take hold of the ball; and then the ring is pushed from the haft, by which means the branches grasp the ball firmly; and so it is extracted from the wound.

ALPHONSO, Alfonso, or Alonzo. This name, so famous in the annals of the Spanish Peninsula, has been borne by no fewer than two-and-twenty of its sovereigns, viz., by eleven of Leon and Castile, five of Leon, and six of Portugal.—(*La Coronica General de España, by Morales; Catalogo Real y Genealogico de España, by Rod. Mendez Silva; History of Spain, by Mariana.*)

1st. *Leon and Castile.*—Alphonso I., surnamed the *Catholic*, was the son of Pedro, Duke of Biscay, and a lineal descendant, it is said, of King Recaredo. On the death of Favila the son of Pelayo, in 739, Alonzo, who had married Ormisinda, the daughter of the latter, was proclaimed king of Asturias. He conducted in person a war against the Moors, which lasted almost throughout his reign; extended his territories by the conquest of many important places; and united to his crown the kingdom of Leon. He was a prince of an excellent understanding, equally skilled in the arts of peace and of war, and fortunate in all his undertakings. He died at Cangas in 757, at the age of 74; and was succeeded by his son Fruela, who founded the city of Oviedo in Asturias.

Alphonso II., surnamed the *Chaste*, son of King Fruela who was assassinated in 768, was but a child at his father's death. He was invested with regal authority by King Silon in 774; on whose demise in 783 he became sole monarch. He was afterwards dethroned by his uncle Mauregatus, assisted by the Moors, and retired into Biscay, where he had numerous friends. Mauregatus reigned five years, and was succeeded by Bermudo, who, two years afterwards, took Alonzo as his partner in the throne. Alonzo engaged in war against the Moors, and obtained a great victory over them at Ledas. Bermudo reigned only six and a half years. Alonzo, taking advantage of the dissensions among the Moors, captured the city of Lisbon. After this event, a great rebellion among his subjects obliged Alonzo to fly into Galicia; but with the assistance of Theudius, he was soon re-instated in his dominions. Charlemagne was invited into Spain by Alonzo; and it was in this reign that the famous battle of Roncesvalles was fought. The city of Oviedo was greatly adorned by Alonzo, who was the first sovereign who made it the capital of the kingdom. Here he died in 843, aged 85, having reigned 52½ years. Some historians have erroneously ascribed his surname of *Chaste* to his having refused to concede the tribute of a hundred virgins to the Moors: but this story is fabulous, that epithet having been derived from his observing an absolute continence towards the queen, his wife, in fulfilment of a vow. He left his throne to Don Ramiro, the son of King Bermudo.

Alphonso III., the *Great*, was 18 years of age on the death of his father Ordoño, in 862. In the first year of his reign the title of King of Galicia was usurped by Fruela, son of King Bermudo, and Alonzo retired to Alava, which was part of his own dominions: but the tyranny of Fruela soon after occasioned his assassination, and Alonzo returned to Asturias. Shortly afterwards, his four brothers, jealous at his elevation, conspired against his life; but they were seized, deprived of their eyes, and cast into prison. Alonzo then commenced those wars against the Moors by which he acquired the epithet of *Great*. He built Sublancia, and Cea, near Leon; also the cities of Porto, Viseo, Chaves, Oca, and Zamora; besides taking from the Moors Coimbra, Simancas, Dueñas, and all the territory of Campos. But fresh conspiracies arrested his victorious career. The malcontents, at the head of whom was his own son Don Garcia, charged him with overtaxing the people for the support of his wars. Alonzo then attacked Don Garcia, and having vanquished him, cast him into prison. Ximena the queen, who was of the blood royal of France, espoused the cause of the insurgents; and Hernandez earl of Castile, the father-in-law of Garcia, united with her other two sons for the deliverance of Don Garcia. The people adopted their cause, and a war ensued which lasted two years; when the king, despairing of any other means to restore peace, abdicated the throne, A.D. 910. But Alonzo could not relinquish the sword with the sceptre. In the true spirit of the age, he undertook, as the lieutenant of his son, an expedition against the Moors, and acquired fresh laurels in this campaign. In the same year, 911, he died at Zambra, after a reign of 48 years, and having added to his dominions a part of Portugal and of Old Castile. He is the reputed author of *Annals of Spain*, which embrace that period from the time of Wamba, towards the end of the seventh century, to that of Ordoño. Alonzo was tall and of a pleasing countenance, affable, and gentle, and exceedingly liberal to the poor.

Alphonso IV., called the *Monk*, King of Leon, began to reign in 924. On the death of his wife, about six years afterwards, he resigned the crown to his brother Don Ramiro, and retired into a cloister: but soon growing weary of the monastic life, he made an attempt to resume the sceptre. Upon this, King Ramiro besieged him in Leon; and having taken him captive, he put out his eyes, and threw him into a dungeon, where he ended his days.

Alphonso V. succeeded his father King Bermudo in 999, being then but five years of age. Gonsalez earl of Galicia, and his wife, were appointed by the late king to be the guardians of his minority; and, on arriving at manhood, he espoused their daughter Donna Elvira. Alonzo made war on the Moors, and lost his life at the siege of Viseo, A.D. 1028. He rebuilt, at his own cost, the city of Leon, which had been ruined by the Moors. During this reign the Moorish kingdom was subdivided into several small principalities. Alonzo was succeeded by his only son, Don Bermudo.

Alphonso VI., surnamed the *Valiant*, was the son of Fernando the Great, king of Castile and Leon. On the death of his father in 1065, the kingdom was divided among his three sons. Sancho, the eldest, received as his portion Castille; to Alonzo was given the kingdom of Leon, the territory of Campos, part of Asturias, and some towns in Galicia; and Garcia, the youngest brother, received a part of Galicia and of Portugal. Peace was not long maintained between the three brothers. Sancho made war on Alonzo, and defeated him in a bloody battle at Piantaca. Alonzo recruited his army, and defeated Sancho on the banks of the river Carrion; but an attack being made on his camp during the night, Alonzo was taken captive, and compelled to abdicate, A.D. 1071. Escaping from the monastery where he was confined, he found refuge with Almenon the Moorish king of Toledo, who lodged him in a superb palace, gave him a retinue of Christians, and assigned him a pension. Sancho took possession of Leon, and advanced into Galicia against Garcia, whose kingdom was in an uproar. The two brothers met at Santarem, where the Galicians were defeated with great slaughter, and Garcia himself captured and thrown into prison. Sancho being assassinated in 1073, Alonzo was re-instated in his dominions, after he had made a solemn declaration that he was guiltless of his brother's death. This solemn oath was administered to him by the famous Roderigo Diaz de Bivar, commonly called the Cid, whose exploits have rendered his name illustrious in the annals of chivalry. Don Garcia, on receiving his freedom, was making efforts to re-instate himself on his throne; when Alonzo, under the pretext of assisting him, obtained possession of his person, and immured him in a dungeon, where he died ten years after. He then turned his arms against the Moors, and committed great ravages in their territories, taking much spoil. No less treacherous than he had proved himself unnatural, Alonzo, after feigning some scruples of conscience, devastated the territories of Hiaya Aldirbil king of Toledo, whose father had befriended him in his adversity; and, assisted by many strangers, he invested his capital, which, after a siege of five years, A.D. 1085, was taken from the Saracens, in whose possession it had been for about 370 years. Alonzo prosecuted the war against the Moors, taking many of their towns; and being sovereign of a great part of Spain, and king of Aragon, he now assumed the imperial title. This prince was married six times. His third wife was Zayda, the daughter of Ben-Abed the Moorish king of Seville. Alonzo having invited the Almoravides from Africa to assist his father-in-law in his project of reducing all Mahometan Spain under his sway, the Almoravide king sent over a large force under the command of Hali Ben-Axa: but that chief soon finding occasion of quarrel with the Moorish king, a battle ensued in which Ben-Abed perished, and Hali took possession of his kingdom, A.D. 1091. The other Moorish princes were quickly subdued or submitted to him; and Alonzo had the mortification to see such of them as were tributary to himself throw off their allegiance, at the same time that he lost those towns which he had received as the portion of Zayda. The army he sent to oppose the victorious Moors was routed near Rhoda; and another mighty force which he gathered for that purpose was defeated at Caçalla near Badajoz with great slaughter. Many strangers now flocked to his assistance from all parts, especially from France under Raymond of Bourgogne and Raymond of Toulouse, upon which the Moors prudently retired without coming to an engagement.

In the year 1093 appeared Peter the Hermit preaching the first crusade for the recovery of Jerusalem from the Saracens. About this time the king married his three daughters; of whom Teresa, illegitimate, was given to Henry of Lorraine, with the title of Earl of Portugal, which he held as a fief of the crown of Castile. This was the origin of the kingdom of Portugal, which title was afterwards assumed, and continued in the line of this prince above 400 years. Alonzo died at Toledo in 1109, after a reign of 43 years, aged seventy-nine. It is worthy of notice, that in 1077, when Gregory VII. declared in a bull that Spain had anciently been tributary to the Holy See, Alonzo consented to pay a tribute, which was abolished by his successors.

Alphonso VII. The same as Alonzo I. of Aragon.

Alphonso VIII. (*Raymond.*) This prince, born in 1106, was proclaimed king by the states of Galicia met at Compostella; and his mother Uraca, on account of his youth, was associated with him in the government. The contentions that arose from this arrangement were only terminated by the death of Uraca in 1126: after which, Alonzo strove to repress the internal dissensions of his kingdom, and by salutary laws to ameliorate the condition of the country. He then made war on the Moors; and, elated with success, he assembled the cortes at Leon, and was solemnly crowned emperor of Spain. He married Eleanor the daughter of Henry II. of England, a princess of great personal attractions. Her jointure consisted of a part of Castile, Burgos, Medina del Campo, with many other towns, and half of all that should be taken from the Moors. Another expedition which Alonzo undertook against the Moors in Africa, was signalised by the brilliant victory of Jaen in 1157: but in returning homewards he died, in the fifty-first year of his age, and 31st of his reign. This prince is distinguished in history for his rigid observance of the rights and privileges of his subjects. His daughter Constance was married to Louis VII. *le Jeune*, king of France; which was the first alliance by marriage between those two crowns. After the example of his predecessors, Alonzo divided the kingdom between his two sons. In 1156 he instituted the order of Saint Julian, which afterwards became so celebrated under the name of Alcantara. See Alcantara.

Alphonso IX., *the Noble*, son of Sancho II., was only three years of age on the death of his father in 1158. His minority was disturbed by the contention of two powerful houses for the regency: but when he had attained the age of fifteen he was proclaimed by the cortes assembled at Burgos, and commenced his reign by making war on those Christian kings of Spain who had leagued together to dispossess him of his heritage. After repulsing them, he turned his arms against the Moors; and at Alarcos, in 1195, sustained one of the most disastrous defeats recorded in the annals of Spain. This disaster encouraged the kings of Leon and Navarre to renew their hostilities. About this time occurred a tragical event illustrative of the fierce spirit of the age. A young Jewess, whose beauty had enthralled the king, was accused as the author of all the public calamities; and the nobles, undaunted by the presence of their sovereign, plunged their daggers into her bosom before his eyes. This outrage aroused Alonzo from inactivity, and he soon repaired the defeat at Alarcos by the splendid victory of Tolosa. He died soon after, in 1214. This prince was an encourager of literature, and founded the university of Palencia, the first in Christian Spain.

It ought to be observed that the kingdoms of Castile and Leon were at this time separate: the prince of whom we shall presently speak reigned over the first; and over the latter reigned another Alonzo, also the ninth of the name. He waged war successfully against the Moors, and was the founder of the celebrated university of Salamanca. He died in 1230, having reigned 42 years.

Alphonso X., surnamed *El Sabio*, the *Wise* or the *Learned*, succeeded his father Fernando the *Good*, king of Castile, in the year 1252. He obtained the appellation of *wise*, not for his political knowledge as a king, but for his scientific and literary accomplishments. In consequence of the general opinion of his princely qualities, and his uncommon generosity, he ascended the throne with universal approbation. The ill-concerted projects of his ambition, however, disturbed the prosperity of his reign. Pretending a better right than Henry III. of England to the territory of Gascony, he directed his first attempt towards its acquisition. The arms of England, however, proved too formidable; and he was compelled to renounce his claim, on condition that Henry's son, afterwards King Edward I., should marry his sister Eleonora. At an expense which drained his treasures, and obliged him to debase his coin, he prepared for an expedition against the Moors in Barbary; but his maternal right to the duchy of Suabia, which he was called to defend, diverted him from it. Thus he formed a connection with the German princes, and became a competitor, with Richard Earl of Cornwall, for the imperial crown, a contest in which they both expended immense sums of money. The claims of several of the princes of the blood gave exercise to his military talents, and he was successful both in opposing and defeating them. He formed the romantic design of visiting Italy in the year 1268; but the states firmly remonstrating, he was obliged to relinquish it. But although he abandoned the design, it produced such discontents among the common people, and conspiracy among the nobles, that it required considerable exertion before the king could allay the ferment. Alonzo being still desirous to ascend the imperial throne, made another attempt after the death of Richard Earl of Cornwall, and even after Rodolph of Hapsburg was actually elected emperor of Germany; and for that purpose took a journey to Beaucaire, to obtain an interview with the pope, in order to prevent him from confirming the election. The Moors, ever ready to draw the sword against him, took this opportunity of entering his dominions for the purpose of ravaging them. This ambitious journey, undertaken at so vast an expense, and productive of so much confusion in his kingdom, proved unsuccessful; for the pope would not realise his claim, or alter the former election. But his excessive ambition was soon punished by domestic calamity; for his eldest son died in this interval, and his second son Don Sanchez, having obtained great reputation in opposing the infidels, to the prejudice of his brother's children, laid claim to the crown. This claim was admitted by the states of the kingdom; but Philip king of France, supporting the cause of the children, whose mother was his sister Blanche of France, involved Alonzo in a war; which occasioned the retreat of his own queen Yolande or Violante to the court of her father, the king of Aragon. While thus harassed with dissensions, he proclaimed war against France, and by the authority of the pope renewed the war with the Moors, which proved so unfortunate, that he reluctantly concluded a truce with them, and engaged in a contest with the king of Granada.

These various measures exhausted his treasure; taxes were multiplied, and the affairs of the kingdom were in such confusion, that he was under the disagreeable necessity of calling an assembly of the states, which was held at Seville in the year 1281, where, on the king's proposal, the states consented to give a currency to copper money. In consequence of the intrigues of Don Sanchez his son, another assembly of the states was held at Valladolid, A.D. 1282, which deprived Alonzo of the regal dignity, and appointed Sanchez regent. Reduced to almost insurmountable difficulties, Alonzo solemnly cursed and disinherited his son, and by his last will, in the year 1283, confirmed the act of exclusion, and appointed for the succession the infants de la Cerda, and, upon the failure of their heirs, the kings of France; and at the same time supplicated the assistance of the king of Marocco against the power of his son. At the commencement of the next year, when Alonzo received information from Salamanca that Sanchez was dangerously ill, his heart relented. He pardoned his son, revoked his curses, and then died, on the 4th of April 1284, in the eighty-first year of his age. His remains were interred in the cathedral of Seville; and he left behind him the character of a learned man, but a weak king. Alonzo has been charged with irreligion and impiety, chiefly on account of a well-known but differently interpreted saying of his, that "if he had been of God's privy council when he created the world, he could have advised him better."

To this prince science is indebted for the set of astronomical observations known as the *Alphonsine Tables*, which were drawn up under his auspices by certain Jews of Toledo. In the palace of Segovia a chamber is still shown as the observatory of Alonzo. He was also distinguished as a poet and a legislator. In the Escurial is preserved a curious manuscript containing some hymns of his composition; and he was the principal compiler of that code of laws which is still extant under the title of *Las Siete Partidas*.

ALPHONSO XI., the *Avenger*. This prince was an infant when he succeeded his father Ferdinand IV. in 1312. During his long minority the kingdom was cruelly distracted by intestine warfare. Assuming the reins of government in his fifteenth year, he strove to repress the turbulent spirit of the nobility, and to put down that system of brigandage to which it had given rise. His inflexible severity towards all such offenders procured for him the title of the Avenger. As commander of the allied armies of Catholic Spain, on the 29th Oct. 1340 he gained a complete victory over the kings of Marocco and Granada, who had besieged Tarifa. The slaughter was immense, and the booty so rich that the value of gold is said to have fallen one sixteenth. In 1342 Alonzo laid siege to Algeziras, where cannons were employed for the first time in Europe by the Moors in defence of their walls. This siege had lasted two years, when the Moors capitulated on condition of a truce between the two nations for ten years: but the king of Castile broke his word a few years after by besieging Gibraltar, where he died of the plague on the 26th March 1350, aged 40. He was the father of Pedro the Cruel, who succeeded him. From this reign dates the institution of *regidors* or jurats, to whom was committed the administration of the communes; and these *regidors* became the exclusive electors of the cortes, in which the people ceased to have a voice.

2d. *Aragon.*—ALPHONSO I., surnamed the *Fighter*, king of Navarre and Aragon, was the second son of Don Sancho Ramirez, and succeeded his brother Pedro I. in 1104. At that period Aragon was exhausted by the interminable wars which its successive sovereigns had waged against the Moors. The power of the Almoravides, which the exertions of the Cid were unable to check, menaced all Christian Spain; and the only prince that still was able to oppose them was the aged Alonzo VI., king of Leon. It was in this juncture of affairs that Alonzo I. by many years of peace had gathered strength to pursue that headlong career which afterwards caused him to be surnamed the *Fighter*. Very shortly after his marriage with Uraca the daughter of Alonzo VI. of Leon, some misunderstanding alienated his affections from that princess. The haughty Castilian nobles, indignant at her treatment, rescued her from the fortress where she was confined, and bore her away in triumph. In the meantime Alonzo was occupied with his schemes of aggrandizement. The capture of Tudela from the Arabs was the prelude to his invasion of the kingdom of Saragoza in 1110. In dissolving his marriage with Uraca, he attempted to retain the greater part of her dowry; but she had a powerful friend in her brother-in-law Henry Count of Portugal, whose army already menaced Navarre. This obliged him eventually to renounce all pretensions to the states of Leon and Castile, and to recognise, as king of Galicia, Alonzo Raymond the son of Uraca, A.D. 1113. His marriage was dissolved by a council of Castilian bishops, and their decision was ratified by the pope. At this period commenced the struggle between the Aragonese and Almoravides. The army of the governor of Granada was cut to pieces near Saragoza, and Alonzo obtained another victory over a large army sent by Ali of Marocco under the command of his ablest generals to avenge Ben Mezdeli. In this short campaign Alonzo displayed extraordinary ability. No longer concealing his designs upon Saragoza, he obliged Amad Dola to surrender that city, from which point he commenced his attempts to subdue the kingdom (A.D. 1118). This hard-earned acquisition was the means of involving him in interminable troubles. In 1120 his territories were menaced by a large force sent against him by Ali; but engaging the enemy near Daroca, he left 20,000 Almoravides dead on the field. This victory placed Daroca and Calatayud in his power. Three years afterwards, while the king of Marocco was fully occupied at home by the rise of a dangerous sect of Almoravides (see ABDUL-MUMEN and ALMOHADES), Alonzo seized the opportunity to invade the territory of Valencia. The brilliant victory he obtained at Alcaraz seemed to open up the way for the conquest of all eastern Spain. In 1125 he undertook a new expedition against Granada. The spoil taken from the Andalucians was dearly bought by the Christians; but it was not upon Alonzo that the Moors made their reprisals. They invaded Estremadura, and defeated the Castilians near Badajoz. The king of Aragon, so far from rendering his neighbours any assistance, determined to take advantage of the critical position of Alonzo Raymond, as well as of the troubles which the death of Uraca had occasioned in several parts of his dominions. But, when on the point of battle with the king of Leon upon his own territory, Alonzo agreed to an accommodation, and resolved to turn his arms in another direction. He imagined the time was arrived for achieving with ease the conquest of Saragoza. Two cities, Mequinenza and Fraga, still held out. He reduced the first, and put the garrison to the sword on account of their devotion to the Almoravides. He then laid siege to Fraga; where, during a sally from the town, he received a mortal wound. Alonzo had been victorious in 29 battles, and his arms had never received a check until this day, when he beheld, whilst dying, the utter destruction of his followers. The camp of the Christians with its rich spoils indemnified the Moors for the losses they had sustained at his hand. His ancient rival, Alonzo Raymond, hastened to avenge his defeat, and to succour the remnant of his army.

Alphonso II. began to reign in 1162, and was almost constantly at war with Raymond V. Count of Toulouse. He was a patron of the troubadours, and wrote some poems in the Provençal language. He died in 1196.

Alphonso III. ascended the throne in 1285. His short reign was remarkable for the establishment of the most liberal political constitution of that age, the *justiza* being invested with the right of citing the king himself to appear before the cortes, and with the power of deposing him if he infringed the privileges of the subject. Alonzo vainly endeavoured to avoid taking the oaths of adherence to the articles to which his predecessors had subscribed, by absenting himself from the solemn ceremony of coronation; but the nobles obliged him to appear according to custom. Under this reign also were united the cortes of Valencia, Catalonia, and Aragon, which each sovereign on his elevation engaged by oath never to disunite. Alonzo died in 1291, aged 26.

Alphonso IV. ascended the throne in 1327. Almost the whole of his reign, which lasted ten years, was occupied in war with the Genoese.

Alphonso V., the *Magnanimous*, commenced his reign in 1416. He was the son of Fernando the *Just*, of Castile, whom the Aragonese had chosen for their king. Alonzo was one of the greatest princes of the fifteenth century. The first act of his reign was to destroy a list containing the names of those who had conspired against him. But the free nature of the constitution, which was almost republican, imposed restraints little in accordance with Alonzo's ardent aspirations after fame, and he resolved to seek a wider sphere of action. Accordingly he left his kingdom, and during a reign of forty-three years scarcely revisited it, unless momentarily, or when urgent affairs demanded his presence. The shores of the Mediterranean were to be witnesses of his exploits, where the possession of the Balearic Isles, Sardinia and Sicily, gave him dominion. His first expedition was directed against Corsica, then in possession of the Genoese. Thence sailing to Naples, he offered to make John II. his heir if he would assist him against Louis of Anjou. Being recalled to Spain by an attack made by the Castilians upon his hereditary states, he left his brother Don Pedro at Naples; and coasting the Adriatic, he suddenly descended on Provençe, and captured Marseilles, which pertained to the Duke of Anjou, his competitor for the kingdom of the two Sicilies. Alonzo, ever generous in war, preserved the city from pillage; and refusing a present that was offered him in acknowledgment of his forbearance, contented himself with carrying away the body of a canonized bishop. After restoring peace at home, he directed his arms anew against Naples, where his cause appeared to be compromised. In 1435, Queen Joanna being dead, he besieged Gaeta; but when he had reduced that place, Philippo Maria Visconti, Duke of Milan, appeared with a fleet before the town, and after a bloody engagement, took Alonzo prisoner, with a great number of his followers. The high character which Alonzo bore induced the conqueror to treat him honourably: he made him his ally, and without ransom restored him to liberty, with all his suite. Immediately on recovering his freedom, Alonzo made his third attempt on the kingdom of Naples. After an obstinate resistance the city was taken by assault, in 1442, and Alonzo entered it in triumph. The states were convoked, and he was solemnly proclaimed; his elevation being sanctioned by Pope Eugenius IV., who had promised to René that honour. Alonzo fixed his residence at Naples, where he died on the 27th June 1458, at the age of sixty-four, while preparing for a new war against several of the Italian princes. Possessed of many noble qualities, he united humanity with valour; but his amorous disposition sometimes inclined him to abuse his authority. He was a lover and patron of literature, and delighted in Cæsar's Commentaries, a copy of which he always carried about with him. His secretary, Antonio de Palermo, has left a life of this prince.

3d. *Portugal.*—Alphonso I., *Enriquez*, son of Henri of Bourgogne, Count of Portugal, and Teresa of Castile, was born in 1094. The Count Henry dying when Alonzo was but three years old, he was placed under the tutelage of his mother; and when he came to age, he was obliged to wrest from her by force that power which her vices and incapacity had rendered disastrous to the state. Being proclaimed Count of Portugal in 1128, he defeated a body of troops which his mother had armed against him, and made her his prisoner. He also vanquished the Castilians who came to support his enemies, and freed Portugal from dependence on the crown of Leon. Then turning his arms against the Moors, on the 26th July 1139 he obtained the famous victory of Ourique, which gave him a crown. Not satisfied, however, with being proclaimed king by his army on the field of battle, he assembled the cortes of the kingdom in 1145 at Lamego, where he received the crown from the hands of the archbishop of Braganza. Holding a naked sword in his hand, he said—"I have delivered you with this sword from the power of the Moors: I have conquered your enemies: you have made me your king. Let us at once establish laws for maintaining order, justice, and peace, in this realm." The constitution of the kingdom was accordingly voted by the deputies, and the freedom of Portugal was proclaimed as follows:—"You are asked if you wish that the king should pay tribute to Castile, and appear before the states of this kingdom as a vassal." Upon which a shout was raised,—"We are free, and our king shall be free also." Such was the result of the famous assembly at Lamego, and the foundation of the Portuguese monarchy. Alonzo continued to signalise himself by his exploits against the Moors, from whom he wrested Lisbon in 1147, after a siege in which both parties displayed the most heroic valour. He next engaged in the war that had broken out among the kings of Spain. Being disabled during an engagement by a fall from his horse which fractured his leg, he was made prisoner by the soldiers of the king of Leon, who obliged him to give up as his ransom almost all the conquests he had made in Galicia. Alonzo was then eighty years old;

but he had still sufficient energy to relieve his son Sancho who was besieged in Santarem by the Moors. This was his last exploit. He died in 1185, at the age of ninety-one, having reigned seventy-three years. Alonzo was of gigantic stature, even seven feet in height according to some authors. His victories and his laws, his Christian life and chivalry, as well as the numerous religious houses he established, are claims on the admiration and the gratitude of the Portuguese, among whom, accordingly, he has long been regarded as a saint.

Alphonso II., the *Fat*, born in 1185, succeeded his father, Sancho I., in 1211. He endeavoured to repress the ambition of the clergy, and to apply a portion of their enormous revenues to purposes of national utility. Having been excommunicated by the pope, he was anxiously negotiating for absolution when death overtook him in 1223, in the 39th year of his age, and 12th of his reign. He framed a code of laws in which it was enacted that capital punishment should not be inflicted until the expiry of twenty days after condemnation.

Alphonso III., son of the preceding, succeeded his brother Sancho II. in 1248. He, like his father, was frequently embroiled with the ecclesiastics. He died in 1279.

Alphonso IV., in 1325 succeeded his father Dionisio the *Liberal*, whose death he had hastened by his intrigues and rebellions; and his persecution of Alonzo Sancho proved him to be no less unnatural as a brother. To an immoderate love of the chase he sacrificed his duties as a king; and on one occasion, while expatiating on his favourite sport before the council, he was plainly told by the indignant ministers of the wrong he was inflicting on the nation, and that, if he did not amend his life, they would depose him. Alonzo was filled with rage; but suddenly recovering himself, he confessed that their announcement had opened his eyes, and that in future they should find him a very different king. Hostilities with the Castilians and with the Moors occupied many years of his reign: but one bloody act, of which the mass of Camöens has perpetuated the memory, has fixed an indelible stain on his character. The murder of Iñez de Castro, who was secretly espoused to his son Don Pedro, recals the sad history of that young prince, and the troubles in which it involved the kingdom. Alonzo was scarcely reconciled to Don Pedro when he died, in the 77th year of his age, A.D. 1376.

Alphonso V., *Africano*, king of Portugal, was the son of Duarte I., whom he succeeded in 1438, being then but six years old. In 1471 he landed in Africa with a fleet of 300 sail and 30,000 men, and there acquired by his conquests the title of *Africano*. During this expedition he heard of an ancient tradition that, at Fez, was jealously preserved a sword which should become the spoil of a Christian prince; and supposing that its accomplishment was reserved for himself, he instituted the chivalrous order of The Sword. In returning to Portugal in 1475, his ambition led him into Castile, where two princesses were disputing the succession to Henry IV. Supported by a powerful party, Alonzo caused himself to be proclaimed king of Castile and Leon. Being defeated at Toro by Ferdinand of Aragon, the husband of Isabella of Castile, he applied for assistance to Louis XI. of France; but finding himself deceived by Louis, he became disgusted with the regal state, and forwarded his abdication to his son. A few days after he appeared in Portugal, and was constrained by his son, Juan II., to resume the sceptre, which he continued to wield for two years longer; after which he fell into a deep melancholy, and retired into a monastery at Cintra, where he died of the plague in 1481, aged 49. He was a brave prince, and ruled equitably; and he was the first king of Portugal who possessed a private library.

Alphonso VI. was the son of that Duke of Braganza who succeeded to the crown as the representative of the ancient dynasty of Portugal. He succeeded his father in 1656; and in 1667 was compelled to abdicate the throne, of which his vices had rendered him unworthy.

ALPHONSUS *a Sancta Maria*, or Alfonso *de Cartagena*, a celebrated Spanish historian, was born in 1396, and died in 1496. He succeeded his father as Bishop of Burgos. He was the author of several works, the principal of which is a History of Spain from the earliest times down to the year 1496, printed at Granada in 1545, fol.

ALPINI, Prospero, in Latin Prosper Alpinus, a celebrated physician and botanist, was born at Marostica, in the republic of Venice, in November 1553. In his early years his inclination led him to the profession of arms, and he served some time in the Milanese. By the encouragement and persuasion of his father, who was a physician, he retired from the army, and devoted his attention to literature. To prosecute his studies with more advantage, he went to the university of Padua, where he was soon after elected deputy to the rector, and syndic to the students. He continued his medical studies with zeal and success; and after having acquired the necessary qualifications, he was admitted to the degree of doctor of physic in 1578. Soon after this he left the university, and settled as a physician in Campo San Pietro, a small town in the Paduan territory, at the invitation of its citizens.

In the course of his studies he had paid particular attention to plants, and had become an enthusiast in botanical science; but the sphere of his present practice was too limited to afford him much opportunity of prosecuting his favourite study. He wished particularly to extend his knowledge of exotic plants; and considered that the only means of attaining this was to study their economy and habits in their native soil. To gratify this laudable curiosity an opportunity soon presented itself. George Emo, the consul for the Venetian republic in Egypt, appointed Alpini his physician. They sailed from Venice in September 1580, and, after experiencing a tedious and dangerous voyage, arrived at Grand Cairo in the following year. Alpini spent three years in Egypt, and, by his industry and assiduity, greatly improved his botanical knowledge, having travelled along the banks of the Nile, visited every place, and consulted every person from whom he expected any new information. From a practice in the management of date-trees, which he observed in this country, Alpini seems to have deduced the doctrine of the sexual difference of plants, which was adopted as the foundation of the celebrated system of Linnæus. He says, that "the female date-trees, or palms, do not bear fruit unless the branches of the male and female plants are mixed together; or, as is generally done, unless the dust found in the male sheath, or male flowers, is sprinkled over the female flowers."

When Alpini returned to Venice in 1586, he was appointed physician to Andrea Doria, prince of Melfi; and during his residence at Genoa, he was esteemed the first physician of his age. The Venetians were unwilling that the Genoese state should number among its citizens a person of such distinguished merit and reputation; and in the year 1593 he was recalled to fill the botanical chair in the university of Padua, with a salary of 200 florins, which was afterwards augmented to 750. He discharged the duties of his professorship for many years with great reputation, till his declining health interrupted his labours. He died in 1617, in the 64th year of his age, and was succeeded as botanical professor by one of his sons. Alpini wrote the following works in Latin:—1. De Medicina Ægyptiorum libri iv. Venice, 1591, 4to; 2. De Plantis Ægypti liber, Venice, 1592, 4to; 3. De Balsamo Dialogus, Venice, 1592. 4to;

Alpiste || Alps. 4. De Præsagienda Vita et Morte Ægrotantium libri vii. Venice, 1601, 4to; 5. De Medicina Methodica libri xiii. Padua, 1611, folio; 6. De Rhapontico Disputatio, Padua, 1612, 4to. Of all these works there have been various editions given to the world; and, besides these, two posthumous treatises were published by his son: 1. De Plantis Exoticis libri ii. Venice, 1627, 4to; 2. Historiæ Naturalis Egypti libri iv. Lugd. Bat. 1635, 4to. Several other works of Alpini remain in manuscript.

ALPISTE, or Alpia, a sort of seed used to feed birds with, especially when they are to be nourished for breeding. The alpiste seed is of an oval figure, of a pale yellow, inclining to an isabel colour, bright and glossy. It is an article of the corn-chandlers and seedmen's trade.

ALPS. On taking a general view of the continent of Europe, we can distinguish two great mountain masses, from which proceed the various chains of mountain groups that characterize it. The first of these is the mountain mass of *St Gothard*, in Switzerland, between the sources of the Rhine, the Rhone, the Etch, and the Aar: the second is the *Wolchonsky-wald*, in Russia, between the Wolga and the sources of the Don, Dnieper, and Dwina.

The mountains connected with St Gothard are the Alps, which in their full extent reach from long. 4° 20′ to 19° E. from Paris, and from lat. 44° to 47° N. The central point of the Alps is in Switzerland, the numerous branches of it extending through Savoy, France, Italy, Germany, Croatia, and Sclavonia. They are bounded on the south-west by the Rhone, in southern France; on the north-east by the Danube, in Hungary; on the south and south-east by the Mediterranean Sea, and the rivers Kulpa and Sau; on the north and north-west by the Danube, in Germany; by the Rhine on the northern boundary of Switzerland; and by the Doubs in the Jura. Hence it appears that this great high land passes through France, Savoy, Switzerland, Italy, Germany, Croatia, and Sclavonia. The southern part of the chain in Croatia, in long. 35°, does not reach its extremity, but continues onwards to the left bank of the Sau and Danube, fully ten degrees of longitude farther.

Origin of the name. In the Celtic language, the word *alb*, *alp* according to some authors, signifies *white*. As the highest peaks of this Alpine land are perpetually covered with snow, they were by the ancient inhabitants named Alps; by the Greeks Αλπεις, who, however, knew only the Maritime Alps; by the Romans Alpes, and by modern writers Alps.[1]

History. The Romans, although they knew well that the Gauls under Bellovesus (620 years before Christ) made an irruption into Upper Italy across the Alps, were entirely ignorant of the route he followed. It was not until Hannibal had crossed the Alps (300 years after Bellovesus) that the Romans thought of examining this grand barrier. Polybius described the Alpine country traversed by the military host under Hannibal, fifty years after that remarkable event; and Cincius Alimentus heard Hannibal himself detail his passage of the Alps. Livy, and other writers, both Latin and Greek, also speak of the Alps. Fifty-two years after Hannibal's irruption into Italy (in the year of Rome 587, before Christ 178), the Romans, under the consuls Claudius and Marcellus, conquered the Cisalpine Gauls, who inhabited the country between the Po and the Alps; and seven years afterwards, under Fulvius Nobilis, they for the first time crossed the Alps to Nice and Antibes, in order to aid the Marsilians against the Ligurians. For one hundred and fifty years from this period, the Romans frequently traversed this chain, partly with the view of subjugating the various tribes inhabiting it, and partly in extending their conquests into Spain, Gaul, and Germany After the death of Cæsar, the whole Alpine population threw off the Roman yoke. The emperor Augustus sent against them (in the year of Rome 747, before Christ 18) his legions, under Drusus, Tiberius, Terentius Varro, and Lucius Silus. This long-continued warfare terminated in the conquest of forty-six Alpine tribes or nations, whose names were inscribed on the celebrated triumphal arch of Augustus, erected near Nice. From this period until the fifth century after Christ, the Romans continued in complete possession of the north and south sides of the Alps.

During the long domination of the Romans, the Alps received the following names, which are still retained by geographers, viz. Maritime, Cottian, Grecian, Pennine, Leopontine, Rhætian, Noric, Carnic, Julian, and Dinarian.

### DIVISIONS OF THE ALPS.

Divisions of the Alps. 1. *Maritime Alps* (Alpes Maritimæ).—These extend from the coast of the Mediterranean Sea, between Oneglia and Toulon, across the Cols Ardente and Tende, to Mont Viso (Vesulus), separating Piedmont from Provence and the Mediterranean Sea.

2. *Cottian Alps* (Alpes Cottiæ) extend from Mont Viso by Mont Genevre to Mont Cenis, a distance of twenty-five leagues, thus separating Piedmont from Dauphiny. It is in this range that we first meet with heights analogous to those of the central chains of the Alps. The Po and the Durance rivers have their sources here. The name is derived from Cottius, who, in the time of Cæsar and Augustus, had his chief place of residence at Seguvium, the present Susa, and ruled as king or chief of this part of the Alps.

3. *Graian or Grey Alps* (Alpes Graiæ) extend from Mont Cenis, across the Iseran and the Little St Bernard, to the Col de Bonhomme, separating Piedmont from Savoy. They were named Grey Alps from their grey colour, owing to the partial cover of snow. The Little St Bernard is considered as the Alpis Graia of the ancients.

4. *Pennine Alps* (Alpes Penninæ), also named by Cæsar Alpes Summæ, extend from the Bonhomme across Mont Blanc, the Great St Bernard, Combon, onwards to Mont Cervin and Mont Rosa, separating Piedmont from Savoy and the Lower Vallais. The Celts named every high mountain a Ben or Penn; hence the loftiest summits and the most exalted of their deities were named Penn. In the time of the Romans, in one of the valleys, a temple was built, and a statue erected in it, to one of their gods, named Penn, by the Romans Deus Penninus, and afterwards Jupiter Penninus. Hence these Alps were named Alpes Penninæ. In this part of the great Alpine range there occur Mont Blanc, the highest mountain in Europe, and Mont Rosa, the next in elevation to that monarch of European mountains.

5. *Lepontine Alps*, also named Alps of Switzerland, or Aulæ. They extend from Mont Rosa on both sides of the Rhone, or valley of the Vallais, across St Gothard, the Moschelhorn, and Bernardino in the Grisons, thus separating Lombardy from Switzerland. The distance from St Gothard to Bernardino is 15 leagues. They were named Lepontine after a people, the Lepontii, who formerly inhabited the confines of Rhætia, Helvetia, and Italy.

[1] Some authors derive Alp from *alb*, a verdant height.

Alps.

6. *Rhætian Alps* (Alpes Rhæticæ) extend from Bernardino through the whole of the Grisons and the Tyrol, to the Dreiherrn peak, on the borders of Saltzburg and Carinthia, and more southerly to Mont Pelegrino; thus separating Lombardy and a great part of the Venetian terra firma from Northern Rhætia and Germany.

7. *Noric Alps* (Alpes Noricæ) extend from the Dreiherrn peak through the whole of Carinthia, on the left bank of the Drau, through Saltzburg, Austria, and Styria, to the Oedenburg plain in Hungary. They have their name from the Roman town Noricum.

8. *Carnic Alps* (Alpes Carniæ) extend from Pelegrino, between the rivers Drau and Sau, to Terglou, at the source of the Sau.

9. *Julian Alps* (Alpes Juliæ) extend from Terglou, between the right bank of the Sau, the Kulpa, and the Adriatic Sea, to the rock Kleck, near Zenk in Dalmatia; thus separating the Friaul from Idria, and in general the whole of Upper Italy from Carinthia, Carniola, Croatia, and Servia. The present Civita di Friuli occupies the site where formerly stood the Forum Julii, which gave name to this division of the Alps.

10. *Dinarian Alps*, so named from Mount Dinaria, which has an elevation of 6046 feet, extend from Kleck to Sophia, ranging along the right bank of the Sau and Danube, and join the Hæmus or Balkan, on the Black Sea.

Direction of the Alps. The general direction of the Alps, exeluding the Maritime Alps, which range nearly from south to north, is from west-south-west to east-north-east. Direction of valleys. The most considerable valleys, those named *longitudinal*, run parallel with the direction of the chain; and others, named *transverse*, run from south and south-east to north and north-west, or from north and north-west to south and south-east.

Great acclivities of the Alps. The great crest of the Alps, the *water-shed* (divortia aquarum) of this vast high land has declining from it two acclivities, one towards the north, the other towards the south. The north acclivity declines towards the ocean, the North Sea, and the Baltic; the south acclivity towards the Mediterranean and Adriatic Seas. The northern acclivity has a gentle inclination, and is much more extensive than the southern, which is comparatively abrupt and steep. From the nature of these two acclivities or inclined plains, we naturally expect to find the principal and most numerous secondary chains on the northern, and this is actually the case. Mont St Gothard, in some degree the central point of the whole chain, is distant in a straight line from the Mediterranean about 52 leagues, from the Adriatic 75 leagues, from the ocean 175 leagues, from the North Sea 168 leagues, from the Baltic 185 leagues.

Heights of mountains.

HEIGHTS OF THE MORE REMARKABLE MOUNTAINS IN THE ALPS.

I. *Maritime Alps.*

| | English Feet. | |
|---|---|---|
| 1. Col de Tende | 5,818 | |
| 2. Mont Venteux | 7,235 | |

II. *Cottian Alps.*

| | | |
|---|---|---|
| 3. Mont Viso | 13,828 | Zach. |
| 4. Mont Genevre | 11,788 | |
| 5. Mont Cenis | 11,460 | |

III. *Graian Alps.*

| | English Feet. | |
|---|---|---|
| 6. Mont Iseran | 13,278 | Welden. |
| 7. Summit of the Little St Bernard | 9,594 | |
| 8. Col de Bonhomme | 8,027 | |

IV. *Pennine Alps.*

| | | |
|---|---|---|
| 9. Mont Blanc | 15,781 | |

Mont Blanc is the highest mountain in Europe. The Elbruz in the Caucasus, which is 16,411 feet, cannot be reckoned a European mountain. Notwithstanding its vast height, Mont Blanc is much inferior in elevation to some mountains in the New World and in Asia; for, according to late measurements, there are in Upper Peru mountains 25,250 feet above the sea; and in the Himalaya ridge summits soaring to a height of 26,000 feet.

| | | |
|---|---|---|
| 10. Great St Bernard | 11,011 | |
| 11. Mont Cervin | 14,784 | |
| 12. Mont Rosa | 15,540 | Welden. |

Mont Rosa is the next in elevation to Mont Blanc, and therefore the second highest mountain in Europe. By some it is stated to be even higher than Mont Blanc, but we do not know the authority for this statement.

| | | |
|---|---|---|
| 13. Col de Geant | 11,275 | |
| 14. L'Alle Blanche | 14,775 | |
| 15. Breithorn | 12,800 | |

V. *Lepontine Alps—Group of St Gothard.*

| | | |
|---|---|---|
| 16. Petchiroa (one of the summits) | 10,529 | Welden. |
| 17. Fienda, another summit | 10,180 | |
| 18. Furca | 14,040 | |
| 19. Piz Pisoc | 12,792 | |
| 20. Pettina | 9,153 | |
| 21. Finsteraarhorn | 14,116 | |
| 22. Schreckhorn | 13,397 | |
| 23. Jungfrau or Virgin | 13,720 | |
| 24. Diablerets | 10,732 | |
| 25. The Simplon[1] | 6,590 | |
| 26. Ruffi or Rossberg | 5,154 | |
| 27. Rigi | 6,050 | |

VI. *Rhætian Alps—Great Rhætian Chain.*

Grisons and Tyrol.

| | | |
|---|---|---|
| 28. Muschel Horn | 10,948 | |
| 29. Bernhardino | 10,187 | |
| 30. Orteles | 12,859 | Welden. |
| 31. Greiner | 9,380 | |
| 32. Brenner | 6,463 | |

*Northern Rhætian Chain.*

Chain between Tyrol and Bavaria.

| 33. Watzmann | 9,655 | |
| 34. Breithorn | 7,772 | |

VII. *Noric Alps.*

| | | |
|---|---|---|
| 35. The Great Glockner | 13,713 | |
| 36. Hohenwart | 11,076 | |
| 37. Hahe-varr | 11,334 | |

VIII. *Carnic and Julian Alps.*

| | | |
|---|---|---|
| 38. Kleck | 6,692 | |
| 39. Terglou | 9,096 | |

[1] There is a great road over the Simplon. It was improved by the Emperor Napoleon at an expense of nine millions of francs. It runs along the Savoy side of the lake of Geneva, and connects the ridge of the Jura with the Alps. At St Maurice it falls in with the road that traverses the Swiss margin of the lake, passes up the Vallais beyond Sion, and conducts the traveller to the lake Maggiore and Milan. See SIMPLON.

Alps.

*Heights of Passes across the Alps.*

| | | English Feet. |
|---|---|---|
| 1. | Pass of Mont Cenis | 6,773 |
| 2. | Pass of the Little St Bernard | 7,194 |
| 3. | Pass of the Great St Bernard | 7,966 |
| 4. | Pass of the Cervin | 10,100 |
| 5. | Pass of St Gothard | 6,800 |
| 6. | Pass of Gemmi | 7,378 |
| 7. | Pass of Airolo | 7,192 |
| 8. | Pass of the Splugen | 6,310 |
| 9. | Pass of Mont Julien | 7,280 |

*Heights of Lakes in the Alps.*

| Convent of St Gothard | 6,796 |
| Hospital of the Grand St Bernard (highest habitation in Europe) | 7,966 |
| Hospital of the Grimsel | 6,003 |

Snow line. The cold of the atmosphere continually increases with the elevation; and at a certain height, depending on climate or latitude, perpetual frost prevails. Where the earth's surface attains this height, it is, with the exception of mural precipices, continually covered with snow. The snow increases from season to season; for though it may melt slowly from the heat of the ground on which it rests, yet it suffers little loss externally in the way of melting, except what the air carries off by evaporation. If in the neighbourhood of Edinburgh we had mountains 6000 feet high, their summits would be always covered with snow, and consequently we should here have perpetual snow within a few hours' walk. But in Great Britain none of the mountains reach to the snow line of the latitude,—an arrangement very different from what prevails in the Alps, where whole ranges are covered with eternal snow. When mountains are covered with perpetual snow, its lower limit, or the snow line, descends in winter and rises again in summer; so that in the Alps in winter the snow line reaches the low country, while in summer it ascends, and in the autumn, when the heat is greatest, it attains its maximum of height.

Glaciers. The lower edge of the snow line differs much from that above it, and might more properly be called the *ice line;* because the snow, owing to the influence of rain, the heat of the sun, and the heat of the earth, is there partially melted every summer, and frozen again in the winter, forming an icy boundary. This ice is named *glacier ice,* or simply *glacier.* Above this zone, the region of the glaciers, the snow is seldom moistened by rain or softened by the rays of the sun. These glaciers or vast accumulations of ice have received particular names in different parts of the Alps. Those in Dauphiny and Savoy are named *glacier;* in Switzerland, *gletcher;* in the Grisons, *wader;* in the Tyrol, *ferner;* in Salzburg and Carinthia, *käs;* and by the Italians who inhabit the Alps, *vedretto.* They fill all the upper, and principally the transverse valleys, from Dauphiny to the frontier of Salzburg; few of them are less than three miles, many 18 or 20 miles in length, from one to two miles broad, and from 100 to 600 feet thick. They frequently run into each other, and thus surround the peaks on all sides, in such a manner that they appear rising like islands through a sea of ice. Where the glaciers are largest, they send down great arms or branches into the cultivated country, and into the fruitful valleys, 3000 feet above the sea. The chain of Mont Blanc affords a striking example of these descending arms; for there are twenty-five glaciers, descending from it into the valleys of Chamouni, Entreves, and Bionnay. The glaciers are frequently traversed by rents, often of great width and depth; so that when hid by a thin covering of snow or ice they become extremely dangerous to travellers. It is therefore proper to have experienced guides when visiting the dreary and desolate scenes where they occur. The unfortunate Mr Escher, mentioned by M. de Luc, was cautioned by his guide not to separate from his companions when they arrived at the glacier. Hurried on, however, by that indescribable sensation which people sometimes experience when they reach lofty summits, and observing at the top of the glacier, a little distance before him, two chamois hunters, who were resting themselves, he hastened to join them; but he disappeared in a moment, and was precipitated to the bottom of a frightful fissure. He met with an instantaneous death, which was caused by the compression of his body in the narrow part of the rent. Bodies of those destroyed in fissures are sometimes brought to light by the glacier streams. Other adventurers have been even less fortunate than Escher; for there are instances in the melancholy records of these dreary regions, of bodies having been found uninjured, lying on projecting ledges in the fissures, and even sometimes suspended in narrow parts of these horribly dark gulfs: thus showing that the wretched sufferers had had a slow and awful death. All around the lower edges of the glaciers there are vast heaps of stones; these are partly masses which have fallen from the mountains on their surface, or which have been thrown from under the glacier in its progress downwards. The collection of earth and stones is termed by the inhabitants of Switzerland, *moraine.* Moraine.

The glaciers are not stationary, but occasionally move downward, and with a motion more or less quick. The movement of the glacier sometimes takes place unexpectedly; as was experienced by the priest of the Grindenwald, who, along with a chamois hunter, felt the glacier over which they were travelling moving under them. The travellers were resting themselves, and had lighted their pipes, when suddenly a frightful noise resembling thunder was heard. Every thing around them began to move; their fowling-pieces, which they had laid on the ice, moved about. Masses of rock, which a few moments before lay quietly on the surface of the glacier, bounded about in all directions; fissures closed with a loud noise, like that of cannon, and forced the water contained in them several fathoms upwards. New rents, from 10 to 12 feet, burst open with indescribably disagreeable noises. The whole mass of the glacier moved forward several yards: a dreadful convulsion appeared approaching; but in a few seconds all was still again, and the dead silence was interrupted only by the call of the marmot. The total number of glaciers in the whole range of the Alps may be between 500 and 600, which together form an icy sea of enormous extent. Number of glaciers.

Avalanches. These are masses of snow separated from the general snowy cover, which in their course downwards carry-

Alps.

ing along with them fragments of rock, and branches and trunks of trees, rapidly increase in size, and sometimes, before reaching the bottom of the valleys, have accumulated to an enormous magnitude. They destroy houses and villages, break down whole forests, and sometimes even interrupt the course of rivers. Those who are unfortunately enveloped in these avalanches have little chance of escape. In 1478 sixty soldiers in the district of St Gothard were destroyed by an avalanche. One hundred men were enveloped in an avalanche in the Great St Bernard, in the year 1500. In 1595 the course of the Rhine was so much interrupted by the fall of a great avalanche across it, that the water rose and drowned many men and cattle. In 1624 three hundred soldiers were enveloped in an avalanche in Italian Switzerland, but the greater number were dug out alive. Many other details of a similar description are to be found in the records of modern travellers.

The snows and glaciers of the Alps already described are the never-failing sources of water for the great rivers which rise from them, as the Rhine, Po, Danube, and Rhone.

Population of the Alps.

The inhabitants, as is well known, are in many respects highly interesting, more especially those inhabiting the more remote and magnificent districts. The population of the whole range may be between 6,000,000 and 7,000,000. Of these, from 1,000,000 to 2,000,000 belong to the Celto-Gallic stem, from 800,000 to 900,000 to the Italian, about 1,000,000 to the Sclavonian, and nearly 5,000,000 to the German states. Among these there may be at least 1,500,000 who lead a pastoral life, and who occupy themselves exclusively with Alpine economy and the rearing of cattle.

Distribution of vegetables.

In the Alps the upper limit of vegetation ascends above the snow line; for we observe plants growing on mountains situated above that line, but which are so steep that snow will not lie on their sides. Thus, an androsacea and a silene were found growing at a height of 10,156 feet, on the mountains around Mont Blanc. At an elevation of 11,041 feet, on the same group of mountains, there were found, growing and in a healthy state, a cardamine, a draba, a gentian, and other plants that do not fear the glacier zone. At elevations between 8188 and 7537 feet, where the snow and glaciers cease, we find growing, not upon rock, but on a fertile soil watered by the snow-water, dwarf willows in the midst of Alpine herbaceous plants. This region presents here and there islands or patches of snow, in places screened from the sun's rays. In the bare patches of ground among these islands, excellent clover grows, which, however, can only be reached by traversing these snowy patches. Lower down we reach that Alpine region so celebrated for the magnificent pasturages it contains; and still lower, between 7537 and 4914 feet, new plants make their appearance; viz., the rhododendron ferrugineum, the rhododendron hirsutum, and ericæa or heaths. We find the alder at 6394 feet; and here we enter into the region of trees. The *pinus mughus* appears at 5553 feet; the *pinus picea*, or pitch pine, at 4780; the birch at 4780 and 4473; the yew at 4473. The region of great trees does not ascend higher than 4338 feet; beech stops here. Oaks do not pass beyond 3510 feet. At this height the *cerealia* cannot be advantageously cultivated. The cherry ranges upwards as high as 3195 feet; walnut tree and chesnut to 2556. The vine is planted as high as 1782. The olive is cultivated at the foot of the Alps, and on the coast of Italy; and there also we find the orange, the citron, and other fruit-trees. Local circumstances occasion changes in the limits of these vegetables: barley, oats, and wheat range to 4473, and even to 5751 feet.

Distribution of animals.

The animal world exhibits similar distributions with the vegetable. Thus, the ibex and the chamois occur among the most elevated summits, amidst snow and ice; but of these two quadrupeds, the chamois in general occupies a lower situation than the ibex. Lower down we meet with the marmot and the white hare, the bear and the mole; still nearer the low country, wolves, foxes, the lynx and the wild cat.

Among the feathered creation the feathered vulture or lammergeyer is the species which is observed at the greatest heights, being seen soaring above very lofty snow-covered pinnacles. The ptarmigan wanders along the edge of the snowline; the heath-cock frequents pine forests; the grey partridge and other birds occur in still lower regions. Various aquatic birds frequent the lakes and rivers, and have also their appropriate distribution. The distribution of fishes is also interesting, as they occur at different heights, whether in lakes or rivers. Where the water is abundantly supplied from the glaciers, fishes do not thrive, and are rarely to be found. Insects, too, as we shall partially explain in our article on the geography of the animal world, are met with in the Alps, from spots amidst the snows of the loftiest peaks to the deepest valleys, increasing in number, variety, and beauty, as we approach the lower country. Even the testaceous molluscæ, and creatures lower in the animal scale, exhibit on the great acclivities of the Alps a similar mode of distribution.

Geological composition.

In this vast high land there are examples of all the different rock formations of which the crust of the earth is composed, from the deepest-seated primitive rock to the most superficial and newest alluvial deposite. The higher and also many of the deeper ranges and valleys are composed of *primitive rocks*, viz. granite, gneiss, mica slate, clay slate, limestone, trap, porphyry, syenite, serpentine, and quartz rock. Resting upon these, and frequently at a great height, rocks of the *transition* class appear, as grey wacke, clay slate, quartz rock, granite, gneiss, mica slate, limestone, syenite, trap and serpentine. The *secondary rocks*, or those of the third class, although frequently occurring at a great height, yet more generally occupy lower situations than the primitive and transition rocks. The following secondary deposites are enumerated by authors as occurring in the Alps. We enumerate them in their order of deposition, beginning with the first or oldest.

1. First secondary sandstone, or coal formation.
2. First secondary limestone, or magnesian limestone.
3. Second secondary sandstone, or new red sandstone.
4. Second secondary limestone, or shell limestone.
5. Third secondary sandstone, or keuper sandstone and marl.
6. Third secondary limestone, or Jura, and Lias, and Oolite limestones.
7. Fourth secondary sandstone, or green and iron sand, and quader-sandstone formation.
8. Fourth secondary limestone, the chalk deposite of geologists.

Resting upon these secondary deposites, we find in many parts vast accumulations of strata of newer rocks belonging to the fourth or *tertiary class.* These tertiary deposites consist of sand, sandstone, and conglomerate; of clays, marls, and coals, and of various limestones; all more or less abounding in fossil organic remains. The bottoms of the valleys, even their sides to a considerable height, are more or less covered with clays, sands, rolled masses, &c., belonging to the *diluvium* of authors. And we find in every situation, from the lofty peak to the bottom of the deep valley, spread over the other deposites already enumerated, a more or less deep cover of that alluvial de-

Alps.

tritus which is daily forming, and which consists of broken masses more or less angular, gravel, sand, clay, loam-clay, shell-marl, peat, &c. The common vegetable soil rests upon this alluvium, in beds varying in thickness from a few inches to several feet.

These secondary and tertiary rocks are variously intermingled with trap and old volcanic rocks, and the diluvial and alluvial deposites with newer igneous or volcanic rocks.

Fossil organic remains.

No fossil organic remains occur in the primitive rocks; few appear in those of the transition class; whereas in the various members of the secondary and tertiary classes fossil plants and animals are abundant, and so disposed as to assist in characterizing the different deposites or formations. The diluvial and alluvial deposites also abound in fossil organic remains; but for details we refer to the article GEOLOGY.

Minerals and ores.

Varieties of almost every species of the European simple minerals are met with in the Alps or their connecting chains; and in the long range of this high land we find gold, and many different and valuable ores of silver, lead, copper, iron, bismuth, nickel, cobalt, zinc, manganese, mercury, antimony, arsenic, molybdena, uranium, titanium, and tungsten. These occur in veins, beds, imbedded masses, or are disseminated in rocks of various descriptions, particularly those of the primitive and transition classes.

Most remarkable mountains.

The loftiest and most interesting mountains are Mont Blanc, Mont Rosa, the Jungfrau, the Great Glockner, and the Ortler. The ascent to the summits of these colossal masses exhibits all those varied displays of scenery, of climate, and of distribution of animal, vegetable, and mineral production which so much excite the curiosity of the traveller and the naturalist. The ascent to the summit of the Great Glockner and the Ortler Spitze is described by Schultes and other travellers; that of Mont Rosa by Saussure, but more particularly by Von Welden, in his account of that mountain; and that of the Jungfrau by Agassiz and Forbes. Mont Blanc being more in the track of travellers, has excited greater attention than any of the other great Alpine mountains. To reach the summit of the highest mountain in Europe has always been an object of desire with adventurous travellers; hence repeated attempts have been made to reach the top of Mont Blanc. Some of these have been successful, others have been the contrary. The first attempt to reach the summit was made in the year 1762, by Pierre Simon of Chamouny, who endeavoured to accomplish it by the Glacier du Buissons, and again from the French side; but failed in both. Another unsuccessful attempt was made by some villagers in 1773; and again in 1783 by M. Bourrit of Geneva. Bourrit made a second attempt in 1784, which was also unsuccessful. In 1785 M. de Saussure, M. Bourrit, and M. Bourrit junior, with fifteen guides, left Bionassy in the beginning of September, and ascended the glacier of the same name. They slept near the base of the Arguille du Gouté, and next day climbed to the summit of it; but the snow was so soft that they could proceed no farther. They returned to the place where they had slept the night before, and next day descended into the valley. In June 1786 six Chamouny guides next attempted it, but gave it up through fatigue and fear: they were alarmed by the black appearance of the sky. Jacques Balma, as they were returning, strayed from the party, and lost his way among the hills and blocks of ice on the glacier, and was unable to regain his party. He remained all night in some hole or cave which he found in the ice. Next morning he wandered about, and discovered a route by which he thought he could reach the summit, and then returned to Chamouny with a determination to keep it a secret. Dr Paccard, a native of Chamouny, had some suspicion that Balma knew an accessible track leading to the summit, and tried in vain to get this information from him; but they agreed at last to go together and make the attempt. Therefore, on the 7th of August 1786, they left the Priory, and slept on the summit of the mountain of La Cote. Thence they started next morning at four o'clock; and after surmounting many difficulties, they attained the summit at half-past six in the evening. They left it at seven, and about midnight arrived at the spot where they had slept the night before; and at eight o'clock on the morning of the 9th returned to Chamouny. M. de Saussure having heard of the success of this journey, hastened to the valley, and, with seventeen guides, immediately attempted to follow the route of Jacques Balma; but from the bad state of the weather he did not succeed. In July 1787 Saussure sent Balma to reconnoitre the glacier, who reported that it was not in a fit state; but on the 1st of August this illustrious philosopher and indefatigable traveller left Chamouny at seven A. M., with a servant and eighteen guides. At two o'clock they arrived on the summit of the mountain of La Cote. Next day they crossed the glacier, and halted on the second plateau at four. Here they passed the night, and next day gained the summit at eleven in the forenoon. They remained on it for nearly four hours, leaving it at about three o'clock, and descended to about 1100 yards below the summit, slept there, and next day reached the Priory. M. Bourrit set out on the enterprise on the day of their return, but bad weather drove him back. On the 9th August of the same year, Colonel Beaufoy, with ten guides, attained the summit, having left Chamouny the day before, and returned to it on the 10th. He was enabled to ascertain that the latitude of the summit of Mont Blanc is 45° 49′ 59″ N. At twelve o'clock the mercury in the thermometer stood at 38° in the shade. At the same hour, in Chamouny, and in the shade, it stood at 78°. In 1788 M. Bourrit, his son, Mr Woodley, and Mr Camper, set out together; but when at a great height, a severe storm separated the party, of whom Mr Woodley was the only one who reached the summit, which was on the 5th of August. He and his guides suffered severely. M. Bourrit never attempted the ascent again. In 1791 four Englishmen made an unsuccessful attempt to reach the summit. On the 10th of August 1802 a native of Lausanne and a German, with seven guides, reached the summit. They remained on it twenty minutes, and then descended part of the way, performing the remainder and arriving at Chamouny on the 11th, having taken three days to accomplish it. On the 10th of September 1812 M. Rodalz of Hamburg got to the summit. On the 4th of August 1818 a Russian gentleman reached the summit. On 12th July 1819 Dr Van Ranselaer and Mr Howard, Americans, ascended the mountain and reached the summit; and on the 13th of August of the same year Captain Undrell, R. N. made a successful attempt. On the 19th August 1820 Dr Hamel, a Moscovite, with three gentlemen and twelve guides, ascended to the great plateau. In climbing from it up the side of Mont Blanc, an avalanche swept away the whole party. Some of them extricated themselves; but three guides were driven into a crevice and perished. On the 22d August 1822 Mr Clissold, who has published an account of his journey, reached the summit. On the 4th September 1823 Mr Jackson arrived on the summit and descended the same day to Chamouny, being, it is understood, the first who ever accomplished this arduous task in so short a time, having been absent only thirty-six hours and a half from Chamouny; but he remained on the summit only three or four minutes. On the 26th August 1825 Dr E. Clarke and Captain M. Sherwill made the ascent, employing three days in the expedition. On the 25th July 1827, M. C. Fellowes and M. H. Hawes gained the summit, having discovered a new route. Their journey occupied nearly three days. On the 9th of August the summit was attained by Mr Auldjo of Cambridge, who has published a highly interesting account of his journey. He says, "My ascent to the Grand Mulet was on the 8th, and thence to the summit on the following day, pursuing the route discovered in July. I remained on the summit one hour, and descended to Chamouni the same day, being absent thirty-seven hours." There have, therefore, been fourteen successful ascents, says Mr Auldjo; and, not including guides, eighteen persons have gained this great height. The majority of these are Englishmen, ten being their number. Of the rest, two are Americans, two Swiss, one Russian, one German, and one Savoyard. Some years ago a party of guides made the ascent for pleasure, and Maria de Mont Blanc, a high-spirited girl, accompanied them, being the only female who has ever reached the summit. Napoleon also ordered a party of guides to ascend, and plant a cross on the summit, which was done; but it was blown down in a day or two afterwards.

Among the more recent successful ascents, may be noticed that of Dr Martin Barry and his party in 1834, that of Mr Albert Smith and his companion in 1851, and that of Messrs Browne and Goodall in June 1852.

The most interesting accounts of the Alps are contained in the following works:—Saussure, *Voyages dans les Alpes*, 4 vols. 4to; 2. Ebel. *über den Bau der Erde in dem Alpin-Gebirge*, 2 vols. 1808; 3. Schultes, *Reisê durch Salzburg*, &c., 4 vols. 1804; 4. *Alpina*, 4 vols. 1806–9. Agassiz, *Etudes sur les Glaciers, et Recherches sur les Glaciers, I. II.* Forbes's *Travels in the Alps*. (R. J.)

ALPS, besides its proper signification, by which it denotes a certain chain of mountains which separate Italy from France and Germany, is frequently used as an appellative to denote any mountains of extraordinary height or extensive range. In this sense, Ausonius and others called the Pyrenean Mountains *Alps*, and Gellius the Spanish Alps, *Alpini Hispani*. Hence also we say, the *British Alps*, meaning the Grampians, &c., the *Asiatic Alps*, meaning the Altaic chain, &c.; the *American Alps*, meaning the Andes, &c.

*ALPS, HIGHER, Department of.* This department is bounded on the north by the department of Isere and Savoy, on the east by Piedmont, on the south by the department of the Lower Alps, and on the west by that of the Drome and part of that of Isere. The soil consists of enormous mountains and narrow valleys. Two-thirds of the surface are useless for agricultural purposes. The north wind, which generally prevails, renders the climate cold; and the snow remains in some of the valleys eight months of the year. The principal river is the Durance, which is extremely rapid, and commits great ravages by its inundations. The extent of this department is 2161 square miles. It is divided into three arrondissements, twenty-four cantons, and 189 communes, having in 1851 a population of 132,038. It returns two members to the chamber of deputies. Gap is the capital town of the department, with a population of 7726.

*ALPS, LOWER, Department of*, in France. This department is bounded on the north by the department of the Upper Alps, on the east by Piedmont, on the south by the department of the Var and the north-east extremity of that of the Bouches-du-Rhone, and on the west by the departments of Vaucluse and the Drome. It presents a succession of high rugged mountains, with vast forests and numerous low rich valleys. Its extent is equal to 2666½ square miles. It is divided into five arrondissements, thirty cantons, and 256 communes, having in 1851 a population of 152,070. The chief town is Digne, with 4119 inhabitants. This department returned two members to the chamber of deputies.

ALPTEGHIN, the founder of the Ghuznevite dynasty, and grandfather of the celebrated Mahmoud of Ghuzni. He was originally a slave in the service of Ahmed-ibn-Ismail, the second sultan of the race of Saman; and having obtained his liberty, rose gradually till he was made governor of Khorassan. He finally revolted, and made himself independent at Ghuzni. He died A.D. 775.

ALPUJARRAS, or ALPUXARAS, a mountainous district in the province of Granada, in the south of Spain, to which the Moors of the capital were banished after the destruction of their kingdom under Ferdinand and Isabella. It is a range parallel to the Sierra Nevada, but separated from it by the Rio Grande, which runs to the Mediterranean by Motril. Its slope there extends about 17 leagues in breadth from Almeria to Motril, and its highest ridge is about 13 from the sea. The mountains are composed of a clay-slate highly favourable to the culture of the vine, and produce the wine called Pedro-Ximenes, so highly prized in Spain. The declivity of this range is very rapid to the north, but on the south the descent towards the Mediterranean Sea is very gradual, and the inclined planes are highly prolific. The highest part of the range is the Sierra de Gador, which has an elevation of 6550 feet, and is covered with snow eight months of the year; but it is below the line of perpetual snow, which in that latitude is upwards of 9500 feet above the sea.

ALQUIERE, a measure used at Lisbon for dry goods, sixty of which equal a moye, or 23·03 English bushels.

ALREDUS, ALURED, or ALUREDUS, of Beverley, one of the most ancient English historians, was born at Beverley, in Yorkshire. He wrote in the reign of Henry I.; but no circumstance of his life is known with any degree of certainty. It is generally believed that he was educated at Cambridge, and that he afterwards became one of the canons and treasurer of St John's at Beverley; and we learn from a note of Bishop Tanner's, that for the sake of improvement he travelled through France and Italy, and at Rome became domestic chaplain to Cardinal Othoboni. He died in the year 1128 or 1129, leaving behind him the following works: —1. The Annals of Alured of Beverley, published at Oxford in 1716, by Mr Hearne, from a manuscript which belonged to Thomas Rawlinson, Esq. It contains an abridgment of our history from Brutus to Henry I., written in Latin, and with great accuracy, elegance, and perspicuity. 2. Libertates Ecclesiæ S. Johannis de Beverlac, &c., a manuscript in the Cottonian library. It is a collection of records relative to the church of Beverley, translated from the Saxon language.

ALRESFORD, a market-town in the middle division of the county of Hants, 7 miles from Winchester and 58 from London. It consists of two parishes, having been in past ages a place of more consideration than of late years, as the river Itchen, on the banks of which it is built, has long ceased to be navigable. Pop. in 1851, 2141.

ALSACE, before the Revolution, a province of France, bounded on the east by the Rhine, on the south by Switzerland, on the west by Lorraine, and on the north by the palatinate of the Rhine. It was formerly a part of Germany, but was given to France by the treaties of Munster and Ryswick. It is one of the most fruitful provinces in Europe, abounding in corn, wine, wood, flax, tobacco, pulse, fruits, &c. The mountains which divide it from Lorraine are very high, and generally covered with fir, beech, oak, and hornbeam. Those on the side of Switzerland are lower, and furnished with all sorts of wood, as well for fuel as for building. The country itself is diversified with rising hills and fertile vales, besides large forests; but that between the rivers Ill, Hart, and the Rhine, as far as Strasburg, is inferior to the rest, on account of the frequent overflowing of the Rhine. In High Alsace there are mines of silver, copper, and lead. There are iron works in several parts of Alsace, and particularly at Betford. At Sulzmatt, near Munster, in High Alsace, there is a mineral spring, which is in great reputation for the cure of palsy and gravel, and as a general tonic. The original inhabitants of Alsace are honest and good-natured, but wedded to their own manners and customs. The fruitfulness of their country renders them indolent and inactive; for the Swiss make their hay and reap their corn, as well as manage the vintage of High Alsace. The common language is the German, but the upper classes in the towns speak French; and even in the country they speak French well enough to be understood. By the late division of France, this province forms two departments, viz., those of the Upper and Lower Rhine; the capital of the former being Colmar, and that of the latter Strasburg.

ALSEN, an island of Denmark, situated in the Little Belt, between Sleswick and Funen, 100 miles west of Copenhagen. It extends in length six leagues, and about two in breadth. The soil is fertile, producing abundance of fruit and variety of grain, with large crops of anise, a carminative much used in seasoning food, and mixing with the bread, over all the Danish dominions. Long. 9. 55. E. Lat. 55. 12. N. Pop. 22,000. Sonderborg its capital has 3100.

ALSFELD, the capital of the bailiwick of the same name in Hesse Darmstadt. It stands on the river Schwalm, and has 3800 inhabitants, chiefly engaged in making coarse woollen cloth.

ALSHASH, the name of a province and of a very beautiful city in Bokhara, supposed to be the same with that which is now called Tashkend, the capital of the eastern part of Turkistan, possessed by the Kassats. It is situated on the river Sihon, now Sirr, and had a well-watered garden for every house; but was ruined by Jenghis Khan, who took the city, and caused a great number of its inhabitants to be massacred. Lat. 43. N.

ALSHEDA, a parish in the province of Jönköping, in Sweden, where a gold mine was discovered in 1738.

ALSIRAT, in the *Mahometan Theology*, a bridge laid over the middle of hell, finer than a hair, and sharper than the edge of a sword, over which people are to pass, after their trial on the day of judgment. To add to the difficulty of the passage, Mahomet affirms that the Alsirat is beset with briars and thorns; which, however, will be no impediment to the good, who shall fly over it like the wind; whereas the wicked shall soon miss their footing and tumble headlong into hell, which is gaping beneath to receive them.

ALSIUM, an ancient city on the coast of Etruria, about 25 miles north-west of Rome. It was much resorted to by the wealthy Romans, and Pompey had a villa here. Its site is now occupied by the modern village of Palo.

ALSOP, Anthony, an English divine and poet, was educated at Westminster School, and from thence elected to Christ Church, Oxford, where he took the degree of M.A. in March 1696, and of B.D. in December 1706. On his coming to the university, he was very soon distinguished by Dean Aldrich, and published *Fabularum Æsopicarum Delectus*, Oxon. 1698, 8vo, with a poetical dedication to Lord Viscount Scudamore, and a preface in which he took part against Dr Bentley in the famous dispute with Mr Boyle. His death, which happened on the 10th June 1726, was occasioned by his falling into a ditch that passed his garden door. A quarto volume was published in 1752, under the title of *Antonii Alsopi, Ædis Christi olim Alumni, Odarum libri duo*. Four English poems of his are in Dodsley's *Collection*, one in Pearche's, several in the early volumes of the *Gentleman's Magazine*, and some in *The Student*. Alsop is respectfully mentioned by the facetious Dr King as having enriched the commonwealth of learning by Translations of Fables from Greek, Hebrew, and Arabic; and not less detractingly by Bentley, under the name of "Tony Alsop, a late editor of the Æsopean Fables."

Alsop, *Vincent*, an English nonconformist divine, was born in Northamptonshire, and educated at St John's College, Cambridge, where he took the degree of master of arts. When he received deacon's orders, he went to Rutlandshire, and settled at Oakham, where he was an assistant to the master of the free school. He was settled at Wilby, in the county of Northampton, whence he was ejected in 1662 for nonconformity. After this he ventured to preach sometimes at Oakham, and at Wellingborough, where he lived, and was once six months in prison for praying by a sick person. After the revolution, Mr Alsop gave public testimonies of his attachment to government; yet upon all occasions he spoke very respectfully of King James, and retained a very high sense of his clemency in sparing his only son when attainted of treason. The remainder of his life he spent in the exercise of his ministry, preaching once every Lord's day; besides which he had a Thursday lecture, and was one of the lecturers at Pinners Hall. On grave subjects he wrote with a becoming seriousness; but where wit might properly be shown, he displayed it to great advantage. He lived to a great age, and, preserving his spirits to the last, died in May 1703.

ALSTAHAUG, a small town of Norway, in the island of Alster, and province of Nordland. It is the seat of the bishop of Nordland and Finmark.

ALSTED, Johann Heinrich, a German Protestant divine, and one of the most indefatigable and voluminous writers of the seventeenth century. He was some time professor of philosophy and divinity at Herborn, in the county of Nassau. From thence he went into Transylvania, to be professor at Weissenberg, where he continued till his death, in 1638. His *Encyclopædia*, the most considerable of the earlier works of that class, was long held in very high estimation. It was published in 1630, in two large folio volumes. His *Thesaurus Chronologicus* has gone through several editions. He also wrote *Triumphus Biblicus*, to show that the principles of all arts and sciences are to be found in the Scriptures. He was a Millenarian, and published, in 1627, a treatise *De Mille Annis*, in which he asserted that the reign of the saints on earth was to begin in 1694.

ALSTON, Charles, M.D., a botanical and medical writer, was born in the west of Scotland in the year 1683. He began his studies at the university of Glasgow; and on the death of his father, the Duchess of Hamilton, to whom he was related, took him under her patronage, and thus afforded him an opportunity of pursuing the bent of his inclination for the study of physic. About the age of 33, along with his friend and companion the celebrated Alexander Monro, he went to Leyden, and studied three years under Boerhaave. On their return to their native country, they, in conjunction with Rutherford, Sinclair, and Plummer, undertook departments in the college of Edinburgh, and by their abilities and industry laid the foundation of that school of physic. The branches of botany and materia medica were long the favourite studies of his life; consequently he undertook that department, and continued to lecture on them with increasing reputation until his death, which happened in November 1760, at the age of 77 years. His talents, which appear to have been naturally great, were improved and strengthened by his great assiduity and industry, and employed successfully in the service of science.

In the year 1753, his dissertation on the sexes of plants, in which he combats the doctrine of Linnæus, was published in the first volume of the *Edinburgh Physical and Literary Essays.* In the fifth volume of the *Edinburgh Medical Essays*, there is a short paper of his on the efficacy of the powder of tin to destroy or expel worms from the bowels. Dr Alston also engaged in a chemical controversy respecting quicklime with Dr Whytt. But the most valuable of all his works are his lectures on the *Materia Medica*, which were published in the year 1770, in two volumes 4to.

ALSTON-MOOR. See ALDSTON-MOOR.

ALT, in *Music*. See MUSIC.

ALT, or ALUT, a branch of the Danube, rising in Transylvania, east of the Carpathians, through which it descends, about 18 miles S.S.E. of Hermanstadt, and falls into the Danube, opposite to Nicopolis, after a course of about 250 miles.

ALTAI. This name has been erroneously extended by geographers to several chains of mountains stretching through the northern parts of Asia, and supposed to form an unbroken chain from the vicinity of the Aral Sea to that of Ochotsk: but in fact no such continuous chain exists; and the true Altai is a group of mountains, certainly of great magnitude, that form the southern boundary of the extensive plains of Siberia. This group extends through 2½ degrees of latitude between 50. and 52. 30. N., and through 21. of longitude, or about 700 geographical miles from west to east, from the junction of the small river Ouba with the Irtysh, near the rich mines of Schlangenberg, to mount Goubi, south of the Baikal. The name *Altai-Alen*, in the Mongolian, signifies "Golden mountains;" and in the curious Chinese geography of the last century, translated by Klaproth in 1831, these mountains are named *Kin-Tchan*, which has the same meaning in Chinese. No doubt they are so named, by both nations, from their remarkable auriferous deposits. The mountains east of the Baikal, which have been confounded with the Altai, are several independent systems of mountains, generally running south-west and north-east, nearly at right angles to the true Altai.

The eastern branch of the Altai is distinguished by the names Mountains of Sayane, Tangnou, and Malakha. The Russians confine the designation of Altai to that portion of the group which projects from the west end of the central chain, like an enormous promontory, into the vast plains of the province of Tomsk, and which contains the loftiest summits of the Altai group. This portion has been improperly divided by western geographers into Great and Little Altai, from an obscure passage in Aboulghassi's *General History of the Tartars*, published at Leyden in 1726. What are now considered as the true Altai by the Russian geographers, are named *Altai-Kolyvan*, the group passing northward between the rivers Irtysh and Jeniseï. It is divided into five parallel chains by deep valleys. The general appearance of these mountains is grand and imposing. They rise beyond the limit of perpetual snow, and some of these towering summits are alpine *needles*, or terminate in abrupt, truncated cones, soaring far above extensive fields of snow. The inaccessible snowy summit of Katunia towers to 12,900 feet; and the fine peak of Bieloukha rises to 10,900 feet above the ocean. Many of the peaks extending to the west of Bielay, and north of Katunia, have an elevation from 7500 to 8500 feet. A glacier, exactly similar to those of Switzerland, and terminated by large ancient *moraines*, descends from the south flank of Bieloukha (the white mountain) to the river Katunia. The next in altitude to Bieloukha are the peaks of Alailon and Irbislon, about 40 leagues farther east, near the sources of the Karugom river. The glaciers of the Altai seldom reach farther down than 8000 feet above the sea.

The basis of the Altai is granite, and other rocks usually denominated primary, which are mingled with diorite porphyries and greenstone. The unstratified rocks are covered by gneiss and mica slate; while the flanks of the mountains present graywacke slate, covered by secondary limestone rocks which the English geologists describe as belonging to the Silurian and Devonian systems.

The rarity of petrifactions in the limestone of the Altai is remarkable; but in one place Humboldt found encrinites in a compact sedimentary rock. He considers the limestone of the Altai in many places as belonging to the carboniferous strata. Mica slate is the principal rock, sometimes passing into chloride slate; granite is not so abundant, and gneiss is rather scarce. The porphyries and diorite often occur in beds. Rose found that the diorites are mixtures of amphibole and albite.

From the south and west slopes of the Altai Kolyvan, immense mineral wealth has been extracted, between the years 1736 and 1845. It was in this chain that in 1725 Niksten Demidof established his copper-works, which have given the name of *Kolyvanskoi* to the whole country; but the scarcity of fuel, and the demand for it since the discovery of the rich auriferous silver, have caused the removal of the copper furnaces to the confluence of the Barnaoulka and the Obi.

The Altai yields gold, silver, copper, and iron in great quantity. All, except the first, occur in the Devonian system of rocks, especially in the vicinity of veins of greenstone or beds of porphyritic rocks. The gold chiefly occurs in alluvial deposits near the plains. It is in the same deposit that the bones of the mammoth (*Elephas Primigenus*) and rhinoceros are found. The quantity of fossil elephant's tusks is so enormous, as to make *ivory mining* an important branch of industry in those countries. The diorite porphyries and granites of the Altai furnish materials for extensive manufactures of superb vases and other ornamental articles. The quantity of malachite found in the copper-mines afford the finest specimens of that beautiful material, and furnished those magnificent ornaments that formed such conspicuous objects in the Great London Exhibition of 1851. The Kolyvan branch of the Altai is better known to Europeans than the rest of the group: but it is believed that other parts of the chains would yield to explorers the same valuable products. (T. S. T.)

ALTAMURA, a city of the kingdom of Naples, in the province of Bari. It is the seat of a royal governor, and confers the title of prince on a noble family. It contains 16,500 inhabitants, a great part of whom are Greeks.

ALTAR, an artificial elevation for the purpose of offering sacrifices. The heathens at first made their altars only of turf; afterwards they were made of stone, of marble, of wood, and even of horn, as that of Apollo in Delos. Altars differed in figure as well as in materials: some were round, others square, and others triangular. All of them were turned towards the east, and stood lower than the statues of the gods; and they were generally adorned with sculpture, representing either the gods to whom they were erected, or their symbols. The height of altars also differed according to the different gods to whom they sacrificed. According to Servius, those altars set apart for the honour of the celestial gods, and gods of the higher class, were placed on some pretty tall pile of building, and for that reason were called *altaria*, from the words *alta* and *ara*, a high elevated altar. Those appointed for the terrestrial gods were laid on the surface of the earth, and called *aræ*. And, on the contrary, they dug into the earth, and opened a pit for those of the infernal gods, which they called βοθροι, λακκοι, *scrobiculi*. But this distinction is not everywhere observed: the best authors frequently use *ara* as a general word, under

Altar. which are included the altars of the celestial and infernal, as well as those of the terrestrial gods. The Greeks also distinguished two sorts of altars: that whereon they sacrificed to the gods was called βωμος, and was a real altar, different from the other whereon they sacrificed to the heroes, which was smaller, and called εσχαρα. Pollux makes this distinction of altars in his *Onomasticon:* he adds, however, that some poets used the word εσχαρα for the altar whereon sacrifice was offered to the gods. The Septuagint version does sometimes also use the word εσχαρα for a sort of little low altar, which may be expressed in Latin by *craticula*, being a hearth rather than an altar.

Before temples were in use, altars were erected sometimes in groves, sometimes in the highways, and sometimes on the tops of mountains; and it was a custom to engrave upon them the name, ensign, or character of the deity to whom they were consecrated.

In the great temples of ancient Rome, there were generally three altars. The first was placed in the sanctuary, at the foot of the statue of the divinity, upon which incense was burnt and libations offered; the second was before the gate of the temple, and upon it they sacrificed the victims; the third was a portable altar or table, upon which were placed the offering and the sacred vessels. Besides these uses of altars, the ancients swore upon them, and swore by them, in making alliances, confirming treaties of peace, and on other solemn occasions. Altars also served as places of refuge for all those who fled to them.

The first altar we read of in the Bible was that erected by Noah on leaving the ark. According to a Rabbinical legend, it was partly formed from the remains of one built by Adam on his expulsion from Paradise, and afterwards used by Cain and Abel, on the identical spot where Abraham prepared to offer up Isaac (Zohar, *In Gen.* fol. 51, 3, 4; Targum, Jonathan, Gen. viii. 20). After the giving of the law, the Israelites were commanded to make an altar of earth: they were also permitted to employ stones, but no iron tool was to be applied to them. This has been generally understood as an interdiction of sculpture, in order to guard against a violation of the second commandment. Altars were frequently built on high places (βωμοί); the word being used not only for the elevated spots, but for the sacrificial structures upon them. They were sometimes built on the roofs of houses: in 2 Kings xxiii. 12, we read of the altars that were on the top of the upper chamber of Ahaz. In the tabernacle, and afterwards in the temple, two altars were erected, one for sacrifices, the other for incense: the table for the shew-bread is also sometimes called an altar.

The altar of burnt-offering belonging to the tabernacle was a hollow square, 5 cubits in length and breadth, and 3 cubits in height: it was made of shittim-wood, and overlaid with plates of brass. In the middle there was a ledge or projection, *deambulacrum*, on which the priest stood while officiating: immediately below this, a brass grating was let down into the altar to support the fire, with four rings attached, through which poles were passed when the altar was removed. As the priests were forbidden to go up by steps to the altar (Exod. xx. 26), a slope of earth was probably made rising to a level with the *deambulacrum*. According to the Jewish tradition this was on the south side: on the east was 'the place of the ashes' (Lev. i. 16): and the laver of brass was probably near the western side, so that only the north and south sides were left.

The altar of burnt-offering in Solomon's temple was of much larger dimensions, "twenty cubits in length and breadth, and ten in height" (2 Chron. iv. 1), and was made entirely of brass.

Of the altar of burnt-offering in the second temple, the canonical Scriptures give us no information excepting that it was erected before the foundation of the temple was laid (Ezra iii. 3, 6) on the same place where it had formerly been built, (Joseph. *Antiq.* xi. 4, 1). From the Apocrypha, however, we may infer that it was made, not of brass, but of unhewn stone, for it is said, "They took whole stones (λίθους ὁλοκλήρους), according to the law, and built a new altar according to the former" (1 Macc. iv. 47). Altar.

The altar of burnt-offering erected by Herod is thus described by Josephus (*De Bell. Jud.* v. 5, 6): "Before this temple stood the altar, 15 cubits high, and equal both in length and breadth, each of which dimensions was 50 cubits. The figure it was built in was a square; it had corners like horns, and the passage up to it was by an insensible acclivity from the south. It was formed without any iron tool, nor did any iron tool so much as touch it at any time." A pipe was connected with the south-west horn, through which the blood of the victims was discharged by a subterraneous passage into the brook Kedron. Under the altar was a cavity to receive the drink-offerings, which was covered with a marble slab, and cleansed from time to time. On the north side of the altar several iron rings were fixed to fasten the victims. Lastly, a red line was drawn round the middle of the altar to distinguish between the blood that was to be sprinkled above and below it.

The second altar belonging to the Jewish worship was *the altar of incense*, called also the golden altar (Numb. iv. 11). It was placed between the table of shew-bread and the golden candlestick, in the most holy place.

This altar in the tabernacle was made of shittim-wood overlaid with gold plates, 1 cubit in length and breadth, and 2 cubits in height. It had horns of the same materials; and round the flat surface was a border of wrought gold, underneath which were the rings to receive "the staves made of shittim-wood, overlaid with gold to bear it withal," Exod. xxx. 1–5 Joseph. *Antiq.* iii. 6, 8.

The altar in Solomon's temple was similar, but made of cedar, overlaid with gold.

The altar in the second temple was taken away by Antiochus Epiphanes (1 Macc. i. 23), and restored by Judas Maccabæus (1 Macc. iv. 49). On the arch of Titus there appears no altar of incense; it is not mentioned in Heb. ix., nor by Joseph. *Antiq.* xiv. 4, 4. (*vide* Tholuck *On the Hebrews*, vol. ii. p. 8; *Biblical Cabinet*, vol. xxxix.) (Winer's *Realwörterbuch*, articles 'Altar,' 'Brandopfer altar,' 'Raucheraltar;' Bähr's *Symbolik des Mosaischen Cultus*, bd. 1. Heidelberg, 1837.)

The altar or table of shew-bread, which stood in the outer apartment of the tabernacle, was made of shittim-wood, covered with laminæ of gold, and was 2 cubits long, 1 broad, and 1½ high. The top of its leaf was surrounded by a rim of gold; the frame, immediately below the leaf, was surrounded by a piece of wood about 4 inches broad, around which was a similar border of gold; and lower down, attached to the legs, were four golden rings for the staves covered with gold by which it was carried. These rings were not found in the table afterwards made for the temple, nor in any of the sacred furniture where they had previously been, except in the ark of the covenant. Upon this table were placed twelve unleavened loaves (in allusion to the twelve tribes), which were changed every Sabbath-day, and sprinkled with frankincense (the *Sept.* adds salt). The bread was called the "bread of the presence," because it was set forth before Jehovah in his holy place. Wine was also placed before the table, in bowls, covered vessels, and cups, which were probably used in making libations. (Exod. xxv. xxxvii. xl., Lev. xxiv., Numb. iv.)

*Forms of Altars.*—The direction to the Israelites, at the time of their leaving Egypt, to construct their altars of unhewn stones or of earth, is doubtless to be understood as an injunction to follow the usage of their patriarchal ancestors; and not to adopt the customs which they had seen in Egypt, or might see in the land of Canaan. That the patriarchal altars were of unhewn stones or of earth, is confirmed by the circumstances under which they were erected, and by the fact that they are always described as being "built."

It may be observed that all the Oriental altars are square or oblong, whereas those of Greece and Rome are more usually round; and that, upon the whole, the Hebrew altars were in accordance with the general Oriental type. It has been supposed that some of those ancient monuments of unhewn stone usually called Druidical remains, were derived from the altars of primitive times: but the ablest archæologists are of opinion that these structures were seldom, if ever, used as altars, but were merely depositories of the dead; an opinion which is strengthened by the fact that human remains are usually found on excavating below them.—See Worsaäe's *Scandinavian Antiquities.*

Altar is also used among Christians for the communion-table. In the primitive church the altars were only of wood, it being frequently necessary to remove them from place to place; but the council of Paris in 509 decreed that no altar should be built but of stone. At first there was but one altar in each church, but the number soon increased; and from the writings of Gregory the Great, who lived in the sixth century, we learn that there were sometimes in the same church twelve or thirteen. In the cathedral of Magdeburg there are no less than forty-nine altars.

The altar is sometimes sustained on a single column, as in the subterraneous chapels of St Cecilia at Rome, &c.; and sometimes on four columns, as the altar of St Sebastian of Crypta Arenaria; but the customary form is a massive frame of stone-work sustaining the altar-table. These altars bear a resemblance to tombs: consequently we read in ecclesiastical history that the primitive Christians chiefly held their meetings at the tombs of the martyrs, and celebrated the mysteries of religion upon them; for which reason it is a standing rule to this day in the church of Rome, never to build an altar without inclosing the relics of some saint in it.

ALTAR-THANE, or Altarist, in old law-books, an appellation given to the priest or parson of a parish, to whom the profits arising from the altar or altarage belonged.

ALTDAMM, or Damm, a fortified city in the circle of Randow, government of Stettin, and Prussian province of Pomerania. It is built in a strong situation at the point where the river Plone discharges its waters into the Lake Damische; and contains 235 houses and 3000 inhabitants. Long. 14. 58. 47. E. Lat. 53. 24. N.

ALTDORF, a town of Bavaria on the Schwartzach, capital of the bailiwick of the same name, and about twelve miles E.S.E. of Nuremburg. It was formerly the seat of a university, now incorporated with that of Erlangen. It has several breweries and toy manufactories; and in its neighbourhood are coal-mines and charcoal works. Pop. 3000. Long. 11. 27. 13. E. Lat. 49. 23. 22. N.

Altdorf, a town on the Schmeidebach, in the bailiwick of Ettenheim, and circle of Upper Rhine, in the duchy of Baden. It has 1300 inhabitants, and a palace belonging to the family of Von Turkheim, with a good library and a botanical garden.

Altdorf, or *Altorf*, a town of Switzerland, capital of the canton of Uri, situated near the southern extremity of the lake of Lucerne, and at the northern end of the pass over Mount St Gothard. It has a handsome parish church, a town-house, two convents, and an old tower, which tradition marks as the place where Tell shot the apple from his son's head. Pop. 1800. Long. 8. 30. E. Lat. 46. 50. N.

ALTDORFER, Albert, a Bavarian painter and engraver, was born in 1488, and died in 1538. His few pictures show surprisingly minute and careful finish, in the ancient German manner, as is seen in his picture of the battle of Arbela, in the museum of Munich. His wood engravings are considered next in execution to those of Dürer, and his copperplates are well known, and very numerous.—See Bartsch. *Peintres-graveur.*

ALTEA, a town of Spain, on the bay of the same name, in the province of Alicante. It contains 5502 inhabitants, principally sailors and fishermen.

ALTELAND, a district in the province of Bremen, in the kingdom of Hanover, denominated a royal justiceship, *königliche Gerichte.* It is situated on the banks of the Elbe, and is divided into three portions by the small rivers Schwinge, Este, and Luhe, which cross it. The extent is 79 square miles, or 50,560 acres. The soil is peculiarly fertile. The inhabitants amount to 15,000, mostly living on separate farms, in prosperous circumstances. As a part of the ancient duchy of Bremen, the district possesses some peculiar privileges.

ALTENA. See Altona.

Altena, a circle in the government of Arnsberg and Prussian province of Westphalia. Its extent is 193 geographical square miles. The chief rivers are the Lenne, which receives the waters of the Nette and the Erse, and the Wipper, both of which run to the Rhine. The agriculture is bad, and in many parts can scarcely produce oats. It has some pasture land, and, besides, yields wood, game, iron, marble, and good stones for building. Its population, which amounts to 43,054, depends almost wholly on the several manufactures which are spread over the whole circle. These comprehend almost every species of iron goods, which, though clumsy in form, are very substantial, and find a ready sale.

Altena, a city, the chief of the circle of the same name, in Prussia. It contains 689 houses, and 4889 inhabitants, who trade in the several kinds of goods made in the vicinity. It is situated on the Lenne. Long. 7. 41. 23. E. Lat. 51. 15. 36. N.

ALTENBERG, a city, capital of the bailiwick of the same name in the circle of Dresden in Saxony. It contains 2042 inhabitants, who depend on the mines, the transit traffic with Bohemia, and the manufacture of bone lace.

ALTENBRUCH, a market-town on the Werne, in the district of Hadeln, in the kingdom of Hanover. It contains 378 houses and 2500 inhabitants; and has a small harbour, by means of which it carries on trade in corn, fruit, and cattle. It is in Long. 8. 51. 3. E. and Lat. 53. 50. 5. N.

ALTENBURG. See Saxe-Altenburg.

Altenburg, the chief town of the duchy of Saxe-Altenburg, near the river Pleisse, and about twenty-four miles south of Leipsic, with which it has been connected by railway since the end of 1842. The town, from its hilly position, is irregularly built, but its streets are wide, and ornamented with many large and beautiful buildings. Its ducal castle is a very ancient building, surrounded by picturesque scenery, with a beautiful garden, and an extensive library. Of its public buildings the most remarkable are the cathedral, and St Bartholomew's church, with its two steeples. It has several other churches, a gymnasium with a considerable library, a theatre, an infirmary, an obstetric institution, and several elementary schools and charitable institutions. The trade in grain is very considerable, as well as in cattle and in silk; and sealing wax, tobacco, woollen goods, and gloves, are among its manufactures. Pop. 15,300.

Altenburg, or Owar, a small but strong town of Hungary, with 3500 inhabitants. It is seated in a marsh, near the river Danube, and is surrounded by deep ditches. It is forty miles south-east of Vienna. Long. 17. 15. E. Lat. 47. 50. N.

Altenburg is also the name of several small towns and villages in Austria, Bavaria, Switzerland, &c.

ALTENKIRCHEN, a circle in the government of Coblentz, and the Prussian province of the Lower Rhine. Its extent is 208 square miles, or 133,120 acres. It contains two market-towns, 155 villages, and 37,857 inhabitants, of whom 18,114 are Roman Catholics, and 19,548 Lutherans. The Jews amount to 195. The whole of the circle is on the Westerwalde, and from its lofty position the soil is unproductive. Its mines of iron, lead, and copper, give the chief employment to the people, who are an industrious race; and the females spin much linen yarn. The circle is watered by the rivers Sieg, Niester, and Wiedbach, the banks of which afford pasturage to cattle. The whole district suffered severely from being the seat of war in 1796.

ALTERANTS, or *Alterative Medicines*, such as correct the bad qualities of the blood, and other humours, without occasioning any sensible evacuation.

ALTERN-BASE, in *Trigonometry*, a term used in contradistinction to the true base. Thus, in oblique triangles, the true base is either the sum of the sides, and then the *difference* of the sides is called the *altern-base*; or the true base is the difference of the sides, and the *sum* of the sides is called the *altern-base*.

ALTERNATE, in *Heraldry*, is said in respect of the situation of the quarters. Thus, the first and fourth quarters, and the second and third, are usually of the same nature, and are called *alternate quarters*.

ALTERNATION, in its primary sense, denotes a succession by turns.

Alternation is sometimes used to express the different changes or alterations of orders in any number of things proposed. This is also called *permutation*, &c., and is easily found by a continual multiplication of all the numbers, beginning at unity. Thus, if it be required to know how many changes or alternations can be rung on six bells, multiply the numbers 1, 2, 3, 4, 5, 6, continually into one another, and the last product gives the number of changes.

ALTERNATIVE is particularly used for the choice of two things proposed. In this sense we say, to take the *alternative* of two propositions.

ALTHEA, a genus of the natural order of Malvaceæ, of which the *A. officinalis*, or marsh mallow, and *A. rosea*, or hollyhock, are the best known.

ALTIN, a money of account in Muscovy, worth three *copecs*, 100 of which make a ruble, worth about 3s. 2½d. sterling.

Altin, a lake of Siberia, in the government of Tomsk, from whence issues the river Ob or Obi, in Long. 85. 55. E. Lat. 52. 0. N. This lake is called by the Russians *Teloskoi Osero*, from the Telessi, a Tartar nation who inhabit its borders, and who give it the name of *Altin-Kul*. By the Calmucks it is called *Altinnor*. It is 77 miles long and 52 broad, with a rocky bottom. The north part of it is sometimes frozen so hard as to be passable on foot, but the southern part is never covered with ice. The water in the Altin lake, as well as in the rivers which run through the adjacent places, only rises in the middle of summer, when the snows on the mountains are melted by the heat of the sun.

ALTING, Heinrich, a German divine, was born at Embden in 1583. His father was minister of the church of Embden, and early destined his son to the same profession. In the year 1602, after a grammatical course, he was sent to the university of Herborn. There he studied with so much assiduity and success, that he had the honour of being appointed tutor to the three young counts of Nassau, Solms, and Isenburg, who studied with the elector prince palatine, first at Sedan, and afterwards at Heidelberg. Alting was appointed preceptor to the prince in 1608, and was chosen to accompany the elector into England. There, among the number of celebrated men to whose acquaintance he was introduced, was Dr Abbot, archbishop of Canterbury. In 1613, returning to Heidelberg after the marriage of the elector with the princess of England, he was appointed professor of theology, and in 1616, director of the College of Wisdom. In 1618, along with Scultetus, he represented the university in the Synod of Dort.

In 1622 Count Tilly took the city of Heidelberg, and devoted it to plunder. In order to escape the fury of the soldiers, Alting endeavoured to pass by a back door into the chancellor's house, which was under guard; but as he was entering, the commanding officer said to him,—"With this battle-axe I have to-day killed ten men, and Alting, if I knew where to find him, should be the eleventh: who are you?" Alting, with singular presence of mind replied—"I am a teacher in the College of Wisdom." The officer took him under his protection; but the Jesuits unfortunately taking possession of the house next day, left the generous officer no time, at his departure, to take care of the teacher in the College of Wisdom. Alting evaded the hands of the Jesuits by hiding himself in a garret; and a cook of the electoral court, who happened to be employed by Count Tilly in the kitchen occupied by him in the chancellor's house, supplied him with food. In this perilous situation he remained till an opportunity offered of making his escape to Heilbron, whither his family had been previously conducted.

But Alting was now as much harassed by ecclesiastical intolerance as he had formerly been endangered by military hostility. With the permission of the duke of Wirtemberg, he retired for a few months to Schorndorf, after the desolation of the palatinate by the victorious forces of Count Tilly.

In 1623 Alting retired with his family to Embden, and afterwards followed to the Hague his late pupil, now king of Bohemia. Such was the unfeigned esteem of this prince for Alting that he still retained him as preceptor to his eldest son, and prevented him from accepting the charge of the church at Embden, and likewise of a professorship in the university of Franeker. In 1627, Alting, with some difficulty, obtained leave from his patron to remove to Groningen, where he was appointed to the chair of divinity; and there he continued to lecture with increasing reputation until his death, which took place in 1644. The ardent desire and repeated endeavours of several universities to appropriate to themselves the honour and benefit of his services, is the most unequivocal proof of the general esteem in which his character was held.

The states of Groningen refused to give their consent to his removal, when the university of Leyden solicited him to come and labour among them. But some time after, the prospect of extensive usefulness in re-establishing the university of Heidelberg, and restoring the churches of the palatinate, determined him to accept the office of professor of divinity and ecclesiastical senator, presented to him by Prince Lewis Philip. In the year 1634, amidst numerous hardships, to which the existing war exposed him, he set out for Heidelberg, and pursued his journey as far as Frankfort; when the battle of Norlingen, in which the imperialists were victorious, rendered his further progress impracticable. He therefore with great difficulty returned to Groningen.

Alting was a man of eminent talents, extensive learning, and amiable dispositions, and always more solicitous to serve the public than to benefit himself. He was averse to quarrels and disputes about trifles, although no friend to the innovations introduced at this period by the Socinians; and, adhering to what he considered the plain doctrine of Scripture, he was equally desirous to avoid fanatical scrupulosity and sophistical subtilty. The productions of his pen are, *Notæ in Decadem Problematum Jacobi Behm*, Heidelbergæ, 1618, Notes on a Decade of Jacob Boehmen's Problems; *Loci Communes*, Common Places; *Problemata*, Problems; *Explicatio Catecheseos Palatinæ*, Explanation of the Palatine Catechism; *Exegesis Augustanæ Confessionis*, &c., Amst. 1647, Exposition of the Augsburg Confession; *Methodus Theologiæ Didacticæ et Catecheticæ*, Amst. 1650, A Method of Didactic and Catechetic Theology. The *Medulla Historiæ Profanæ*, Marrow of Profane History, published under the name of Paræus, was written by Alting.

Alting, *Jacob*, son of the preceding, was born at Heidelberg, in 1618. After the usual course of grammatical studies he became a student, and soon after professor of divinity in the university of Groningen. The oriental languages were his favourite studies, and in 1638 he put himself under the tuition of a Jewish rabbi at Embden. Determining to take up his residence in England, he arrived there in 1640, and was admitted to clerical orders by Dr Prideaux, bishop of Worcester. By an offer of the Hebrew professorship in the university of Groningen, he was soon induced to alter his plan of life, and consequently returned to Germany in 1643. His active assiduity in the study of the languages, and his knowledge in other sciences, procured him universal esteem and great reputation as a scholar. About this time he received many academic honours; he was admitted doctor of philosophy, academic preacher, and at last professor of divinity in conjunction with a colleague, Samuel des Marets, with whom, as being an admirer and follower of the subtleties of the scholastics, Alting had a long and painful controversy, which was only terminated by a formal reconciliation when Marets was on his deathbed.

By the permission of the curators of the university, Des Marets appeared as public accuser of Alting, and produced a long list of erroneous propositions to the divines of Leyden, for their opinion. The divines pronounced Alting innocent of heresy, but imprudently fond of innovation; and they declared Des Marets deficient in modesty and candour. Such was the protection given to Alting, that whenever any of the order of ecclesiastics proposed any further measures against him, they were immediately rejected by the civil power.

Alting died of a fever in 1679. The fondness which he showed for rabbinical learning, gave birth to the general report that he was inclined to become a Jew. His opinions, which seem to have excited more general attention than they deserve, may be seen at large in his writings, which were collected a few years after his death, and published in five volumes folio, by his pupil, the well-known Balthasar Bekker.

ALTING, *Menso*, the elder, father of Heinrich Alting, a distinguished divine of the Reformed Church, was born in 1541, and died in 1612. He was president of the Consistory of the Calvinist church at Embden, and took a prominent part in the controversy with the Lutheran party. His grandson, of the same name, was a burgomaster of Groningen, and wrote a valuable geographical work entitled *Notitia Germaniæ Inferioris*, &c. He was born in 1636, and died in 1713.

ALTINUM, an ancient town of Venetia on the right bank of the Silis. Its site is occupied by the modern village of Altino.

ALTITUDE, *Accessible* and *Inaccessible*. See GEOMETRY.

*ALTITUDE of the Eye*, in *Perspective*, is a right line let fall from the eye, perpendicular to the geometrical plane.

ALTITUDE, in *Astronomy*, is the distance of a star or other point in the mundane sphere from the horizon. This altitude may be either *true* or *apparent*. If it be taken from the rational or real horizon, the altitude is said to be true or real; if from the apparent or sensible horizon, the altitude is apparent, or rather, the apparent altitude is such as it appears to our observation, and the true is that from which the refraction has been subtracted.

The true altitudes of the sun, fixed stars, and planets, differ but very little from their apparent altitudes, because of their great distance from the centre of the earth, and the smallness of the earth's semidiameter when compared therewith. But the difference between the true and apparent altitude of the moon is about 52°.

*ALTITUDE Instrument*, or *Equal Altitude Instrument*, is that used to observe a celestial object when it has the same altitude on the east and west sides of the meridian.

ALTKIRCH, an arrondissement in the department of the Upper Rhine, in France. The extent is 446 square miles, or 285,440 acres, and it contains seven cantons and 158 communes, with 149,874 inhabitants, in 1851. The chief city of the arrondissement is of the same name, and is situated on a hill whose base is washed by the river Ill, about two leagues from Mulhausen. It has 3371 inhabitants. Long. 7. 11. E. Lat. 47. 37. N.

ALTMUHL, a river of Bavaria which rises seven miles north-east of Rothenburg, and flows into the Danube between Ratisbon and Kehlheim, after a course of 150 miles. This river has lately been connected with the Regnitz by the Ludwigo Canal, by which means the rivers Rhine and Danube are now united.

ALTO *BASSO*, or *in ALTO et in BASSO*, in *Law*, signifies the absolute reference of all differences, small and great, high and low, to some arbitrator or disinterested person. The following are examples of the use of the phrase:—*Pateat universis per præsentes, quod Willielmus Tylar de Yetton, et Thomas Gower de Almestre, posuerunt se in* Alto *et in* Basso, *in arbitrio quatuor hominum;* viz., *de quadam querela pendente inter eos in curia. Nos et terram nostram* altè *et* bassè *ipsius domini Regis supposuimus voluntati.*

ALTO-FAGGOTTO, a wind instrument of music, resembling in form a small bassoon. It is played with a reed and mouthpiece similar to a clarinet, and produces a very fine tone.

*ALTO Relievo.* See RELIEVO and SCULPTURE.

*ALTO Ripieno.* See MUSIC.

ALTOMONTE, a very handsome town of Italy, in the kingdom of Naples, in Calabria Citerior, 15 miles north-west of Bisignano. Long. 16. 22. E. Lat. 39. 40. N.

ALTON, a market-town in the hundred of the same name in the county of Hants, 47 miles from London, and 16 from Winchester. It stands on the river Wey, and is a well-built place. Pop. in 1851, 2828.

ALTON, or ALVETON, a village in Staffordshire, five miles north of Uttoxeter. Here may be seen the ruins of a castle which is supposed by some to have been built before the Norman conquest; but Dr Plot is of opinion that it was erected by Theobald de Verdun in the beginning of the reign of Edward II.

ALTONA, or ALTENA, a city in the duchy of Holstein, a part of Germany, but included within the dominions of Denmark. It is situated on the banks of the Elbe, and only separated from Hamburg by a ditch between the suburbs of the two cities. It is on an ascent, very gradually rising from the water's edge, with streets well-built, overlooking each other. In 1847 it contained 32,200 inhabitants, of whom 2300 were Jews, who are here allowed the free exercise of their religion, and have two synagogues and a high rabbi. Altona is a free port, and carries on a very extensive shipping trade, and also engages in the herring and whale fisheries. The number of vessels that entered the harbour in 1845 was 5253. The ship-building is considerable, and there are manufactures of woollen, cotton, silk, tobacco, leather and glass; besides breweries, distilleries, and sugar-refineries. The town is well built, and contains a royal observatory, a town-house, six churches, an anatomical theatre, a gymnasium, a public library, and an orphan asylum, &c. Altona was raised from the insignificance of a fishing village on passing into the possession of the Danes in 1640, who erected it into a city in 1664. It was burnt to the ground in 1713 by the Swedes under General Stenbock. It is in Long. 9. 57. 15. E. and Lat. 53. 43. 30. N.

ALTORF. See ALTDORF.

ALTRANSTADT, a town in Saxony, famous for the treaty between Charles XII. king of Sweden and Augustus elector of Saxony, in 1706, wherein the latter resigned the kingdom of Poland.

ALTRINGHAM, or ALTRINCHAM, a township and market-town in the county of Chester, 180 miles from London. It is a neat and clean place. Its manufactures are chiefly cotton and worsted. There are many gardens in its neighbourhood which supply Manchester with vegetables. The Duke of Bridgewater's canal passes the town, and it is connected with Manchester by railway. Pop. in 1851, 4488.

ALTSOL, or ZWOLEN, an imperial free city on the Gran, where that river falls into the Zalathna, in the lower circle of the palatinate of Solor in Hungary. It has one church, and a castle that belonged to Prince Esterhazy. Pop. 2400. Long. 19. 12. 47. E. Lat. 48. 21. 50. N.

ALTSTRELITZ, or OLD STRELITZ, a town in the duchy of Mecklenburg-Strelitz in Germany. It has an old castle, several tanneries, and tobacco manufactories, and a great horse market. Population 3800, of whom about 600 are Jews. This town was founded about the year 1349, and is two miles to the south of New Strelitz.

ALUCEMAS, SAN AGUSTIN Y SAN CARLOS DE LAS, a small rocky island, with a garrison and criminal establishment, belonging to Spain, on the coast of Africa, between Capes Morro and Quilates in Marocco. Long. 4. 12. W. Lat. 35. 16. 30. N. It contains 28 houses, including the governor's residence, an hospital, and a church. It is supplied with the necessary articles of consumption from the neighbouring coast of Ceuta.

ALUDELS, in the older and more complicated chemical apparatus, were earthen pots without bottoms, inserted into each other, and used in sublimations.

ALUM, a compound salt employed by dyers and other artists in their different processes. It is soluble in water, has an astringent, acid, and sweetish taste; reddens vegetable blues, and crystallizes in regular octahedrons. When heated, it liquefies; and if the heat be continued, the water of crystallization is driven off, the salt frothes and swells, and at last a white matter remains, known by the name of *burnt alum.*

Its constituents are sulphuric acid, alumina, an alkali, and water. The alkali may be either *potash*, *soda*, or *ammonia.* Hence there are three distinct species of alum, depending upon the nature of the alkali which each contains. *Potash alum* (in which the alkali is potash) is the common alum of this country. In France both potash and ammoniacal alum are manufactured; while soda alum is met with native in different states, and probably in considerable quantity, in South America; for it is curious that, on that continent, soda almost uniformly replaces potash. Instead of nitrate of potash, which occurs in the old continent, there are great deposites of nitrate of soda in South America. It is likely that albite will be found replacing felspar in the granite of South America.

The progress made by chemists in the discovery of the constitution of alum was very slow. The species first investigated was potash alum. That it contained sulphuric acid as a constituent, was known even to the alchemists. Pott and Margraaf demonstrated that alumina was another constituent. Mr Pott, in his *Lithogeognosia*, showed that the earth of alum, or the precipitate obtained when an alkali is poured into a solution of alum, is quite different from lime and chalk, with which it had been confounded by Stahl. Margraaf went much farther. He not only showed that alumina is one of the constituents of alum, but that this earth possesses peculiar properties, is different from every other substance, and is one of the ingredients in common clay. (*Expériences faites sur la Terre a'Alun:* Margraaf's *Opusc.* ii. 111.) Margraaf showed likewise, by many experiments, that crystals of alum cannot be obtained by dissolving alumina in sulphuric acid, and evaporating the solutions. The crystals formed are always soft, and quite different in their appearance from alum crystals. But when a solution of potash or ammonia is dropt into this liquid, it immediately deposits perfect crystals of alum. (*Sur la Régénération de l'Alun:* Margraaf's *Opusc.* ii. 86.) He mentions likewise, that manufacturers of alum in general were unable to procure the salt without a similar addition, and that at first it had been customary to add a quantity of putrid urine, and that afterwards a solution of carbonate of potash was substituted in its place. But subsequent chemists do not seem to have paid much attention to these important observations of Margraaf: they still continued, without any rigid examination, to consider alum as a sulphate of alumina.

Bergman indeed had observed, that the addition of potash or ammonia made the alum crystallize, but that the same effect was not produced by the addition of soda or of lime. (*De Confectione Aluminis:* Bergman's *Opusc.* i. 225.) He had observed likewise, that sulphate of potash is frequently found in alum. He decomposed the solution of alum by means of ammonia, evaporated the filtered liquid to dryness, and exposed the residue to a red heat. A quantity of sulphate of potash often remained behind in the crucible. (*Ibid.* p. 326.) From these facts he drew the conclusion that sulphate of potash readily combines with sulphate of alumina. Yet it is obvious, from the whole of his dissertation, that he had no conception that alum is a double salt. He ascribed the difficulty of crystallization to the excess of sulphuric acid present. He thought that the only use of the potash was to saturate this excess; and advises manufacturers to substitute clay instead of potash, as a method which would not only saturate the excess of acid, but increase the quantity of alum. This very bad advice was not, we presume, followed by any alum-makers. If they had tried it, they would soon have been convinced of its injurious consequences. Instead of alum, they would have obtained an insoluble, tasteless powder, well known by the name of *alum saturated with its earth.*

After Klaproth had discovered the existence of potash as an ingredient in *leucite* and *lepidolite*, it occurred to Vauquelin, that it was probably an ingredient likewise in many other minerals. He recollected that alum crystals often make their appearance during the analysis of stony bodies; and, considering that alum cannot be obtained in crystals without the addition of potash, he began to suspect that this alkali constituted an essential ingredient in the salt. A set of experiments, undertaken on purpose to elucidate this important point, soon satisfied him that his conjecture was well founded. Accordingly, in the year 1797 he published a dissertation, demonstrating that alum is a double salt, composed of sulphuric acid, alumina, and potash. (*Annales de Chimie*, xxii. 258.) Soon after, Chaptal published the analysis of four different kinds of alum, namely, Roman alum, Levant alum, British alum, and alum manufactured by himself. This analysis led to the same result as that of Vauquelin. (*Ann. de Chim.* xxii. 280.)

Since that time alum has been admitted by chemists to be a triple salt; and various analyses of it have been made to determine its constituents. Vauquelin (*Ann. de Chim.* l. 167), Thenard and Roard (*ibid.* tom. lix. 72), Curaudau (*Journal de Physique*, lxvii. 1), and Berzelius (*Ann. de Chim.* lxxxii. 258), successively published the results of their experiments. These analyses gradually led to an accurate knowledge of the composition of this salt. The atomic weights of the constituents of alum are as follows:—

| | |
|---|---|
| Sulphuric acid | 5 |
| Alumina | 2·25 |
| Potash | 6 |
| Soda | 4 |
| Ammonia | 2·125 |
| Water | 1·125 |

Potash alum is a compound of

| | |
|---|---|
| 4 atoms sulphuric acid | = 20 |
| 1 atom potash | = 6 |
| 3 atoms alumina | = 6·75 |
| 25 atoms water | = 28·125 |
| Hence the integrant particle of it weighs | 60·875 |

Every atom of the sulphuric acid is combined with an atom of base; so that potash alum is a compound of sulphate of potash and sulphate of alumina, in the proportion of one atom of the former salt to three atoms of the latter. We may therefore state the constituents of potash alum as follows:—

| | |
|---|---|
| 3 atoms sulphate of alumina | = 21·75 |
| 1 atom sulphate of potash | = 11 |
| 25 atoms water | = 28·125 |
| | 60·875 |

Soda alum differs from potash alum in containing sulphate of soda instead of sulphate of potash. Its constituents are as follows:—

| | |
|---|---|
| 3 atoms sulphate of alumina | = 21·75 |
| 1 atom sulphate of soda | = 9 |
| 25 atoms water | = 28·125 |
| | 58·875 |

The weight of an integrant particle of this alum is only 58·875; because the alum of soda weighs only 4, while that of potash is 6.

The constituents of ammoniacal alum are as follows:—

| | |
|---|---|
| 3 atoms sulphate of alumina | = 21·75 |
| 1 atom sulphate of ammonia | = 7·125 |
| 25 atoms water | = 28·125 |
| | 57 |

The weight of the integrant particle is only 57, because ammonia has an atomic weight of only 2·125.

One of the most remarkable differences between these three species of alum is the solubility of each in water. At the temperature of 60°, 100 parts of water dissolve

9·37 parts of ammoniacal alum,
14·79 parts of potash alum,
327·6 parts of soda alum.

This great solubility of soda alum renders the manufacture of it very difficult. It does not easily crystallize; indeed, when the weather is hot, crystals of it can hardly be obtained. This great solubility, together with the inferior weight of its integrant particle, would render it more convenient and more economical for dyers and calico printers, provided it could be furnished at the same rate with common alum. But the greater difficulty attending the making of it would probably prevent it from being saleable at a price sufficiently low to make it available as a mordant.

Soda alum was first mentioned by Mr Winter in 1810, in his account of the Whitby alum processes (Nicholson's *Jour.* xxv. p. 254, 255); but before that time it had been made by Charles Macintosh, Esq. of Crossbasket. Mr William Wilson, at Hurlet, near Glasgow, afterwards made it in considerable quantities. Specimens of it have been still more recently sent by Dr Gillies from the neighbourhood of Mendoza, in South America, where it occurs native in considerable quantity.

These three different species of alum differ also somewhat from each other in their specific gravities, which are as follows:—

| | |
|---|---|
| Ammoniacal alum | 1·56 Sp. Gr. |
| Potash alum | 1·75 |
| Soda alum | 1·88[1] |

The word *alumen*, which we translate *alum*, occurs in Pliny's *Natural History*. In the 15th chapter of his 35th book, he gives us a detailed description of it. By comparing this with the account of *στυπτηρια* given by Dioscorides in the 123d chapter of his 5th book, it becomes quite obvious that he alludes to the same substance. Hence it follows, that *στυπτηρια* is the Greek name for *alumen.* Pliny informs us that alumen was found naturally in the earth. He calls it *salsugo terræ.* Different substances, he informs us, were distinguished by the name of alumen; but they were all characterized by a certain degree of astringency, and were all employed in dyeing and in medicine. The light-coloured alumen was useful in brilliant dyes, the dark-coloured only in dyeing black or very dark colours. One species of alumen was a liquid, which was apt to be adulterated; but, when pure, it had the property of striking a black with the juice of the pomegranate. This property seems to characterize a solution of sulphate of iron in water. It is quite obvious that a solution of our alum would possess no such property. Pliny says that there is another kind of alum which the Greeks call *schistos.* It forms in white threads upon the surface of certain stones. From the name *schistos*, and the mode of formation, there can be little doubt that this species was the salt which forms spontaneously on certain slaty minerals, as alum slate and bituminous shale, and which consists chiefly of sulphate of iron and sulphate of alumina. Possibly in certain places the sulphate of iron may have been nearly wanting, and then the salt would be white, and would answer, as Pliny says it did, for dyeing bright colours. Several other species of alumen are described by Pliny, but we are unable to make out to what minerals he alludes.

The alumen of the ancients, then, was not the same with the alum of the moderns. It was most commonly a sulphate of iron, sometimes probably a sulphate of alumina, and usually a mixture of the two. But the ancients were unacquainted with our alum. They were acquainted with sulphate of iron in a crystallized state, and distinguished it by the names of *misy*, *sory*, *chalcanthum.* (*Pliny*, xxxiv. 12.) As alum and green vitriol were applied to a variety of purposes in common, and as both are distinguished by a sweetish and astringent taste, writers, even after the discovery of alum, do not seem to have discriminated the two salts accurately from each other. In the writings of the alchemists we find the words *misy*, *sory*, *chalcanthum*, applied to alum as well as to sulphate of iron; and the name *atramentum sutorium*, which ought to belong, one should suppose, exclusively to green vitriol, applied indifferently to both.

When our alum was discovered is entirely unknown. Beckman devoted a good deal of time to trace the history of this salt, and published a curious dissertation on the

[1] The soda alum whose specific gravity is here given was the native, from the province of St Juan, on the north of Mendoza. It contains less water, and therefore is probably heavier than common soda alum.

subject; but his attempts to trace its origin were unsuccessful. The manufacture of it was discovered in the East, but at what time or place is totally unknown. It would appear that, about four or five hundred years ago, there was a manufactory of it at Edessa in Syria, at that time called Rocca; hence, it is supposed, the origin of the term *Rock alum*, commonly employed in Europe: though there are others who pretend that the term originated at Civita Vecchia, where alum is made from a yellow mineral in the state of a hard rock.

Different alum works existed in the neighbourhood of Constantinople. About the time of the fall of the Grecian empire, the art of making alum was transported into Italy, at that period the richest and most manufacturing country in Europe. Bartholomew Pernix, a Genoese merchant, discovered alum ore in the island of Ischia, about the year 1459. Nearly at the same time John di Castro, who was well acquainted with the alum works in the neighbourhood of Constantinople, suspected that a mineral fit for yielding alum existed at Tolfa, because it was covered with the same trees that grew on the alum mineral near Constantinople. His conjecture was verified by trials, and the celebrated manufactory at Tolfa established. Another was begun in the neighbourhood of Genoa; and the manufacture flourished in different parts of Italy. To this country it was confined for the greater part of a century. Various manufactories of it were established in Germany by the year 1544. In the time of Agricola there was a manufactory of it at Commotau, in Bohemia. About the same time an alum work was established at Alcmaron, near Carthagena, in Spain.

England possessed no alum works till the reign of Charles I. Thomas Chaloner, Esq. son of Dr Chaloner, who had been tutor to Charles, while hunting on a common in Yorkshire took notice of the soil and herbage, and tasted the water. He found them similar to what he had seen in Germany, where alum works were established. In consequence of this, he got a patent from Charles for an alum work. This manufactory was worth two thousand a year, or perhaps more. But some of the courtiers thinking this too much for him, prevailed with the king, notwithstanding the patent, to grant a moiety of it to another person. This was the reason why Mr Chaloner was such a partisan of the parliament, and such an enemy of the king, that, at the end of the civil war, he was one of those who sat in judgment upon his majesty and condemned him.[1] Since that time various alum works have been established in different parts of England and Wales; but no one at present exists in Britain except the Whitby works, originally established by Mr Chaloner, and two works at Hurlet and Campsie, both in the neighbourhood of Glasgow.

Several alum works likewise exist in Sweden, particularly in West Gothland. There is one, for example, at Hænsæter, near the borders of the Wene Lake, on the west side of the mountain called Kinnekulle. But, for a description of the Swedish works, we refer to Bergman's *Opuscula*, vol. i. p. 284, or the English translation, vol. i. p. 342. We do not know if any alum works exist in Poland or Russia; but as the greater part of these extensive countries consists of alluvial soil to a great depth, it is probable that little alum ore will be found in them.

Various minerals are employed in the manufacture of alum, but by far the most important of them are the following three: *alum-stone, alum-slate, bituminous shale.*

Alum-stone was first observed at Tolfa, in the neighbourhood of Rome; afterwards in Hungary; and Cordier has shown that it is very common in volcanic rocks, but that it never occurs anywhere else. (*Annales des Mines*, tom. iv. p. 205, and tom. v. p. 303.)

The colour is white, greyish-white, or sometimes yellowish-white; most commonly amorphous; but it occurs also crystallized in rhomboids approaching to cubes, the angles being about 89° and 91°. In some crystals the apex of the rhomboid is replaced by a tangent plane. The size of these crystals varies from 0·03937 to 0·11811 of an inch in length.

The specific gravity is 2·7517; but the amorphous specimens, owing probably to cavities, are rather lighter. Haüy states the specific gravity to be 2·587; harder than calcareous, but softer than fluor spar; fracture foliated in a direction perpendicular to the axis of the rhomboid; in all other directions the fracture is conchoidal; fragments irregular, with blunt edges; easily pulverized; feels harsh, and does not stain; decrepitates before the blowpipe; gives out sulphureous acid when heated on platinum-foil; and tastes of alum when applied to the tongue. In a strong heat it loses its acid, and becomes tasteless.

The constituents of the pure crystals, according to the analysis of Cordier, are—

| | |
|---|---|
| Sulphuric acid | 35·495 |
| Alumina | 39·654 |
| Potash | 10·021 |
| Water and loss | 14·830 |
| | 100 |

This approaches very nearly to

| | |
|---|---|
| 3 atoms trisulphate[2] of alumina... = | 35·25 |
| 1 atom sulphate of potash......... = | 11 |
| 7 atoms water..................... = | 7·875 |
| | 54·125 |

We see from this constitution that alum-stone contains in itself all the ingredients of alum. The absence of iron accounts for the superior purity for which Roman alum was so long celebrated.

In the alum manufactory at Campsie, near Glasgow, the alum is made from a shale taken out of the old abandoned coal-pits in the neighbourhood. At first this shale furnished alum by simple lixiviation with water. This process having been continued for a number of years, a great quantity of washed shale gradually accumulated in the neighbourhood of the works. This shale, when burnt, was found to yield a new crop of alum. Now, in this burnt shale thin bands of a greyish-white matter occasionally make their appearance, intermixed with portions having a yellow colour, and which are unequally distributed. The fracture is earthy; the matter is opaque, friable, and has an astringent, acid, and sweetish taste. The specific gravity is 1·887.

It occurred to the writer of this article, that this substance bore a considerable analogy to *alum-stone*. This induced him to subject it to chemical examination.

When digested in water it dissolves, with the exception of a white powder, amounting to 15·31 per cent., which is a subsulphate of alumina.

---

[1] *Letters written by Eminent Persons in the Seventeenth and Eighteenth Centuries*, &c.; *and Lives of Eminent Men*, by John Aubrey, Esq. vol. ii. p. 281. Lond. 1813.

[2] By *trisulphate of alumina* is meant a compound of *three* atoms of alumina and *one* atom of sulphuric acid. *Tersulphate* indicates a compound of three atoms of sulphuric acid and one atom of base.

When heated it melts somewhat like alum, and gives out pure water. When heated to redness it swells out like alum, and finally leaves a yellowish-white, porous, tasteless matter, nearly similar to what would be left by alum treated in the same manner, making allowance for the difference of colour.

The constituents were found to be—

1. Insoluble portion, amounting to 15·31 per cent.

| | |
|---|---|
| Alumina | 5·11 |
| Sulphuric acid | 10·20 |
| | 15·31 |

2. Soluble portion, amounting to 84·69 per cent.

| | |
|---|---|
| Sulphuric acid | 30·225 |
| Alumina | 5·372 |
| Peroxide of iron | 8·530 |
| Potash | 1·172 |
| Water | 36·295 |
| Loss, chiefly water | 3·096 |
| | 84·690 |

These constituents are equivalent to

24 atoms sulphate of alumina,
9 atoms bipersulphate of iron,
1 atom bisulphate of potash;

and each of these atoms is combined with about 5 atoms of water.

From this analysis we see that the substance which appears after burning the Campsie shale is not the same with *alum-stone;* but it constitutes an excellent article for the manufacture of alum, being highly productive; and is consequently much valued by the manufacturers.

Alum-slate is a much more abundant mineral than alum-stone. It is said to alternate with primitive clay-slate. It occurs abundantly along with transition-slate; and there can be little doubt that it occurs likewise in the flœtz formations. In West Gothland in Sweden, it constitutes a part of different hills, as Kinnekulle, Hunneberg, and Halleberg; in all of which it appears to alternate with flœtz trap rocks. It occurs likewise abundantly at Whitby, in Yorkshire. We have never ourselves been upon the spot; but, from the general structure of Yorkshire and the neighbouring counties, indeed of the whole east coast of England, there can be very little doubt that, in this position, it is also a flœtz rock.

Alum-slate, as the name implies, is a slaty rock, though sometimes it occurs in balls. The colour is bluish-black, with a strong shade of grey; fracture straight slaty; fragments tabular; its internal lustre is glimmering; it retains its colour in the streak, but acquires more lustre; soft; not particularly brittle; when exposed to the air it effloresces, and acquires an aluminous taste.

This mineral has never been accurately analyzed; but there can be no doubt that it contains silica, alumina, iron, sulphur, charcoal, and often likewise potash. Probably this was the mineral upon which the *alumen scissile* of the ancients was found.

Bituminous shale, the *Brandschiefer* of the Germans, is a slaty mineral, which almost constantly accompanies beds of coal, and accordingly is very common in Great Britain. Its colour is brownish-black; its fracture is thin slaty; fragments tabular; internal lustre glimmering, but the colour is not altered; very soft; rather sectile; feels rather greasy; easily frangible. When heated it burns with a pale flame and sulphureous odour, and becomes white. It has never been accurately analyzed; but it is probably nothing more than slate-clay, which occurs so abundantly in the independent coal formation, impregnated with the matter of coal. Its other principal constituents must be silica, alumina, and iron pyrites.

Alum.

Slate-clay itself, at least not sufficiently impregnated with coaly matter to deserve the name of bituminous shale, is frequently employed in the making of alum. This is the case in the neighbourhood of Glasgow.

Several native varieties of sulphate of alumina and soda alum occur in South America, some of the most remarkable of which it may be proper to specify.

1. Sulphate of alumina from Rio Saldana. It is said to occur in nests in the transition-slate of the Andes. The colour is white, here and there tinged yellow, obviously from external impurities. It occurs in fine crystalline needles; lustre silky; taste that of alum, but stronger; specific gravity 1.6606; soft; before the blowpipe behaves like alum. The writer of this article subjected it to a chemical analysis, and found its constituents as follows:—

| | |
|---|---|
| Water | 46·375 |
| Alumina | 14·645 |
| Peroxide of iron | 0·500 |
| Soda | 2·262 |
| Sulphuric acid | 35·872 |
| Mechanical impurity, consisting of ferruginous silica | 0·100 |
| | 99·754 |

This is equivalent to

1 atom sulphate of alumina,
6 atoms water,
$\frac{7}{100}$ atom sulphate of soda,
$\frac{1}{80}$ atom persulphate of iron.

So that if the sulphate of soda and persulphate of iron be only accidental ingredients, the mineral is a compound of

| | |
|---|---|
| 1 atom sulphate of alumina | = 7·25 |
| 6 atoms water | = 6·75 |
| | 14 |

2. Polcura, or alum-earth, found near the summit of a lofty ridge near El Paso de las Damas, in the Chilian Andes, and used as a mordant by the inhabitants in dyeing red. This mineral was brought over to Great Britain by Dr Gillies, who was kind enough to favour the writer of this article with a specimen. It occurs in hard masses, partly earthy, partly fibrous. The fibres have a silky lustre. The colour is white, and the taste that of alum.

When digested in water, a portion was dissolved, and a portion remained in the form of a white insipid earth. The quantity of insoluble matter differed very much in different parts of the specimen. The least was 8·62, and the greatest 34·65 per cent. This insoluble matter contained a little sulphur; for, when heated, it emitted a blue flame with the smell of sulphureous acid. The rest of it was a mixture of alumina and silica, tinged yellow by peroxide of iron. The portion dissolved in water, being subjected to analysis, was found to consist of

| | |
|---|---|
| 1 atom disulphate[1] of alumina | = 9·5 |
| 1 atom sulphate of soda | = 9 |
| | 18·5 |

3. Soda-alum. It occurs native in the province of St Juan, situated to the north of Mendoza, on the east side of the Chilian Andes, at about lat. 30° S. The alum is white, and composed of fibres adhering longitudinally,

[1] By *disulphate of alumina* is meant a compound of *one* atom of sulphuric acid and *two* atoms of alumina.

and having a certain breadth, but very thin. It bears some resemblance to fibrous gypsum, but is harder, not being scratched by the nail, though the knife scratches it with great ease. It is sectile. The outer fibres are white and only slightly translucent, as if they had lost a portion of their water; but the internal fibres are transparent, and have a silky aspect.

It tastes precisely like alum, and is very soluble, water at the temperature of 62° dissolving 3·773 parts of it, and boiling water dissolving any quantity whatever. When exposed to heat, it behaves very nearly as common alum.

Its constituents were found to be—

| | |
|---|---|
| Sulphuric acid | 20·000 |
| Alumina | 6·360 |
| Soda | 4·000 |
| Silica | 0·012 |
| Lime | 0·136 |
| Protoxide of iron | 0·423 |
| Peroxide of iron | 0·110 |
| Water | 22·209 |
| | 53·250 |

It will be observed that the sulphuric acid constitutes just four atoms, the soda one atom, and the alumina just 0·29 less than three atoms. But the quantity of lime and oxides of iron present is exactly equivalent to 0·29 atom of alumina. Hence these substances appear to have displaced a small quantity of alumina in the salt. The water amounts to very nearly twenty atoms. It is obvious from all this, that the true constitution of the salt is—

| | |
|---|---|
| 3 atoms sulphate of alumina | = 21·75 |
| 1 atom sulphate of soda | = 9·00 |
| 20 atoms water | = 22·50 |
| | 53·25 |

It contains five atoms less water than soda-alum artificially crystallized.

4. There is a mineral called *aluminite*, which was observed in the environs of Halle many years ago, and which was afterwards detected by Mr Webster in the chalk rocks of Newhaven in Sussex, which, if it were sufficiently abundant, would constitute an excellent material for the manufacture of alum.

Its colour is snow-white. It occurs in reniform pieces of greater or smaller size; fracture fine earthy; dull; streak glistening; opaque; adheres feebly to the tongue; soils very slightly; very soft; feels fine, but meagre; specific gravity 1·7054. Its constituents, as determined by three several analyses of Stromeyer, are—

| | |
|---|---|
| 1 atom sulphuric acid | = 5 |
| 3 atoms alumina | = 6·75 |
| 9 atoms water | = 10·125 |
| | 21·875 |

It is therefore a hydrous trisulphate of alumina.

Four different processes are employed in the manufacture of alum, according to the nature of the mineral from which the alum is to be extracted.

The process employed at Tolfa is the simplest of all. If the Tolfa stone be kept constantly moistened with water for about two months, it falls to powder of itself, and yields alum by lixiviation. But this is not the process employed by the manufacturers. The alum-stone is broken into small pieces, and piled on the top of a perforated dome, in which a wood fire is kindled. The smoke and flame of the wood penetrate through the pieces of alum-stone, and a sulphureous odour is disengaged, owing to the decomposition of a portion of the sulphuric acid in the stone. This roasting is twice performed; the pieces of ore which, the first time, were at the edge of the dome, being the second time put in the middle. The process of roasting this stone requires considerable attention. If the heat be too great, the quality of yielding alum is destroyed: if the heat be too small, the stone does not readily fall to powder. There can be little doubt that the unroasted stone would yield more alum than the roasted; but probably the additional labour requisite in the latter case would more than swallow up the increase of product.

The roasted stone, which has now acquired a reddish colour, is placed in rows between trenches filled with water. This liquid is so frequently sprinkled on it, that the stone is always moist. In two or three days it falls to powder, like slacked quicklime; but the daily watering is continued for a month. The success of this part of the operation is said to depend very much on the weather. When the weather is rainy, the alum is all washed out, and little or nothing left for the manufacturer to extract. In such cases, it is obvious that the alum-stone should be protected from the rain by a shed.

When the stone has by this process been reduced to a sufficiently fine powder, it is thrown into a leaden boiler filled two thirds with water. During the boiling, the powder is frequently stirred up, and the water that evaporates is replaced. When the boiling has been continued for a sufficient time, the fire is withdrawn, and time allowed for the earthy matter to subside to the bottom. A cock is then opened, which allows the clear liquor to flow out into deep wooden square vessels, so made that they can be easily taken to pieces. Here the alum gradually crystallizes, and attaches itself to the sides and bottom of the vessel. The mother liquid is now drawn off into shallower wooden troughs, where more alum crystals are deposited. The liquid has now a red colour, and is muddy; and the last alum crystals are mixed with this red matter. They are washed clean in the mother liquor, which is finally pumped into a trough, and used in subsequent processes.

The alum obtained at Tolfa is known by the name of *Roman alum*, and is in very high estimation. It is always mixed with a little reddish powdery matter, which is easily separated from it. What this red matter is, has not been ascertained; but it is not peroxide of iron. To the eye it has very much the appearance of a vegetable matter. We have some notion that it is added artificially by the sellers of Roman alum. Probably Roman alum at first had a red tinge, in consequence of the red matter in the mother liquor remaining partially attached to it. The goodness of the alum may have given the purchasers a partiality to the red colour, and induced the sellers to add a red powder artificially. We have never had an opportunity ourselves of examining this matter, but have been informed by those who have, that it contains no iron.

It is not improbable that this process would be improved by grinding the Tolfa stone to a fine powder in a mill, without any previous roasting, and then keeping the powder moistened with water for a considerable time. If the residual earth, after the alum is extracted, be boiled with sulphuric acid, the liquid yields alum crystals by evaporation. This is a demonstration that neither the alumina nor the potash is exhausted, and that the sulphuric acid driven off by the roasting is so much alum lost to the manufacturer. Indeed the quantity of sulphuric acid in the alum-stone is not sufficient to occupy the whole of the potash in the formation of alum. It would be necessary to add about one tenth of the weight of the alum-stone of sulphuric acid, if it were wanted to employ the whole potash present in the stone. The consequence of this addition, supposing no loss, would be an additional quantity of alum, amounting to rather more than one fifth of the weight of the alum-stone employed.

Alum-slate, being very different in its composition, requires a different treatment to fit it for yielding alum. If the alum-slate contain a notable quantity of lime or magnesia, it does not answer the purposes of the manufacturer so well. Indeed the proportion of lime present may be conceived to be such that no alum whatever would be obtained. As alum-slate has never been subjected to accurate analysis, we do not know in what proportion these two earths exist in it, or whether they may not, in many cases, be absent altogether. The essential ingredients in alum-slate, for the alum-makers, are alumina and iron pyrites.

The first process is to roast the ore. In Sweden, where the fuel is wood, and consequently expensive, it is customary to use the alum-slate itself as fuel for roasting the ore. For this purpose a small layer of brushwood is covered with pieces of alum-slate, and set on fire; and, as the combustion proceeds, new layers of alum-slate are added. It is usual to place alternate layers of roasted and unroasted alum-slate. The combustion continues for a month or six weeks. At Whitby, coal is employed for roasting the alum-slate. Indeed the alum-slate of Whitby is lighter coloured than that of Sweden, and probably would not burn of itself. So great is the quantity of combustible matter in the Swedish alum-slate, that it is employed as fuel for burning limestone. Great quantities of limestone are burnt in this manner at Hunneberg, near the south side of the lake Wener. The roasted ore has usually a brown colour. When it is red, the quantity of alum which it yields is considerably diminished.

By this roasting the pyrites is decomposed. The sulphur is converted into sulphuric acid, while the iron is oxidized. In what manner this change is produced it is not easy to say. Indeed it does not seem certain that pyrites is a constant ingredient in alum-slate. We have never been able to detect any, by the eye, in any specimens of Whitby alum-slate which we have examined. At Hænsæter, in Sweden, no sulphate of iron crystallizes when the liquid is evaporated; yet, if pyrites had been present, it is difficult to see any reason that should prevent this salt from being formed. Hence it is probable, that in alum-slate the sulphur is sometimes at least combined with other substances than iron. It must always be in a state of combination; for, if it were in a loose state, it would be driven off by the roasting. This point deserves to be elucidated by analyzing different varieties of alum-slate.

The roasted ore has an astringent taste, owing to the sulphate of iron and sulphate of alumina which it contains. The next process is to lixiviate it with water, in order to dissolve these salts. For this purpose it is put into reservoirs made of wood or masonry, with a stopcock at the bottom to draw off the water. The usual method is to keep the water for twelve hours in contact with ore that has been twice lixiviated; then to draw it off, and allow it to remain for an equal period on ore that has been once lixiviated. Lastly, it is run upon fresh ore, and allowed to remain on it for twelve hours longer. If the specific gravity of the liquid thus treated be 1·25 at the temperature of 55°, it may be considered as saturated with sulphate of alumina and sulphate of iron. But we presume that this specific gravity is not often obtained.

The liquid, thus impregnated with salt, is now boiled down in leaden vessels to the proper consistency for crystallization. In Sweden, the fuel employed for this purpose is alum-slate. By this means a double effect is produced; the liquid is evaporated, and the alum-slate is roasted. During the boiling, abundance of oxide of iron falls mixed with selenite, if lime be one of the constituents of the alum-slate. When the liquid is sufficiently concentrated, it is let into a square reservoir, in order to crystallize. Great quantities of sulphate of iron crystals are usually deposited in this vessel. These are collected by drawing the liquid off into another reservoir. When all the sulphate of iron that can be obtained has been separated, a quantity of sulphate of potash, muriate of potash, or putrid urine, is mixed with the liquid. The sulphate of potash is procured from the sulphuric acid-makers, and the muriate of potash from the soap-makers. By this addition, alum is formed in the liquid, and it gradually deposits itself in crystals on the sides of the vessel. These crystals are collected, and dissolved in the smallest quantity of boiling water that will take them up. This solution is poured into large wooden casks. In a fortnight or three weeks the alum crystallizes, and covers the sides and bottom of the cask. The hoops are now taken off, and the staves of the cask removed. A mass of alum crystals, having the shape of the cask, remains. This mass is pierced, the mother liquor allowed to run out, and preserved for a subsequent process. The alum, being now broken in pieces, is fit for sale.

The manufacture of alum from bituminous shale and slate-clay bears a considerable resemblance to the manufacture from alum-slate, but differs in several particulars. There are two works of this kind in the neighbourhood of Glasgow, managed with great skill, and excellent in every respect. We shall give a sketch of the processes followed in these works. The bituminous shale and slate-clay employed are obtained from old coal-pits, which are very extensive in the neighbourhood of Glasgow. The air in these coal-pits is moist, and its average temperature about 62°. The shale, having been exposed for many years, has gradually opened in the direction of its slaty fracture, so as to resemble in some respects a half-shut fan; and all the chinks in it are filled with a saline efflorescence in threads. This salt is white, with a shade of green; has a sweetish astringent taste; and consists of a mixture of sulphate of iron and sulphate of alumina. In order to obtain these salts in a state of solution, nothing more is requisite than to lixiviate this shale with water. The lixiviated ore being left exposed to the weather, forms more salt, which is gradually washed out of it by the rain-water, and this water is collected and preserved for use.

The next step in the process is to boil down the liquid to a sufficient state of concentration. At Campsie, all these boilers are composed of stone, and the heat is applied to the surface. This is a great saving, as leaden vessels are not only much more expensive, but require more frequent renewal. When the liquid is raised to a sufficiently high temperature in the stone reservoir, pounded sulphate of potash, or muriate of potash, as they can be procured, is mixed with it; and there is an agitator in the vessel, by which it is continually stirred about. This addition converts the sulphate of alumina into alum. The liquid is now let into another trough, and allowed to remain till it crystallizes. In this liquid there are two salts contained in solution, viz. sulphate of iron and alum; and it is an object of great consequence to separate them completely from each other. The principal secret consists in drawing off the mother liquor at the proper time; for the alum is much less soluble in water than the sulphate of iron, and therefore crystallizes first. The first crystals of alum formed are very impure. They have a yellow colour, and seem to be partly impregnated with

Alum. sulphate of iron. They are dissolved in hot water, and the solution poured into troughs, and allowed to crystallize a second time. These second crystals, though much purer, are not quite free from sulphate of iron; but the separation is accomplished by washing them repeatedly with cold water; for sulphate of iron is much more soluble in that liquid than alum. These second crystals are now dissolved in as small a quantity of hot water as possible, and the concentrated liquid poured while hot into large casks, the surface of which is covered with two cross beams. As the liquor cools, a vast number of alum crystals form on the sides and surface. The casks are allowed to remain till the liquid within is supposed to be nearly of the temperature of the atmosphere. This, in winter, requires eleven days; in summer, fourteen or more. We have seen the liquid in a cask that had stood eleven days in summer, still more than blood-hot. The hoops are then removed, precisely as in the manufacture of alum from alum-slate.

There always remains in the boilers a yellowish substance, consisting chiefly of peroxide of iron. This is exposed to a strong heat in a reverberatory furnace, and it becomes red. In this state it is washed, and yields more alum. The red residue is ground to a fine powder, and dried. It then answers all the purposes of Venetian red as a pigment. By altering the temperature to which this matter is exposed, a yellow ochre is obtained instead of a red.

In France, where alum-ores are by no means abundant, alum is manufactured from clay. This method of making the salt was first put in practice by Chaptal, when professor of chemistry at Montpellier. His methods have been since gradually improved, and brought to a state of considerable perfection. The first process tried was this: the clay was reduced to a fine powder in a mill, and then mixed with sulphuric acid. After remaining some days, it was exposed for twenty-four hours to a temperature of about 130°. It was then lixiviated, and the liquid mixed with urine or potash. This method being found inconvenient, was abandoned for the following: the clay being well ground, was mixed with half its weight of the saline residue from a mixture of sulphur and nitre. This residue is little else than sulphate of potash. The mixture was formed into balls about five inches in diameter, which were calcined in a potter's furnace. They were then placed on the floor of a chamber in which sulphuric acid was made. The acid vapour caused them to swell, and to open on all sides. In about a month they were sufficiently penetrated with the acid. They were then exposed to the air, under shades, that the saturation might become more complete. Finally, they were lixiviated, and the liquid being evaporated, yielded pure alum.

This process has been considerably improved by Berard, the present proprietor of the Montpellier alum work. Instead of exposing the calcined balls to the fumes of sulphuric acid, he sprinkles them with a quantity of sulphuric acid of the specific gravity 1·367, equal to the weight of the clay employed: but it is obvious that the proportion must vary with the nature of the clay. The solution takes place with the greatest facility, and crystals of alum are obtained by evaporating the liquid.

Another process was put in practice by Chaptal, in the neighbourhood of Paris, and is still followed, or was at least followed some years ago, by M. Bouvier. A mixture is made of 100 parts of clay, 50 parts of nitre, and 50 parts of sulphuric acid of the specific gravity 1·367; and this mixture is put into a retort, and distilled. Aquafortis comes over, and the residue in the retort being lixiviated with water, yields abundance of excellent alum.

We may mention another process described by Caraudau, and certainly practicable, and even easy, though we do not believe that it would be attended with profit. He forms 100 parts of clay into a paste with water, holding 5 parts of common salt in solution. This paste is formed into cakes, and calcined in a reverberatory furnace. The calcined mass is reduced to powder, and well mixed with the fourth part of its weight of concentrated sulphuric acid. When the muriatic acid vapours are dissipated, as much water is added as there had been employed of acid, and the mass is carefully kneaded. A strong heat is produced; the composition swells; more water is added; and at last a solution of potash, in which the alkali amounts to one fourth of the acid employed. The liquor is now drawn off, and, on cooling, it yields a copious deposite of alum crystals. (T. T.)

ALUNNO, Nicolo, a painter of Foligno, who flourished between 1468 and 1492. The heads in his historical pictures are generally portraits, which gave a vivacity and force to his compositions rarely seen in works of that age. *Lanzi Stor. Pittor. II.*

ALUNTIUM, or Alontium, in *Ancient Geography*, a town in the north of Sicily, situated on a steep eminence at the mouth of the Chydas; said to be as old as the war of Troy. It is now in ruins; and from these has arisen the hamlet San Filadelfo, in the Val di Demona.

ALVA de Tormes. See Alba.

Alva. Alva, or Alba, *Fernando Alvarez de Toledo, Duke of,* was born in 1508, and descended from one of the most illustrious families in Spain. His grandfather, Ferdinand of Toledo, was his preceptor in the military and political arts; and he displayed his valour at the battle of Pavia and at the siege of Tunis. The ambitious Charles V. selected Alva as a proper instrument for conducting his military enterprises. In 1538 he made him his general; and, after several operations, in which he displayed both valour and military skill, in 1542 he successfully defended Perpignan against the dauphin of France.

In 1546 Alva was made general-in-chief of the army which marched against the German Protestants, who were marshalled under the banners of the elector of Saxony. Francis, the king of France, died at Rambouillet, and by his death a considerable change was made in the state of Europe. Charles therefore instantly began his march from Egra on the borders of Bohemia, and entering the southern frontier of Saxony, attacked Altorf upon the Elster. Incessantly pushing forward, he arrived on the evening of the 23d of April on the banks of the Elbe, opposite to Muhlberg. The river at that place was three hundred paces in breadth and about four feet in depth, its current rapid, and the bank possessed by the Saxons was higher than that which he occupied. In opposition to the opinion of the duke of Alva and his other officers, Charles, with undaunted courage, though with inexpressible difficulty, led his army through the river and engaged the Saxons. The elector displayed great personal courage and military knowledge; but having received a wound in the face, he at last surrendered himself prisoner. The emperor proceeded towards Wittenberg, whither the remains of the Saxon army had fled, carrying along with him the captive prince, as a spectacle of consternation and amazement to his own subjects. But when he approached the town, he found it defended by the vigorous efforts of the elector's wife, Sibylla, along with the inhabitants. He summoned her once and a second time to open the gates, informing her that if she persisted in her obstinacy the elector should answer for it with his head. Accordingly he brought his prisoner to an immediate trial. The proceedings against him were as irregular as the stratagem was barbarous. Instead of consulting the states of the empire, or remitting the cause to any court, which, according to the German constitution, might have legally taken cognizance of the elector's crime, he subjected the greatest prince in the empire to the jurisdiction of a court-martial. The emperor selected the unrelenting duke of Alva as a proper instrument to carry into effect any measure of violence and oppression, and therefore made him president of that court, composed of Spanish and Italian officers. Moved more by the entreaties of his wife than by a sense of his own danger, the elector, in order to save his life, submitted to all the rigorous and unjust measures that were proposed; but when it was added that he should also renounce the Protestant faith and become a Roman Catholic, he refused to act in opposition to his conscience, and bravely fell a sacrifice to the cause of truth.

In 1552 Alva was intrusted with the command of the army intended to invade France, and was constrained by the opinion and authority of the emperor to lay siege to Mentz, in opposition to his own military knowledge; but, notwithstanding all his valour and abilities, the duke of Guise successfully defended the place. In consequence of the success of the French arms in Piedmont, he was made commander-in-chief of all the emperor's forces in Italy, and at the same time invested with unlimited power. Success did not, however, attend his first attempts, and after several unfortunate attacks he was obliged to retire into winter quarters. The next year he was sent into the pope's territories; and, had he not been restrained by his master, he would have taken possession of all his fortified places, and deterred Henry from entering into any new connection with him, and have thereby prevented the renewal of the war. Philip was strongly disposed to peace, but Alva was inclined to severe measures. He yielded, however, to the instructions of his master, until being deluded, and sometimes haughtily answered, he at length sent Pino de Loffredo with a letter to the college of cardinals, and another to Paul, in which, after enumerating the various injuries which his master had received, and renewing his former offers of peace and friendship, he concluded with protesting that, if his offers were again rejected, the pope should be chargeable with all the calamities that might follow. The pope threw Loffredo into prison; and, had not the college of cardinals interposed, he would even have put him to death; and on account of Philip's failing to pay tribute for Naples, he deprived him of the sovereignty of that kingdom. This violent conduct of Paul gave great offence throughout all Europe, and greatly lessened his influence in Italy; but Philip, though a young, ambitious, and powerful monarch, and of a temper impatient of injuries and affronts, moved with a religious veneration, discovered an amazing reluctance to proceed to extremities. After much time spent in negotiation, Philip was at last forced to give orders for Alva to take the field. He cheerfully obeyed, and began his march in the beginning of September 1556, with a well-disciplined army; and after reducing several towns in the Campagna di Roma, he pursued his conquests to the very gates of Rome. The circumstances, however, in which Alva found his army induced him to make a truce of forty days, and after several negotiations he yielded to peace. One of its terms was, that the duke of Alva should in person ask forgiveness of the haughty pontiff whom he had conquered. Proud as the duke was by nature, and accustomed to treat with persons of the highest dignity, yet such was the superstitious veneration then entertained for the papal character, that he confessed his voice failed him at the interview, and his presence of mind forsook him. Not long after this he was sent at the head of a splendid embassy to Paris, to espouse, in the name of his master, Elizabeth, daughter of Henry, king of France.

Philip II., his new master, being strongly devoted to the Roman see, and determined, by the most unrelenting severity and unbounded cruelty, to reclaim rebels to his government and dissenters from his faith, pitched upon Alva as the fittest person to carry this system into practice. With this design, therefore, he was sent into the Low Countries in 1567. Having received his orders, armed with such power as left only the shadow of authority to the natural governor, and provided with 10,000 veterans, he marched towards that devoted country. When he arrived, he soon showed how much he merited the confidence which his master reposed in him, and instantly erected a bloody tribunal to try all persons who had been engaged in the late commotions which the civil and the religious tyranny of Philip had excited. He imprisoned the counts Egmont and Horn, the two popular leaders of the Protestants, and soon brought them to an unjust trial, and condemned them to death. In a little time he totally annihilated every privilege of the people, and, with uncontrolled fury and cruelty, put multitudes of them to death. Beholding herself deprived of all authority, and her subjects devoted to destruction, the duchess of Parma resigned her office, disdaining to hold a nominal power, while the actual government was in the hands of Alva. This event increased the general tide of wretchedness, and every place was filled with scenes of horror and dismay. Unable for the present to administer the least aid, the prince of Orange saved his life by flight. This noble prince suddenly collecting an army in Germany, returned to the relief of his countrymen; and at the same time Prince Lewis, his brother, marched with an army into Friesland. Although success at first attended Lewis, yet the activity and experience of Alva prevailed, and he was totally defeated. The prince of Orange proved a more formidable foe; and it required the united talents of Alva and his son Frederick of Toledo to prevent the prince from making a descent upon the Netherlands. But notwithstanding all the address and military skill of the prince of Orange, the descent was prevented; and Alva had the glory of baffling that great leader, and of compelling him, after great loss of men, to disband the remainder of his army. Alva could now indulge his cruelty unrestrained. The executioner was instantly employed in removing all those friends of freedom whom the sword had spared. In most of the considerable towns Alva built citadels. In the city of Antwerp he erected a statue of himself, which was a monument no less of his vanity than of his tyranny: he was figured trampling on the necks of two smaller statues, representing the two estates of the Low Countries. By his unusual and arbitrary demand of new supplies from the states, he greatly aggravated this haughty insult. The exiles from the Low Countries, roused to action by his oppression, fitted out a kind of piratical fleet, and, after strengthening themselves by successful depredations, ventured upon the bold exploit of seizing the town of Briel. Thus Alva, by his cruelty, became the unwitting instrument of the future independence of the seven Dutch provinces. The fleet of the exiles having met the Spanish fleet, totally defeated it, and reduced North Holland and Mons. Many cities hastened to throw off the yoke: while the states-general assembling at Dordrecht, openly declared against Alva's government, and marshalled under the banners of the prince of Orange. This situation of affairs convinced Alva of the instability of a government upheld by terror and oppression; he therefore began, when too late, to employ more lenient measures. His preparations to oppose the gathering storm were concerted with his usual vigour, and he succeeded in recovering Mons, Mechlin, and Zutphen, under the conduct of his son Frederick, where his soldiers more than retaliated upon the prince of Orange. With the exception of Zealand and Holland, he regained all the provinces; and at last his son stormed Waerdan, and massacring its inhabitants with the most savage cruelty, proceeded to invest the city of Haarlem. Fully convinced of the miseries that awaited their surrender, this city stood an obstinate siege; and nothing less than the inflexible and persevering spirit of Alva could have overcome difficulties almost insurmountable. Despairing of success, Frederick was at one time disposed to raise the siege, but the stern reproaches of his father urged him on; and at length the inhabitants, overcome with fatigue, surrendered. The victorious Frederick gave tolerable conditions to the town; but his inhuman father arriving on the third day after the surrender, sacrificed to his vengeance many who had been flattered with a promise of mercy. Their next attack was upon Alcmaar; but the spirit of desperate resistance was raised to such a height in the breasts of the Hollanders, that the Spanish veterans were repulsed with great loss, and Frederick constrained reluctantly to retire. Alva now resolved to try his fortune by sea, and with great labour and expense fitted out a powerful fleet, with which he proceeded to attack the Zealanders; but was entirely defeated, and the commander taken prisoner. About the same period the prince of Orange proceeded to attack the town of Gertruydenberg. Alva's feeble state of health and continued disasters induced him to solicit his recal from the government of the Low Countries; a measure which, in all probability, was not displeasing to Philip, who was now resolved to make trial of a milder administration. In December 1573 that devoted country was relieved from the presence and oppressions of the duke of Alva, who, returning home, accompanied by his son, made the infernal boast that during the course of six years, besides the multitudes destroyed in battle and massacred after victory, he had consigned 18,000 persons to the executioner.

Returning from this scene of oppression and blood, he was treated for some time with great distinction by his master. Justice, however, soon overtook the crimes of Alva; for his son, having debauched one of the king's attendants, under promise of marriage, was committed to prison; and being aided in his escape by his father, and married by him to a cousin of his own, Alva was banished from court, and confined in the castle of Uzeda. In this disgraceful situation he remained two years, when the success of Don Antonio, in assuming the crown of Portugal, determined Philip to turn his eyes towards a person in whose fidelity and abilities he could on this occasion most confide. A secretary was instantly despatched to Alva, to ascertain whether his health was sufficiently vigorous to enable him to undertake the command of an army. The aged chief returned an answer full of loyal zeal, and was immediately appointed to the supreme command in Portugal. It is a striking fact, however, that the enlargement and elevation of Alva were not followed by forgiveness. In 1581 Alva entered Portugal, defeated Antonio, drove him from the kingdom, and soon reduced the whole under the subjection of Philip. Entering Lisbon, he seized an immense treasure. and suffered his soldiers, with their accustomed violence and rapacity, to sack the suburbs and vicinity. It is reported, that Alva being requested to give an account of the money expended on that occasion, sternly replied, "If the king asks me for an account, I will make him a statement of kingdoms preserved or conquered, of signal victories, of successful sieges, and of sixty years' service." Philip deemed it proper to make no further inquiries. Alva, however, did not enjoy the honours and rewards of his last expedition, for he died in 1583, at the age of 74. See HOLLAND.

ALVARADO, PEDRO DE, a native of Badajos, who, as the lieutenant of Hernando Cortes the famous conqueror of Mexico, was himself scarcely less celebrated. He died in 1541.—See Barcia, *Historiadores Primitivos;* and De Solis, *Historia de la Conquista.*

ALVARES DE LUNA, treasurer and favourite of John II., king of Castile, celebrated for the powerful ascendency which he gained over this prince. He was a natural son of Don Alvaro de Luna, lord of Cañete in Aragon, and of a woman of infamous character. He was born in 1388, and named Peter; but Pope Benedict XIII. who was charmed with his wit though yet a child, changed Peter to Alvares. He was introduced to court in 1408, and made a gentleman of the bed-chamber to King John, in whose service he acquired the most distinguished favour. In 1427 the hostility of the courtiers occasioned his banishment from court for a year and a half. His absence was a source of the utmost affliction to the king, who could now speak or think of nothing but Alvares. He was therefore recalled; and being invested with his former authority, he revenged himself severely upon his enemies, by persuading the king to banish them. He spent 45 years at court, and during 30 of them maintained such an ascendency over the king, that nothing could be done without his concurrence: nay, it is related by Mariana, that the king could not change an officer or servant, or even his clothes or diet, without the approbation of Alvares. He was master of the treasury, and had so gained the affections of the subjects by his profusion, that the king, though his eyes were now opened, and his favour withdrawn, was afraid to complain. A day of retribution however was at hand; the popular favour, as well as the affections of the monarch, declined, and Alvares was thrown into prison. Being brought to trial and condemned, he was removed to Valladolid, and there beheaded in the market-place. He met his fate with the utmost intrepidity.

ALVAREZ, FRANCISCO, of Coimbra, a priest, and almoner to Emanuel king of Portugal, was sent in 1515 as secretary to Duarte Galvaon on an embassy to David, king of Abyssinia. The expedition having been delayed by the way, it was not until 1520 that he reached Abyssinia, where he remained six years, and returned to Lisbon in 1527. In 1540, the year of his death, he published at Lisbon an account of his travels in one volume folio, entitled *Descripçam das Terras de Preste Joam, &c.* This curious work was translated in Latin, under the title of *De Fide, Regione, et Moribus Æthiopum*, by Damien Goez, a Portuguese gentleman; and has often been reprinted and translated into other languages. The information it contains must, however, be received with caution, as the author is prone to exaggerate, and does not confine his remarks to his own observation.

ALVAREZ, *Don Jose*, an eminent Spanish sculptor, born at Priego in 1768. He was originally a stone mason, but by talent and perseverance he gained the royal gratuity, which sent him to study at Rome, and there obtained much reputation for his invention, the expression, and the grace of his figures. He was favourably noticed by Napoleon when studying at Paris; and was considered by his countrymen as the Canova of modern Spain. His Ganymede is his masterpiece. He was an uncompromising *Spanish Patriot;* on which account he was imprisoned at Rome, where he chiefly resided. He returned to Madrid in 1826, but died in about a year. There was another Spanish sculptor of merit named MANUEL ALVAREZ, who flourished about the middle of the last century.—See *Bermisdez Diccionario.*

ALVERCA, a town and small port on the Tagus, 16 miles north-east of Lisbon. Pop. 3000.

ALVEOLUS, in *Natural History*, the name of the waxen cells in bee-hives. Also the name of a sea-fossil, of the order of Polyparia, of a conical figure, composed of a number of cells like bee-hives, joined into each other with a pipe of communication.

ALVINZ, a market-town on the Maros, in the Austrian province of Transylvania. It contains a Catholic, a Greek, and a Reformed church, and a Franciscan monastery. The inhabitants, who are chiefly Bulgarians and Magyars, amount to 3500.

ALYATTES, king of Lydia, father of Crœsus. He was buried under an immense tumulus near Sardis, by the lake Gygæa; which is described by Chandler as still retaining the form mentioned by Herodotus, among a multitude of smaller tumuli, though erected 562 years B.C.

ALYZIA, an ancient city of Acarnania, about 15 stadia from the coast, the ruins of which are still to be seen in the valley of Kandile.

ALWAIDII, a sect of Mahometans who believe all great crimes to be unpardonable. The Alwaidii stand in opposition to the Morgii. They attribute less efficacy to the true belief in the salvation of men than the rest of the Mussulmans.

ALWUR, in Central India, the capital of the native state of the same name, in the province of Rajpootana, and the residence of the reigning Rajah. This chief has attracted the notice and commendation of the British Government by his departure from the native mode of administering his possessions, and introducing the British method in its place. Under the reformed system the custom of farming the revenue has been abolished; justice is administered separately in the civil and criminal department; revenue duties are no longer blended with those of police, and the troops are maintained by cash payments instead of territorial assignments. The experiment is the more interesting, inasmuch as since its introduction this principality has been represented by competent authority (the late Colonel Sutherland) as one of the most flourishing native states of India. Distance north-west from Calcutta 900 miles. Lat. 27. 34. Long. 76. 40. (E. T.)

ALYPIUS *of Antioch*, a geographer of the fourth century. He was sent by the emperor Julian into Britain as deputy-governor; and after remaining in this situation for some time, he received orders from the emperor to rebuild the temple of Jerusalem. An account of the extraordinary interruption of that undertaking by fiery eruptions from the earth, is given under the article JEWS; and may be read at length in Ammianus Marcellinus, xxxiii. Among the letters of Julian are two (29 and 30) addressed to Alypius; one inviting him to Rome, the other thanking him for a geographical treatise, which no longer exists.

ALYPIUS, one of the seven Greek writers on music whose works are collected and published, with a commentary and explanatory notes, by Meibomius. The time in which he flourished cannot be precisely ascertained. He is said to have written before Euclid and Ptolemy; and Cassiodorus arranges his work, entitled *Introduction to Music*, between those of Nicomachus and Gaudentius. In this work is to be found the most complete nomenclature of all the sounds of the different scales and modes in the ancient Greek music which have escaped the wreck of time.

*ALYPIUS of Tagasta*, a Christian divine of the fourth century. He was baptized at Milan in 388, and consecrated bishop of Tagasta in Africa in 394. He assisted his friend St Augustine in opposing the tenets of the Donatists, who claimed the exclusive honour of being the true Church. In 419 he was sent by the African bishops to Honorius, and was employed by Pope Boniface against the Pelagians. Alypius died in 430. There is extant an epistle of his in Greek addressed to St Cyril, on the heresy of Nestorius.

ALYTARCHA, a magistrate who, at the games instituted in honour of the gods, presided over the officers who carried rods to clear away the crowd and keep order. In the Olympic games, the alytarchai had the same command, and obliged every person to preserve order and decency.

ALYTH, a burgh in Perthshire, with 1840 inhabitants, who support themselves by the manufacture of linen-thread and weaving.

ALZIRA. See ALCIRA.

AMA, in *Ecclesiastical Writers*, denotes a vessel wherein wine, water, or the like, was held for the service of the eucharist. In this sense the word is also written amula; sometimes also hama, and hamula.

AMABYR, a barbarous custom which formerly prevailed in several parts of England and Wales, being a sum of money paid to the lord when a maid was married within his lordship. The word is old British, and signifies *the price of virginity*.

AMAC, surnamed Bokharai, a very distinguished Persian poet, and one of the illustrious men who adorned the court of Kheder Khan. His most celebrated poems are the *History of the loves of Joseph and Zoleiskah*, from the Koran, and an Elegy on the daughter of the Sultan Sandjar.

AMADEUS V. count of Savoy, succeeded his uncle Philip in 1285. In him it appeared that mental excellence can rise superior to riches or extent of territory; for although his dominions were by no means extensive, nor his riches great, yet, in consequence of his wisdom and success, he obtained the surname of *Great*. The cautious prudence of Amadeus, however, enabled him greatly to increase his territory by means of marriage, purchase, and donations. In this situation, with extended dominion, and distinguished for wisdom and prudence, he rose to such eminence among the European powers, that he was constituted their umpire to settle their differences; which office he performed with much reputation to himself and advantage to them. In his character valour and wisdom were combined: for when the Turks attempted to retake the isle of Rhodes from the knights of St John of Jerusalem, he acquired great renown by the valour with which he defended it. A Maltese cross with the letters F. E. R. T. in future became the arms of Amadeus and his successors, in memory of this signal victory. The explanation of this motto is said to be *Fortitudo ejus Rhodum tenuit*, his valour preserved Rhodes. For this important service the grand-master conferred on him the grant of a palace at Lyons. Andronicus, the emperor of the East, had married his daughter; and in order to promote the views of his son-in-law, Amadeus took a journey to Avignon to persuade Pope John XXII. to preach a crusade in favour of Andronicus. He died there in the year 1323. Deep penetration, keen discernment, consummate prudence, great valour, together with no small portion of the religious superstition of his time, appear the most striking features in his character.

AMADEUS VIII. count of Savoy, succeeded his father Amadeus VII. in 1391. With the large sum of 45,000 florins of gold he purchased the country of Genevois from its last earl. Anxious to extend his territories, he purchased the city of Rumilli, upon the lake of Geneva, from the widow of the count of Genevois; and thus the house of Savoy became so powerful, that the emperor Sigismund erected Savoy into a duchy in the year 1416. Historians relate that he assisted John Paleologus against the duke of Milan, who endeavoured to wrest from him the duchy of Montferrat. Deeply sensible of the services which he had received, Paleologus not only resigned to the duke Chivas, Brandis, and several other estates, but submitted to hold all the marquisate of Montferrat as a fief from the house of Savoy. These fortunate acquisitions of territory were not yet limited; for upon the marriage of his daughter with Philip Maria, duke of Milan, he received Vercelli; and about the same time the count of Crescentino submitted to become his feudary. In his ambitious pursuit he laid claim to the sovereignty of the city of Geneva; but that claim, though enforced by the pope, was rejected by the citizens with disdain; and the emperor Sigismund, taking it under his protection, declared it an imperial city. After such an extensive acquisition of dominion, and amassing such sums of money, he formed the singular scheme of abandoning his throne and family; and for that purpose retired to a religious house at a place called *Ripaille*. But although he resigned the dukedom of Savoy to his eldest son Lewis, and made his youngest son Philip count of Genevois, yet their honours were merely nominal; for he constrained them to live on a very scanty allowance, while he in his retirement received all the revenues, and collected such sums of money, that he is said to have purchased the papal honours. Having assumed great sanctity of manners during the previous part of his life, the motives for his retirement were generally reckoned religious; but it was soon discovered that his hermitage was the abode of voluptuous pleasure and of the most refined luxury. Instead of a religious habit, he wore purple robes; and upon his mantle was embroidered a golden cross. His table groaned under a weight of dainties, and the softest music cheered his daily feast: in short, such was the luxury of the place, that in the French language the phrase *faire ripaille* signifies to make exquisitely good cheer.

He instituted a secular knighthood in that place, under the appellation of St Maurice. The brethren assumed the name of hermits, wore beards, and excluded women from their community; and in other respects exhibited the character of decent epicures.

When he obtained the papal dignity, and was crowned by the cardinal of Arles at Basil, all Europe was filled with astonishment in consequence of his elevation; for he had never entered into holy orders. But he had found means to remove every objection, the council confirmed his election, and with pretended reluctance he put on the pontifical ornaments, and was consecrated in the church of St Maurice, under the title of Felix V. The papal dignity was severely contested between him and Eugenius; and, notwithstanding all the importunities of the council, the emperor refused to acknowledge his elevation. This religious dispute involved all Europe in contention. Historians relate that Germany remained neutral, while France, England, Italy, Spain, and Hungary, declared for Eugenius; but Aragon, Poland, and Bretagne, recognised the council only; at the same time that Savoy, Switzerland, Basil, Strasburg, Pomerania, and one of the duchies of Bavaria, recognised Felix. The emperor Frederick III. held a council at Frankfort, before which both the popes urged their respective rights by means of deputies. This attempt, however, to establish peace in Europe proving unsuccessful, the emperor repaired to the vicinity of Basil, and had a personal interview with Felix. Amadeus, that he might the more freely indulge his sensual appetite, again repaired to his favourite retreat; and after the fathers of the council had frequently solicited him in vain to reside at Basil, he prevailed upon them to remove to Lyons, which was near the seat of his pleasures. During the contest Eugenius had excommunicated Felix, the council, and several of the German princes, so that the whole church was then filled with confusion and disorder. The struggle, however, was terminated by the death of Eugenius, when the cardinals at Rome elected Thomas de Sarzan, who assumed the name of Nicholas V. In this state of affairs Amadeus deemed it prudent to enter into a negotiation for the resignation of the papal crown. His policy and address were such that Nicholas was induced to annul all the acts of Eugenius; to confirm the determination of the council of Basil to appoint him perpetual apostolical legate in Savoy, Piedmont, and the other places of his own dominions; and even to confer on him the bishoprics of Basil, Lausanne, Strasburg, and Constance. Nor did his vanity forsake him even in this political transaction, for he provided that he should continue to wear the pontifical dress, unless in a very few particulars. In order to gratify the same haughty disposition, he stipulated that he should not be obliged to go to Rome to attend any general council; and that when he had occasion to approach the pope, he should rise to receive him, and instead of kissing his toe, should be permitted to kiss his cheek. Amadeus retired to Lausanne, and died there at the age of 69, in the year 1451.

Amadeus IX., count of Savoy, succeeded his father Lewis, in his dominion and honours. His bodily constitution was weak, and he was afflicted with the falling-sickness; yet, on account of his piety, virtue, benevolence, and justice, he was surnamed the *Happy*. The clemency of his temper was such that he readily pardoned those who offended him, and in few instances was he induced to punish. In his character the virtue of benevolence shone with peculiar splendour among the other virtues of the Christian. In 1472, in the seventh year of his reign, and the thirty-seventh of his life, he died universally lamented by all his loyal subjects.

AMADIA, a trading town of Asia, in Kurdistan, belonging to the Turks. It is seated on a high mountain. Long. 42. 43. E. Lat. 37. 25. N.

AMADIS de Gaula, the hero of a famous romance of chivalry, written in prose by Vasco Lobeira, a Spaniard, about the end of the twelfth century. It has appeared in numerous editions, and under a variety of forms, both in prose and in verse. The Gaula of the original signifies Wales, and the subject, characters, and localities, are British: the story relates to the fabulous achievements of Welsh and English heroes, previous to the time of Arthur and the knights of the Round Table; and was probably derived by Lobeira from some ancient British or Welsh legend.—See Warton's *History of English Poetry*.

AMADOU, a kind of brown match, tinder, or touchwood, which comes from Germany. It is made of a sort of large mushroom, *Boletus igniarius*, which commonly grows on old trees, especially the oak, ash, and fir. This substance, after being boiled in common water, is dried and well beaten, is then put into a strong ley prepared with saltpetre, after which it is again put to dry in an oven. The druggists sell this match wholesale in France, and it is also retailed by hawkers. Some give to the amadou the name of *pyrotechnical sponge*, because of its aptness to take fire. It is used in surgery to stop hæmorrhage.

AMAIN, in the sea language, a term importing to lower something at once. Thus, *to strike amain* is to lower or let fall the topsails; *to wave amain* is to make a signal, by waving a drawn sword, or the like, as a demand that the enemy strike their topsails.

AMAK, a small island in the Baltic Sea, near Copenhagen, from which it is separated by a canal over which there are three bridges. Amak is about six miles long and three broad, and is chiefly peopled by the descendants of a colony from East Friesland, to whom the island was consigned by Christian II. at the request of his wife Elizabeth, sister of Charles V., for the purpose of supplying her with vegetables, cheese, and butter. From the inter-marriages of these colonists with the Danes, the present inhabitants are chiefly descended; but as they wear their own dress, and enjoy peculiar privileges, they appear a distinct race from the natives. The island contains about 6000 inhabitants. It has two churches, in which the ministers preach occasionally in Dutch and Danish. Long. 12. 35. E. Lat. 55. 30. N.

AMAL, a town of Sweden, in the province of Wenersborg, seated on the lake Wener. It has a good harbour, and carries on a great trade, in iron, timber, deals, and tar. Long. 12. 40. E. Lat. 58. 50. N.

AMALAGAN, one of the Ladrone Islands in Lat. 18. 4. N. Long. 165. 24. 3. E.

AMALARIC was the son of Alaric II., and king of the Visigoths. Deprived of his father when an infant, he would have been bereft of his crown, had not his grandfather Theodoric, king of the Ostrogoths, interposed in his behalf. In defence of the royal infant, Theodoric expelled from the throne his natural brother, who had usurped the government; and, ruling the kingdom during his life, preserved the crown to the natural heir. In 526 the grandfather died, and Amalaric assumed the royal authority. In 527 he married Clotilda, the daughter of Clovis, an amiable lady, who inherited both the piety and orthodoxy of her mother, who was of the same name. The Catholic historians relate, that the king, being violently attached to the Arian cause, used means indicative rather of a cruel than of a pious disposition, to compel his queen to embrace the same opinions. With all the firmness of a great mind, and the amiable patience of a Christian, she endured her wrongs for a considerable period; but at length, worn out with injurious treatment, she was forced to apply to her brothers for assistance, and sent them a handkerchief stained with her blood, in proof of her cruel usage. In order to relieve their sister, one of them, Childebert, king of Paris, entered the territories of Amalaric, who then resided with his court at Narbonne; and their forces having joined battle, the troops of Amalaric were totally defeated, and the king himself forced to save his life by flying into Spain, A.D. 531. It is reported that, when endeavouring to regain Narbonne, he was either slain by an assassin employed by Theudis, his successor, or fell in battle. Some historians say that he died in Barcelona.

AMALASONTHA, or AMALESUENTA, the daughter of Theodoric the Great, king of the Ostrogoths, was born about the year 498. The sister of Clovis was her mother; and in 515 she married Eutharic, the only remaining heir of the legal race of the Amali. Her father having formed the design of making him his successor, sent to bring him from Spain for that purpose. But he never arrived at the destined honour; for Eutharic died before his father-in-law, leaving an only son, Athalaric. The well-known abilities of Amalasontha induced Theodorie to place Athalaric, to whom he had left the kingdom of Italy, under the care of his mother. This princess inherited an ample share of her father's talents, which he had been exceedingly careful to improve by means of a liberal education. She became a great proficient in the philosophy and morals of that age, and with equal elegance and grace could converse in the Greek, Latin, and Gothic languages. Nor were her talents merely qualified to adorn private life: she displayed them in the administration of public justice, and in political discussion. When the chiefs of the Goths were strongly inclined to treat the Romans as a conquered people, she mildly restrained their violent oppression and their ungovernable rapacity. She relieved her subjects from some of the severer impositions of her father; but carefully retained all his laws, magistrates, and political institutions. She patronised learning with an assiduous care, by regularly paying the salaries of public teachers, and giving every encouragement to the improvement of genius. Prompted by maternal affection and a highly cultivated mind, she exerted all her ingenuity in the education of her son Athalaric. Unfortunately, however, both for the mother and the son, neither the general character of the Gothic nation, nor the wayward inclinations of the boy, seconded her laudable endeavours. The Gothic nobles murmured against the effeminate education of their prince, and insisted upon his release from the bondage of learning, and from the restraints of a mother. The unfortunate youth was thus dragged from the habitation of learning, prudence, and virtue; and, plunging into all the extravagancies of dissolute pleasure, his mind became inspired with contempt and aversion for his virtuous mother. At the early age of sixteen, he fell a victim to his debaucheries and follies, and Amalasontha was left devoid of any legal claim to the crown. Spurning the idea of retiring to a private station, she chose her cousin Theodat as her coregent. Theodat, a man of great ability but little principle, soon entered into an intrigue with the ambassador of the emperor Justinian, by which he agreed to remove the unfortunate queen, to make way for the union of the Byzantine and Gothic powers. He accordingly issued an order for her confinement in an island on the lake Bolsena; and in the year 535 she was strangled in the bath. Some historians ascribe this deed to the influence of the empress Theodora, whose jealousy was excited by the respect paid to Amalasontha by Justinian.

AMALEKITES, a powerful people who dwelt in Arabia Petræa, between the Dead Sea and the Red Sea, or between Havila and Shur (1 Sam. xv. 7), sometimes in one country and sometimes in another. It does not appear that they had cities, for there is no mention of any but one in the Scriptures (1 Sam. xv. 5): they lived generally in hamlets, caves, or tents. They were the descendants of Amalek, the son of Eliphaz, by Timna his concubine, and the grandson of Esau. (Gen. xxxvi. 12, and 1 Chron. i. 36.) Amalek succeeded Gatam in the government of Edom.

The Israelites had scarcely passed the Red Sea on their way to the wilderness, before the Amalekites came to attack them in the deserts of Rephidim (Exod. xvii. 8, &c.), and cruelly put to the sword those who were obliged either through fatigue or weakness to remain behind. Moses, by Divine command, directed Joshua to take vengeance upon this people for their inhumanity. He accordingly fell upon them and defeated them with great slaughter (Exod. xvii. 13).

The ground of the enmity of the Amalekites against the Israelites is generally supposed to have been an innate hatred, from the remembrance of Jacob's depriving their progenitor both of his birthright and blessing. Their falling upon them, however, and that without any provocation, when they saw them reduced to so low a condition by the fatigue of their march and an excessive drought, was an inhuman action, and justly deserved the severe punishment inflicted on them by Joshua. Under the Judges (vi. 3), we see the Amalekites united with the Midianites and Moabites in a design to oppress Israel; but Ehud delivered the Israelites from Eglon, king of the Moabites (Judg. iii.), and Gideon (chap. viii.) delivered them from the Midianites and Amalekites. About the year of the world 2930, Saul marched against the Amalekites, advanced as far as their capital, and put all the people of the country to the sword; but he spared the best of the cattle and movables, contrary to a Divine command; which act of disobedience was the cause of his future misfortunes.

After this war the Amalekites scarcely appear any more in history. However, about the year of the world 2949, a troop of Amalekites came and pillaged Ziklag, which belonged to David (1 Sam. xxx.), where he had left his two wives, Ahinoam and Abigail; but on returning from an expedition which he had made in the company of Achish into the valley of Jezreel, he pursued, overtook and dispersed them, and recovered all the booty which they had carried off from Ziklag.

The Arabians maintain that Amalek was the son of Ham, and grandson of Noah; that he was the father of Ad, and grandfather of Schedad. Calmet thinks that this opinion is

Amalfi.

by no means to be rejected, as it is not very probable that Amalek, the son of Eliphaz, and grandson of Esau, should be the father of a people so powerful and numerous as the Amalekites were when the Israelites departed out of Egypt. Moses, in the Book of Genesis (xiv. 7), relates, that in Abraham's time, long before the birth of Amalek the son of Eliphaz, the five confederate kings carried the war into Amalek's country, about Kadesh; and into that of the Amorites, about Hazezon-tamar. Moses also (Num. xxiv. 20) relates, that the soothsayer Balaam, observing at a distance the land of Amalek, said, in his prophetic style, "Amalek is the first, the head, the original of the nations; but his latter end shall be that he perish for ever." Our commentator observes that this epithet of the first of nations cannot certainly agree with the Amalekites descended from the son of Eliphaz, because the generation then living was but the third from Amalek. Besides, Moses never reproaches the Amalekites with attacking their brethren the Israelites; an aggravating circumstance which he would not have omitted had the Amalekites been descended from Esau, in which case they would have been the brethren of the Israelites. Lastly, we see the Amalekites almost always classed in Scripture with the Canaanites and the Philistines, and never with the Edomites; and when Saul made war upon the Amalekites, and almost utterly destroyed them, we do not find that the Edomites made the least attempt to assist them, or to avenge their cause afterwards. Thence it is thought probable that the Amalekites who are so often mentioned in Scripture were a free people descended from Canaan, and devoted to the curse as well as the other Amorites, and very different from the descendants of Amalek, the grandson of Esau.

The accounts which the Arabians give us of the Amalekites destroyed by Saul are as follows: Amalek was the father of an ancient tribe in Arabia, exterminated in the reign of Saul. This tribe contained only the Arabians who are called *Pure*, the remains whereof were mingled with the posterity of Joktan and Adnan, and so became Mosarabes or Mostaarabes; that is to say, Arabians blended with foreign nations. They further believe that Goliath, who was overcome by David, was king of the Amalekites; that the giants who inhabited Palestine in Joshua's time were of the same race; and that at last part of the Amalekites retired into Africa while Joshua was yet living, and settled upon the coasts of Barbary, along the Mediterranean Sea. The son of Amalek was Ad, a celebrated prince among the Arabians. Some make him the son of Uz, and grandson of Aram the son of Shem. Be this as it may, the Mahometans say that Ad was the father of an Arabian tribe called *Adites*, who were exterminated, as they tell us, for not hearkening to the patriarch Eber, who preached to them the unity of God. Ad had two sons, Schedad and Schedid.

AMALFI, seven miles to the west of Salerno, and thirty to the south of Naples, was one of the first Italian cities in which the spirit of commercial enterprise revived after it had been suppressed by the irruption of the barbarians. Though now an obscure village, containing only about 3500 fishermen, it attained, at a remote epoch, to distinction as a maritime republic, and is said by Gibbon to have preceded Venice in re-opening an intercourse with the East. But the more recent researches of Darn, who enjoyed sources of information inaccessible to previous historians, show that this statement is inaccurate, and that Venice carried on a considerable traffic with the Levant before any competitor appeared in the field. But the Amalfitans entered at a very early period on this career, with singular energy and success. In the ninth century, their city is said to have had 50,000 inhabitants. They were extensive navigators and merchants. Their trade comprised the products of Africa, Arabia, and the East; and their settlements in Antioch, Jerusalem, and Alexandria, acquired the privileges of independent colonies. William of Apulia, a writer of the eleventh century, has noticed Amalfi in verses, partly quoted by Gibbon, and said by him to "contain much truth and some poetry."

Amalgam || Amalgamation.

The government was popular under the administration of a duke and the supremacy of the Greek emperor. The mariners who swarmed in her ports excelled in the theory and practice of navigation and astronomy.

We are said to owe a peculiar and not easily exaggerated debt of gratitude to Amalfi. It was, says Sismondi, a citizen of that republic, Flavio Gioja, who invented the compass or introduced it into navigation; in her was found a unique copy of the Pandects which revived the knowledge and the study of jurisprudence in the west; and the maritime laws of Amalfi (*Tabula Amalphitana*) early acquired in the Mediterranean the same influence that was enjoyed by the laws of the Rhodians in antiquity, and that was acquired at a later period by the laws of Oleron in the countries bordering on the Atlantic. Very large deductions must, however, be made from this too partial statement. Gioja may have improved the compass by rendering the needle more suitable to the purposes of navigation; but if he did this much, it is all, for there can be no doubt that it had already been applied to them. Some authorities treat as a fable the story of the famous manuscript of the Roman law carried off by the Pisans from Amalfi, and now at Florence. And though there be no reasonable ground for this exaggerated scepticism, Savigny and others have shown that the study of the civil law was vigorously prosecuted long previously to the alleged discovery of the MS. referred to. The statements respecting the Tabula Amalphitana appear to be entitled to no credit, and to be wholly founded on a mistake. Though several distinguished authorities have referred to this table, none of them quote it, or appear to have seen it. No trace or vestige can now be found of any such table or law. And the presumption is, that it never had any real existence, and that some other law had been mistaken for it. Though brilliant, the prosperity of Amalfi was but short. It was sacked by the Pisans in 1135, when the MS. of Justinian's Compilations is said to have fallen into their hands, and was soon after subjugated by the Normans. Her commerce having been diverted into other channels, she speedily sunk into total obscurity.[1]

At present Amalfi is subject to Naples, and is the see of an archbishop. It is but a shadow of what it was in its flourishing state, when it extended over the stupendous rocks that hang on each side, still crowned with battlemented walls and ruined towers. Its buildings, Mr Swinburne says, are not remarkable for elegance or size, and contain at most 4000 inhabitants, who seem to be in a poor line of life. The cathedral is an uncouth building. Under the choir is the chapel and tomb of the apostle St Andrew, to whose honour the edifice was dedicated, when Cardinal Capuano, in 1208, brought his body from Constantinople.

AMALGAM, mercury united with any other metal.

AMALGAMATION, the operation of making an amalgam, or mixing mercury with any metal.

For the combination of one metal with another, it is generally sufficient that one of them be in a state of fluidity. Mercury being always fluid, is therefore capable of amalgamation with other metals without heat, iron excepted; nevertheless, heat considerably facilitates the operation.

[1] For the above description we are chiefly indebted to Mr M'Culloch's History of Commerce contained in his Treatises on Economical Policy.

To amalgamate without heat requires nothing more than rubbing the two metals together in a mortar; but the metal to be united with the mercury should be previously divided into very thin plates or grains. When heat is used (which is always most effectual, and with some metals indispensably necessary), the mercury should be heated till it begin to smoke, and the grains of metal made red hot before they are thrown into it. If it be gold or silver, it is sufficient to stir the fluid with an iron rod for a little while, and then to throw it into a vessel filled with water. This amalgam is used for gilding or silvering on copper, which is afterwards exposed to a degree of heat sufficient to evaporate the mercury.

Amalgamation with lead or tin is effected by pouring an equal weight of mercury into either of these metals in a state of fusion, and stirring with an iron rod. Copper amalgamates with great difficulty, and iron not at all.

AMALIA, Grand Duchess of Saxe-Weimar, the enlightened patroness of Wieland, Herder, Schiller, and Goethe, governed the duchy after her husband's death till 1775, when she resigned it to her son. She died in 1807. See Weimar.

AMALTEO, Girolamo, Giovanni Battista, and Cornelio, three celebrated Latin poets of Italy, who flourished in the sixteenth century. Their compositions were printed at Venice in 1627, and at Amsterdam in 1684. One of the prettiest pieces in that collection is an epigram, by Girolamo, on two children of extraordinary beauty, each of whom was deprived of an eye:

> Lumine Acon dextro, capta est Leonilla sinistro:
> Et potis est formâ vincere uterque Deos.
> Parve puer, lumen quod habes concede sorori;
> Sic tu cæcus Amor, sic erit illa Venus.

Amalteo, *Pomponio*, an excellent painter of the *second*, or most brilliant epoch of the Venetian school, a pupil of Pordenone, distinguished for his correct design, as well as for his skill in colouring. He was born in 1505, and died in 1588.—See *Zanetti*, and *Lanzi*, tom. iii.

AMALTHÆA, the name of the Cumæan Sibyl, who offered to Tarquinius Superbus nine books containing the Roman destinies, and demanded 300 pieces of gold as their price. The monarch disregarding her demand, she threw three of them into the fire, and returning asked the same price for the remaining six; which being also denied, she burnt three more, and returning demanded the same price for the three that were left. Tarquin, astonished at her behaviour, consulted the pontiffs, who advised him to buy them. These books were so highly esteemed, that two magistrates (*duumviri*) were created to consult them upon extraordinary occasions.—See *Roman History*, xix.

Amalthæa, in *Pagan Mythology*, daughter of Melissus, king of Crete, and nurse of Jupiter, whom she fed with honey and goats' milk. According to others, Amalthæa was a goat, which Jupiter translated into the sky, with her two kids, and gave one of her horns to the daughters of Melissus, as a reward for their care over his infant years. This horn had the peculiar property of furnishing them with whatever they wished for, and was thence called the *cornu copiæ*, or horn of plenty.

AMAMA, Sixtinus, professor of the Hebrew tongue in the university of Franeker, a man of great learning, was born in Friesland, and studied under Drusius. He published a criticism upon the translation of the Pentateuch; collated the Dutch translation of the Bible with the original and the most accurate translations; and wrote a censure of the Vulgate translation of the historical books of the Old Testament, Job, the Psalms, and Canticles. It is impossible to answer the reasons whereby he shows the necessity of consulting the originals. This he recommended so earnestly, that some synods, influenced by his reasons, decreed that none should be admitted into the ministry but such as had a competent knowlege of the Hebrew and Greek text of the Scriptures. Amama died in 1629.

AMAND, Marc Antoine Gerard, Sieur de St, a French poet, was born at Rouen, in Normandy, in 1594. In the epistle dedicatory to the third part of his works, he tells us that his father commanded a squadron of ships in the service of Elizabeth, queen of England, for 22 years, and was for three years a prisoner in the Black Tower at Constantinople. He mentions also that two brothers of his had been killed in an engagement with the Turks. His own life was spent in a continual succession of travels, which proved of no advantage to his fortune. The miscellaneous poems of this author are chiefly of the burlesque and the amorous kind; and though they abound in blemishes, yet his manner of reading them was so agreeable, that they were universally admired. Amand wrote also a very devout piece, entitled *Stances à M. Corneille, sur son Imitation de Jésus Christ*, which was printed at Paris in 1656. He was admitted a member of the French academy when it was first founded by Cardinal Richelieu, in the year 1633; and M. Pellisson informs us that in 1637, at his own desire, he was relieved from the obligation of making a speech, which each member was obliged to make in rotation, on condition that he should collect the burlesque terms, and compile the comic part of the dictionary which the academy had undertaken. For this task he was peculiarly adapted, his writings proving him to be extremely conversant in these terms, which he seems to have diligently collected from the market-places, and other resorts of the populace. He died in 1661.

Amand, *Saint*, a town in France in the department of Cher, capital of the arrondissement of the same name, about 40 miles W.N.W. of Moulins. It is situated on the river Cher. It was built in 1410, on the ruins of Orval. Its principal trade is in cattle, chesnuts, and leather. Population of the town, 7747; of the arrondissement, 103,723. Lat. 46. 40. N. Long. 2. 30. E.

Amand, *Saint*, a town of France, in the department du Nord, on the river Scarpe, about 7 miles N.W. of Valenciennes. It is much frequented for its mud baths, and its mineral and artesian wells. Large quantities of flax are grown in the vicinity. Pop. 9500. Lat. 50. 27. N. Long. 3. 25. E.

AMANTEA, a seaport town and bishop's see of the kingdom of Naples, situated near the bay of Euphemia, in the province of Calabria, 15 miles south-west of Cosenza. Pop. 3000.

AMANUS, a mountain of Syria, separating it from Cilicia; a branch of Mount Taurus (Cicero, Strabo, Pliny), extending chiefly eastward, from the sea of Cilicia to the Euphrates. It is now called *Monte Negro*, or rather *Montagna Neres*, by the inhabitants; that is, the watery mountain, as abounding in springs and rivulets.

AMARA SINHA, a celebrated Sanscrit poet and grammarian, who published a valuable Thesaurus of that language, called *Amara Kosha*. He is believed by some to have flourished in the fifth century of our era. It is stated by Wilson, that his work contains only the *roots* of Sanscrit, amounting to 10,000. The best edition of his work is that of Scrampore, by H. T. Colebrooke, in 1806, reprinted in 1829. See Wilson's *Sanscrit Dict.*, and *Asiat. Res.* vii.

AMARANTE, an order of knighthood instituted in Sweden by Queen Christina in 1653, at the close of an annual feast celebrated in that country called *Wirtschaft*. This feast was solemnized with entertainments, balls, masquerades, and similar diversions, and continued from evening till the next morning. Christina considering the name too vulgar, changed it into that of the *feast of the gods*, because each of the party represented some heathen deity. The queen herself assumed the name of *Amarante;* that is, unfading, or immortal. The young nobility, dressed in the habit of nymphs and shepherds, served the gods at table. At the end of the feast the queen threw off her habit, which was covered with diamonds, leaving it to be pulled in pieces by the maskers; and, in memory of so gallant a feast, founded a military order, called in Swedish *Geschilschafft*, into which all that had been present at the feast were admitted, including sixteen lords and as many ladies, besides the queen. Their device was the cipher of *Amarante*, composed of two A's, the one erect, the other inverted, and interwoven together; the whole enclosed with a laurel crown, with this motto, *Dolce nella memoria*.

AMARANTACEÆ, a natural order of plants, some of which are indigenous with us; but most of them are tropical. None of them are poisonous.

AMARAPURA. See Ummerapura.

AMARYNTHIA, or Amarysia, a festival of Artemis, celebrated with extraordinary splendour at Amarynthus in Eubœa, and afterwards at Athens, and elsewhere.

AMARYLLIDEÆ, a natural order of plants with monopetalous flowers, and bulbous roots, several of which are deadly poisons, as the *Hæmanthus toxicanus* used by the Bosjesmans of the Cape, to poison their arrows. Many of them contain wholesome fecula when the acrid juice is separated from it.

AMASA, son of Abigail, a sister of David king of Israel, and commander of Absalom's army in his rebellion. He afterwards obtained a similar command from his uncle.—(2 Sam. xvii. 25, xix. 13.)

AMASIA, an ancient town of Turkey, in Natolia, and the birthplace of Strabo the geographer. It is the residence of a bashaw, and gives its name to the province where it is situated, which produces the best wines and fruits in Natolia. It is situated near the river Iris or Yeshil-Irmak, and was anciently the residence of the kings of Cappadocia. Long. 36. 26. E. Lat. 40. 33. N.

AMASIS, king of Egypt, ascended the throne B.C. 569. From the rank of a common soldier he gradually rose to be one of the principal officers in the court of Apries. Being commissioned by his prince to pacify some insurgents who had rebelled against the royal authority, he attached the disaffected subjects to his own interest, and took up arms against his master. Apries, apprised of his treachery, sent another of his officers to bring the rebel before him; but this messenger returning with an insolent reply from Amasis, was barbarously mutilated by the tyrannical monarch. The nobles who still remained obedient to their prince, shocked by the barbarity with which he treated his ambassador, immediately joined the standard of the usurper. The tyrant, thus deserted by his subjects, took the field with an army of mercenaries, and meeting Amasis near Memphis, was defeated and taken prisoner. The usurper treated the captive prince with great lenity; but so violent was the popular hatred, that he was compelled to deliver him into the hands of his enraged countrymen, who instantly put him to death by strangling.

Under his prudent administration Egypt enjoyed the greatest prosperity. He adorned it with numerous and splendid buildings, among which were a portico to the temple of Minerva, at Sais, and the great temple of Isis, at Memphis. He also erected a colossus before the temple of Vulcan, 75 feet in length, resting on its back; and on the basis stood two statues, each 20 feet high, cut out of the same stone. Besides these, he erected several monuments in Greece.

The liberality and respect for science which Amasis displayed, and the encouragement he gave to learned strangers, particularly to the Greeks, to visit his country, manifested an enlightened mind. To induce Grecian strangers to remain in Egypt, he marked out settlements for them on the sea-coast, permitting them to build temples, and to observe all the rites of their religion unmolested. Solon, the celebrated lawgiver, is reported to have visited Amasis. Such was his generorsity, that when the temple of the Delphians was burnt, he presented them with 1000 talents to assist them in rebuilding it. To gratify the vanity, or secure the alliance of the Greeks, he married a Grecian lady, named Ladice, the daughter of Battus. The evening of his reign was clouded by the prospect of the invasion of Cambyses, king of Persia, who shortly after subjugated his kingdom. In this emergency Phanes, captain of the Greek auxiliaries in the service of Amasis, being offended at his master, deserted his cause, and went over to the enemy. Polycrates also, tyrant of Samos, who had long been a friend and ally of the Egyptian monarch, now joined the standard of Cambyses. Whether apprehensions of the impending storm tended to impair his health, is not related; but about this time he died, in 525 B.C., after a reign of 44 years.

AMATI, Pasquale, an Italian antiquary, born at Savignano in 1716, the author of several learned works, the best known of which is that—*De Restitutione Purpurarum*.

His two sons were also distinguished: the elder, Girolamo, was the author of several dissertations on inscriptions, and other learned works; and Basilio, the younger son, wrote *L'Isola del Congresso triumvirale*, &c., and some poetry.

AMATUS LUSITANUS, properly João Roderiguez, a learned Hebrew physician of the sixteenth century. Concealing his religion, he studied at Salamanca, and long lived in Italy, where he was called to attend Pope Julius III., about the middle of that century. The fear of the Inquisition drove him to Thessalonica, where he openly professed the Jewish religion. His remarks on Dioscorides show him to have been skilled in Greek and Arabic; and his Latin work on practical medicine contains many curious observations. He was born in Portugal in 1511, and died at Thessalonica (Saloniki) in 1568.

AMAUROSIS, ἀμαὺρωσις, a deprivation of sight, the eye remaining seemingly unaffected. A perfect amaurosis is when the blindness is total. When there is still a power of distinguishing light from darkness, the disease is called by M. de St Ives an *imperfect amaurosis*. There is a periodical sort, which comes on instantaneously, continues for hours or days, and then disappears.

AMAXICHI, a seaport and capital of Santa Maura, one of the Ionian Islands. The town is small and ill built; and the harbour is only fit for small craft. Population 6000. It is the residence of a British governor and of a Greek archbishop.

AMAZIAH, the eighth king of Judah, succeeded his father Joash in the 25th year of his age. At the commencement of his reign he showed some reverence for the Divine authority, but, in the language of Scripture, "not with a perfect heart." He speedily inflicted capital punishment on the murderers of his father; but from respect to the law of Moses he spared their families, an extension of clemency not very common in those times. He gave early proof of his military spirit, by collecting a numerous army to attack the Edomites. This force was composed not only of all his own subjects capable of bearing arms, but of a powerful body of auxiliaries hired from the children of Israel. By the advice of a prophet, however, the Israelites, amounting to 100,000 men, were dismissed, and he prosecuted his enterprise with the remainder of his army. Having engaged the Edomites in the valley of Salt, he defeated them with the loss of 10,000 men, and following up his victory, made himself master of Selah, their metropolis. He also possessed himself of the enemy's idols, and impiously made them the objects of his adoration. Meanwhile the Israelites, whom he had discharged, either offended by their dismissal, Amazon. or disappointed of their hope of plunder, turned their arms against the kingdom of Judah, and plundered many of the cities. Amaziah, elated by his success, sent a hostile challenge to Joash, king of Israel, to which Joash contemptuously replied in a fable. (2 Kings xiv. 9.) Indignant at the insult, Amaziah immediately took the field, and encountering the Israelites at Bethshemesh, was defeated and taken prisoner. After his victory, Joash procceded to Jerusalem, carrying along with him his vanquished enemy; and having broken down part of the wall of the city, and plundered the temple and palace, he returned with the spoil to Samaria. This misfortune seems to have damped the military ardour of Amaziah; for although he reigned 15 years after his defeat, we are not informed of his engaging in any hostility with his neighbours. He fell by the hands of conspirators, in the 29th year of his reign. (2 Kings xiv.; 2 Chron. xxv.)

AMAZON, Maranon, or Orellana, a river of South America, and the largest in the world. Its proper and most remote source is the Ucayale, a branch of which rises near La Paz, in 18° of south latitude. The Marañon, a more northern branch, rises in a lake north-eastward of Lima, and, after a course of many miles to the north, is joined by the Chinchipe at Jaen. From this point, which is only about 200 miles from the Pacific Ocean, the river continues navigable to its embouchure in the Atlantic, a distance of 2100 miles in a direct line, or 3000 miles by the course of the stream. Humboldt measured the height of this spot by the barometer, and found it to be 194 toises, or 1240 English feet; and hence it appears that the fall in the bed of the river is on an average about five inches per mile; but the inclination is of course greater in the upper than in the lower part of the stream. Condamine found the width of the river at some distance below Jaen to be 135 toises, or 860 feet, and the depth to exceed 180 feet. The Marañon is joined by the Ucayale in west longitude 73°, by the Napo at $71\frac{1}{2}$°, by the Japura at 65°. The other most considerable branches are the Negro on the north side, and the Juruay, the Madeira, and the Tapajos, on the south. Many of the tributaries of the Amazon greatly surpass in size the Rhine or the Danube; and their number is very great. It flows through 22° of longitude, near the equator. The country, watered by the river and all its branches, embraces an area of 2,100,000 square English miles, and includes one third part of South America. At a pass called the Pongo, about 140 miles below Jaen, the bed of the stream is suddenly contracted from 250 fathoms to 25, the Amazon having here cut its way through the rocks, which rise like perpendicular walls to a great height. At the junction with the Napo, in longitude $71\frac{1}{2}$°, its breadth is 900 fathoms, and its depth was found to exceed 100 fathoms. Between the Negro and the Madeira it has the breadth of a league, which extends to two leagues at those parts where islands abound; but during the annual swell of the water it covers a great part of the adjoining country, and has then no determinate limits. At Pauxis, 200 miles from the sea, the tides are sensibly felt every ten hours; and Mr Condamine infers, from the time which the swell of the waters requires to travel this distance, that there must be a succession of tides in the river at all times, and that its surface of course presents an undulating line. This traveller computes that the water passes from Jaen to the sea in 45 days, flowing about 66 miles per day, or $2\frac{3}{4}$ miles in the hour. But the influence of the tides is felt 400 miles from the embouchure. In the rainy season the rapidity of this river is four miles an hour; and where it meets the ocean its breadth is fully thirty miles. The sea retreats before this mighty mass of rushing water, which causes a very agitated swell; and the river current is said to be still perceptible at more than 400 miles from the shore. Some reckon the Rio Tunguragua the source of the Marañon, which would give it a course of 3300 English miles; but if we consider the Rio Ucayale as its source, its course cannot be less than 3700 English miles.

Amazons. It receives enormous tributaries,—from the north the Rio Napo and Rio Putumayo, each about 700 miles long; the Yapura, 900 miles; the Rio Negro, 1400;—from the south, the Yavari, the Yutia, the Tefe, the Puru, and above all, the Rio Madeira, that joins the Marañon after a course of 1800 miles; besides the Topayos of 900, and the Xingu of 1000 miles.

It is a remarkable fact that the great South American rivers, the Marañon and Orinoco join, by a large branch, the Rio Cassiquiare. The Amazon traverses a region thickly covered with lofty forests, which are the haunts of the jaguar, bear, panther, and many other wild animals, and are inhabited by numerous small tribes of savages, among whom the Spaniards and Portuguese have established missionaries. The river abounds in fish, many of which are of the most delicious kinds; and turtles of an excellent quality are numerous. Large alligators are seen stretched motionless in the mud, like trunks of trees. Nearly all the branches of this noble stream are navigable to a great distance from their junction with the main trunk; and collectively, the whole afford an extent of water communication unparalleled in any other part of the globe. What adds to this advantage is, that as the wind and the current are always opposed to each other, a vessel can make her way either up or down with great facility, by availing herself of her sails in the one case, and committing herself to the force of the current in the other.

AMAZONS, in *Antiquity*, a nation of female warriors, who are said to have founded an empire in Asia Minor, upon the river Thermodon, along the coasts of the Black Sea. They are reported to have formed a state, out of which men were excluded, their commerce with that sex being confined to strangers. They killed all their male children, and cut off the right breasts of their females, to make them more fit for the combat. From the last circumstance they are supposed to derive their name, viz., from the privative α, and μάζος, *mamma*, breast. But Bryant, in his *Analysis of Ancient Mythology*, vol. iii. p. 463, rejects this account as fabulous; and observes that they were in general Cuthite colonies from Egypt and Syria, who formed settlements in different countries, and that they derived their name from *zon*, the sun, which was the national object of worship.

The Amazons are mentioned by the most ancient of the Greek writers. In the third book of the Iliad, Homer represents Priam speaking of himself as having been present, in the earlier part of his life, in a battle with the Amazons; and some of them afterwards came to the assistance of that prince during the siege of Troy.

The Amazons are particularly mentioned by Herodotus. That historian informs us that the Greeks fought a battle with them on the river Thermodon, and defeated them. After this victory the Greeks carried off in three ships all the Amazons they had taken prisoners. But while they were out at sea, the Amazons conspired against the men, and killed them all. Having, however, no knowledge of navigation, nor any skill in the use of the rudder, sails, or oars, they were driven by wind and tide till they arrived at the precipices of the Lake Mæotis, in the territories of the Scythians. Here the Amazons went ashore, and marching into the country, seized and mounted the first horses they met with, and began to plunder the inhabitants. The Scythians at first conceived them to be men; but after having several skirmishes with them, and taking some prisoners, they discovered them to be woman. They were then unwilling to carry on hostilities against them; and by degrees a number of the young Scythians formed connections with them, and were desirous that these gentle dames should live with them as wives, and be incorporated with the rest of the Scythians. The Amazons agreed to continue their connection with their Scythian husbands, but refused to associate with the rest of the inhabitants of the country, and especially with the women. They afterwards prevailed upon their husbands to retire to Sarmatia, where they settled.

Diodorus Siculus says, "There was formerly a nation who dwelt near the river Thermodon, which was subjected to the government of women, and in which the women, like men, managed all the military affairs. Among these female warriors, it was said, was one who excelled the rest in strength and valour. She assembled together an army of women, whom she trained up in military discipline, and subdued some of the neighbouring nations. Afterwards, having by her valour increased her fame, she led her army against the rest; and being successful, she was so puffed up, that she styled herself the daughter of Mars, and ordered the men to spin wool, and do the work of the women within doors. She also made laws, by which the women were enjoined to go to the wars, and the men to be kept at home in a servile state, and employed in the meanest offices. They also debilitated the arms and thighs of those male children who were born of them, that they might be rendered unfit for war. They seared the right breasts of their girls, that they might be no interruption to them in fighting: whence they derived the name of Amazons. Their queen, having become extremely eminent for skill and knowledge in military affairs, at length built a large city at the mouth of the river Thermodon, and adorned it with a magnificent palace. In her enterprises she adhered strictly to military discipline and good order; and she added to her empire all the adjoining nations, even to the river Tanais. Having performed these exploits, she at last ended her days like a hero, falling in a battle in which she had fought courageously. She was succeeded in the kingdom by her daughter, who imitated the valour of her mother, and in some exploits excelled her."

Diodorus also mentions another race of Amazons who dwelt in Africa, and whom he speaks of as being of greater antiquity than those who lived near the river Thermodon.

Justin represents the Amazonian republic as having taken its rise in Scythia. The Scythians had a great part of Asia under their dominion upwards of 400 years, till they were conquered by Ninus, the founder of the Assyrian empire. After his death, which happened about 1150 years before the Christian era, and that of Semiramis and their son Ninyas, Ilinus and Scolopites, princes of the royal blood of Scythia, were driven from their country by other princes, who like them aspired to the crown. They departed with their wives, children, and friends; and being followed by a great number of young people of both sexes, they passed into Asiatic Sarmatia, beyond Mount Caucasus, where they formed an establishment, supplying themselves with the riches they wanted, by making incursions into the countries bordering on the Euxine Sea. The people of those countries, exasperated by the incursions of their new neighbours, having united, surprised and massacred the men.

The women then resolving to revenge their death, and at the same time to provide for their own security, resolved to form a new kind of government, to choose a queen, enact laws, and maintain themselves without men, even against the men themselves. This design was not so very surprising as at first sight appears: for most of the girls among the Scythians had been inured to the same exercises as the boys; to draw the bow, to throw the javelin, to manage other arms; to riding, hunting, and even the painful labours that seemed reserved for men; and many of them among the Sarmatians accompanied the men in war. No sooner had they formed their resolution than they prepared to execute it, and exercised themselves in all military operations. They soon secured the peaceable possession of the country; and, not content with showing their neighbours that all their efforts to drive them thence or subdue them were ineffectual, they made war upon them, and extended their own frontiers. They had hitherto made use of the instructions and assistance of a few men that remained in the country; but finding at length that they could stand their ground and aggrandize themselves without them, they killed all those whom flight or chance had saved from the fury of the Sarmatians, and for ever renounced marriage, which they now considered as an insupportable slavery. But as they could only secure the duration of their new kingdom by propagation, they made a law to go every year to the frontiers, to invite the men to come to them; to deliver themselves up to their embraces, without choice on their part, or the least attachment; and to leave them as soon as they were pregnant. Those whom age rendered fit for propagation, and who were willing to serve the state by breeding girls, did not all go at the same time in search of men: for in order to obtain a right to promote the multiplication of the species, they must first have contributed to its destruction; nor was any one thought worthy of giving birth to children till she had killed three men.

If from this commerce they brought forth girls, they educated them; but, with respect to the boys, if we may believe Justin, they strangled them at the moment of their birth.

Plutarch, treating of the Amazons in his life of Theseus, considers the accounts which have been preserved concerning them as partly fabulous and partly true. He gives some account of a battle which had been fought between the Athenians and the Amazons at Athens; and he relates some particulars of this battle which had been recorded by an ancient writer named Clidemus. In another place he says, "It appears that the passage of the Amazons through Thessaly was not without opposition; for there are yet to be seen many of their sepulchres near Scottussa and Cynocephalæ;" and in his life of Pompey, speaking of the Amazons, Plutarch says, "They inhabit those parts of Mount Caucasus that look towards the Hyrcanian Sea, not bordering upon the Albanians, for Gelæ and Leges lie between; and with these people do they yearly, for two months only, accompany and cohabit, bed and board, near the river Thermodon. After that they retire to their own habitations, and live alone all the rest of the year."

Quintus Curtius has given a circumstantial account of the visit of the Queen of the Amazons to Alexander the Great.

Justin also repeatedly mentions this visit of Thalestris to Alexander; and in one place he says that she made a march of 25 days in order to obtain this meeting with him. The interview is likewise mentioned by Diodorus Siculus.

The Amazons are represented as being armed with bows and arrows, with javelins, and also with an axe of a particular construction, which was denominated the axe of the Amazons. According to the elder Pliny, this axe was invented by Penthesilea, one of their queens. On many ancient medals are representations of the Amazons armed with these axes. They are also said to have had bucklers in the shape of a half-moon.

That at any period there should have been women who, without the assistance of men, built cities and governed them, raised armies and commanded them, administered public affairs, and extended their dominions by arms, is undoubtedly so contrary to all that we have seen and known of human affairs, as to appear in a very great degree incredible; but that women may have existed sufficiently robust and sufficiently courageous to have engaged in warlike enterprises, and even to have been successful in them, is certainly not impossible, however contrary to the usual course of things. That much of what is said of the Amazons is fabulous, there can be no reasonable doubt; but it does not therefore follow that the whole is without foundation. The ancient medals and monuments on which they are represented are very numerous, as are also the testimonies of ancient writers. It seems not rational to suppose that all this originated in fiction, though it be much blended with it. We now know that in the Negro kingdom of Dahomey the present ruler of that country, who humbled the power of the Ashantees, has among his choicest troops battalions of women, who are as fearless and redoubtable as the ancient Amazons.

AMBACHT is a word which denotes a kind of jurisdiction or territory, the possessor whereof has the administration of justice, both in *alto* and *basso;* or of what is called in the Scottish law, *a power of pit and gallows*, i. e., a power of drowning and hanging. In some ancient writers, ambacht is particularly used for the jurisdiction, government, or chief magistracy of a city. The word is very ancient, though used originally in a sense somewhat different. Ennius calls a mercenary, or slave hired for money, *ambactus;* and Cæsar gives the same appellation to a kind of dependents among the Gauls, who, without being slaves, were attached to the service of great lords.

AMBARVALIA, in *Antiquity*, an annual ceremony among the Romans, on the Ides of May, when, in order to procure from the gods a happy harvest, they conducted the victims thrice round the corn-fields in procession before sacrificing them. *Ambarvalia* were either of a private or public nature: the private were performed by the master of a family, and the public by the priests, called *fratres arvales*, who officiated at the solemnity. The prayer preferred on this occasion, the formula of which we have in Cato, *de Re Rustica*, cap. cxlii. was called *carmen ambarvale.* At these feasts they sacrificed to Ceres a sow, a sheep, and a bull or heifer; whence they took the name of *suovetaurilia.* The method of celebrating them was, to lead a victim round the fields, while the peasants accompanied it, and one of their number, crowned with oak, hymned forth the praises of Ceres in verses composed for the occasion. The processions and ceremonies of *Rogation*, or *Gang-week* of the Latin Church, bore a great resemblance to the ancient ambarvalia. Since the Reformation the perambulation of the parish boundaries has been substituted in their place.

AMBASSADOR, a word of disputed origin, but probably adopted into the English language from the French, means, in its general sense, a minister authorised by any state to represent it in some other. In its distinctive sense, as indicating a particular kind of minister so appointed, it means the highest class; and by authority as well as practice, there are states which may be represented at others, yet are understood not to be entitled to appoint so high a representative as an ambassador. Messages require to be interchanged by all moderately civilised nations, unless those which, like the Chinese or the Japanese, peculiarly isolate themselves. Hence such messages, and the manner in which they were sent and received, are familiar occurrences in all histories. Some understanding that the persons who undertook such a function should enjoy freedom and safety in the state to which they were sent was absolutely necessary for its performance. The Romans adopted strict rules for the safety of ambassadors; but the less definite provisions of other nations were liable to be affected by momentary impulses, and many incidents of ancient warfare arose out of insults or injuries committed on ambassadors. It was on the ground of an insult offered to his ambassadors that Alexander destroyed Tyre. The Persian invasions of Greece were stimulated by the slaughter of the ambassadors of Darius—who, however, demanding earth and water as tokens of dependence, were rather messengers of hostility than ambassadors, in anything like the modern sense of the term. Ambassadors now communicate privately with sovereigns or official persons, not with legislative bodies. In Greece, however, ambassadors sometimes pleaded the cause of their state in the public assemblies, and in Rome they were formally received by the senate. The *legatus* of the Romans answered pretty nearly to our Ambassador Extraordinary; but the term was also used to mean another and totally different officer who accompanied the proconsul or governor of a province, and was more like a colonial secretary. It became the practice to give honorary legations of this kind on account of the privileges which they conferred on the holder in the province to which he was accredited. There is, however, a distinction of a generic and very characteristic kind between the ambassador of modern diplomacy and any ancient representatives of states. The ambassador of old was chosen for a particular message or negotiation, and a permanent resident representative of one state within another was unknown, at least as a system. It is not yet intelligible to nations beyond the circle of European diplomacy. The Turks had the inveterate practice, on going to war with a state, of committing its representative to the seven towers; and though the reason assigned for the practice was the safety of the person of the ambassador from outrage, even this, if it were sincere, showed that the feelings of hatred indulged against a member of a hostile state would break out too strongly to be controlled even by that despotic government. The Chinese, and their neighbours nearer Hindustan, can look on an ambassador or diplomatic agent as merely a dignified spy, to whose presence nothing but necessity compels them to submit. Nor are they entirely wrong, since the European embassies may be counted a mutually tolerated system of espionage. Even Wickefort calls the ambassador an honourable spy, protected by the law of nations; and La Bruyere says epigramatically, that the ambassador's function is to cheat without being cheated. The understanding that an ambassador was a person ever ready to do whatever he could with safety to the advantage of his own country, and the injury of that to which he was accredited, became a standing object of sarcasm with the wits of the seventeenth century. Sir Henry Wotton, himself an ambassador, when asked to write something in an album at Augsburg, could not resist a sarcasm on the same subject, and spoke of an ambassador as a person sent abroad to lie for the good of his country. In its English form, his apophthegm generally involves a pun or equivoke in the words "lie abroad," of which the original Latin is, however, not susceptible. Scioppius published it as a declaration of the morality of English diplomacy, and brought Wotton under temporary disgrace with King James; to whom the jest seemed the more dangerous that it announced that false and treacherous system of diplomacy on which he with most of the sovereigns of the age acted when it was safe to do so.

Permanent embassies, with the eminent personal privileges conceded to ambassadors, have existed in feudal Europe from an early time. To find the origin of an institution seemingly so much at variance with the selfish and ravenous national habits amidst which it arose, we must look to the peculiar sacredness claimed for their persons by the great community of European monarchs. The privileges of the ambassador did not arise from principles of jurisprudence founded on general public utility, but from the practice of the sovereign investing his representative with his own sacredness, and the acknowledgment on the part of the brother sovereign of the

Ambassador.

sufficiency of the investiture. Thus in ages when international law was rude and little respected, ambassadors claimed privileges which would in the present day be deemed preposterous; such total exemption from liability to the laws, civil or criminal, of the country to which they were accredited, and the right to have their official places of residence respected, as sanctuaries for criminals fleeing from justice. Ambassadors of old, in fact, thus received concessions which, though claimed by them as belonging properly to their masters as sovereign princes, and descending to themselves only as substitutes, would not practically have been enjoyed by sovereign princes though theoretically conceded to them. The advantage obtained over a state by seizing the person of the sovereign, would have rendered it unsafe for the principal to trust to privileges which, in the less available person of his representative, were scrupulously respected.

From this fictitious royalty came many of the practical peculiarities of the embassies of the present day. The qualification of "Excellency" applied to ambassadors is a communication from the titles of sovereign princes. They have the right of appearing covered before sovereigns in their formal audiences—a right not actually exercised, but still symbolically acknowledged. The ambassador's immunities extend to the persons brought in his train, not as participating in his fictitious sovereignty, but as his subjects who are exempt from the authority of the state to which he is accredited, and responsible solely to him as their local and temporary sovereign. Thus, by the "exterritoriality," as it has been termed, of an embassy, the persons of the ambassador and his suite, his dwelling-house and his carriages were all deemed a part of his own nation, as inviolable by diplomatic understanding as the court of his sovereign was by distance and armed protection. The most prominent relic at the present day of this fictitious royalty, is the splendour and costliness of the embassies of the great powers —qualifications in which the United States of America, not having the same traditional dignity to support, have had the good sense not to compete with them.

As the theory, indeed, of the ambassador's rank and privileges were that he represented, not the state or people from whom he came, but the king, a disposition has often been shown to deny at least the higher privileges of embassy to republics. Until Cromwell's power commanded respect, the representatives of the English Commonwealth were treated with much indignity, and two of them were slain by royalist refugees—Dorislaus in Holland, and Ascham in Spain. In 1663 the court of Louis XIV. haughtily refused to concede the usual honours to the representatives of the Swiss cantons. It is not the practice of the United States to profess to accredit ambassadors of the highest diplomatic grade, nor does their condition in European diplomacy fortunately tempt them to transgress this prudent rule. On the other hand, it is not usual to accredit the highest class of ambassadors to that frugal government; though, for the adjustment of the late difficulties about the Oregon boundary, Lord Ashburton was commissioned with high and peculiar power to negotiate with the States. It is curious to find in the article *Ambassadeur* in the *Encyclopédie Moderne*, written between the fall of Louis Philippe and the re-establishment of the empire by Louis Napoleon, complaints of the still extant humiliations to which republican ambassadors are liable.

The privileges conceded to the fictitious sovereignty of the ambassador, like many other institutions of a like barbarous origin, have been directed in the progress of civilisation to serviceable ends. That the representative should be able to keep himself from being in any way involved in the social or political movements of the state to which he is accredited, is an unquestionable advantage. The exterritoriality has been found serviceable in adjusting many difficulties in international law; that which is done under the auspices of the ambassador, as a marriage in his chapel, being deemed the same in law as if it had taken place in his country. Thus in very intolerant countries an embassy has often acted as a little centre of toleration, which governments, prevented by high priestly influences from avowedly acting on liberal principles, have been glad rather to cherish than discourage.

It has always been difficult in countries not despotic to preserve the sacredness of embassies when circumstances have made them offensive to the people. Thus it was difficult to keep Gundomar the celebrated Spanish ambassador in James the First's reign from violence by the London mob for introducing sedan-chairs, which they called a device for enslaving Englishmen and making them do the work of beasts. In the anti-Popery riots of 1780 the chapels of the Bavarian and Sardinian embassies were burned. It has ever been usual to exact high satisfaction for injuries offered to ambassadors, and despotic courts have had no difficulty in conceding the demand where this was rendered prudent by the power of the offended party. Diplomatic difficulties of a serious kind have often occurred, however, in constitutional countries where the asserted privileges of the foreign ambassador were found to clash with the undoubted rights of the home citizen. In 1668 the Portuguese minister was imprisoned for debt in Holland, and in 1708 a similar event produced a serious diplomatic difficulty in England. The Russian ambassador, having had his audience of leave, was arrested for debt by some tradesmen in the open streets of London. Deeming that he was attacked by bravos, he defended himself, and was not secured without suffering much violence and indignity. The Czar immediately demanded the infliction of capital punishment on those who had been guilty of the outrage. Much parade was made about instituting prosecutions against all the parties concerned in the affair; but it was impossible for the government ultimately to treat it otherwise than as a matter for which unfortunately the law made no provision. All that could be done was to pass an act to remedy the defect; and to sooth the Czar its preamble denounced in very angry terms the unparalleled wickedness of those turbulent and disorderly persons who had outrageously insulted the person of his excellency the ambassador-extraordinary of his Czarish majesty, emperor of Great Russia, to whom a copy of the act was sent with distinguished pomp. The diplomatic body in general, discontented with the haughty tone of the English court, took up the question. When the bill was passing they objected to some parts of it, and particularly to a condition of the protection of ambassadors' retinues, that their names should be recorded with the Secretary of State and the sheriffs of London; but parliament, then exulting in the continental triumphs of Marlborough, received their demands with haughty silence.

It happened almost at the same time that the British government had shown a memorable instance of the sternness with which it insisted on preserving the inviolability of its own ambassadors. When the Earl of Manchester was ambassador at Venice in 1708, some persons had managed, under the protection of his diplomatic privileges, to attempt smuggling operations, and in the efforts to detect them, the Earl's gondola was seized with smuggled goods in it. In such matters the British government has generally acted on the knowledge that in despotic states the government can prevent or cause all such incidents. In this instance, there were high state-reasons for demanding satisfaction, since there was reason to suppose that the Senate was secretly in league with France, then projecting an invasion of

Britain; and Lord Manchester would not be appeased until three official persons were sent to the galleys and others pilloried. In 1716, Britain again excited the indignation of the diplomatic circle by the seizure of the Swedish representative and his correspondence. His residence was suddenly surrounded by a party of soldiers, and his confidential papers—some of which his wife was concealing—were appropriated. The question whether such an act was consistent with the law of nations, was pretty effectually answered in the particular occasion, by an exposure of the resident's flagitious breach of this law, in employing his opportunities as ambassador to foster treason and make arrangements for an invasion of the country to which he was accredited.

The rank of ambassadors is regulated by a double gradation—the importance of the object of the mission, and the rank of the court they represent. It has always been the object of governments rising in power, like that of Prussia under the great Frederic, to obtain some step in diplomatic rank, while old states have resisted the demand and endeavoured in other ways to hold their previous relative position. Ambassadors have, from incidental circumstances, been admitted to a representative rank in some courts, which has been denied to them in others. Thus the representatives of the knights of Malta were in the middle of the eighteenth century received as ambassadors of the highest order at the courts of Rome and Vienna.

The various sources of distinction, founded on the title given to the ambassador, the rank of the state sending, that of the state receiving, and sometimes the social rank of the ambassador himself, make an almost insoluble complexity of positions, which have exercised the ingenuity of the writers on diplomacy. But the complexity has this advantage, that when there is an earnest wish to transact business, means are found for evading questions of etiquette. The great resource of those states whose right to send a minister of the highest order is disputed, is to transact their business through a minister of a secondary class; for as the class may depend as much on the rank of the court sent to as that of the court accrediting, direct assumptions or humiliations are thus avoided.

It has been usual since the Congress of Vienna to divide representatives into three great classes—ambassadors, envoys, and residents or *charges des affaires*. The first and second are accredited from the head of the government, and communicate with the head; the third class have instructions from the foreign department of their own government, and communicate with that of the state they are sent to. The term Ambassador-Extraordinary having been applied to those sent on temporary missions of high importance, the term extraordinary came to be extended to the permanent ambassadors at the courts of the great powers, as it was deemed desirable that no diplomatic rank should be deemed higher than theirs. There are at present (1853) accredited from Britain, ambassadors-plenipotentiary at the courts of France and Turkey. To Austria, Prussia, Russia, Spain, Denmark, Sweden, Hanover, Sicily, the Netherlands, Belgium, Sardinia, the United States, and Brazil, there are envoys extraordinary. In smaller states our representatives are called ministers plenipotentiary, or *charges des affaires;* and in some states, many of them important in trade, though not in diplomacy, as China, a consulate is deemed sufficient. The ceremonial system connected with embassies has naturally ceased to retain its old importance of late years, a portion of it only being preserved by routine, but it is still usual to gratify oriental courts by receiving their representatives with noisy pomp. The manner in which an ambassador's conduct must be regulated by the relative condition to each other of the states between which he acts, belongs to the subject of diplomacy. The ambassador has occupied a large place in the treatises on diplomacy and international law from Grotius downwards, and Wickefort devoted two considerable quarto volumes to *L'Ambassadeur et ses Fonctions*. See Diplomacy, International Law.

Ambassador.

We subjoin the official return of the allowances of the ambassadors, envoys, ministers, chargés d'affaires, secretaries of legation, or secretaries of embassy, and paid attachés, in the diplomatic service of Britain.

(J. H. B.)

AMBE, in *Surgery*, the name of an instrument formerly used for reducing dislocated bones; in *Anatomy*, a term for the superficial jutting out of a bone.

AMBER. *Bernstein*, Germ.; *Succin, carabé, ambre jaune*, Fr.; *Electrum, succinum*, Lat.; *Yellow mineral resin*, Haidinger.

This substance has been in repute from the earliest times, and, in consequence of certain properties it possesses, gave rise to many romantic and fabulous stories. According to the poets, when the sisters of Phaethon were lamenting his fate, their tears, instead of mixing with the waters of the Po, into which he had been precipitated by the thunder of the incensed Jupiter, consolidated, and were transformed into amber, on which the ancients set such an immense value. Sophocles, too, according to Pliny, hesitates not to avouch that beyond India it proceeds from the tears that fall from the eyes of the birds Meleagrides wailing and weeping the death of Meleager. Again, the electricity of this substance, which was long observed before it could possibly be understood, was another source of surprise and conjecture, and induced individuals to believe that amber was possessed of some living principle; and Thales went so far as to imagine it had a soul, and even Pliny appears to have entered into the same idea. This property, which has subsequently been discovered in a multitude of other bodies, gave rise to the science of electricity,—a denomination derived from the Greek ελεκτρον, by which name amber was known to the ancients. The Arabian name Karabé, meaning *attract-chaff*, is also very significant of this property. We thus find that a bit of amber was the first electric machine ever put in use. Little, however, did Pliny and the philosophers of his days, when debating on the tears of the sisters of Phaethon, or of the birds that wept the fate of Meleager, dream of the researches of their successors, or of the effects to be produced by the multiplication and concentration of the power originally discovered in a bit of amber.

It was not surprising that a substance so prized and so valuable should be found to possess many important medicinal qualities. It is to be suspected, however, that, taken *per se*, the virtues it possesses may be summed up in what Pliny states, viz., "True it is, that a collar of amber beads worn about the necks of young infants, is a singular preservative to them against secret poison, and a countercharm for witchcraft and sorceries." The same feelings may probably have handed down even to our own time the superstitious veneration with which the necklace of *lammer beads* has always been held among the lower classes of our own countrywomen, whose necks may still be seen ornamented with this esteemed heirloom, while their backs are supporting a load of fish or of salt to the market.

The use of amber in medicine might now be considered as *nil*, were it not that chemists have succeeded in extracting from it, by distillation, a liquid of a very pungent smell, which is a good antispasmodic, but now little used. The oil of amber entered into the composition of the syrup of karabé, in the older pharmacopœias.

As a matter of course, the origin of amber was also wrapt in mystery, but for this there seems to be no longer occasion; with very few exceptions, it seems always to occur in beds of bituminous wood. "Near the sea-coast in Prussia there are regular mines for the working of amber: under a stratum of sand and clay, about 20 feet thick, a stratum of bituminous wood occurs, from 40 to 50 feet thick, of a blackish brown colour, and impregnated with pyrites. Parts of these trees are impregnated with amber, which sometimes is found in stalactites depending from them. Under the stratum of trees were found pyrites, sulphate of iron, and coarse sand, in which were rounded masses of amber. The mine is worked to the depth of 100 feet; and, from the circumstances under which the amber is found, it seems plain that it originates from vegetable juices." (*Phillips.*) The next unequivocal example of this being the fact as to the origin of amber occurs in the brown coal of Hasen Island in Greenland. Here it presents itself usually in very small specks; but these are often of a highly brilliant transparent character. Similar repositories are found in France, at St Paulet, department du Gard; at Coboalles, in the province of the Asturias in Spain; and in Saxony. Nowhere, however, does amber occur so abundantly as on the Prussian coasts of the Baltic, between Köningsberg and Memel.

[1] The salaries of the mission in Persia are not charged upon the Consolidated Fund, but are paid out of the sum of L.12,000, which is received annually by the Treasury from the East India Company towards defraying the general expenditure of the diplomatic service in Persia.

The bed of coal which we have described above seems to extend under the sea; and, subsequent to every heavy storm, a large quantity of amber is sure to be found on the coast. It is secured by fishermen by means of nets, and being the property of the crown, is delivered to the proper officers at a certain rate. It is said that the revenue derived from this sometimes amounts to 16,000 or 17,000 dollars. This has been the great source of supply to the whole of Europe from the earliest times.

Besides these sources, amber is found in other situations removed from all apparent connection with vegetable origin. In the neighbourhood of Paris it occurs in small grains in the plastic clay; it likewise occurs at Aix in Provence, disposed in clay; and it has often been found among the gravel in the neighbourhood of London. The coasts of Sicily and the Adriatic likewise afford amber. The most beautiful specimens are perhaps those which are found at Catania. They often possess a beautiful play of colour, approaching to purple, not to be observed in the product of other places.

The predominant colour of amber is yellow, generally of a pale straw colour; but it passes into honey yellow and yellowish white. Occasionally it is perfectly transparent, and in this state it is in the greatest esteem for work.

It has been said that individuals had invented the means of rendering opaque and dark-coloured amber transparent, and of even communicating peculiar colours; but these processes have perished with the inventors. It is said, that by exposing opaque amber, covered with sand, in an iron pot, to a gentle heat for forty hours, or by boiling it for twenty hours in rapeseed oil, it will become transparent; but in either case it loses its electric qualities.

In mineralogical cabinets amber is placed among the inflammable substances. It occurs in irregular and spheroidal masses, with a rough uneven surface. It presents no natural cleavage; its fracture is conchoidal; its lustre is resinous, and the streak white.

It is brittle, and its hardness varies from 2·0 to 2·5; specific gravity 1·078 to 1·081; and, when rubbed, acquires a strong negative electrical virtue. According to the analysis of Drapier it consists of

| | | | |
|---|---|---|---|
| Carbon | 80·59 | Lime | 1·54 |
| Hydrogene | 7·31 | Alumina | 1·10 |
| Oxygene | 6·73 | Silica | 0·63 |

These three earthy ingredients seem to be accidental; for Schrötter found in it only carbon, 78·82; hydrogene, 10·23; oxygene, 10·95; equivalent to $C^{10}\ H^{8}\ O$.

It burns with a pale yellow flame, with a good deal of black smoke, and evolves an agreeable odour, leaving a carbonaceous residue. It is cut into various ornaments and works of art, and is a favourite article for the construction of mouthpieces to smoking apparatus.

One of the most singular peculiarities in the history of amber, is the circumstance of its very often containing insects and even reptiles enclosed within it. The high prices which such rarities commanded set the ingenious to work to imitate and forge specimens to all appearance genuine; which has cast so much discredit upon the fact itself, that all specimens of this description are now viewed with jealousy and suspicion. That, however, being admitted, there can be no doubt whatever that such objects are actually found in amber, and sometimes present appearances which it would be extremely difficult if at all possible to imitate. Of those insects which have been orginally inclosed in amber, some are plainly seen to have struggled hard for their liberty, and even to have left their limbs behind them in the attempt; it being no unusual thing to see, in a mass of amber that contains a stout beetle, the animal wanting one, or perhaps two of its legs, and those legs left in different places, nearer that part of the mass from which it has travelled. This also may account for the common accident of finding legs or wings of flies, without the rest of their bodies, in pieces of amber; the insects having, when entangled in the yet soft and viscid matter, escaped at the expense of leaving those limbs behind them. Drops of clear water are sometimes also preserved in amber. These have doubtless been received into it while soft, and preserved by its hardening round them. Beautiful leaves of a pinnated structure, resembling some of the ferns or maidenhairs, have been found in some pieces; but these are rare, and the specimens of great value. Mineral substances are also found at times lodged in masses of amber. Some of the pompous collections of the German princes boast of specimens of native gold and silver in masses of amber; but as there are many substances, as sulphurets of metals, and mica, that have all the glittering appearance of gold and silver, it is not to be too hastily concluded that these metals are really lodged in these beds of amber. The most celebrated manufactures of amber are, in Prussia, at Köningsberg and Dantzic; in Sicily, at Catania and Tripani; at Leghorn; and at Constantinople.

The value of amber depends upon its colour, its lustre, and its size. In 1576 a mass weighing 11 pounds was found in Prussia, and deemed worthy of being presented to the emperor; latterly a mass of 13 pounds was found, for which 5000 dollars were said to be refused. Such masses are of very great rarity. The principal demand for the amber of commerce is among the Armenians, through whom it is conveyed to Egypt, Persia, China, and Japan; and a great quantity is purchased to be consumed at the shrine of Mahomet, by the pilgrims bound to Mecca.

*Amber Tree*, the English name of a species of Anthospermum.

AMBERG, a walled town of Bavaria, in the circle of the Upper Palatinate, and capital of a bailiwick of the same name. It is situated on the river Vils, on the road between Ratisbon and Bayreuth, and 26 miles east of Nuremburg. It was formerly the capital of the circle of Upper Palatinate, and at present is the seat of its appeal court. It has a castle, an arsenal, eight churches (of which St Martin's has many beautiful paintings and monuments), a Franciscan cloister, a theatre, elementary and advanced schools, and several manufactories, including a royal manufactory of arms. In its vicinity is an extensive iron mine, and a chapel of the Virgin Mary, much resorted to by pilgrims. Pop. in 1846, 10,225. Lat. 49. 26. 52. N. Long. 11. 47. 27. E. The bailiwick has an area of 288 square miles, or 184,320 acres.

Amberg, a lofty mountain of East Gothland, in Sweden. On this mountain, near the Wetter lake, antimony has been found. On its top is the burying-place of one of the ancient kings of the country. The spot is marked by a flat stone.

AMBERGER, Christopher, a German painter, born at Amberg, who obtained reputation chiefly by his portraits, carefully finished in the style of Holbein. His historical pieces are small, hard, and dry, and are chiefly to be seen in his native place. He died in 1568, about 78 years of age.

AMBERGRIS, or Gray Amber, is a solid, opaque, ash-coloured, fatty, inflammable substance, variegated like marble, remarkably light, rugged, and uneven in its surface, and of a fragrant odour when heated. It does not effervesce with acids; it melts freely over the fire into a kind of yellow rosin; and is hardly soluble in spirits of wine.

Ambergris is found swimming upon the sea, on the sea-coast, or in the sand near the sea-coast; especially in the Atlantic Ocean, on the sea-coast of Brazil, and that of Madagascar; on the coasts of Africa, of the East Indies, China, Japan, and the Molucca Islands; but most of the ambergris which is brought to England comes from the Bahama Islands, from Providence, &c., where it is found on the

Ambergris.

coast. It is also sometimes found in the abdomen of whales by the whale-fishermen, always in lumps of various shapes and sizes, weighing from half an ounce to a hundred and more pounds. The piece which the Dutch East India Company bought from the king of Tydore weighed 182 pounds. An American fisherman from Antigua found, inside a whale, about fifty-two leagues south-east from the Windward Islands, a piece of ambergris which weighed about 130 pounds, and sold for L.500 sterling.

The most satisfactory account of the real origin of ambergris is that given by Dr Swediaur, in the 73d volume of the *Philosophical Transactions.*

We are told by writers on ambergris, that sometimes claws and beaks of birds, feathers of birds, parts of vegetables, shells, fish, and bones of fish, are found in the middle of it, or variously mixed with it. Of a very considerable number of pieces, however, which Dr Swediaur examined, he found nonc that contained any such thing; though he allows that such substances may sometimes be found in it; but in all the pieces of any great size, whether found on the sea or in the whale, he always found a considerable number of black spots, which, after the most careful examination, appeared to be the beaks of the *Sepia Octopodia;* and these beaks, he thinks, might be the substances which have hitherto been always mistaken for claws or beaks of birds or shells. The presence of these beaks in ambergris proves evidently that all ambergris containing them is in its origin, or must once have been, of a very soft or liquid nature; as otherwise those beaks could not so constantly be intermixed with it throughout its whole substance.

That ambergris is found either upon the sea and sea-coast, or in the bowels of whales, is a fact universally credited. It is, however, of consequence to know whether ambergris is found in all kinds of whales, or only in a particular species of them; whether it is uniformly to be met with in those animals; and if so, in what part of their body it is to be found.

All these questions we find very fully discussed by Dr Swediaur. According to the best information that he could obtain from several of the most intelligent persons employed in the spermaceti whale-fishery, and in procuring and selling ambergris, it appears that this substance is sometimes found in the belly of the whale, but in that particular species only which is called the *spermaceti whale*, and which, from its description and delineation, appears to be the *Physeter macrocephalus* of Linnæus.

The persons who are employed in the spermaceti whale-fishery confine their views to the *physeter macrocephalus.* They look for ambergris in all the spermaceti whales they catch, but it seldom happens that they find any. Whenever they harpoon a spermaceti whale, they observe that it constantly not only vomits up whatever it has in its stomach, but also generally discharges its fæces at the same time; and if this latter circumstance takes place, they are commonly disappointed in finding ambergris in its belly. But whenever they discover a spermaceti whale, male or female, whieh seems torpid and sickly, they are always pretty sure to find ambergris, as the whale in this state seldom voids its fæces upon being harpooned. They likewise generally meet with it in the dead spermaceti whales, which they sometimes find floating on the sea. It is observed also, that the whale in which they find ambergris often has a morbid protuberance, or, as they express it, a kind of gathering in the lower part of its belly, in which, if cut open, ambergris is found. It is remarkable that all those whales in whose bowels ambergris is found, seem not only torpid and sick, but are also constantly leaner than others; so that, if we may judge from the constant union of these two circumstances, it would seem that a larger collection of ambergris in the belly of the whale is a product of disease, and probably sometimes the cause of its death. As soon as they harpoon a whale of this description, torpid, sickly, emaciated, or one that does not void on being harpooned, they immediately either cut up the above-mentioned protuberance, if there be any, or they rip open its bowels from the orifice of the anus, and find the ambergris sometimes in one, sometimes in several lumps, of generally from three to twelve and more inches in diameter, and from one pound to twenty or thirty pounds in weight, at the distance of two, but most frequently of about six or seven feet from the anus, and never higher up in the intestinal canal, which, according to their description, is in all probability the intestinum cæcum, hitherto mistaken for a peculiar bag made by nature for the secretion and collection of this singular substance. That the part cut open to come at the ambergris is no other than the intestinal canal is certain, because they constantly begin their incision at the anus, and find the cavity everywhere filled with the fæces of the whale, which, from their colour and smell, it is impossible to mistake. The ambergris found in the intestinal canal is not so hard as that which is found on the sea or sea-coast, but soon grows hard in the air. When first taken out it has nearly the same colour, and the same disagreeable smell, though not so strong, as the more liquid fæces of the whale; but on exposing it to the air, it grows by degrees not only grayish, having its surface covered with a grayish dust like old chocolate, but it also loses its disagreeable smell, and, when kept for a certain length of time, acquires the peculiar odour which is so agreeable to most people.

In considering whether there be any material difference between the ambergris found upon the sea or sea-coast and that found in the bowels or among the fæces of the whale, Swediaur refutes the opinion that all ambergris found in whales is of an inferior quality, and therefore much lower in price. Ambergris, he observes, is only valued for its purity, lightness, compactness, colour, and smell. There are pieces of ambergris found on different coasts, which are of a very inferior quality; whereas there are often found in whales pieces of it of the first value; nay, several pieces found in the same whale, according to the above-mentioned qualities, are more or less valuable. All ambergris found in whales has at first, when taken out of the intestines, very nearly the same smell and blackish colour as the liquid excrements of that animal; sometimes it is quite hard, sometimes softish, but never so liquid as the natural fæces. By being accumulated after a certain length of time in the intestinal canal, it seems even there to become of a whiter colour, and less ponderous, and to acquire its agreeable smell. The only reason why ambergris found floating on the sea generally possesses this agreeable smell and hardness in a superior degree is because it is commonly older, and has been longer exposed to the air. It is more frequently found in males than in females: the pieces found in females are generally smaller than those found in males, and inferior in quality. The disproportionately high price obtained for the larger pieces, therefore, proceeds from an intrinsic value in respect to quality, rather than a fictitious value on account of their rarity.

From the preceding account, and his having constantly found the beaks of the sepia in all pieces of ambergris of any considerable size, Dr Swediaur concludes, with great probability, that all ambergris is generated in the bowels of the physeter macrocephalus or spermaceti whale, and there mixed with the beaks of the sepia octopodia, which is the principal food of that whale. It seems most probable that this substance is nothing more than the bile of the animal secreted in undue quantity, and altered by disease.

The opinion of Dr Swediaur with regard to the origin of ambergris has been confirmed by the information of Captain J. Coffin, master of a ship employed in the southern whale-fishery, given to a Committee of Privy Council in the year 1791. The ambergris of the whale taken by Captain Coffin was mostly sold at 19s. 9d. per ounce; and a small part of it, when it was scarce, at 25s. It was bought partly for home consumption, and partly for exportation to Turkey, Germany, and France. (*Philosophical Transactions*, vol. lxxxi.)

The use of ambergris in Europe is now nearly confined to perfumery, though it has formerly been recommended in medicine by several eminent physicians. In Asia and part of Africa ambergris is not only used as a medicine and a perfume, but considerable use is also made of it in cookery, by adding it to several dishes as a spice. The Turks make use of it as an aphrodisiac.

Ambergris may be known to be genuine by its fragrant scent when a hot needle is thrust into it, and its melting like fat of a uniform consistence; whereas the counterfeit will not yield such a smell, nor prove of such a fat texture.

AMBERT, chief town of the arrondissement of the same name in France, department of Puy de Dôme. The town is situated on the river Dore, 35 miles south-east of Clermont, and is chiefly celebrated for its paper-works and cheese; besides which it manufactures ribands, lace, woollens, and pins. Population of town in 1851, 8044; of arrondissement, 90,048. The arrondissement is divided into eight cantons, and those into fifty-two communes, with an area of 477 square miles, or 305,280 acres.

AMBIANI, or Ambianensis Civitas, now Amiens, a city of Picardy. It is called *Samarobriva* by Cæsar and Cicero; which, according to Valesius, signifies the bridge of the *Samara* or *Somme*. *Ambiani* is a later name, taken from that of the people, after the usual manner of the lower age. This people, according to Cæsar, furnished 5000 men for the siege of Alesia.

AMBIDEXTER, a person who can use both hands with the same facility, and for the same purposes, that the generality of people use their right hand. Many think that, were it not for education and habit, all mankind would be ambidexters; and, in fact, we frequently find nurses obliged to be at a good deal of pains before they can bring children to forego the use of their left hand. The apparent cause why the right arm is generally most in use is, that the impetus of the heart is more *directly* communicated, in the ordinary structure, to the right subclavian artery than to the left, and therefore more blood is thrown into the former: but in true ambidexters the structure is similar on both sides.

Ambidexter, among *English Lawyers*, a juror or embracer who accepts money of both parties for giving his verdict; an offence for which he is liable to be imprisoned, for ever excluded from a jury, and to pay ten times the sum he accepted.

AMBIENT, a term used for such bodies, especially fluids, as encompass others on all sides. Thus, the air is frequently called an ambient fluid, because it is diffused round the earth.

AMBIGENÆ Oves, in the heathen sacrifices, an appellation given to such ewes as, having brought forth twins, were sacrificed together with their two lambs, one on each side. We find them mentioned among other sacrifices to Juno.

AMBIGENAL Hyperbola, a name given by Sir Isaac Newton to one of the triple hyperbolas of the second order, having one of its infinite legs falling within an angle formed by the asymptotes, and the other without.

AMBIGUOUS, a term applied to a word or expression which may be taken in different senses. An anonymous writer has published a dictionary of ambiguous words, *Lexicon Philosophicum de Ambiguitate Vocabulorum*, Francof. 1597, 4to.

AMBIT, in *Geometry*, is the same with what is otherwise called the perimeter of a figure.

Ambit was particularly used in *Antiquity* to denote a space of ground to be left vacant between one building and another. By the laws of the twelve tables, houses were not to be built contiguous, but an ambit or space of $2\frac{1}{2}$ feet was to be left about each for fear of fire. The ambitus of a tomb or monument denoted a certain number of feet in length and breadth around the same, within which the sanctity assigned to it was limited. The whole ground wherein a tomb was erected was not to be secreted from the common uses; for this reason, it was frequent to inscribe the ambit on it, that it might be known how far its sanctity extended: thus, *in fronte pedes tot, in agrum pedes tot.*

AMBITION (*ambitio*) is generally used, in a bad sense, for an immoderate or illegal desire of power. In the strict meaning of the word, however, it signifies the same with the *ambitus* of the Romans.

AMBITUS, in *Roman Antiquity*, the competition for some magistracy or office, and formally going round the city to solicit the interest and votes of the people. *Ambitus* differed from *ambition*, as the former lies in the act, the latter in the mind. Ambitus was of two kinds; one lawful, the other infamous. The first, called also *ambitus popularis*, was when a person offered his service to the republic frankly, leaving it to every body to judge of his pretensions as they found reasonable. The means and instruments here made use of were various: 1. *Amici*, or friends, under different relations, including *cognati, affines, necessarii, familiares, vicini, tribules, clientes, municipes, sodales, collegæ;* 2. *Nomenclatura*, or the calling and saluting every person by his name; to which purpose the candidates were attended by an officer, under the denomination of *interpres* or *nomenclator;* 3. *Blanditia*, or obliging persons, by serving them or their friends, patrons, or the like, with their vote and interest on other occasions; 4. *Prensatio*, the shaking every person by the hand, offering him his service, friendship, &c. The second kind was that wherein force, cajoling, money, or other extraordinary influence, was made use of. This was held infamous, and several severe laws (*leges de ambitu*) were enacted from time to time, to prevent bribery. Ambitus was practised not only at Rome and in the forum, but in the meetings and assemblies of other towns in Italy, where numbers of citizens were usually found, on account of trade and business. The practice ceased in the city from the time of the emperors, as offices were not then to be obtained by courting the people, but by favour of the prince. Persons who had causes depending practised the same, going about among the judges to implore their favour and mercy. They who practised this were called *ambitiosi*. Hence we also meet with *ambitiosa decreta*, and *ambitiosa justa*, used for such sentences and decrees as were thus procured from the judges contrary to reason and equity, either gratuitously or for money.

AMBLESIDE, a small market-town of Westmoreland, about a mile from the head of Windermere, and 12 miles north-west of Kendal. During the summer months it is much frequented by tourists, on account of its beautiful situation and the numerous places of interest in its vicinity, including Rydal Mount, for many years the residence of the poet Wordsworth. In a field near the lake, are indistinct remains of Roman fortifications, in which coins, urns, and other relics, have been frequently discovered. It has a free grammar school, and manufactories of coarse woollens. Market-day Wednesday.—Pop. in 1851, 1592.

AMBLETEUSE, a decayed seaport town of France, in the department of the Pas de Calais, on the English Channel, 12 miles south-west from Calais, and 6 north from Boulogne. From the accumulation of sand in its harbour it has lost its importance as a seaport, and the town is now almost deserted. Pop. 581. At this port Cæsar embarked his cavalry when he invaded England; and at it James II. landed when he abdicated the crown.

AMBLYGON, in *Geometry*, denotes an obtuse-angled triangle, or a triangle one of whose angles consists of more than 90 degrees.

AMBLYGONITE, a mineral of greenish-white colour, found in Norway and Saxony. It appears to be a phosphate of alumina and lithia, according to Berzelius. Its form is a rhombic prism. Specific gravity 3·01.

AMBLYOPY, among *Physicians*, signifies an obscuration of the sight, so that objects at a distance cannot be clearly distinguished.

AMBO, or AMBON, a kind of pulpit or desk in the ancient churches, where the priests and deacons stood to read or sing part of the service, and preach to the people; called also *Analogium.* The term is derived from *αναβαινειν, to mount.* The ambo was mounted upon two sides; whence some also derive the appellation from the Latin *ambo*, both. The ambo was ascended by steps; which occasioned that part of the office performed there to be called the *Gradual.* The modern reading-desks and pulpits have been generally substituted for the ancient ambos; though in some churches remains of the ambos are still seen. In that of St John Lateran at Rome there are two moveable ambos.

AMBOISE, a town of France, in the former province of Touraine, now the department of the Indre and Loire, seated at the confluence of the rivers Loire and Masse. The town is the capital of a district, and has been rendered famous in history by the conspiracy of the Protestants in 1560, which opened the fatal wars of religion in France. The castle is situated on a craggy rock, extremely difficult of access, and the sides of which are almost perpendicular. At its foot flows the Loire, which is here crossed by a handsome wooden bridge with stone piers. To this fortress the duke of Guise, when he expected an insurrection among the Huguenots, removed Francis II., as being a place of perfect security. Only two detached parts of the ancient castle now remain, one of which was constructed by Charles VIII. and the other by Francis I. The former of these princes was born and died at Amboise. Pop. 4859. Manufactures, fire-arms, files, &c.

AMBOISE, *François d'*, son of a surgeon to Charles IX. of France. His eloquence and extensive information raised him in 1572 to the place of solicitor of the French nation. He afterwards applied to the study of the law, and became one of the most accomplished advocates of the parliament of Paris. He was next advanced to be counsellor in the parliament of Bretagne, and afterwards to be a master of requests and counsellor of state. He visited different countries, and published the history of his travels, and several poetical pieces. He prefixed an apologetical preface to the edition of Abelard's works in 1616, and with much industry collected many of his manuscripts. His brother Adrian rose to considerable consequence in the church; and his brother James was not less eminent as a physician.

AMBOISE, *George d'*, a French cardinal and minister of state, was born in the year 1460. His father was a descendant of the renowned house of Amboise, and through the influence of his powerful connections the path of church preferment lay open before his son: he accordingly destined him to the clerical order. In these sanguine expectations he was not disappointed; for he had sufficient influence to procure for him the bishopric of Montauban at the early age of fourteen. Louis XI. appointed him one of his almoners; and in the course of political events he became strongly attached to the duke of Orleans, and suffered imprisonment in his cause. When this prince, however, had regained his favour at court, he was elevated to the archbishopric of Narbonne. After he had remained there for some time, he changed that station for the archbishopric of Rouen. When the duke of Orleans was governor of Normandy, he made him lieutenant-general; and in that situation he was of essential service to the province in restoring justice and order. When the duke of Orleans became Louis XII. Amboise was suddenly raised to the elevated station of cardinal and prime minister. The same regard to equity which characterised his conduct when lieutenant-general induced him to diminish the imposts, which rendered him very popular as first minister of France. In 1499, by his advice, the king undertook the conquest of the Milanese; and on their revolt the prime minister was sent to quell the rebellion. The great confidence which Louis had reposed in him induced the pope to make him his legate in France; and in that station he piously laboured to reform the ecclesiastical orders. He enforced his doctrine by precept, and not only set them an example of holding only one benefice at a time, but also devoted two-thirds of its revenue to the poor, and to the repair of religious edifices. According to his own account, he was ambitious of the papal chair "merely for the purpose of effecting the reformation of abuses and the correction of manners." It is said that, upon the death of Pius III., he would have been elected pope had he not been deceived by the Italian cardinals. Disappointed in his views with regard to the papal honours, he persuaded his master to declare war against the Venetians, to whose influence he attributed his failure. But this imprudent undertaking was suddenly interrupted; for, in the prosecution of his journey for the Venetian war, he was seized with illness in the city of Lyons. Affliction rouses the reflecting powers of the mind, and calls to remembrance the past actions of life. The consciousness of his past errors called forth his pathetic expression of compunction to the lay-brother who attended him at the convent of the Celestines: "Frère Jean, que n'ai je été toute ma vie frère Jean!" In the year 1510, and in the 50th of his age, he breathed his last in that place. Industry, steadiness, and good intention, characterised his conduct as a prime minister; and under his liberal patronage the arts and sciences flourished during his administration. It may be proper to add that, assisted by some of the ablest lawyers in the kingdom, he formed a code of laws to reform the reigning abuses in the nation. Thus, by steadily pursuing the general welfare, he obtained the appellation of the "father of the people."

AMBOYNA is one of the Moluccas or Spice Islands, in the Eastern Archipelago, and belongs to the Dutch. It lies south-west of Ceram, in S. Lat. 3. 41. E. Long. 128. 10., and is 32 miles in length, of a very irregular figure, with a superficial area of 13·3 geographical square leagues. Though but fourth-rate in size, it is the most populous of all the Moluccas, Ceram excepted, the number of its inhabitants in 1840 being 29,660. Its proper name is Hitoe; but it is usually designated Amboyna, from its town. The town of Amboyna contains 13,000 inhabitants, and is situated on the south-east of the island, in the peninsula of Leitimor, which is united to Hitoe by an isthmus about one mile broad. The arm of the sea separating these two very unequal peninsulas forms the extensive bay and roadstead of Amboyna, which affords good anchorage for ships, with shelter from most winds. In the exterior bay there are no dangerous rocks or shallows: on the contrary, it has a depth of 50 fathoms, except in a few places; as, for instance, in the roadstead itself, towards the point of the Gibbet, and the other side of the bay, within the point of Laha. Ships, however, seldom cast anchor in this last place, unless, when attempting to enter the bay, the wind suddenly becomes

Amboyna.

contrary, which would otherwise compel them to take to the open sea.

Amboyna is a clean neat town, with broad unpaved streets running at right angles to each other, and intersected by numerous rivulets. The houses are of wood, roofed with palm leaves, and mostly of one story, the better to endure the shock of earthquakes, which are not infrequent. The Chinese and the Europeans occupy separate quarters of the town. An esplanade of 250 yards reaches from Fort Victoria to the town, and is terminated by a handsome range of houses, with a double row of nutmeg trees in front. Another fort has been erected in a more advantageous position, and is called Van der Capellen, in honour of the late excellent governor of that name. The town-house is a neat structure of two stories, fronting the esplanade. There are two Christian churches, a fine garden and menagerie, several bazaars and markets, and a hospital. The site of the town is level; but immediately to the east and south the country is hilly, and many mountain-streams descend to the sea close to the town: the country around is highly picturesque, and diversified with numerous villas; the forests are rich and varied, vegetation is most luxuriant, and the air is embalmed with the odours of flowers. Viewed from the sea, the aspect of this fertile island is high and mountainous, watered by innumerable streams, and interspersed with clove plantations. The average temperature is 80° Fahr., rarely sinking below 72°, and until the great earthquake in 1835 the climate was accounted highly salubrious; but since that period fever has been very prevalent, probably in consequence of mephitic vapours still exhaling from the fissures in the earth. Amboyna produces most of the common tropical fruits and vegetables, including the sago-palm, bread-fruit, cocoa-nut, sugar-cane, maize, coffee, pepper, cotton, &c., and a small quantity of very fine indigo. The variety of its ornamental woods is such, that Rumphius, the author of the *Herb Amboniense*, had a cabinet composed of no fewer than 400 of its choice native woods. The governor of the Moluccas resides here, having under his jurisdiction the islands of Boeroe, Amblauw, Ceram, Manippa, Kilang, Bonoe, Haroekoe, Honimoa or Saparoea, Noesa-laut, and Hila. The varied climatic effects of the monsoons are felt at Amboyna, Ceram, Banda, the east coast of Celebes, and the adjacent seas; the east monsoon bringing rains, lightning, and hurricanes, the west monsoon fine weather. The monsoons also occasion irregularities of the tides.

This island is especially remarkable for producing the best cloves of commerce, and formerly was appropriated almost exclusively to that production; for its Dutch legislators, in order to secure a monopoly, exterminated thousands of clove trees, prohibited their culture in the other islands subject to them, and often burnt whole cargoes of spices, with the view to keep up their market-price. By an act passed in 1824 these prohibitory laws were abolished; and consequently the fraud, extortion, and tyranny to which they gave rise: the cultivation of land was opened to all; but on account of the indolence and indifference of the natives the government deemed it advisable to assign a plantation of this tree to each *negory*, or village, under the superintendence of a chief, who is bound to deliver the annual produce to government at a just valuation.[1]

The clove-tree (*Caryophyllus aromaticus*) attains the height of 30 or 40 feet, is slender and elegant, with a light-coloured stem, branches little spread, the leaves entire, small, and oblong. It bears about its fifteenth year, and its average duration is 75 years. The spice is the undeveloped flowers of the plant, the tubular part being the *calyx*, and the knob the unexpanded *corolla*. A tree will yield annually from 5 lb. to 20 lb. of cloves, according to its size and vigour; and some very large trees are said to produce even so much as 50 lb. It flourishes best in a dry, rocky soil, sheltered from blasts and sea-spray, and requires much care. In the other Moluccas it bears earlier, and is hardier; but it is in Amboyna that this plant is produced in greatest perfection. From the leaves is extracted an oil powerfully aromatic. The harvest takes place in November and December, and averages from 250,000 to 300,000 lb. of cloves, which are dried quickly in the shade to preserve their aroma. The sago-tree (*Sagus Rumphii*), which furnishes the principal food of the Amboynese, is in danger of becoming extinct in that island from the constant destruction of the trees—a circumstance deserving the attention of the government. In Amboyna a tree now yields but about 400 lb. of sago, while those of Ceram give 1200 lb. or more. It flowers between its 20th and 25th year, and after lasting two years in this state, languishes and dies; but before this period the pith has become ligneous, and is useless. The best sago is in small round grains of a pale reddish-white: as usually found in commerce the grain is larger, and whitened artificially.

The natives of Amboyna are a mixed race of Haroforas or aborigines, Malays, Chinese, Arabians, and various European nations, with a consequent variety of complexion and feature; and it is worthy of remark that the descendants of the Portuguese are much darker than the aborigines. Of the latter very few now remain, and they are confined to the mountains. The Malays constitute the main population. They are indolent and effeminate, but expert fishers. Their *corocoros*, or war-canoes, are often 100 feet long, and carry 80 men. They live in wooden houses of one story, with roofs of palm-leaves, and windows of matted cane Malay, the common language, is pleasing in utterance: the Arabic character is employed in writing it, which they derived from the Arabians in the middle of the 16th century. The natives are of middle height and well formed. They are high spirited and of facile disposition, with more inclination for the military life than the inhabitants of the other Moluccas. Their costume differs little from that of the Malays of Java: it consists of a loose frock and trousers, and a round hat, their glossy hair twisted into a queue, or turned up with a comb. The chiefs of the villages dress like the Europeans. Mohammedanism is the prevailing religion; but some profess Christianity, and distinguish themselves by black garments.

If the ancient statistical documents may be relied on, this island once contained 50,000 inhabitants. The great decrease at the present day has been ascribed to several causes; such as piracy, the ravages of smallpox and cholera, enrolment for military service in 1806, 1809, and 1826, the insurrections of 1817 and 1829, and the epidemic of 1837: to which may be added the grievous oppression they so long endured.

Amboyna has the usual domestic animals, but is very barren in indigenous mammals. Its birds are few in species, nor is it richer in mollusca and zoophytes. The splendid

[1] Many errors have been propagated respecting the policy of the Dutch with regard to their East India possessions; the fact being that the chartered privileges of the Dutch Chamber of Commerce (like those of our own East India Company under its original charter), constitute a monopoly of the carrying trade in the hands of that body, to the exclusion of the majority of the Dutch merchants and merchant seamen; and all that the British have received in accordance with the provisions in the treaty of 1824 is a parity of exclusion with the great majority of the Dutch themselves.—See *Edinburgh Review*, No. cxcv. p. 71.

Amboyna. and valuable shells sold by the Chinese merchants at Amboyna are rarely found on its shores; and in this and other instances mistakes have frequently arisen in making Amboyna the habitat of animals not found there. In the Moluccas but thirty mammiferous animals have hitherto been observed: they do not possess a single quadruman, nor any formidable beast of prey: the feline tribe is not even represented: no marsupialia: the insectivora are wanting: of the rodentia there is but the *mus decumanus*, which is found everywhere, or a species nearly allied to it: no edentata: the pachydermata are represented by the wild boar and the horse, and the ruminantia by the deer (*Cervus axis*): the monotremata are wanting. The birds of these islands form characteristic groups: such are the cockatoos with plumage almost purely white, and parrots beautifully variegated with scarlet, purple, and bright blue. Among the gallinaceæ are the *megapodes*, remarkable for the disproportionate size of their eggs, and their habit of subjecting them to the heat of fermenting vegetable matter, instead of hatching them in the usual way. The serpents that occur in Amboyna are described by M. Schlegel as the following:—*Calamaria brachyorrhos, Lycodon modestus, Dendrophis rhodopleuron, Dipsas irregularis*, and the *Homalopsis Schneideri*, and *Python Schneideri*, inhabiting Amboyna; and in the surrounding seas are found the *Hydrophis striata, H. pelamis, H. pelamoides, H. colubrina*, and probably some others. The entomology of these isles is peculiarly rich; and we may specially notice the brilliant *lepidoptera*, and the *phasma* of enormous size. In the pith of the sago tree is found the larva of a *cerambix*, which is eaten as a great delicacy, like the *grugru* worm of the West Indies. The seas are very prolific: the dugon is common: the antarctic whale, the porpesse, the balænoptera or *finner*, but especially the cachalot (*Physeter macrocephalus*) which yields the spermaceti of commerce, attract many English, American, and other vessels to these seas. Extravagant estimates have been made of the number of cachalots annually taken; but it is stated that 190 large whaling vessels are annually engaged in this pursuit.

*Geology.*—The greatest part of the island of Amboyna is composed of rocks of ignigenous formation. To the north of Leitimor, near the village of Roebang, there is a hill several hundred feet in height composed entirely of granite; in other places this rock underlies serpentine, and a calcareous rock of more recent formation. The island in other parts presents a volcanic aspect; and earthquakes and sudden oscillations of the sea, from time to time, attest the agency of subterranean fire. Pennant mentions a dreadful eruption of the Wawani Mountain of Amboyna in 1691. Sulphur is found in some quantity, and gold occurs in the granite districts.

*History.*—Amboyna was first visited in 1512 by the Portuguese, who established a factory there in 1521; but they did not obtain peaceable possession of it till 1580. They were dispossessed by the Dutch, after repeated attempts, in 1605. The British seized it in 1615; and in turn were expelled by the Dutch, but retained a factory in the island. The destruction of this establishment by the Dutch in 1622, and the frightful tortures inflicted on the unfortunate persons connected with it, long formed the theme of fruitless political negotiations; till Oliver Cromwell compelled them to give the sum of L.300,000, together with a small island, as compensation to the descendants of those who suffered in the "Amboyna massacre." In 1796, the British, under the Admiral Rainier, captured Amboyna, but restored it to the Dutch at the peace of Amiens. They re-captured it in 1810; and once more restored it to the Dutch after the treaty of Paris in 1814.

The sources of public revenue are customhouse and port dues, imposts on merchandise, a monopoly of arrack, and various licenses. The exports are spices and other natural produce: the imports chiefly opium, and some Indian and European goods.—See *Coup-d'œil General sur les Possessions Neerlandaises dans l'Inde Archipélagique, par* C. J. Temminck. Cannabich, *Lehrbuch*. (T. S. T—L.)

Ambracia. AMBRACIA, or AMPRACIA, an important town of ancient Epirus, on the left bank of the river Arachthus, about eight miles from the Ambracian Gulf. It was well fortified by walls of about three miles in circumference, besides being defended on the one side by the river Arachthus, and on the other by steep and craggy hills, on one of which stood the Acropolis. It was originally a Thesprotian town, but tradition stated that it was founded by Ambrax son of Thesprotus, or by Ambracia daughter of Augeas. About the year B.C. 635, a colony of Corinthians settled here, on which it became a Greek city. It soon became the most important Corinthian colony on the Ambracian Gulf, and about the time of the Peloponnesian war the Ambracians had attained their highest importance. They then had possession of the whole of Amphilochia, including its town named Argos. A colony from Ambracia had settled here, and after a time drove out the original inhabitants, and took possession of the town. The expelled Amphilochians threw themselves under the protection of the Acarnanians, who, with the assistance of the Athenians, retook Argos. The Ambracians two years after (about B.C. 430) made an unsuccessful attack on the town. Having obtained the assistance of Eurylochus the Lacedæmonian general, they again determined to attack the town (B.C. 426), but were repulsed with great slaughter by the conjoined armies of the Amphilochians and Acarnanians under the command of Demosthenes, their general Eurylochus being left dead on the field. Being greatly weakened by this last defeat, they for some time took no active part in the affairs of Greece. Ambracia subsequently fell into the hands of the Macedonians, and at a later period became subject to Pyrrhus, who made it the capital of his dominions, and enriched it with numerous works of art. It afterwards came into the possession of the Ætolians, and in the war between them and the Romans it sustained the siege for which it is so celebrated. In B.C. 189, the Roman consul M. Fulvius Nobilior resolved to attack the town, and formed two camps, one on each side of the river, but with a communication between them; the Romans being posted in one, and the Epirots, their allies, in the other. He then threw up two lines, one of circumvallation, the other of contravallation; and built a wooden tower in form of a castle, over against the citadel.

The lines being completed, the city was attacked in five different places at once. The battering-rams shook the wall on all sides; and the Romans, from their moveable towers, pulled down the battlements with a kind of scythes, which they fastened to long beams. The besieged made a vigorous defence. They were night and day on the walls, and indefatigable in preventing the effects of the rams and scythes. The strokes of the former they deadened by letting down upon them beams, large stones, lumps of lead, &c., by means of pulleys, when they were in motion; the others they rendered useless, by pulling the beams to which they were fastened into the city with hooks contrived for the purpose.

But while these operations were going on, the Ætolians concluded a peace with the Romans, and the city thereupon opened its gates to the besiegers, who removed many of its valuable works of art to Rome. Its ruin was afterwards completed by Augustus, who removed its inhabitants to Nicopolis, a city which he founded in commemoration of his victory at Actium.

The modern Arta occupies the site of the ancient Ambracia, where remains of its fortifications are still to be seen.

From this time the city of Ambracia made no figure in history.

AMBRESBURY. See Amesbury.

AMBROGI, Domenico, or del Brizio, a Bolognese painter who excelled in design, especially in cabinet pieces. He was the pupil and favourite of Francesco Brigio, who was the most distinguished scholar of the Caracci, excepting Domenichino and Guido. Domenico was living in 1678.

AMBRONES, a people of Gaul who lived near the foot of the Alps, about Embrun, between Switzerland and Provence. They invaded the Roman territories in conjunction with the Cimbri and Teutones; but were defeated with great slaughter by Marius, about 101 years before Christ. Their women, who during the engagement had staid in a kind of fortification made with their carts, on seeing their husbands flying, and the Romans at their heels, armed themselves with axes, and, gnashing with their teeth, fell with fury on the pursuers and the pursued. Their first rage being spent, they desired to surrender themselves upon the single condition that their chastity should not be violated; but this equitable request being denied, they first killed their children and then themselves, not one remaining alive out of the whole multitude.

AMBROSE, of Alexandria, lived in the beginning of the third century, and was the intimate friend of Origen. Jerome and Eusebius differ in the account they give of this man. The one denominates him a Marcionite, the other a Valentinian; but they both agree that he was converted to the orthodox faith by the preaching of Origen. As is generally the case with new proselytes, he became very zealous, and was appointed deacon either at Alexandria or at Cæsarea, where Protectetus was presbyter. Origen dedicated many of his works, and among others his book on martyrdom, to Ambrose, at whose desire and expense they were published. Origen and Ambrose were alike indefatigable in their application to study, and lived on terms of the most intimate friendship. According to some historians, Ambrose died a martyr, along with his friend Protectetus, in the persecution under Maximin, about the year 236; but the dedication of Origen's eight books against Celsus proves, that though he died before Origen, yet he lived to the year 250, or near that period. Origen speaks of him as a man of sincere piety, and much devoted to the study of the sacred Scriptures.

Ambrose, *Saint*, Bishop of Milan, was one of the most eminent fathers of the church in the fourth century. He was a citizen of Rome, and born in France; according to some historians, in the year 334, but according to others in 340. At the period of his birth his father was prætorian prefect of Gallia Narbonensis; but upon his death the widow repaired to Rome with her family. Ambrose received a religious education, and was reared in habits of virtue by his mother, an accomplished woman, and eminent for her piety. The names of his instructors in the rudiments of Greek and Roman literature have not been transmitted to posterity: but in these branches he made early proficiency; and, having directed his attention to the law, he employed his eloquence with such reputation in the prætorian court of Anicius Probus, that he was soon deemed worthy of a place in the council. After he had continued in this station for some time, Probus appointed him consular of Liguria and Emilia, comprehending the territories of Milan, Liguria, Turin, Genoa, and Bologna. Milan was chosen for the place of his residence; and, by the prudent and gentle use of his power, he conducted the affairs of the province with general approbation and growing popularity.

In the year 374 Auxentius the bishop of that city died, and his death gave sudden change to the fortune and literary pursuits of Ambrose. At that period the tide of religious contention ran high between the orthodox and the Arians, and there ensued a violent contest concerning the choice of a new bishop. When the people were assembled in the church to elect, Ambrose, in the character of governor of the place, presented himself to the assembly, and in a grave, eloquent, and pathetic address, admonished the multitude to lay aside their contentions, and, in the spirit of religious meekness, to proceed to the important work of choosing a bishop. It is reported that when Ambrose had finished his address, a child cried out, "Ambrose is bishop." The agitated multitude suddenly caught the superstitious flame, and regarding this as a miraculous intimation, they unanimously elected Ambrose bishop of Milan. Some suppose that this was entirely a device of Ambrose or his friends, and others ascribe it to mere accident. Ambrose strongly affected reluctance, and even pretended to fly from the city in order to avoid the intended honour. The place of his concealment, however, was soon discovered when the emperor's confirmation of his election was made known to him; and, after being baptized, he was ordained bishop of Milan, about the end of the year 374. Whatever we may think of the singular conduct of Ambrose in accepting an office for which he was certainly unqualified in respect of previous studies, habits, and employments, it must be admitted that he immediately betook himself to the necessary studies, and acquitted himself in his new elevation with ability, boldness, and integrity. Having appropriated his money to the poor, and settled his lands upon the church, with the exception of making his sister tenant during life; and having committed the care of his family to his brother, he entered upon a regular course of theological study, under the care of Simplician, a presbyter of Rome, and devoted himself to the labours of the church.

Compelled by the irruption of the Goths and the northern barbarians, who rushed down upon the Roman empire, spreading terror and desolation all around, Ambrose, along with several others, fled to Illyricum; but his exile was of short duration, for the northern invaders having been quickly defeated by the forces of the emperor, and driven back with considerable loss into their own territories, he and his companions returned to their respective habitations.

His eloquence and abilities soon found ample scope in the dispute between the Arians and the orthodox. About this era the doctrine of Arius concerning the person of Christ had been extensively received, and had many powerful defenders both among the clergy and the common people. Ambrose espoused the cause of the Catholics: Gratian, the son of the elder Valentinian, marshalled on the same side; but the younger Valentinian, who was now become his colleague in the empire, adopted the opinions of the Arians; and all the arguments and eloquence of Ambrose were insufficient to reclaim the young prince to the orthodox faith. Theodosius, the emperor of the East, also professed the orthodox faith; yet there were numerous adherents to Arius scattered throughout his dominions. In this distracted state of religious opinion, two leaders of the Arians, Palladius and Secundianus, confident of numbers, prevailed upon Gratian to call a general council from all parts of that empire. This request appeared so equitable that he complied without hesitation; but Ambrose, foreseeing the consequence, prevailed upon the emperor to have the matter determined by a council of the western bishops. A synod, composed of 32 bishops, was accordingly held at Aquileia in the year 381. Ambrose was elected president; and Palladius being called upon to defend his opinions, declined, insisting that the meeting was a partial one, and that the whole bishops of the empire not being present, the sense of the Christian church concerning the question in dispute could not be obtained.

Ambrose. Ambrose mentioned several precedents in favour of the authority of the court; and added, that the oriental bishops, being acquainted with the place and nature of the meeting, might have been present, if they had deemed the matter in discussion worthy of their attention. Palladius persisted in his refusal to plead his cause; and on a vote being taken, he, along with his associate Secundianus, was ejected from the episcopal office.

Ambrose was equally zealous in combating the heathen superstitions. Upon the accession of Valentinian II., many of the senators who remained attached to the pagan idolatry made a vigorous effort to restore the worship of the heathen deities. Symmachus, a very opulent man and a great orator, who was at that time prefect of the city, was intrusted with the management of the pagan cause, and drew up a petition, praying that the altar of Victory might be restored to its ancient station in the hall of the senate, and for the proper support of seven vestal virgins, and the regular observance of the other pagan ceremonies. Great eloquence and peculiar insinuation characterised the petition. He argued that this form of religion had long been profitable to the Roman state, reminded the emperor how much Rome had been indebted to Victory, and that it had been the uniform custom of the senators to swear fidelity to the government upon that altar. He likewise produced many facts to prove the advantages derived to the state from its ancient religious institutions, and insinuated that it was one divinity that all men worshipped under different forms, so that ancient practice should not be rashly laid aside. He even proceeded so far as to state the justice of increasing the public revenue by robbing the church, and attributed the late famine which had overtaken the empire to the neglect of the ancient worship. To this petition Ambrose replied in a letter to Valentinian, arguing that the devoted worshippers of idols had often been forsaken by their deities; that the native valour of the Roman soldiers had gained their victories, and not the pretended influence of pagan priests; that these idolatrous worshippers requested for themselves what they refused to Christians; that voluntary was more honourable than constrained virginity; that as the Christian ministers declined receiving temporal emoluments, they should also be denied to pagan priests; that it was absurd to suppose that God would inflict a famine upon the empire for neglecting to support a religious system contrary to his revealed will in the Scriptures; that the whole process of nature encouraged innovations, and that all nations had permitted these, even in religion; that heathen sacrifices were exceedingly offensive to Christians; and that every Christian prince should suppress these pagan ceremonies. In the epistles of Symmachus and of Ambrose both the petition and the reply are preserved, in which sophistry, superstition, sound sense, and solid argument, are strangely blended. It is scarcely necessary to add, that the petition was unsuccessful.

The increasing strength of the Arians proved too formidable for Ambrose. The young emperor and his mother Justina, along with a considerable number of clergy and laity professing the Arian faith, requested from the bishop the use of two churches, one in the city, the other in the suburbs of Milan. The prelate believing the bishops to be the guardians both of the temporal and spiritual interests of the church, and that the religious edifices were the unquestionable property of the church, positively refused to deliver up the temples of the Lord into the impious hands of the heretics. Filled with indignation, Justina resolved to employ the imperial authority of her son in procuring by force what she could not procure by persuasion. Ambrose was required to answer for his conduct before the council. He went, attended by a numerous crowd of people, whose impetuous zeal so overawed the ministers of Valentinian, that he was permitted to retire without making the surrender of the churches. The day following, when he was performing divine service in the Basilica, the prefect of the city came to persuade him to give up at least the Portian church in the suburbs. Still continuing obstinate, the court proceeded to violent measures: the officers of the household were commanded to prepare the Basilica and the Portian churches to celebrate divine service upon the arrival of the emperor and his mother at the ensuing festival of Easter. The order respecting one of them was carried into effect; but the court perceiving the growing strength of the prelate's interest, deemed it prudent to use more lenient measures. But all measures proved in vain; the bishop boldly replied, "If you demand my person, I am ready to submit: carry me to prison or to death, I will not resist; but I will never betray the church of Christ. I will not call upon the people to succour me; I will die at the foot of the altar rather than desert it. The tumult of the people I will not encourage; but God alone can appease." This strong declaration was followed by a torrent of eloquence from the pulpit, enforcing his theme with the most fervent zeal. But the court remained unconvinced; and another attempt being made, under a strong guard of ferocious Goths, to seize the Basilica, when they were about to enter, Ambrose thundered the sentence of excommunication against them, and so overawed them that they retired, while he and his friends remained in possession of the churches. About this time also an Arian bishop challenged Ambrose to a dispute before the emperor; but he declined, saying that matters of faith should be determined by a council of bishops.

Many circumstances in the history of Ambrose are strongly characteristic of the general spirit of the times. The chief causes of his victory over his opponents were, his great popularity, and the superstitious reverence paid to the episcopal character at that period of society. But it must also be admitted that he used several indirect means to obtain and support his popular authority. Many indigent persons were supported by his liberal bounty: in his explanations of Scripture he made constant and severe allusions to existing and public characters: and the alternate mode of singing had no small effect upon the minds of the vulgar. At a time when the influence of Ambrose required vigorous support, he fortunately was admonished in a dream to search for the remains of Gervasius and Protasius, two martyrs who quietly reposed under the pavement of the church. Their skeletons were found entire, stained with blood, and the head of one of them separated from the body. The vulgar crowded in thousands to behold these venerable relics. According to report, a blind man was restored to sight, several demons were expelled, and sick persons healed, by touching these bones. Ambrose exulted in these miracles, and appealed to them in his eloquent sermons; while the court derided and called in question their existence. The bishop continued firm in his opinions, the people believed, and the existence of the miracles was established. It is a very singular fact that these and many other miracles obtained current credit among the Christian historians of the second, third, and fourth centuries: and Dr Cave, in speaking of them, says, "I make no doubt but God suffered them to be wrought at this time on purpose to confront the Arian impieties."

Although the court was displeased with the religious principles and conduct of Ambrose, yet it respected his great political talents; and when necessity required, his aid was solicited and generously granted. When Maximus usurped the supreme power in Gaul, and was meditating a descent upon Italy, Valentinian sent Ambrose to dissuade him from the undertaking; and the embassy was successful. On a second attempt of the same kind

Ambrose was again employed; and although he was unsuccessful, it cannot be doubted that if his advice had been followed, the schemes of the usurper would have proved abortive; but the enemy was permitted to enter Italy, and Milan was taken. Justina and her son fled; but Ambrose remained in his station, and proved beneficial to many of the sufferers, by causing the plate of the church to be melted for their relief. Theodosius, the emperor of the East, espoused the cause of Justina, and by force of arms regained the kingdom.

In the year 390 a tumult happened at Thessalonica, in which Botheric, one of the imperial officers, was slain. At this Theodosius was so enraged that he issued a royal mandate for the promiscuous massacre of the inhabitants of that place; and about 7000 persons were butchered without distinction or mercy. The courageous Ambrose, informed of this deed, wrote to the emperor a severe reproof, and an earnest admonition, charging him not to approach the holy communion with his hands stained with innocent blood. When the emperor was about to enter the church of Milan to attend upon the service, the bishop met him, and with a stern countenance prohibited him from approaching the temple of God. The emperor reminded him that David had been guilty of murder and of adultery. The bishop replied, "You have imitated David in his guilt; go and imitate him in his repentance." The prince obeyed the priest, and, by a course of penitential sorrow during the space of eight months, he laboured to regain the favour of the church. After the termination of this period he was absolved, but at the same time was made to sign an edict that an interval of thirty days should intervene before the sentence of death or confiscation should be put in execution. When we reflect on the pernicious effects of sudden and violent passion, we must acknowledge that this measure was fraught with policy and humanity.

The undaunted courage of Ambrose received another severe trial in the year 392, after the assassination of Valentinian, and the base usurpation of Eugenius. Rather than join the standard of the usurper he fled from Milan; but after the army of Theodosius was victorious, he generously supplicated the emperor for the pardon of those who had supported the cause of Eugenius. Theodosius, soon after he had acquired the uncontrolled possession of the Roman empire, died at Milan. The bishop did not long survive the emperor, but died in the year 397. In his last illness he preserved perfect composure of mind, informing his friends that he had endeavoured so to conduct himself that he might neither be ashamed to live nor afraid to die.

On many accounts the character of the bishop of Milan stands high among the fathers of the ancient church. With unvarying steadiness he delivered his religious sentiments on all occasions; with unwearied assiduity he discharged the duties of his office; with unabated zeal and boldness he defended the orthodox cause in opposition to the Arians; with a liberal hand he fed the numerous poor who flocked to his dwelling; with uncommon generosity he manifested kindness to his adversaries; and with Christian affection he sought the happiness of all men. His general habits were amiable and virtuous, and his powers of mind were uncommonly vigorous and persevering. Ambition and bigotry were the chief blemishes in his character.

The writings of Ambrose are voluminous, although little more than adulterated editions of Origen and other Greek fathers. The great design of his writings was to defend and propagate the Catholic faith. In some of these he recommends perpetual celibacy as the perfection of Christian virtue. Modern judgment and taste may perhaps induce us to esteem some of the writings of Ambrose absurd, trivial, and even ludicrous; but there is a smartness and vigour in his style, and there are excellent sentiments interspersed, which render the writings of the bishop of Milan worthy of a perusal. With his usual severity and acrimony, Gibbon too severely censures this prelate. "Ambrose," says he, "could act better than he could write; his compositions are destitute of taste or genius, without the spirit of Tertullian, the copious elegance of Lactantius, the lively wit of Jerome, or the grave energy of Augustin." The most accurate and complete edition of his works is that published by the Benedictines, printed at Paris in 1686 and 1690, in two volumes folio.

AMBROSE, *Isaac*, an eminent Presbyterian minister, was educated at Brazen-nose College, Oxford, where he took the degree of bachelor of arts, and became minister of Garstang, and afterwards of Preston in Lancashire, whence he was ejected for nonconformity in 1662. It was usual for him to retire every year for a month into a little hut in a wood, where he shunned all society, and devoted himself to religious contemplation. Dr Calamy observes, that he had a very strong presentiment of the approach of death, and took a formal leave of his friends at their houses a little before his departure; and on the last night of his life he sent his discourse concerning *angels* to the press. The next day he shut himself up in his parlour, where, to the great surprise and regret of all who saw him, he was found just expiring. He died in 1663–4, in the 72d year of his age. He wrote several other books, as the *Prima, Media, et Ultima,* or *the First, Middle, and last Things; War with Devils; Looking unto Jesus, &c.*

AMBROSE, *Saint*, an island in the South Pacific Ocean, on the coast of Chili, four or five leagues due west from St Felix Island. It lies in Long. 80. 55. W. and Lat. 26. 13. S. There is a large rock four miles to the northward of the island, called from its appearance *Sail-rock.* Captain Roberts, who was there in 1792, found St Felix Island inaccessible. On St Ambrose Island his crew, in seven weeks, killed 13,000 seals. The island has little else to recommend it. Fish and crawfish abound.

AMBROSIA (α, privitive, and βροτος, *mortal*), in *Heathen Antiquity*, generally denotes the solid food of the gods, in contradistinction to their drink, which was called *nectar.* But the name ambrosia is also applied to drink, ointments, and fragrance delighting the gods.

AMBROSIAN OFFICE or RITE, in *Ecclesiastical History*, a particular formula of worship in the church of Milan, which takes its name from St Ambrose, who instituted that office in the fourth century. Each church originally had its particular office; and when the pope in aftertimes took upon him to impose the Roman office upon all the western churches, that of Milan sheltered itself under the name and authority of St Ambrose; from which time the Ambrosian ritual has prevailed.

AMBROSIN, in the *Middle-age Writers*, denotes a coin struck by the lords or dukes of Milan, whereon St Ambrose was represented on horseback, with a whip in his right hand.

AMBROSIUS AURELIANUS, or AURELIUS AMBROSIUS, a famous general of the ancient Britons, of Roman extraction. He was educated at the court of Aldroen of Armorica, who, at the request of the Britons, sent him over with 10,000 men to assist them against the Saxons, whom Vortigern had invited into Britain. Ambrosius was so successful against the Saxons, that the Britons chose him for their king, and compelled Vortigern to surrender to him all the western part of the kingdom, divided by the Roman highway now called *Watling Street.* Some time after, the Britons being discontented with Vortigern, and having withdrawn their allegiance from him, he retired to a castle in Wales. Here, being besieged by Ambrosius, and the castle taking fire, he perished in the flames, and left his rival sole monarch of Britain, who now assumed the imperial purple, after the manner of the Roman emperors. Geoffrey of Monmouth tells us that Ambrosius built Stonehenge, near Salisbury, in Wiltshire. See STONEHENGE.

After the Britons had defeated the Saxons, and obliged them to retire northward, Ambrosius is said to have convened the princes and great men at York, where he gave orders for repairing the churches destroyed by the Saxons, and restoring the exercise of religion to its former lustre. "He was a man," says Geoffrey, "of such bravery and courage, that when he was in Gaul no one durst enter the lists with him; for he was sure to unhorse his antagonist, or to break his spear into shivers. He was, moreover, generous in bestowing, careful in performing religious duties, moderate in all things, and more especially abhorred a lie. He was strong on foot, stronger on horseback, and perfectly qualified to command an army." The same author tells us that he was poisoned at Winchester, by one Eopa, a Saxon disguised as a physician, and hired for that purpose by Pascentius, one of the sons of Vortigern; but the generally received opinion is, that he was killed in a battle which he lost in the year 508, against Cerdic, one of the Saxon generals.

AMBRY, a place in which are deposited all utensils necessary for house-keeping. In the ancient abbeys and priories there was an office under this denomination, wherein were laid up all charities for the poor.

AMBUBAIÆ, in *Roman Antiquity*, were immodest women who came from Syria to Rome, where they lived by prostitution, and by playing on the flute. The word is derived from the Syriac *abub*, which signifies a flute.

AMBULANCE, an admirable invention of Baron Percy of the armies of France, for removing wounded men from the field of battle. It consists of covered waggons on springs, in which the wounded are removed to the hospitals. Those on whom operations have been performed in the field are thus carried safely to considerable distances; and thus, too, the sick may be removed. The medical men are also, by a sort of wooden horse on wheels, rapidly conveyed to the point where their services are most wanted. In the army of the East, the ambulance was fastened on a camel.—See Larrey, *Mem. de Chir. Milit.* i.

AMBULANT, or AMBULATORY. They gave in France the name of *Ambulant Commissioners*, to those commissioners or clerks of the king's farms who had no settled office, but visited all the offices within a certain district, to see that nothing was done in them against the king's right and the interest of the farm.

AMBULANT is also used to denote those brokers at Amsterdam, or exchange agents, who have not been sworn before the magistrates. They transact brokerage business, but their testimony is not received in the courts of justice.

AMBULATORY, a term anciently applied to such courts, &c., as were not fixed to any certain place, but held sometimes in one place and sometimes in another, in opposition to stationary courts. The court of parliament was anciently ambulatory: so also were the courts of king's bench, &c.

AMBURBIUM, in *Roman Antiquity*, a procession made by the Romans round the city and pomœrium, in which they led a victim, and afterwards sacrificed it, in order to avert some calamity that threatened the city. This festival was for the city of Rome what the Ambarvalia was for the fields.

AMEDABAD, or AHMEDABAD, an ancient and celebrated city of Hindustan in the province of Guzerat, of which it was formerly the Mahometan capital. It is situate on the banks of the river Sabermatty, which washes its western walls, and after a course of about 120 miles falls into the Gulf of Cambay, near the city of that name. It was built in the year 1412 by the Sultan Ahmed Shah of Guzerat, on the site of a town still more ancient. It soon became a populous and splendid city; and in the early part of the seventeenth century, after the subjugation of Guzerat by the emperors of Delhi, was a noted emporium of eastern commerce, to which the Dutch and other European merchants resorted for the purchase of goods. Here were manufactories of rich gold and silver flowered silks of every description; steel, gold, ivory, enamel, mother-of-pearl, and lackered ware, as well as of silk and cotton piece-goods, which were exported through Cambay. This state of prosperity continued until the rise of the Mahrattas, who captured the city in the early part of the last century, and levied a tax on every article, however trifling, and whether of luxury or of necessity, which was either brought within or sent out beyond its walls. Thenceforward Amedabad declined from its ancient splendour; its various manufactories, with some trifling exceptions, rapidly fell into decay and ruin; and its former grandeur is now marked only by the ruins of minarets, palaces, aqueducts, and caravansaries, which extend nearly thirty miles around. In 1780 it was stormed and captured by the British, but shortly afterwards restored by them to the Mahrattas. At that period, from being one of the largest capitals in the East, Amedabad was reduced to a circumference of five miles and three-quarters, surrounded by high walls, with irregular towers every fifty yards, and having twelve principal, besides many inferior gates. On the outside of the walls the country was in a state of desolation, the resort of wild beasts and of noxious reptiles.

In 1818, upon the overthrow of the Peishwa, Amedabad reverted to the British. On its present condition there is little to remark. Some additional consequence was conferred on the city during the administration of the government of Bombay by Sir John Malcolm, who made it the seat of the political residency, previously stationed at Baroda; but in 1838 this advantage was lost by the re-transfer of the residency to its former location. The extent and strength of the walls of Amedabad have been already noticed; but these having become greatly dilapidated, the government in 1834 authorised their thorough repair at a cost of L.25,000. The city contains 130,000 inhabitants: its principal streets are well lighted during the night with oil, and the requisite supply of water for the inhabitants is raised from the river and distributed through the city by pipes of tile. Distance from Bombay, 290 miles; from Poona, 320; from Delhi, 490; and from Calcutta 1020 miles. Long. 72. 36. E. Lat. 23. N. (E. T.)

AMEDIANS, an order of monks in Italy, so called from their professing themselves *amantes Deum*, lovers of God; or rather *amati Deo*, beloved of God. They wore a gray habit and wooden shoes, had no breeches, and girt themselves with a cord. They had 28 convents, and were united by Pope Pius V. partly with the Cistercian order, and partly with that of the Soccolanti, or wooden-shoe wearers.

AMEDNUGGUR, or AHMEDNUGGUR, in Hindustan, the principal place of the British district of the same name in the presidency of Bombay, and formerly the capital of one of the independent kingdoms of the Deccan. It was built in 1494 by Ahmed Nizam Shah, who made it the seat of government of his new monarchy. The rise of the kingdom of Ahmednuggur, and its subversion by Shah Jehan, emperor of Delhi; the subsequent cession of its territories to the Mahrattas; and their final transfer to the British, will be found more fully detailed under the article DECCAN. Distance of the city of Ahmednuggur from Bombay east, 122 miles; from Calcutta by Nagpore south-west, 930. Lat. 19. 6. Long. 74. 46. (E. T.)

AMELAND, an island in the North Sea, being a part of the province of Friesland, in Holland, from which it is separated by a strait called the Wat. It contains three villages, one hamlet, and 3300 inhabitants, who chiefly subsist by fishing, as seamen, by burning lime from mussel-shells, and by agricultural pursuits. Some corn is grown, and butter and cheese are made.

AMELIA, a county in Virginia, situated between the Blue-ridge and the Tide-waters, having Cumberland county on the north, Prince George county on the east, and Lunenburg county on the south and west. In 1810 Amelia contained 10,594 inhabitants, but in 1850 they had declined to 9755.

AMELIA ISLE, on the north-east coast of Florida, lies about twelve leagues north of St Augustin, and about nine or ten miles from the mouth of St John's river. It is 20 miles long and two broad, is very fertile, and has an excellent harbour. Its north end lies opposite to Cumberland Island, between which and Amelia Isle is the entrance to St Mary's river, in Long 81. 36. W. Lat. 30. 35. N.

AMELOT DE LA HOUSSAYE, *Abraham Nicolas*, was born at Orleans in 1634. He was much esteemed at the court of France, and was appointed secretary of an embassy which that court sent to the commonwealth of Venice, as appears by the title of his Translation of Father Paul's History of the Council of Trent; but he afterwards published writings which gave such offence that he was imprisoned in the Bastile. The first works he printed were the History of the Government of Venice, and that of the Uscoks, a people of Croatia. In 1683 he published his translations into French of Machiavel's Prince, and Father Paul's History of the Council of Trent, with political Discourses of his own upon Tacitus. These performances were well received by the public. He did not prefix his own name to the two last-mentioned works, but concealed himself under that of La Mothe Josseval. His translation of Father Paul was attacked by the partisans of the pope's unbounded power and authority. In France, however, it met with great success; all the advocates for the liberty of the Gallican church promoting the success of it to the utmost of their power, though at the same time there were three memorials presented to have it suppressed. In 1684 he printed, at Paris, a French Translation of Balthasar Gracian's *Courtier*, with the title of *L'Homme de Cour*. In 1686 he published *La Morale de Tacite de la Flatterie*, in which work he collected several particular facts and maxims, which represent in a strong light the artifices of court-flatterers, and the mischievous effects of their poisonous discourses. He wrote several other works; and died at Paris in 1706, at the age of 73.

AMELOTTE, DENIS, a celebrated French writer, was born at Saintonge in 1606. He maintained a close correspondence with the fathers of the Oratory, a congregation of priests founded by Philip of Neri. He wrote the life of Charles of Gondren, second superior of this congregation, and published it at Paris in 1643. In this work he said something of the famous abbot of St Cyran which greatly displeased the Port Royalists, who, out of revenge, published a libel against him, entitled *Idée Général de l'Esprit et de Livre de P. Amelotte*. He was so much provoked by this satire, that he did all in his power to injure them. They had finished a translation of the New Testament, and were desirous to have it published; for which purpose they endeavoured to procure an approbation from the doctors of the Sorbonne, and a privilege from the king. Amelotte, however, by his influence with the chancellor, defeated their intention. In this he had also a view to his own interest, being about to publish a translation of his own. Amelotte's translation, with annotations, in four volumes octavo, was printed in the years 1666, 1667, and 1668, and, according to F. Simon, contains some very gross blunders. He entered into the congregation of the Oratory in 1650, and continued amongst them till his death, which happened in 1678.

AMEN, אמן, signifies *true, faithful, certain*. It is made use of likewise to affirm anything, and was a sort of affirmation used often by our Saviour: Ἀμήν, Ἀμήν, λέγω ὑμῖν, i. e., *Verily, verily, I say unto you*. Lastly, it is understood as expressing a wish: as, *amen, so be it*, (Numb. v. 22); or an affirmation, *amen; yes, I believe it*, (1 Cor. xiv. 16.) The Hebrews end the five books of Psalms, according to their way of distributing them, with the words *amen, amen;* which the Septuagint have translated γένοιτο, γένοιτο; and the Latins *fiat, fiat*. The Greek and Latin churches have preserved this word in their prayers, as well as *alleluiah* and *hosannah;* because they observe more energy in them than in any terms which they could use in their own languages. At the conclusion of the public prayers, the people answered with a loud voice, Amen; and St Jerome says, that at Rome, when the people answered amen, the sound of their voices was like a clap of thunder: *In similitudine cœlestis tonitrui amen reboat.*

AMEND, or AMENDE, in French legislation, a pecuniary punishment imposed by a judge for any crime, false prosecution, or groundless appeal.

*AMENDE Honorable*, a species of punishment formerly inflicted in France upon traitors, parricides, or sacrilegious persons, in the following manner: The offender being delivered into the hands of the hangman, his shirt was stripped off, a rope put about his neck, and a taper placed in his hand; he was then led into court, where he implored pardon of God, the king, the court, and his country.

*AMENDE Honorable* is a term also used for making recantation in open court, or in presence of the person injured.

AMENDMENT, in *Parliamentary Language*, is used to signify a word, clause, or paragraph, proposed as an alteration in, or addition to, a bill under consideration. See PARLIAMENT.

AMENTUM. See BOTANY.

AMENTUM, in *Roman Antiquity*, a thong tied about the middle of a javelin or dart, either to give it rotation, or in order to recover the weapon as soon as it was discharged. The ancients made much use of the amentum, thinking it helped to enforce the blow. It was called ἀγκυλή by the Greeks, and the expression *Hastæ ansatæ* probably refers to the same. Amentum sometimes denoted a latchet that bound the sandals.

AMERCEMENT, or AMERCIAMENT, in *Law*, a pecuniary punishment imposed on offenders at the mercy of the court. It differs from a fine, in being imposed arbitrarily, in proportion to the fault; whereas a fine is a certain punishment settled expressly by some statute.

AMERIA, an ancient city of Umbria, situated on a hill between the rivers Tiber and Nar, a few miles above their junction. Its site is occupied by a small modern town of the same name.

# AMERICA.

America.

OUR object in this article is to take a comprehensive survey of the American continent in its physical, moral, and general relations. In attempting this, we do not intend to go much into detail upon those subjects which will be more fully and appropriately discussed in the distinct articles assigned in this work to the several states included in the western world; but we shall dwell at some length upon those great features, peculiarities, and classes of facts, which either belong to it as a whole, or can be most advantageously considered or described when all its parts are viewed in connection with one another. Such are the climate and physical structure of the country, the geographical distribution of its cultivated plants, its indigenous population, its animal tribes, its commercial and political capabilities, and its means of progressive improvement. The new continent may be styled emphatically "a land of promise." The *present* there sinks into nothing in itself, and derives all its importance from the germs it contains of a mighty future. The change must not only be great, but rapid, beyond all which the past history of mankind would lead us to expect. Even after we have familiarised our minds with the principles upon which its progress depends, we find it difficult to reconcile ourselves to the consequences that inevitably result from them. But time will do its work; and the great-grandsons of those now in existence may live to see the new world contain a greater mass of civilised men than the old. It is this greatness in prospect which lends an interest to the Western continent similar to that which the Eastern derives from its historical recollections. The same circumstance requires that we should dwell at some length on the physical structure of America, and on those indigenous tribes which, in the course of three centuries, will only live in poetry and tradition. The future history of the new world must be read by us in the configuration of its surface, the distribution of its mountains and rivers, the productions of its soil, its natural and political capabilities, and in the character rather than the numbers of its civilised inhabitants.

The continental part of America extends from the 54th degree of south to the 71st of north latitude, its extreme length, from the Straits of Magellan to those of Behring, being 10,500 English miles. The islands of Tierra del Fuego reach one degree beyond its southern extremity into the Antarctic Ocean; and Greenland, which is connected by geographers with America, has been traced to the 78th degree of north latitude, and probably is prolonged much farther into the polar circle. The late discoveries of Captains Parry, Ross, and Franklin, have given us much more exact ideas than we formerly possessed of the northern regions of America. The coast of the mainland has been traced almost completely from Behring's Straits to Fox's Channel on Hudsons' Bay, and is found to run in a direction east and west, in an uneven line near the parallel of 70°. The bounds of continental America may therefore be considered as nearly determined on every side. The additional lights furnished by Captain Parry's and other recent voyages render it extremely probable that a great archipelago of islands occupies all the space between the northern coast of the continent and the 80th parallel; and there is even some reason for believing that the country known by the name of Greenland is traversed from east to west by arms of the sea, like the regions on the west side of Baffin's Bay.

The new continent, when compared with the old, enjoys three important advantages. First, it is free from such vast deserts as cover a large part of the surface of Asia and Africa, and which not only withdraw a great proportion of the soil from the use of man, but are obstacles to communication between the settled districts, and generate that excessive heat which is often injurious to health, and always destructive to industry. Secondly, no part of its soil is so far from the ocean as the central regions of Asia and Africa. Thirdly, the interior of America is penetrated by majestic rivers, the Mississippi, Amazon, and Plata, greatly surpassing those of the old continent in magnitude, and still more in the facilities they present for enabling the remotest inland districts to communicate with the sea.

America.

According to the geographical system adopted in the old world, America ought to be considered as two distinct continents, connected by the isthmus of Darien. Its two great divisions have evidently more of a defined and separate character than Africa and Asia, or than Asia and Europe; but though this arrangement may be very properly adopted for the purpose of description, it is too late now to think of assigning separate names to regions which have so long been known by a common appellation. In the physical arrangement of the parts of South and North America there is a remarkable resemblance. Both are very broad in the north, and gradually contract as they proceed southward, till they end, the one in a narrow isthmus, and the other in a narrow promontory. Each has a lofty chain of mountains near its western coast, abounding in volcanoes, with a lower ridge on the opposite side, destitute of any trace of internal fire; and each has one great central plain declining to the south and the north, and watered by two gigantic streams, the Mississippi, corresponding to the Plata, and the St Lawrence to the Amazon. In their climate, vegetable productions, and animal tribes, the two regions are very dissimilar.

The extent of the American continent and the islands connected with it is as follows:—

| | Square Eng. miles. |
|---|---|
| North America | 7,400,000 |
| South America | 6,500,000 |
| Islands | 150,000 |
| Greenland, and the islands connected with it lying north of Hudson's Straits, may be estimated at | 900,000 |
| | 14,950,000 |

The American continent, therefore, with its dependent islands, is fully four times as large as Europe, about one-third larger than Africa, and almost one-half less than Asia, if we include with the latter Australia and Polynesia. It constitutes about three-tenths of the dry land on the surface of the globe. Of the continental part of North America, a considerable portion is condemned to perpetual sterility by the rigour of the climate, as we shall explain more fully by and by. At present it is sufficient to state, that if we draw a line from the head of Cook's Inlet, in latitude 61°, on the west side, to the straits of Bellisle on the east, so as to pass through Fort Churchill, on Hudson's Bay, we shall cut off a space rather exceeding one million and a half of square miles, which may be considered as incapable of cultivation. At the south extremity of America, a small tract, extending 200 miles north of the straits of Magellan, though far within the limits of the temperate zone, is nearly in the same condition. These and the summits of the Andes are the only parts of the American continent which are rendered incapable of cultivation by the severity of the climate.

The vast chain of the Andes is distinguished by several peculiar features from all other mountains in the world. It has its principal direction nearly north and south, while all the great ridges of the old continent run from east to west; it is unparalleled in its prodigious length, in the richness of its mineral treasures, and in the number and magnitude of its volcanoes. The Andes, if we connect with them the Mexican Cordillera and the Rocky Mountains, extend from the Straits of Magellan in a line which may be considered as unbroken, to Point Brownlow on the shores of the Arctic Ocean, in the latitude of 70°, over a space equal to 10,000 miles in length, or two-fifths of the circumference of the globe. Their height, which attains its maximum within the tropics, declines towards both poles, but in such a manner that, with a few exceptions, its higher summits ascend to the line of perpetual snow from one extremity to the other. It may thus be said to carry the temperature of the pole over the whole length of the American continent. The chain of the Andes is common to the two parts of America, and is in fact the link which connects them and makes them one continent. As we propose, however, to describe North and South America separately, we shall reserve the details for another part of this article.

South America is a peninsula of a triangular form. Its greatest length from north to south is 4550 miles; its greatest breadth 3200; and it covers an area, as already mentioned, of 6,500,000 square English miles, about three fourths of which lie between the tropics, and the other fourth in the temperate zone. From the configuration of its surface, this peninsula may be divided into five distinct physical regions, 1. The low country skirting the shores of the Pacific Ocean, from 50 to 150 miles in breadth, and 4000 in length. The two extremities of this territory are fertile, the middle a sandy desert. 2. The basin of the Orinoco, a country consisting of extensive plains or *steppes*, called Llanos, either destitute of wood or merely dotted with trees, but covered with a very high herbage during a part of the year. During the dry season the heat is intense here, and the parched soil opens into long fissures, in which lizards and serpents lie in a state of torpor. 3. The basin of the Amazon, a vast plain, embracing a surface of more than two millions of square miles, possessing a rich soil and a humid climate. It is covered almost everywhere with dense forests, which harbour innumerable tribes of wild animals, and are thinly inhabited by savages, who live by hunting and fishing. 4. The great southern plain, watered by the Plata and the numerous streams descending from the eastern summits of the Cordilleras. Open *steppes*, which are here called Pampas, occupy the greater proportion of this region, which is dry, and in some parts barren, but in general is covered with a strong growth of weeds and tall grass, which feeds prodigious herds of horses and cattle, and affords shelter to a few wild animals. 5. The country of Brazil, eastward of the Parana and Araguay, presenting alternate ridges and valleys, thickly covered with wood on the side next the Atlantic, and opening into steppes or pastures in the interior.

Mountains. The Andes.

The Andes skirt the shores of the Pacific Ocean, like a vast rampart opposed to its encroachments, along the whole line of the western coast, from 12° of north to 53° of south latitude. They derive their name from *anti*, a Peruvian word signifying copper. Except at some points where they have been examined by scientific men, their structure is yet but imperfectly known; and hence they are often incorrectly exhibited in our maps. Though often described as a single chain, they generally consist of a succession of ridges, divided by high and narrow valleys; but these ridges, instead of running in parallel lines, generally ramify from central points in all directions, and thus present the appearance of a confused assemblage of small chains. Between the latitude of 33° and 6° south, they spread out their base to an extent of 300 miles, and even much farther, if we take in the smaller subordinate chains. In the intervals between the ridges are situated many lakes, of which the most considerable are Ondalgola, Pataipo, Hages, and the great lake of Titicaca, 200 miles in length. This lake, and the lake Parimé, in Guiana, are the only sheets of fresh water in South America which vie in magnitude with those singular reservoirs placed on the course of the St Lawrence. From the latitude of 6° south to 2° north, the Andes contract their breadth, and form an elevated plateau. One part of this constitutes the Paramo, or desert of Assuay, a plain at the height of 13,000 feet above the sea, and embracing a surface of 50 square miles, where snow-storms are frequent, and only a few alpine plants grow. Farther north lies another range of table-land, from 9000 to 9440 feet in height, near the north extremity of which the town of Quito is situated. On this elevated plain are placed two lines of lofty summits, standing detached from each other, and crowned with diadems of perpetual snow. Their symmetrical disposition led Bouguer to consider the space between the eastern and western lines as a valley; but Humboldt remarks that it is really the crest of the Cordillera, upon which, as a base, the cones or masses of Pinchincha, Antisana, Atacazo, Chimborazo, and others, rest. When we have lived in this elevated spot for some time, "we forget that every thing which surrounds the observer, those villages which proclaim the industry of a mountainous people, those pastures covered with herds of lamas and flocks of European sheep, those orchards, those fields cultivated with care, and promising the richest harvests, hang as it were suspended in the lofty regions of the atmosphere, at a height exceeding that of the Pyrenees." From Quito, a single chain extends to Popayan, where it parts into three parallel chains. The westmost of these ridges, which scarcely rises to an elevation of 5000 feet, divides the valley of the river Cauca from the Pacific Ocean; and a branch proceeding from it passes through the isthmus of Panama, where it sinks to the small elevation of 600 or 800 feet above the sea. The second, or central ridge, maintains nearly the general height of the main trunk, and has summits which rise into the regions of perpetual snow. It separates the valley of the Cauca from that of the Magdalena. The pass of Quindiu, described by Humboldt, is one of the Quebradas, or transverse ravines, which open a passage through this mountain. It is so narrow in some places as to have the appearance of a gallery cut artificially and open to day. It is steep and uneven, and is kept almost perpetually wet by the rains. Travellers are carried through this ravine in chairs strapped on the backs of porters, who follow this mode of life voluntarily for the sake of gain, and think themselves sufficiently paid with twelve or fourteen piasters for a toilsome journey of fifteen or twenty days. Even the bottom of this ravine, at its highest point, is 11,400 feet above the sea, and of course exceeds the highest summit of the Pyrenees in altitude. The third or eastern ridge separates the valley of the Magdalena from the plains of the Rio Meta, and has its northern termination at Cape Vela, in longitude 72°. This chain, though lower than the centre one, has summits which reach to the height of 14,000 feet. Between the eastern and central chains is situated the city of Santa Fe de Begota, in a large and beautiful plain 8700 feet above the sea, and which, from the perfect level of its surface, and the barrier of rocks that incloses it, appears to have been an ancient lake. The waters of this plain escape by a narrow outlet, and rushing down a cleft, leap at two bounds to a depth of 573 feet, forming the celebrated fall of Tequendama, which, in the attributes of beauty and sublimity, is said not to be surpassed in the world. These three parallel ridges are properly component parts of the main trunk, like the two ridges of Upper Peru.

South America.

The mean height of the Andes in Peru, or that of the continuous ridge, independent of projecting cones, is estimated by Humboldt at 11,000 or 12,000 feet (1850 toises): in Chili, according to Mr Miers, the most elevated summits, at the latitude 33°, only reach the height of 15,000 feet, and the mean height of the chain is in some places as low as 8000; in Patagonia its height is unknown. Till lately, the loftiest summits were supposed to be in Quito, where Chimborazo attains the prodigious altitude of 21,440 English feet, and the volcanic cones of Antisana and Cotopaxi have the elevations of 19,150 and 18,890 feet respectively; but Mr Pentland, an English gentleman attached to the Peruvian embassy, has ascertained, by measurements performed with care, that the mountains of Quito are greatly surpassed in altitude by some of those of Upper Peru. The Andes here form two chains, which are separated by a large district of table-land, the northern extremity of which is occupied by the lake Titicaca. The eastern chain presents, between the 14th and 17th parallels, a range of snow-covered peaks, of which several have an elevation exceeding 20,000 feet. Among these, towards the north, in the latitude of 15° 30′, is Sorate, 25,250, and farther south Illimani, 24,450 feet in height. The former, therefore, is nearly 4000 feet higher than Chimborazo, but still 3000 feet lower than the loftiest summits of the Himalaya. The western chain is lower than the eastern, but one of its summits has an altitude of 18,800 feet. Mr Pentland concludes from astronomical observations, that the eastern chain is 310 geographical or 360 English miles from the coast. The mineral wealth of the district has attracted a large population to this table-land, which, with the single exception of Thibet, is probably the highest inhabited soil on the face of the globe. Here are flocks, gardens, cultivated fields, and populous cities, suspended above the region of the clouds. La Paz, with 20,000 inhabitants, and Potosi, which had once 150,000, are situated in this plain, at the height of 12,190 and 13,500 feet above the level of the sea; and there are cottages near the mines at 15,700 feet, an elevation exceeding that of Mont Blanc.[1] This table-land, from Cusco to Potosi, was the primitive seat of the empire of the Incas, and the centre of Peruvian civilisation.

Though nothing appears more capricious than the distribution and elevation of mountains, they yet afford, on the great scale, striking proofs of beneficent design, and of adaptation to the wants of civilised man. Many chains of mountains, for instance, enter within the regions of eternal frost with one or more of their summits; but there is not a single great chain in any of the fruitful and habitable parts of the world which so far transcends this limit as to present an unbroken line of snow along its whole length. The height of the curve of congelation diminishes as we approach the pole; and if there were not a corresponding diminution in the elevation of the mountains, or if the principal chains in the different habitable zones were raised a little higher, they would sever the nations living on their opposite sides as effectually as a wall of brass reaching above the clouds. The Andes, if we disregard their projecting summits, form an unbroken dike about $2\frac{1}{4}$ miles high, and 4500 miles long. Were three or four thousand feet added to their height, all access across, from one side of the chain to the other, would be denied to the foot of man. If great perils attend the short journey to the summit of Mont Blanc, what human skill or power could encounter the terrors of a snowy desert a hundred miles in breadth, beset with avalanches, and visited with storms? In these circumstances, such towns as Arica and La Paz, or Mendoza and Santiago, which are separated only by a journey of three days, would be as far asunder, for the purposes of traffic or intercourse, as England and Jamaica. But the line which bounds the means of communication varies from clime to clime. Were the Alps as elevated as the Andes, all the passes across the former would be closed; and were the Scandinavian chain as high as the Alps, Sweden and Norway could only communicate by sea. Though the altitude of the Andes in Patagonia has never been measured, various circumstances show that the chain descends as it advances from the torrid zone to its southern termination. In Quito and Peru, the back or crest of the ridge is free from snow, which only rests upon isolated summits; and with the aid of such arrangements as would be created by a dense population, the means of passing from one side to the other might perhaps be found wherever they were deemed necessary. In Chili, beyond the latitude of 30°, the highest point of the most frequented pass was found by Mr Miers to be 11,920 feet above the sea; and the courier travels through it even in winter. In Peru and Quito the passes in many cases consist of deep fissures, called *quebradas*, apparently produced by earthquakes, extremely narrow, and often descending to the depth of nearly a mile.[2] In Patagonia, where the snow descends much lower, the passes must be few; but there are some—and this circumstance authorises the conclusion that the height of the chain is smaller here than in Chili.

Transverse chains.

Three branches or transverse chains proceed from the Andes, nearly at right angles to the direction of the principal chain, and pass eastward across the continent, about the parallels of 18° of south, and 4° and 9° of north latitude. The most northern of these is "the Cordillera of the coast," which parts from the main trunk near the south extremity of the lake Maracaybo, reaches the sea at Porto Cabello, and then passes eastward through Caraccas to the Gulf of Paria. Its length is about 700 miles, and its medium height from 4000 to 5000 feet; but the Silla de Caraccas, one of its summits, has an elevation of 8400 feet; and its western part, which is at some distance from the sea, contains the Sierra of Merida, 15,000 feet in height. The second transverse chain is connected with the Andes at the parallels of 3° and 4° north, and passing eastward, terminates in French Guiana, at no great distance from the mouth of the Amazon. It consists properly of a succession of chains nearly parallel to the coast, and is sometimes called the Cordillera of Parimé, but is named by Humboldt the "Cordillera of the Cataracts of the Orinoco," because this river, which flows amidst its ridges in the upper part of its course, forms the cataracts of Maypure at the point where it descends into the plains. Its mean height is estimated at 4000 feet above the level of the sea; but about 70° and 75° west longitude, it sinks to less than 1000 feet, and at other points rises to 10,000. This chain divides the waters of the Orinoco and the rivers of Guiana from the basin of the Amazon, and is covered with magnificent forests. Its breadth is supposed to be from 200 to 400 miles, and it incloses amidst its ridges the great lake Parimé, in longitude 60°, and several of smaller size. On a table-land forming part of it, about the 67th degree of longitude, the Cassiquiari forms an intermediate channel which connects the rivers Orinoco and Amazon, so that, during the annual floods, a part of the waters of the former flow into the latter. This singular phenomenon was made known long ago by the Spanish missionaries, but was thought to be a fable till the truth was ascertained by Humboldt. The length of this chain is about 1500 miles. The third transverse chain, which bears various names, and is little known, crosses the continent between the parallels of 12° and 18°, connect-

South America.

ing the Andes with the mountains of Brazil, and dividing the waters of the Amazon from those of the Plata. It is a broad plateau of elevated land rather than a distinct mountainous ridge, and consists of low hills or uneven plains, with very little wood, presenting in some places extensive pastures, and in others tracts of a poor sandy soil. Its average height probably does not exceed 2000 or 3000 feet above the level of the sea.[1]

The mountains of Brazil, which are of moderate height, and occupy a great breadth of country, form an irregular plateau, bristled with sharp ridges running in a direction approximately parallel to the eastern coast. They extend from 5° to 25° of south latitude, and their extreme breadth may be about 1000 miles. Itacolumi, about 250 miles north-west of Rio Janeiro, which is celebrated for its auriferous sands and gravel, and gives birth to three great rivers, the Parana, the St Francisco, and the Tocantin, is considered the most elevated summit, and the stem of the whole group. According to the German miner Eschwege, it rises to the height of 5710 English feet[2] above the level of the sea; and the ordinary elevation of the numerous ridges which branch off from it is supposed to be 3000 or 4000 feet. The western parts of this chain, which are near the centre of the continent, are supposed to be lower than those on the coast; but they are probably as high, if Dr Spix is correct in stating that the mean heat of the year is below 65° of Fahrenheit (15° or 16° of Reaumur).

Geology.

The geology of the South American mountains, particularly the Andes, is distinguished, like their physical form and arrangement, by some remarkable peculiarities. The chain of the Andes, as we have already stated, may be considered as an immense dike, from two to three miles in height, and from one to three hundred in breadth. The first and most peculiar feature of this chain is, that it contains within its limits thirty active volcanoes,[3] or nearly one-fifth of all that are known in the world. They are irregularly distributed in linear groups from Patagonia to New Granada. The most southerly or Chilian group extends from 43½° to 30° south latitude. After an interval of 8° without volcanoes, we have a second group, that of Bolivia in Peru, extending from the 21st to the 15th deg. of south latitude. About 14° beyond this, the third group, that of Quito appears, extending about 2° on each side of the equator. A fourth line or group, 500 miles in length, occurs in the isthmus, chiefly in the state of Guatemala; and a fifth, consisting of five vents, crosses Mexico in an east and west direction. Some of these throw out smoke merely, some mud and water, and only a few produce eruptions of lava. They are of various elevations, up to 18,800 feet. Over nearly the whole chain earthquakes are extremely frequent, and at times fearfully destructive. The fundamental rock of the Andes is granite, or a rock of kindred nature, which, from being almost peculiar to the chain, has been termed Andesite. It is a combination of albite and hornblende, often united with mica, and sometimes, though rarely, with quartz, passing on the one hand into granite, and on the other into felspar porphyry. Trachyte and syenite occur in analogous positions, that is, generally at the base, and occasionally at the summits of the chain. The fundamental rock is covered by vast masses of felspar or claystone porphyry, which had issued from below at numerous points, "studded over a breadth of 50 or 100 miles;" and being tilted, fractured, and long exposed to denudation in the sea, produced thick beds of porphyry conglomerate, which are seen in every variety of position and inclination. Incumbent on these, or mingled with them are mica slates, probably metamorphic, and clay slates, with silurians, and above these carboniferous sandstones, gypsum, and rocks of the oolite and chalk series. Tertiary deposits cover the plains at the eastern foot of the chain, forming in Patagonia a succession of terraces, one below another, extending to the Atlantic. Mr Darwin thinks that the Andes of Chili, after being raised above the sea, had subsided at least twice to the extent of six or eight thousand feet, and this conclusion applies to the whole chain. The Andes are rich in metals, abounding in mines of copper, silver, gold, &c. Crystalline schists occupy the greater part of Brazil and of Venezuela, and Guiana. A deposit of fine mud, from 20 to 100 feet thick, is found on the banks of the Parana, and covers the plains called Pampas, from Buenos Ayres, nearly as far south as the river Colorado. It is an estuary deposit, of post-tertiary or quarternary age, formed, as Mr Darwin thinks, by the Parana and its tributaries, when the land was lower "by a few fathoms" than it is now. It contains fossil remains of large mammalia in vast numbers, all of extinct species, and many of them even of extinct genera, including the Megatherium, Megalonix, Scelidotherium, Mylodon, Holofractus, Toxodon, Macrouchenia, Glyptodon, Mastodon, a great Dasypus, with a Ctenomys, Hydrochœrus, and other rodents. The horse and the elephant have been found in the fossil state from Spain to eastern Siberia, and from Russian America to Patagonia, affording a presumption, as Mr Darwin observes, that when these quadrupeds lived the two continents were connected at or near Behring's Straits.[4]

The transverse chain of the coast of Caraccas consists partly of primitive and partly of secondary formations. The Cordillera of Parimé, so far as it has been examined, is entirely composed of primitive rocks, viz., granite, gneiss, mica slate, and hornblende; the Cordillera of Chiquito, which divides the Plata from the Amazon, is only known at its eastern extremity, where it joins the mountains of Brazil. These last consist of a great number of ridges, running in general south and north. Granite abounds in those nearest the Atlantic, but the prevailing rock everywhere else, as far westward as the mountains of Cujaba, in longitude 55°, is a quartzy mica slate, intermixed however with granite, gneiss, and quartz rock, and having portions of secondary sandstone resting on its sides or in its low valleys. This quartzy mica slate, in Brazil, is the matrix of the gold and diamonds; and the former is generally accompanied with platinum and iron. The direction of the strata approaches to north-east and south-west, and the dip, where observed, is from 50° to 70° to the south-east. These mountains, like the Andes, are in many parts covered with a stratum of clay.[5] The rocks of the plains have been but partially examined. Humboldt thinks that the northern Llanos of Caraccas are of old red sandstone.

Climate.

The latitude and elevation of the land in each country, its position in reference to the sea, with the direction of the prevailing winds, are the chief circumstances which determine the nature of the climate. We have already mentioned that three-fourths of South America lie within the tropics, and the remaining fourth in the temperate zone; but, in both divisions, it might be naturally inferred that a huge wall like the Andes, rising into the atmosphere to the height of two or three miles, and running across the course of the tropical and extra-tropical winds, would exert a powerful influence on the temperature, humidity, and the distri-

South America.

bution of the seasons. This is actually the case; and it is this vast chain of mountains, with its prolongation in North America, which affords a key to the most remarkable peculiarities in the climate of the whole continent. The subject, we think, has not been hitherto well understood, but admits of being explained in a very simple manner.

The trade-winds blowing from the east occupy a zone 60 degrees in breadth, extending from 30° of south to 30° of north latitude. Beyond these limits are variable winds; but the prevailing direction in the open sea, where no accidental causes operate, is well known by navigators to be from the west. Now these winds are the agents which transport the equable temperature of the ocean, and the moisture exhaled from its surface, to the interior of the great continents, where it is precipitated in the shape of rain, dew, or snow. Mountains attract the moisture which floats in the atmosphere; they obstruct also the aerial currents, and presenting great inequalities of temperature, favour precipitation. Rain, accordingly, in all countries falls most abundantly on the elevated land. Let us consider, then, what will be the effect of a mural ridge like the Andes in the situation which it occupies. In the region within the 30th parallel, the moisture swept up by the trade-wind from the Atlantic will be precipitated in part upon the mountains of Brazil, which are but low, and so distributed as to extend far into the interior. The portion which remains will be borne westward, and, losing a little as it proceeds, will be arrested by the Andes, and fall down in showers on their summits. The aerial current will now be deprived of all the humidity which it can part with, and arrive in a state of complete exsiccation at Peru, where no rain will consequently fall. That even a much lower ridge than the Andes may intercept the whole moisture of the atmosphere, is proved by a well-known phenomenon in India, where the Ghauts, a chain only 3000 or 4000 feet high, divide summer from winter, as it is called; that is, they have copious rains on their windward side, while on the other the weather remains clear and dry; and the rains regularly change from the west side to the east, and *vice versa*, with the monsoons. In the region beyond the 30th parallel, this effect will be reversed. The Andes will in this case serve as a screen to intercept the moisture brought by the prevailing west winds from the Pacific Ocean; rains will be copious on their summits, and in Chili on their western declivities, but none will fall on the plains to the eastward, except occasionally, when the winds blow from the Atlantic. The phenomena of the weather correspond in a remarkable manner with this hypothesis. On the shore of the Pacific, from Coquimbo, at the 30th parallel, to Amotape, at the 5th of south latitude, no rain falls; and the whole of this tract is a sandy desert, except the narrow strips of land skirting the streams that descend from the Andes, where the soil is rendered productive by irrigation. From the 30th parallel southward the scene changes. Rains are frequent; vegetation appears on the surface, and grows more vigorous as we advance southward. "At Conception," says Captain Hall, "the eye was delighted with the richest and most luxuriant foliage; at Valparaiso the hills were poorly clad with a stunted brushwood and a poor attempt at grass, the ground looking starved and naked; at Coquimbo the brushwood was gone, with nothing in its place but a vile sort of prickly pear bush, and a thin sprinkling of gray wiry grass; at Guasca (latitude 28½°) there was not a trace of vegetation, and the hills were covered with bare sand."[1] It follows from the principle we have laid down, that in this southern part of the continent the dry tract should be found on the east side of the mountains, and such is the fact. At Mendoza, in latitude 30°, rain scarcely ever falls, and the district along the east foot of the Andes is known to consist chiefly of parched sands, on which a few stunted shrubs grow, and in which many of the streams that descend from the mountains are absorbed before they reach the sea. The whole country, indeed, south of the Plata, suffers from drought; but on the eastern side this is remedied to some extent by winds from the east or south-east, which bring occasional rains to refresh the soil. From Amotape northward, on the other hand, the west coast is well watered and fruitful; and this is easily accounted for. The line of the coast here changes its direction, and trends to the north-east as far as the Isthmus of Panama, where the mountains sink to a few hundred feet in height, and leave a free passage to the trade-wind, which here often assumes a direction from the north-east, or even the north. The exhalations of the Atlantic are thus brought in abundance to the coast of Quito, which is in consequence well watered; while the neighbouring district of Peru suffers from perpetual aridity.

Our principle applies equally to the explanation of some peculiar facts connected with the climate of North America. The western coast of Mexico, as far as St Blas or Mazatlan, in latitude 23°, is well watered, because, *first*, the continent here is narrow; *secondly*, the table-land of Mexico, which is much lower than the Andes of Chili, is not so effectual a screen to intercept the moisture; and, *thirdly*, there is reason to believe that a branch of the trade-wind, which crosses the low part of the continent at Panama and Nicaragua, sweeps along the west coast during part of the year, and transports humidity with it. But beyond the point we have mentioned drought prevails. Sonora, though visited occasionally by rains, consists of sandy plains without herbage, where the streams lose themselves in the parched soil without reaching the sea; and even Old California, which has the ocean on one side, and a broad gulf on the other, and ought apparently to be excessively humid, is covered with sterile rocks and sandy hills, where the vegetation is scanty, and no timber is seen except brushwood.[2] This dry region extends as far as 33° or 34°; but immediately beyond this we have another change of scene. New California is described as in all respects a contrast to the Old. It is rich, fertile, and humid, abounding in luxuriant forests and fine pastures; and the American possessions to the northward preserve the same character. How can we account for this singular diversity of climate, except upon the principle which has been explained, namely, that in all regions where ranges of mountains intersect the course of the constant or predominant winds the country on the windward side of the mountains will be moist, and that on the leeward dry; and hence parched deserts will generally be found on the west side of countries within the tropics, and on the east side of those beyond him? Our hypothesis applies equally to the country east of the Rocky Mountains. For the space of about 3000 miles from the foot of this chain the surface consists of dry sands or gravel, sometimes covered with saline incrustations, almost destitute of trees and herbage, and watered by streams flowing from the mountains, which are sometimes entirely absorbed by the arid soil.[3] The central and eastern part of the basin of the Mississippi would in all probability have been equally barren had the configuration of the land been a little different in the south. A tract of country extremely low and level extends along both sides of this river; and a portion

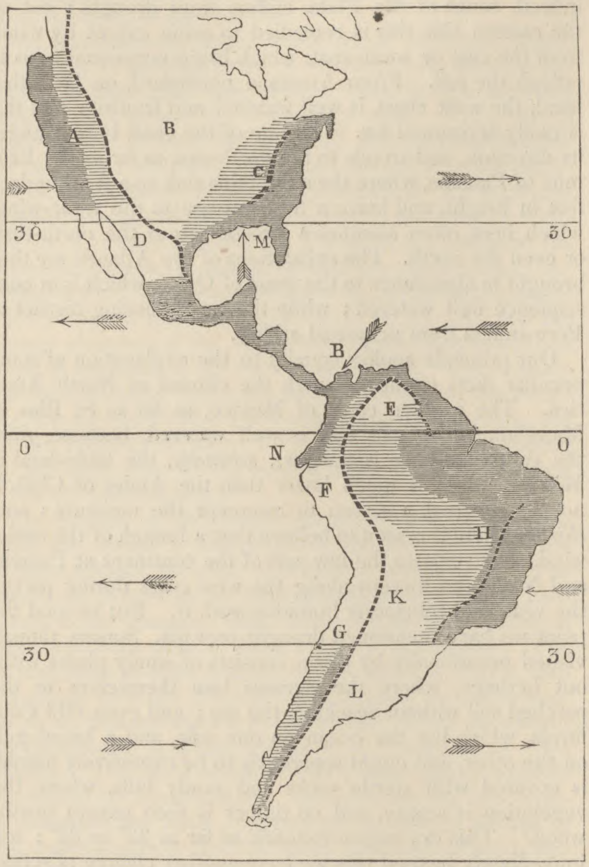
South America.

of the trade-wind blowing from the Mexican Gulf, finding its motion westward obstructed by the high table-land of the Cordillera, is deflected to the right, and ascends the valley of the Mississippi and Ohio. This wind, whose course was first traced by Volney, bears with it the humidity of the torrid zone, and scatters fertility over a wide region that would otherwise be the abode of barrenness.



The views on the subject of climate we have been unfolding will enable us to throw some light on an interesting point—the distribution of forests. We are induced to think, that in all countries having a summer heat exceeding 70°, the presence or absence of natural woods, and their greater or less luxuriance, may be taken as a measure of the amount of humidity, and of the fertility of the soil. Short and heavy rains in a warm country will produce grass, which, having its roots near the surface, springs up in a few days, and withers when the moisture is exhausted; but transitory rains, however heavy, will not nourish trees, because after the surface is saturated with water, the rest runs off, and the moisture lodged in the soil neither sinks deep enough, nor is in sufficient quantity to furnish the giants of the forest with the necessary sustenance. It may be assumed that 20 inches of rain falling moderately, or at intervals, will leave a greater permanent supply in the soil than 40 inches falling, as it sometimes does in the torrid zone, in as many hours. It is only necessary to qualify this conclusion by stating, that something depends on the subsoil. If that is gravel, or a rock full of fissures, the water imbedded will soon drain off; if it is clay or a compact rock, the water will remain in the soil. It must be remembered, also, that both heat and moisture diminish as we ascend in the atmosphere, while evaporation increases; and hence that trees will not grow on very high ground, though its position in reference to the sea and the prevailing winds should be favourable in other respects. In speaking of the *region of forests*, we neither restrict the term to those districts where the natural woods present an unbroken continuity, nor extend it to every place where a few trees grow in open plains. It is not easy to give a definition that will be always appropriate; but in using the expression, we wish to be understood as applying it to ground where the natural woods cover more than one-fourth of the surface.

South America.

The small map of America prefixed will enable the reader to follow our statements with ease. The long hatched lines show the positions of the chains of mountains; the shading represents the regions of forests; the dense forests being marked by the double shading, and the thinner ones by the open lines. The white spaces represent the lands on which little or no wood grows. The equator and the parallel of 30° on each side are indicated by the horizontal lines marked 0 and 30. The arrows show the direction of the prevailing winds; but it must be remembered that, though the intertropical wind is assumed to have its course right from the east, this is only true at the equator, its direction inclining to north-east as we approach the northern tropic, and to the south-east as we approach the southern. In North America A is the woody region on the west coast, extending from latitude 35° to about 58°, and of unknown breadth. B the region on the east side of the Rocky Mountains, partly a bare desert, partly covered with grass and dotted with trees. C the forests of the Allegany chain, thick on the east and south, and thin on the west; bounded by a curved line passing from St Luis, in Mexico, through Lake Huron, to the mouth of the St Lawrence, in latitude 50°. The arrow at M points out the direction of the wind, which ascends the valley of the Mississippi, and nourishes the western part of these forests; and the arrow at R that which blows across the isthmus of Panama. D is the table-land of Mexico, graduating on the north-west into the dry plains of Sonora and California, all bare, or nearly bare, of wood. E is the Llanos or bare plains of Caraccas, nearly fenced round with mountains. F G is the long strip of bare dry sands on the west side of the Andes which constitutes Lower Peru and the north part of Chili; and N is Amotape, its northern boundary. H is the great region of forests which constitutes the basin of the Amazon, and occupies all the rest of Brazil. Near the equator the moisture is so excessive, that after 150 or 200 inches of rain[1] have fallen on the east coast, there is still sufficient humidity in the atmosphere to afford copious showers to all the country up to the Andes. Here, therefore, the woods reach from side to side of the continent. But as we recede from the equator the humidity diminishes rapidly; and though the continent becomes narrower towards the south, the supply of rain falls off in a still greater proportion, and the forests extend over a much smaller space. At the foot of the Andes, the forests extend to 16° or 18° of south latitude; on the east coast to 25° or probably 30°. K L are the *Pampas* or open lands of Buenos Ayres, extending on the east side of the Andes, from Cape Horn to the latitudes just mentioned. If we divide this region into three parts, the eastmost, refreshed by occasional rains from the Atlantic, is covered with a strong nutritive herbage; the second, which is drier, displays a thin coarse wiry grass; and the third portion, which extends to the Andes, receiving little or no rain, is nearly a desert: all the three are destitute of timber, but the surface of the third is dotted with dwarfish shrubs.[2]

South America.

I is the southern part of Chili. Here the prevailing winds, which are from the west, coming loaded with the moisture of the Pacific Ocean, produce copious rains to nourish the herbage and the forests. This applies, however, chiefly to the country south of the 35th parallel. From that to Coquimbo, in latitude 30°, the wood is scanty. Beyond 50° on the east coast of North America, and 55° or 58° on the west, very little wood grows, in consequence of the rigour of the climate.

Climate.

Great misapprehensions have arisen with regard to the climate of America, from comparisons being drawn between the east side of the new continent and the west side of the old. We have already pointed out the influence of winds blowing from the sea, in modifying the state of the atmosphere over the land, both as to heat and humidity. When this circumstance is attended to, and when the east and west sides of the old and the new continents are respectively compared with one another, the difference is found to be small, and easily accounted for. In the torrid zone, and on the sea-shore, the temperature of both continents is found to be the same, viz., 82°; but in the interior the difference is rather in favour of America. There is no counterpart in the new world to the burning heats felt in the plains of Arabia and Gedrosia. Even in the western and warmest part of the parched steppes of Caraccas, the hottest known region in America, the temperature of the air during the day is only 98° in the shade, which rises to 112° in the sandy deserts which surround the Red Sea. At Calabozzo, farther east in the Llanos, the common temperature of the day is only from 88° to 90°; and at sunrise the thermometer sinks to 80°.[1] The basin of the Amazon is shaded with lofty woods; and a cool breeze from the east, a minute branch of the trade-wind, ascends the channel of the stream, following all its windings, almost to the foot of the Andes. Hence this region, though under the equator, and visited with almost constant rains, is neither excessively hot nor unhealthful. Brazil, and the vast country extending westward from it between the Plata and the Amazon, is an uneven table-land, blest with an equable climate. At Rio Janeiro, which stands low, and is exposed to a heat comparatively great, the temperature in summer varies from 16° to 22° of Reaumur, and the mean is only about 19° (74° Fahr.) Farther north, and in the interior, the Indians find it necessary to keep fires in their huts; and in the country near the sources of the Paraguay, hoar-frost is seen on the hills during the colder months, and the mean temperature of the year falls below 65° or 67°.[2] On the declivities of the Andes, and on the high plains of Upper Peru, the heats are so moderate that the plants of Italy, France, and Germany, come to maturity. Lower Peru, though a sandy desert, enjoys a wonderful degree of coolness, owing to the fogs which intercept the solar rays. At Lima, which is 540 feet above the sea, the temperature varies from 53° to 82°, but the mean for the whole year is only 72°. In the plains of La Plata, the mean temperature of the year is very nearly the same as at the corresponding north latitudes on the east side of the Atlantic. At Buenos Ayres, for instance, the mean annual heat is 19° 7′ of the centigrade thermometer (68° Fahr.), while that of places on the same parallel in the old world is 19° 8′. The range of temperature is probably greater in the basin of the Plata; but as we advance southwards, the diminishing breadth of the continent makes the climate approximate to that of an island, and the extremes of course approach each other. In the Straits of Magellan the temperature of the warmest month does not exceed 43° or 46°; and snow falls almost daily in the middle of summer, though the latitude corresponds with that of England. But the inference drawn from this, that the climate is unmatched for severity, is by no means just, for the winter at Staten Island is milder than in London. In point of fact, the climate of Patagonia is absolutely colder than that of places in the same latitude in Europe; but the difference lies chiefly in the very low temperature of the summer. This peculiarity no doubt results chiefly from the greater coolness of the sea in the southern hemisphere; far beyond the parallel of 48°, the difference of temperature in the North and South Atlantic amounts, according to Humboldt, to 10° or 12° of Fahrenheit's scale.[3] If we push our researches a step farther, and inquire what is the cause of the great warmth of the Northern Sea, we shall be forced to admit that a very satisfactory answer cannot be given. Something may be due to the influence of the Gulf Stream, a minute branch of which is supposed to carry the waters of the torrid zone to the shores of Shetland and Norway; but such an agent seems too trifling to account for the phenomenon. The sum, then, of the peculiar qualities which distinguish the climate of South America may be briefly stated. Near the equator the new continent is perhaps more humid than the old; and within the tropics generally, owing to its vast forests, the absence of sandy deserts, and the elevation of the soil, it is cooler. Beyond the tropics the heat is nearly the same in the southern temperate zone of Amercia and the northern one of the old continent, till we ascend to the neighbourhood of Cape Horn, where we have cold summers, and a very limited range of the thermometer in the western hemisphere.

North America.

Nine-tenths of North America lying under the temperate zone, the climate follows a different law from what is observed in the southern peninsula, and presents more striking contrasts with that of the best known parts of the old world. The long narrow region now denominated Central America, which connects the two great divisions of the continent, stretching from Panama to Tehuantepec, has in general a very humid atmosphere; but, for a tropical country, it must be only moderately hot, as every part of it is within a small distance of the sea. At Vera Paz the rains fall during nine months of the year. Mexico is hot, moist, and unhealthy on the low coasts; but two-thirds of its area, comprising all the populous districts, consist of table-land, from 5000 to 9000 feet in height. In consequence of this singular configuration of its surface, Mexico, though chiefly within the torrid zone, enjoys a temperate and equable climate. The mean heat at the capital, which is 7400 feet above the sea, is 62½°, and the difference between the warmest and coldest months, which exceeds 30° at London, is here only about 12°; but the atmosphere is deficient in moisture, and the country suffers from drought. Beyond the parallel of 24° the western shores are hot and arid.

In the extensive region lying between the parallels of 30° and 50°, which comprehends three-fourths of the useful soil of North America, we have three well-marked varieties of climate, that of the east coast, the west coast, and the basin of the Mississippi. On the east coast, from Georgia to Lower Canada, the mean temperature of the year is lower than in Europe by 9° at the latitude of 40°, and by 12½° at the latitude of 50°, according to Humboldt's calculation. In the next place, the range of the thermometer is much greater than in Europe, the summer being much hotter and the winter much colder. At Quebec the temperature of the warmest month exceeds that of the coldest by no less than 60½° of Fahr.; while at Paris, which is nearly under the

North America.

same latitude, the difference is only 31°. In the third place, the climate undergoes a more rapid change in America as we proceed from south to north, a degree of latitude in the middle of the temperate zone producing a decrease of annual temperature of 1·13° in Europe, and of 1·57° in America. The comparison is greatly to the disadvantage of America when made in this form; but when the east coasts of the two continents are compared, the case is altered: the old world is found to have no superiority over the new, for Pekin has still colder winters and warmer summers than Philadelphia, which is under the same latitude. It is the west coast of the new continent which ought to exhibit the climate of Europe; and from the few facts known, we have reason to believe that it is quite as mild and equable. At the mouth of Columbia River, in latitude 46½°, Captain Lewis and Clarke found the rains to be copious and frequent; but they had very little frost, and saw no ice even in the depth of winter. From observations made in 1822–3–4, it appears that the mean heat of the warmest month was about 62°, of the coldest about 36°, and of the whole year 51°.[1] Now, the place is under the same latitude with Quebec, where the snow lies five months, and the mean temperature during the three winter months is 18° below the freezing point. This single circumstance marks emphatically the contrast in the climate of the east and west coasts of North America. But the mouth of Columbia River is also under the same parallel with Nantes at the mouth of the Loire, where snow and ice are no strangers in the cold season of the year. We have therefore, good grounds to conclude that the west coast of America, in the middle latitudes, has nearly as mild and equable a climate as the west coast of Europe. The climate of the great central valley, or basin of the Mississippi, has a considerable affinity to that of the east coast. It was long a matter of dispute in what the difference between the two consists; but this seems at last to have been clearly settled, by the meteorological registers kept at the military posts of the United States. From a comparison of four of these registers, from posts near the centre of this great valley, with others kept on the Atlantic coast in the same latitudes, it appears that in the hottest month the temperature is from 5° to 6° higher, and in the coldest month as much lower, in the basin of the Mississippi, than on the coasts of New England. The proportion of fair weather to cloudy is as 5 to 1 in favour of the east coast.[2] The climate of the interior, therefore, exhibits in still greater excess those extremes of temperature which distinguish the eastern coast of this continent from the western, and from the shores of Europe. The fourth region of extra-tropical America includes the parts beyond Mount St Elias on the west coast, and, in the interior, the plains extending from the 50th parallel to the Polar Seas. The intensity of the cold in this tract of country is scarcely equalled by any thing that is known under the same parallels in Northern Asia. The northernmost spot in America where grain is raised is at Lord Selkirk's colony, on Red River, in latitude 50°. Wheat, and also maize, which requires a high summer heat, are cultivated here.[3] Barley would certainly grow as far north as Fort Chippewyan, in latitude 58¾°, where the heat of the four summer months was found by Captain Franklin to be 4° higher than at Edinburgh. There is even reason to believe, that both this species of grain and potatoes might thrive as far north as Slave Lake, since the spruce fir attains the height of 50 feet three degrees farther north, at Fort Franklin, in latitude 65°. These, however, were low and sheltered spots; but in this dreary waste generally, it will not be found practicable, we suspect, to carry the arts of civilized life beyond the 60th parallel; and the desirable country, capable of supporting a dense population, and meriting the name of temperate, can scarcely be said to extend beyond the 50th parallel. At 65° the snow covers the ground in winter to the depth of only two feet, but small lakes continue frozen for eight months. The sea is open only for a few weeks, fogs darken the surface, and the thermometer in February descended, in one instance to *minus* 58°, or 90° below the freezing point. At Melville Island, under the 75th parallel, such is the frightful rigour of the climate, that the temperature of the year falls 1° or 2° below the zero of Fahrenheit's scale. It is a peculiarity in the climate of America, that beyond the parallel of 50° or 52°, it seems to become suddenly severe at both extremities. At the one, summer disappears from the circle of the seasons; at the other, winter is armed with double terrors.

The mountains of North America will not detain us long. The branch of the Andes which divides the seas at the isthmus of Panama is very low, the highest point of the railroad now in progress (1852) is only 300 feet above the sea. At the isthmus of Tehuantepec, a route has been traced whose most elevated point is 702 feet. The most considerable elevations are on the south-west side of the isthmus; and twenty-one volcanoes, scattered over this limited space, afford proof that the sources of internal fire exist here in unexampled abundance. From Puebla to Durango the Mexican mountains no longer present the appearance of a chain, but spread out to a table-land or elevated plain, from 5000 to 9000 feet in height, and from 100 to 300 miles in breadth. Across this plain, exactly at the 19th parallel, five volcanoes are distributed in a line running east and west, as if a vast rent, extending from the Atlantic to the Pacific, had opened a passage for the internal fires of the globe at this spot. Two of these on the east side of the continent, with a group of four or five other cones lying between Jalapa and Cordoba, have an elevation exceeding 17,000 feet, and are the only mountains in New Spain that rise to the region of perpetual snow, which commences here at 15,000 feet above the level of the sea. Jorullo, the lowest of the five volcanoes, rose suddenly in the middle of a plain, in September 1759, after fearful concussions of the ground, continued for fifty or sixty days. It is 1600 feet high, and is surrounded by a number of smaller cones or burning masses, all resting on a portion of the plain four square miles in extent, which was heaved up in the form of a tumefied dome. Near the tropic the Mexican Cordillera divides into three parts. One runs parallel to the eastern coast at the distance of thirty or forty leagues, and terminates in New Leon. Another proceeds in a north-western direction, and sinks gradually as it approaches the Californian Gulf in Sonora. The third or central Cordillera traverses Durango and New Mexico, divides the sources of the Rio Gila from the Rio Brava del Norte, and forms the eastern ridge or main trunk of the Rocky Mountains, which terminates at the Arctic Ocean about 140° of west longitude. From the southern point of California, a lower chain skirts the coast as far as the volcano of Mount St Elias, in latitude 60°; and between this chain and the eastern several intermediate ones occur, the whole forming apparently an elevated plateau from 200 to 800 miles in breadth. Many of the summits of the Rocky Mountains are within the regions of perpetual snow; and several of their peaks have been found to measure 11,000, 11,320, 13,538, and 16,000 feet.[4] In one of the valleys included in the plateau of the Rocky Mountains, is situ-

North America. ated the great salt lake Utah, in west longitude 112° and north latitude 41°. The lake, whose waters are intensely saline, is nearly 300 miles in circumference, and its shores, for a breadth of several miles, are covered with an incrustation of very pure salt. In this valley or basin, which measures about 500 miles each way, and contains much fertile soil, the Mormons, a new religious sect of very peculiar tenets, established themselves in 1847. It is a convenient halting station for the American emigrants who pass by land to California.

If we run a line westward across the continent of North America at the latitude of Delaware Bay (38°), the geological formations present themselves in the following order:—1. Tertiary and cretaceous strata on the shores of the Atlantic; 2. Gneiss underlying these strata, and presenting itself on the eastern slope of the Allegany or Appalachian mountains, but covered at parts by New Red Sandstone; 3. Palæozoic rocks, consisting of Silurian, Devonian, and carboniferous strata, curiously bent into parallel foldings, with synclinal and anticlinal axes, the crests of the latter forming the ridges of the Allegany Mountains, which in this region rise to the height of 2500 feet. Upon these palæozoic rocks rest three great coal-fields—the Appalachian, that of Illinois, and that of Michigan, covering a large portion of the space between the Alleganies and the Mississippi, and embracing collectively an area equal to the surface of Great Britain. From the Mississippi westward the country has not been thoroughly explored, but the Silurian, carboniferous, and secondary rocks, are said to extend to the base of the Rocky Mountains. Here the crystalline schists again present themselves, and not only form the crests of the two chains, but extend to the shores of the Pacific. Both in Oregon and California they have been greatly disturbed by eruptive rocks of many varieties. Among these Mr Dana names traps, porphyries, serpentines, hypersthenes, trachytes, and cellular lavas. Sandstones of the Silurian or carboniferous age are mingled with these, and along with the mica and chlorite schists (perhaps metamorphic), were no doubt the matrix of the gold found in the gravel. It is generally in such situations—that is, among the crystalline and palæozoic strata, where they have been penetrated by intrusive masses of igneous rock, that the precious metals have been found.[1]

The Ozark mountains resemble the Alleganies in their mineral structure, containing the same rocks from the granite to the carboniferous, and probably upwards to the chalk. In British America, and the desolate country northward to the Arctic Ocean, there is no considerable chain east of the Rocky Mountains, and the rocks, so far as known, consist chiefly of crystalline and palæozoic schists.

Rivers. In no single circumstance is the superiority of America over the old world so conspicuous as in the number and magnitude of its navigable rivers. The Amazon alone discharges a greater quantity of water than the eight principal rivers of Asia, the Euphrates, Indus, Ganges, Oby, Lena, Amour, and the Yellow River and Kang-tse of China.[2] The Mississippi, with its branches, affords a greater amount of inland navigation than all the streams, great and small, which irrigate Europe; and the Plata, in this respect, may probably claim a superiority over the collective water of Africa. But the American rivers not only surpass those of the old world in length and volume of fluid, but they are so placed as to penetrate everywhere to the heart of the continent. By the Amazon, a person living at the eastern foot of the Andes, 2000 miles of direct distance from the Atlantic, may convey himself or his property to the shores of that sea in forty-five days, almost without effort, by confiding his bark to the gliding current. If he wishes to return, he has but to spread his sails to the eastern breeze, which blows perennially against the stream. The navigation is not interrupted by a single cataract or rapid, from the Atlantic to Jaen, in west longitude 78°, where the surface of the stream is only 1240 feet above the level of its estuary at Para. The remotest and least accessible part of North America is the great interior plain extending from the Rocky Mountains to the Alleganies and the lakes, between the parallels of 40° and 50°; but the Mississippi, Missouri, and St Lawrence, with their branches, are so wonderfully ramified over this region, that when it is filled with civilised inhabitants, two centuries hence, those who dwell in its inmost recesses, at the falls of the Missouri, for instance, 1700 miles from the Atlantic, will have a more easy communication with the ocean than the population of the interior of Spain and Hungary. It is only necessary to cast the eye over a map of South America, to see that all the most sequestered parts of the interior are visited by branches of the Plata and the Amazon. These streams, having their courses in general remarkably level, and seldom interrupted by cataracts, may be considered without a figure, as a vast system of natural canals, terminating in two main trunks, which communicate with the ocean at the equator and the 35th degree of south latitude. Since the invention of steam navigation, rivers are, in the truest sense of the term, Nature's highways, especially for infant communities, where the people are too poor, and live too widely dispersed, to bear the expense of constructing roads. There is little risk in predicting, that in two or three centuries the Mississippi, the Amazon, and the Plata, will be the scenes of an active inland commerce, far surpassing in magnitude anything at present known on the surface of the globe. The Mississippi is navigable for boats from the sea to the falls of its principal branch the Missouri, 1700 miles from the Mexican Gulf in a direct line, or 3900 by the stream; and the whole amount of boat navigation afforded by the system of rivers, of which the Mississippi is the main trunk, has been estimated as equal to 40,000 miles in length, spread over a surface of 1,350,000 square miles. Perhaps this is rather beyond the truth; but let us call the navigation 35,000 miles, and the following table will exhibit the lengths, size of the basins, and probable extent of the navigable waters of the greater rivers of America.

| | Length, miles. | Area of basin, sq. miles. | Navigable waters, miles. |
|---|---|---|---|
| Mississippi to source of Missouri | 4300 | 1,350,000 | 35,000 |
| St Lawrence through the lakes | 2200 | 600,000 | 4,000 |
| Orinoco | 1800 | 400,000 | 8,000 |
| Amazon, not including Araguay | 4000 | 2,100,000 | 50,000 |
| Plata, including Uruguay | 2400 | 1,200,000 | 20,000 |

The Amazon contains many islands, is broad, and in the upper part so deep, that on one occasion Condamine found no bottom with a line 103 toises long. At its mouth, two days before and after the full moon, the phenomenon called a *Bore* occurs in a very formidable shape. It is a wave of water rushing from the sea, with its front as steep as a wall

Rivers.

and as high as a house. No small vessel can encounter it without certain destruction.

The estuaries of all these great American rivers open to the eastward; and thus Providence seems to have plainly indicated that the most intimate commercial relations of the inhabitants of America should be with the western shores of the old world. It should at the same time be observed, that this position of the great rivers of America is but one example of a physical arrangement which is common to the whole globe; for it is remarkable that, in the old world as well as in the new, no river of the first class flows to the westward. Some, as the Nile, the Lena, and the Oby, flow to the north; others, as the Indus and the rivers of Ava, to the south; but the largest, as the Wolga, Ganges, Great River and Yellow River of China, the Euphrates, and the Amour, have their courses to the east or south-east. This arrangement is not accidental, but depends most probably on the inclination of the primary rocks, which, in all cases where their *direction* approaches to the south and north, seem to have their steepest sides to the west and the longest declivities to the east. We have examples in the Scandinavian Alps, the mountains of Britain, the Ghauts of India, the Andes, and the Rocky Mountains.

Physical regions of North America.

North America, like the Southern peninsula, naturally divides itself into five physical regions: 1. The table-land of Mexico, with the strip of low country on its eastern and western shores; 2. The plateau lying between the Rocky Mountains and the Pacific Ocean, a country with a mild and humid atmosphere as far north as the 55th parallel, but inhospitable and barren beyond this boundary; 3. The great central valley of the Mississippi, rich and well wooded on the east side, bare but not unfertile in the middle, dry, sandy, and almost a desert on the west; 4. The eastern declivities of the Allegany Mountains, a region of natural forests, and of mixed but rather poor soil; 5. The great northern plain beyond the 50th parallel, four-fifths of which is a bleak and bare waste, overspread with innumerable lakes, and resembling Siberia both in the physical character of its surface and the rigour of its climate.

Numbers.

The origin, history, languages, and condition of the American nations present ample materials for speculation; but before touching on these subjects, the question presents itself, What is the amount of the indigenous population? Humboldt, in a later edition of his work on Mexico, published in 1823, estimates the whole number of Indians in the New World as follows:—

| | |
|---|---|
| Civilised or settled Indians of Spanish America | 7,530,000 |
| Ditto in Brazil | 260,000 |
| Independent Indians to the east and west of the Rocky Mountains, on the frontiers of Mexico, and in Central America | 400,000 |
| Independent Indians of South America | 420,000 |
| Total Indian population of America | 8,610,000 |

Indigenous population.

The indigenous population of America presents man under many aspects, and society in various stages, from the regular but limited civilisation of Mexico and Peru, to savage life in its most brutal state of abasement. At one extremity of the country we find the pigmy Esquimaux of four feet and a half in height, and at the other the Patagonian giants of seven feet. In complexion the variety is great, and may be said to embrace almost every hue known elsewhere on the face of the earth, except the pitchy black of the negro. About one-half of all the known languages belong to America; and if we consider every little wandering horde a distinct community, we have a greater number of nations here than in all the rest of the world. Amidst all this diversity, philosophers have thought they were able to discover certain general characters, sufficiently marked to distinguish the American nations from those of the old continent. It is foreign to our purpose to inquire whether the varieties of form, stature, and complexion, in the human species, are modifications produced by external causes operating differently on distinct portions of the progeny of one primitive pair, or whether several races were originally created, and have given birth, by their mixture, to the amazing varieties we witness. We assume the former opinion as true, because the probabilites seem to be in its favour; but the phenomena present themselves to us in the same light in whichever way they originated.

Aborigines

Physiologists are not at one in their accounts of the characteristics of the aborigines of the new world, nor are they agreed as to whether they should be considered one race or several. Blumenbach places them all under one class, except the Esquimaux. Bory St Vincent, an ingenious but fanciful writer, in a recent work,[1] divides them into four races, or into five if we include the Esquimaux, under the following designations:—1. The *Colombian*, which comprehends the tribes formerly inhabiting the Allegany Mountains, Canada, Florida, the eastern coasts of Mexico, and Central America; and the Caribs, who occupied the West India Islands and Guiana. 2. The *American*, embracing the tribes which occupy all the other parts of South America east of the Andes, except Patagonia. 3. the *Patagonian* race, inhabiting the south extremity of the continent. 4. The *Neptunian*, inhabiting the western coasts of both divisions of the continent, from California to Cape Horn, and which he considers as essentially the same with the race spread over the Malay Peninsula and the Indian Archipelago. With this race he classes the Mexicans and Peruvians. By another writer[2] the species are reduced to two, the *Colombian* and the *American;* the former including all the North American tribes, with the Caribs, the Mexicans, and Peruvians, and other inhabitants of the Cordillera; and the latter the Brazilian Indians and Patagonians. None of these systems, when compared with facts, is very satisfactory. Dr Prichard thinks that the mutual resemblance among the American nations has been exaggerated by some writers; yet it is certain that there is more of a common family character in their organisation than in that of the indigenous population of Asia or Africa. "The Indians of New Spain," says Humboldt, "bear a general resemblance to those who inhabit Canada, Florida, Peru, and Brazil. We have the same swarthy and copper colour, straight and smooth hair, small beard, squat body, long eye, with the corner directed upwards towards the temples, prominent cheek-bones, thick lips, and expression of gentleness in the mouth, strongly contrasted with a gloomy and severe look. Over a million and a half of square leagues, from Cape Horn to the river St Lawrence and Behring's Straits, we are struck at the first glance with the general resemblance in the features of the inhabitants. We think we perceive them all to be descended from the same stock, notwithstanding the prodigious diversity of their languages. In the portrait drawn by Volney of the Canadian Indians, we recognise the tribes scattered over the Savannahs of the Apure and the Carony. The same style of features exist in both Americas."

Form of skull.

The American race is distinguished by the form of the skull, which strongly resembles the Mongol type. The forehead recedes more than in any other variety of the

[1] *L'Homme, Essai Zoologique*, vol. ii. Paris, 1827.
[2] *Histoire Naturelle des Races Humaines*, par A. Desmoulins. Paris, 1826.

Aborigines

human species; the cheek-bones are prominent, but not so angular, as in the Mongol head; the occiput is rather flat, the cavity for lodging the cerebellum small, the orbits large and deep. The nose is generally aquiline, but in some tribes flat; and the nasal cavities are large. Compared with the head of the Negro, that of the American is much broader, and the teeth are less prominent: when placed by the side of the Caucasian head, it is seen to be smaller in size, less rounded and symmetrical, and less developed in the part before the ear. The skull is generally thin and light. There are, however, many deviations from this central form. The Carib skull, and the Araucanian, are large; the Peruvian small, and singularly flattened behind, so as to present a short line from the forehead to the occiput.

Complexion.

The colour of the Americans, though it includes a considerable diversity of shade, is more uniform than that of the inhabitants of Asia or Africa; and, what is more remarkable, its varieties do not bear any visible relation to the temperature of the climate. A brownish yellow, or copper colour, as it has been called, pervades nearly all the numerous tribes from the Arctic Ocean to Cape Horn, but still with many different degrees of intensity. The eastern nations of Chili have but a slight tinge of the brown colour, and the Boroanes are said to be as white as the northern Europeans. On the north-west coast, from latitude 43° to 60°, there are tribes who, though embrowned with soot and mud, were found, when their skins were washed, to have the brilliant white and red which is the characteristic of the Caucasian race. But within the tropics, the Malapoques in Brazil, the Guayanis in Paraguay, the Guiacas of Guiana, the Scheries of La Plata, have tolerably fair complexions, sometimes united with blue eyes and auburn hair; and, in the hot country watered by the Orinoco, Humboldt found tribes of a dark, and others of a light hue, living almost in juxtaposition. It is remarkable, too, that the nations whose colour approaches nearest to black are found in the temperate zone, namely, the Charruas of the Banda Oriental, in latitude 33° south, and the Cochimies, Pericus, and Guaycurus, spread over the peninsula of California. These people have skins of a very deep hue, but are not absolutely black; and they have neither the woolly hair of the negroes, nor their social and good-humoured disposition. The Charruas especially are distinguished by a high degree of that austerity and stern fortitude which are common to the American nations.[1] The Caribs and some Brazilian tribes have the yellowish hue of the Chinese, and the same cast of features. Among the nations dwelling on the west side of the Alleganies, and near the northern lakes, there is also a considerable variety of complexion; but the brown or copper shade is found more or less in them all. It may be said, then, of the American nations, that, with the exception of two or three tribes on the north-west coast, who probably arrived from Asia at a later period than the others, the two extremes of complexion, the white of Northern Europe and the black of Ethiopia, are unknown amongst them; and that, when compared with the Moors, Abyssinians, and other swarthy nations of the Old World, their colour inclines less to the yellow, and more to the reddish brown. In stature the variety is great. The North American tribes are generally above the middle size, and of a slender shape. The Brazilian nations and the Peruvians are short and squat. The Caribs of the Orinoco, and the Abipones, Mocoby, and other tribes which rove over the Pampas west of the Plata, are tall and strong; and the Patagonians, a Chilian tribe, exceed in strength and stature all the other races in the known world.

Dr Morton, a recent authority, says that the most natural division of the Americans is into two families, the *Toltecan* and the *American;* the former of which bears evidence of centuries of half-civilisation, while the latter embraces all the barbarous nations of the new world, with the exception of the Polar tribes, which are evidently of Mongolian origin. In each of these, however, there are several subordinate groups, which may be distinguished as the *Appalachian*, the *Brazilian*, the *Patagonian*, and the *Fuegian.* The Appalachian branch includes all the nations of North America, except the Mexicans, together with the tribes of South America north of the River Amazon and east of the Andes. In this race the head is rounded, the nose large, salient, and aquiline: the eyes dark brown, with little or no obliquity of position; the mouth large and straight; the teeth nearly vertical; and the whole face triangular. The neck is long, the chest broad, but rarely deep, the body and limbs muscular, and seldom disposed to fatness. In character these nations are warlike, cruel, and unforgiving; they turn with aversion from the restraints of civilised life, and have made but little progress in mental culture or the useful arts. The Brazilian branch is spread over a great part of South America, east of the Andes, including the whole of Brazil and Paraguay, between the River Amazon and 35° south latitude. Their physical characteristics differ but little from those of the Appalachian branch; they possess, perhaps, a larger and more expanded nose, with larger mouths and lips. The eyes are small, more or less oblique, and far asunder; the neck short and thick; the body and limbs stout and full, even to clumsiness. In character also, they differ little. None of the Americans are less susceptible of cultivation; and what they are taught by compulsion seldom exceeds the humblest elements of knowledge. The Patagonian branch includes the nations to the south of the Plata, as far as the Straits of Magellan; including also the mountain tribes of Chili. They are chiefly distinguished by their tall stature, handsome forms, and indomitable courage. The Fuegians, who call themselves *Yacannacunnee*, rove over the sterile wastes of Tierra del Fuego, which is computed to be half the size of Ireland, and yet their whole number has been computed by Forster at only 2000. The physical aspect of the Fuegians is altogether repulsive. They are of low stature, with large heads, broad faces, and small eyes. Their chests are large, their bodies clumsy, with large knees, and ill-shaped legs. Their hair is lank, black, and coarse, and their complexion a decided brown, like that of the more northern tribes. Their expression of face is vacant, and their mental operations are to the last degree slow and stupid; they are almost destitute of the usual curiosity of savages, caring little for anything that does not minister to their present wants.

Long, black, lank hair is common to all the American tribes, among which no traces of the frizzled locks of the Polynesian, or the woolly texture of the African negro has ever been observed. The beard is very deficient, and the little that nature gives them assiduously root out. A copper-coloured skin has been also assumed by most writers as a characteristic distinction of the Americans; but their real colour is in general brown, of the hue most nearly resembling that of cinnamon; and Dr Morton coincides in opinion with Dr M'Culloch that no epithet derivable from the colour of the skin so correctly designates the Americans as that of the brown race. There are, however, among them occasional and very remarkable deviations, including all the varieties of tint from a decided white to an unequivocally black

[1] *Mithridates Einleitung Amerikanischen Sprachen*, p. 313; Prichard's *Researches*, vol. ii. pp. 396, 492.

Aborigines

skin. That climate has a very subordinate influence in producing these different hues must be inferred from the fact that the tribes which wander in the equinoctial regions are not darker than the mountaineers of the temperate zone. The Puelches, and other tribes of the Magellanic regions, beyond 55° south latitude, are darker than the Abipones, Mocobies, and Tobos, who are many degrees nearer the equator; and the Botecudos are of a clear brown colour, sometimes approaching nearly to white, at no great distance from the tropic; while the Guyacas under the line are characterised by a fair complexion; the Charruas, who are almost black, live at the 50° south latitude; and the still blacker Californians are 25° north of the equator. Everywhere, indeed, it is found that the colour of the American depends very little on the local situation which he actually occupies; and never, in the same individual, are those parts of the body which are constantly covered of a fairer colour than those which are exposed to a hot and moist atmosphere. Children are never white when they are born, as is the case among even the darkest of the Caucasian races; and the Indian caçiques, who enjoy a considerable degree of luxury, and keep themselves constantly dressed, have all parts of their body, except the palms of the hands and the soles of the feet, of the same brownish-red or copper colour. These differences of complexion are, however, extremely partial, forming mere exceptions to the general tint which characterises all the Americans, from Cape Horn to Canada. The cause of such anomalies is not easily ascertained; that it is not climate is sufficiently obvious; but whether or not it arises from partial immigrations from other countries remains yet to be decided. The Americans might also be divided into three great classes distinguished by the pursuits on which they depend for subsistence, namely, hunting, fishing, and agriculture. The greater number of them are devoted to hunting; the fishing tribes are not numerous, and are wholly destitute of the spirit of maritime adventure, and even of fondness for the sea. A few tribes were strictly agricultural before the arrival of Europeans, but a much greater number have become so since. Many tribes regularly resort to all these modes of subsistence, according to the seasons; employing the spring in fishing, the summer in agriculture, and the autumn and winter in hunting.

The intellectual faculties of this great family appear to be decidedly inferior, when compared with those of the Caucasian or Mongolian race. The Americans are not only averse to the restraints of education, but are for the most part incapable of a continued process of reasoning on abstract subjects. Their minds seize with avidity on simple truths, but reject whatever requires investigation and analysis. Their proximity for more than two centuries to European institutions has made scarcely any perceptible change in their mode of thinking or their manner of life; and, as to their own social condition, they are probably in most respects exactly as they were at the earliest period of their national existence. They have made few or no improvements in constructing their houses or their boats; their inventive and imitative faculties appear to be of very humble capacity, nor have they the smallest taste for the arts and sciences. One of the most remarkable of their intellectual defects is the great difficulty they find in comprehending the relations of numbers; and Mr Schoolcraft, the United States Indian agent, assured Dr Morton that this deficiency was one cause of most of the misunderstanding in respect to treaties entered into between the United States Government and the native tribes. The natives sell their lands for a sum of money, without having any conception of the amount; and it is only when the proceeds come to be divided, that each man becomes acquainted with his own interest in the transaction. Then disappointment and murmurs invariably ensue.

The Toltecan family embraces the civilised nations of Mexico, Peru, and Bogota extending from the Rio Gila in 33° north latitude along the western shore of the continent to the frontiers of Chili; and on the eastern coast, along the Gulf of Mexico, in North America. In South America, on the contrary, this family chiefly occupied a narrow strip of land between the Andes and the Pacific Ocean, bounded on the south by the great desert of Atacama. Farther north, however, in New Granada, were the Bogotese, a people whose civilisation, like their geographical position, was intermediate between that of the Peruvians and the Mexicans. But, even before the Spanish conquest, the Toltecan family were not the exclusive possessors of the regions which we have assigned to them; they were only the dominant race or caste, while other tribes of the American race always constituted a large mass of the population. The arrival of the Spaniards reduced both classes alike to vassalage; and three centuries of slavery and oppression have left few traces of Mexican and Peruvian civilisation, except what may be gleaned from their history and antiquities. These nations can no longer be identified in existing communities; and the mixed and motley races which now respectively bear the name, are as unlike their predecessors in moral and intellectual character, as the degraded Copts are unlike the ancient Egyptians. It is in the intellectual faculties that the great difference between the Toltecan and the American families consists. In the arts and sciences of the former we see the evidences of an advanced civilisation; their architectural remains everywhere surprise the traveller and confound the antiquary. Among these are pyramids, temples, grottoes, bas-reliefs, and arabesques; while their roads, aqueducts, and fortifications, and the traces of their mining operations, sufficiently attest their attainments in the practical arts of life.[1]

Languages.

It is the absence of civilisation which has broken human speech into such a countless variety of dialects; and the lower any race of people have sunk in the abasement of savage life, the more languages multiply amongst them. Every unwritten tongue is subject to continual fluctuations, which will be numerous and rapid in proportion as the tribe using it is exposed to frequent vicissitudes of fortune, and the individuals composing it have little intercourse with one another. When the population of one of these societies increases, it splits into several branches; and if these have little intercourse, the original language divides by degrees into as many dialects. These smaller societies subdivide in their turn with the same effects; and, in such continual subdivisions, the dialects of the extreme branches deviate farther and farther from one another, and from the parent tongue, till time, aided by migrations and wars, producing mixtures of different hordes, obliterates all distinct traces of a common origin. The cause of these changes becomes more obvious when we reflect on the principles which give stability to a language. These are, 1. the abundant use of writing; 2. the teaching of a language as a branch of education; 3. frequency of intercourse among all the people speaking it; 4. the existence of an order of men, such as priests or lawyers, who employ it for professional purposes; 5. stability of condition in the people, or exemption from vicissitudes and revolutions; 6. a large stock of popular poetry, which if universally diffused, may almost become

[1] *Crania Americana*, &c., by Samuel George Morton, M.D., 1 vol. 4to, published at Philadelphia in 1839, pp. 62 to 86.

Aborigines. a substitute for writing. All these conditions were wanting (with some trifling exceptions) in the whole of the wandering tribes of America. The great multiplication of languages, therefore, proves two things; first, that the people are in the lowest state of savage life; and, secondly, that they have been for many ages in this condition; for time is a necessary element in the process of splitting human speech into so many varieties. Now, it is a remarkable fact, that there were as many languages spoken among a population of two or three millions of American savages, as among the six hundred millions of human beings scattered over the old continent! We call them two or three millions, because we exclude the civilized inhabitants of Mexico and Peru, and because a considerable number of the facts collected by Hervas and Vater relate to a period from 50 to 100 years back, since which, some of the tribes they allude to have become extinct. Balbi, in his Ethnographical Atlas, has enumerated 423 languages, which are, or at no distant period were, spoken in America by the indigenous population. Of these, 211 belong to North, 44 to Central, and 168 to South America; but as the list includes only those tongues of whose structure something is known, it does not embrace more than one or two of the 116 dialects noticed by the missionaries in Quito, some of which have ceased to exist; and many others, unknown, or known imperfectly, are also left out. There cannot be a doubt that the greater multiplicity of tribes in South America is accompanied with a corresponding multiplicity of languages, and that we may add at least 100 for omissions in this section of the continent. Vater says expressly that the number of languages in America "exceeds five hundred." As a general result, then, we may state, that there are (or *were* within a century past) from 500 to 600 distinct dialects in the new world, without including in our enumeration any which do not differ from one another as widely as the Spanish from the Italian, or the German from the Dutch.[1]

Under this prodigious diversity of dialects, a remarkable analogy of structure has been detected in all those which are well known, and is believed to pervade the whole. The American languages are extremely complicated and artificial, and have extraordinary powers of combination. The verb, besides inflections applicable to the varieties of time, has numerous moods, which may be described as reflected, transitive, compulsive, applicative, meditative, communicative, reverential, frequentative; and forms which indicate by suffixes and affixes whether the object be animate or inanimate, male or female, &c.[2] "From the country of the Esquimaux to the straits of Magellan," says Humboldt, "mother tongues entirely different in their roots have, if we may use the expression, the same physiognomy. Striking analogies of grammatical construction are discovered, not only in the more perfect languages, as that of the Incas, the Ayemara, the Guarani, the Mexican, and the Cora, but also in languages extremely rude. It is in consequence of this similarity of structure that the Indians of the missions could learn the tongue of a different tribe much more easily than the Spanish; and the monks had hence adopted the practice of communicating with a great number of hordes through the medium of one of the native languages." The complication of grammatical forms which these dialects display has induced Mr Duponceau of Philadelphia to give them the name of *Polysynthic*. Now the remarkable facts are, first, that this characteristic should not be found in any of the known languages of the old world, except in a faint degree in the Basque, and the dialect of Congo; Aborigines. and, next, that it should belong, not to one or two, but with slight exceptions, so far as is known, to all the languages of America, so extremely numerous, and many of which have nothing else in common. How is this diffusion of a peculiar and common character over materials so dissimilar to be accounted for? To us it seems to imply a community of origin in the tribes, whether few or many, which peopled the continent. As no person has the full command of all the vocables in his native language, individual terms must be continually dropping out of dialects preserved by oral communication; and new ones will be introduced as new wants and new objects solicit attention. But during the gradual change which thus takes place, the new words will be combined and modified according to the rules which belong to the genius of the spoken dialect with which they are incorporated; and thus it may happen that the grammatical forms of an ancient language may live, while its materials perish. The changes of structure which present themselves in the history of European languages, it must be remembered, took place in *progressive* communities. Among nations like the American Indians, whose barbarism, we may suppose, remained almost stationary, the forms of speech might be more permanent, though its substance was in a state of slow but constant mutation. We do not mean, however, that the community of origin alluded to was entire and absolute among the American nations. Since weak tribes are often incorporated with strong ones in the present times, it might happen that small parties of separate and dissimilar races might be blended by conquest or treaty with the larger nations of the American stock, and in a generation or two lose their distinctive character, by adopting the language and manners of their new confederates or masters. Neither must it be imagined that there is an entire absence of mutual affinities among the 423 tongues enumerated by Balbi. On the contrary, six, eight, or more, are sometimes united in one family by analogies, in their roots and grammatical forms, as strong as those which obtain among the languages of the Teutonic stem in Europe, the Icelandic, Swedish, Danish, German, Dutch, and English. If philologists had complete vocabularies of them all, it might probably be found that the 500 or 600 American languages could be arranged into eight or ten "reigns," to use Balbi's term, or into forty or fifty families, each characterized by affinities sufficiently clear to prove that its component members had sprung from a common parent. On the other hand, the complete absence, in so many instances, of common roots in the dialects of contiguous tribes,—the fading and almost obliterated traces of resemblance in languages which had once been identical,—are very remarkable phenomena, and prepare us for a result which could not have been anticipated otherwise—that none of all the American tongues has any distinct marks of a common origin with any one of those of Asia, Africa, Europe, or Polynesia. The sole exception is the Esquimaux idiom, which belongs to the same family with that of the Tschutskoi, a people having the same physical aspect, who inhabit the extreme north-eastern parts of Asia. Upon a painful comparison of the known languages of the new world with those of the old, only 170 words have been found in the former which have a distinct resemblance to words of the same signification in the latter. These are derived from 83 American tongues; three fifths of them have a resemblance to words in the Mantchou, Tonguse, Mongol, and Samoiede

Aborigines.

dialects, and two fifths to words in the Celtic, Tschoud, Biscayan, Coptic, and Congoese. This number is too small to prove any thing by itself; but it is not entirely to be disregarded when taken in connection with the analogies which have been traced in the physical character, customs, superstitions, and monuments, of the people of the two continents. And if we admit, on the ground of their similarity of organization, that the greater number of the American languages have had a common origin, even in those cases where coincident terms are no longer to be discovered, perhaps it ought to be acknowledged that the affinity between the languages of the two continents is as great as could be expected. In this, as in many questions connected with geology, *time* is the element which solves the difficulty; and when a longer course of observation has enabled us to detect the laws which govern the changes of oral language among barbarous and savage nations, the facts will probably speak to us in clearer terms.[1]

Though any attempt to reduce the American population under a few general classes, either on physical or ethnographical grounds, would be idle, a brief survey of the most remarkable nations, or families of nations, will enable us to form a more distinct idea of the whole.

Esquimaux.

All the northern coast of the new continent is tenanted by the Esquimaux, a dwarfish race, rarely exceeding five feet in height, and of the same stock with the Greenlanders, the Tschutskoi, the Samoiedes, and the Laplanders. Near Mackenzie's River their territories commence at the 68th parallel, and extend to the Arctic Ocean. They occupy all the northern Archipelago, the shores of Hudson's and Baffin's Bays, of Labrador, and of Russian America, round by Behring's Straits, to the peninsula of Alyaska. They live entirely by fishing, the whale and the seal being their most common food; they inhabit skin tents during their short summer, and in winter caves or houses built with snow in the shape of domes, within which a single rude lamp is kept perpetually burning. They are crafty and dirty, but appeared to Captain Franklin more intelligent and provident than the northern Indians. There is a wide diversity in their dialects, which still display decided marks of identity in their roots. They are the only American race whose Asiatic origin is indisputable.

The north-west coast of Russian America, from Cook's Inlet to the 48th parallel, is inhabited by four tribes, of whom the Kaluschi are the most remarkable. These people are distinguished from all the native races of America by having as fair a complexion when their skins are washed as the inhabitants of Europe; and this distinction, accompanied sometimes with auburn hair, has been considered as indicating an origin different from that of the copper-coloured tribes who people all the rest of the continent.

Allegany Indians.

The Indians of the east coast belong almost entirely to three stems; and, before the arrival of the English colonists, occupied both sides of the Allegany Mountains, from the Gulf of Mexico to Canada and New Brunswick. 1. The Delaware or Algonquin Indians, comprehending the Ottogamies, Shawanese, Naragansets, Chippeways, Knisteneaux, Delawares, and other nations, to the number of thirty or forty, were spread over the space between the Mississippi and the Atlantic, as far north as Hudson's Bay; and all spoke dialects of one language. They preserved a tradition, to which some credit has been given, that they had migrated from the west many centuries before the white men crossed the Atlantic, and gained possession of their country by expelling the Allegewis (or Alleganies), its former occupants. The latter nation, it is said, lived in towns; and it has been conjectured that they were the race who had constructed the long mounds and walls, and the circular and polygonal inclosures, like fortresses, which are scattered in great numbers over the region between the Ohio and the lakes. 2. The Iroquois, often called the "Five Nations," and the "Six Nations," but comprehending 15 tribes or more, among whom were the Mohawks, Oneidas, Hurons, and Senecas, all spoke dialects of one language. They lived on the south side of the great lakes, and finally obtained a complete ascendency over the Algonquin race. 3. The Florida Indians, including the Creeks, Seminoles, Choctaws, Chickasaws, Natches, and Mobiles. The Cherokees and Creeks, two of these nations, who dwell in Alabama and Georgia, have made greater advances in agriculture and the useful arts than any of the other tribes within the territories of the United States. They not only cultivate maize, potatoes, and cotton, but raise cattle and hogs for the market. The former, who have some hundreds of negro slaves, have established schools, set up a newspaper, and even adopted a political constitution, modelled on those of the Anglo-Americans. It has been recently discovered that the

---

[1] Vater remarks, in the introduction to his account of the American languages, that they have, comparatively speaking, a considerable number of words in common with the Finnish. He finds, however, only 51 similar words where the affinity should be most distinct, namely, in all the languages of North America and Northern Asia. We subjoin a tabular view of the number of words he has detected in the American languages agreeing in sound and sense with words in some of the principal tongues of the old continent and its islands.

| | | | | |
|---|---|---|---|---|
| 8 words picked from | 7 American languages, | resemble the same number of words in the | | *Coptic.* |
| 8 words in | 8 American languages | | do | *Japanese.* |
| 11 do. in | 8 | do | do | *Malay.* |
| 4 do. in | 1 | do. (Quichua) | do | *Sanscrit.* |
| 20 do. in | 16 | do. (chiefly from eastern and tropical parts of America) | do | in 13 languages of *Western Africa.* |
| 8 do. in | 6 | do. (chiefly from the east side) | do | *Basque.* |
| 18 do. in | 10 | do | do | *Celtic.* |

Vater admits that many of these resemblances may be accidental; and some of them are evidently too faint to be of any value. We must at the same time keep in view, that philologists have rarely the means of making a complete and satisfactory comparison. In general they are furnished with only 40 or 50 words, significant of the most common objects, out of some thousands constituting the dialect of a tribe or people; and these few words are taken down hastily by travellers, mariners, or missionaries, of different nations, who are often betrayed into errors by imperfect means of communication, and must in their turn mislead the philologist by their dissimilar systems of orthography. To enable the reader to judge of the sort of resemblances collected by Vater, we give his comparison of six Irish words with six Algonquin, remarking, however, that this is decidedly the most favourable specimen in his tables:—

| | *Irish.* | *Algonquin.* |
|---|---|---|
| Island | inis | inis |
| Falsehood | gai | ga |
| Water | uisce | isca |
| Soft | bog | boge |
| All | cac-uile | kak-eli |
| Each thing | cac-eini | kak-ina |

(*Einleitung Amerikanischen Sprachen*, p. 332–351.)

Aborigines. Osages, Missouris, Kanses, and some other tribes inhabiting the country beyond the Mississippi, as far as the Rocky Mountains, speak dialects which are allied to those of the Iroquois; a fact which tends strongly to confirm the opinion entertained by the latter, that their original residence was far in the west. The Natches, near the Mississippi, had a monarchical government, and a class of nobles like the Mexicans. They had temples in which the sun was worshipped, and a perpetual fire kept up. Traces of this superstition existed also among the Gaspes, in New Brunswick. Tribes belonging to these three families, with the Wocons and Katawbas, now almost extinct, occupied nearly all the region east of the Mississippi, from the Gulf of Mexico to Hudson's Bay, comprising more than a million of square miles. The Katawbas alone, however, are said to have included 20 tribes, and nearly as many dialects. The Powhattans were a confederacy of 33 tribes, comprehending 10,000 persons. It is probable that when the English settlers landed in the country, the region mentioned was inhabited by a quarter of a million of Indians, divided into many tribes, and speaking dialects belonging to half a dozen of radically distinct languages. These nations have furnished brilliant models of the most shining qualities of savage life—a high sense of honour, according to their perceptions of duty, mutual fidelity among individuals, a fortitude that mocks at the most cruel torments, and a devotion to their tribe which makes self-immolation in its defence easy. On the other hand, they treat their wives cruelly, and their children with indifference. The apathy under the good and ill of life which the Stoic affected, is the grand element of the Indian's character. Gloomy, stern, and severe, he is a stranger to mirth and laughter. All outward expression of pleasure or pain he regards as a weakness; and the only feeling to which he ever yields, is the boisterous joy which he manifests in the moment of victory, or under the excitement of intoxication. He is capable of great exertions in war or the chase, but has an unconquerable aversion to regular labour. He is extremely improvident; eats enormously while he has abundance of food, without thinking of the famine which may follow; and, when liquors are supplied to him, wallows in the most beastly intoxication day after day. Most of the Indians believe in the existence of a supreme being, whom they call the Great Spirit; and of a subordinate one, whose nature is evil and hostile to man. To the latter their worship is principally addressed, the Good Spirit, in their opinion, needing no prayers to induce him to aid and protect his creatures. In some cases, however, as when influenced by a dream, they offer sacrifices to the Good Spirit. These consist generally of part of an animal taken in the chase, which is stuck upon the head of a high pole set vertically in the ground, and left in this situation to decay by the action of the elements. The remainder of the carcass is boiled and eaten; and the feast is accompanied with prayers, dancing, and singing. Human sacrifices are not unknown amongst them, but are rare. In their fasts, which are long and severe, they smear the face and other visible parts of the body with charcoal, and abstain from food till the sun has gone down; and this is practised day after day for one or two weeks. Some of them believe in tutelar spirits; and in most of the tribes there are jugglers or soothsayers, who pretend to discover lost property, and foretell the issue of hunting or warlike expeditions. By some tribes, deities are supposed to reside in the sun and moon. They generally believe in a future state, in which the souls of brave warriors and chaste wives enjoy a tranquil and happy existence with their ancestors and friends, spending their time in those exercises in which they delighted when on the earth. The Dacotas believe that the road to these "villages of the dead" leads over a rock with an edge as sharp as a knife, on which only the good are able to keep their footing. The wicked fall off, and descend to the region of the Evil Spirit, where they are hard worked, and severely flogged by their relentless master. Suicide is common among the women of this tribe, in consequence of the cruel treatment they are exposed to; but the practice is viewed as immoral. It is commonly effected by the woman hanging herself upon a tree; and as the popular belief is, that she is doomed to drag this tree after her for ever in the land of spirits, it is said to be usual for a female in committing the act to select as small a tree as will bear her weight.

Customs. Polygamy is allowed; and a number of wives is considered as adding to a man's consequence. When a young man has formed an attachment to a girl, he throws a deer, a gun, or some valuable article, into her father's hut. This is repeated for several days, till the father asks the young man what his object is, and whether he wishes to obtain his daughter. The young man having answered in the affirmative, the relations of the girl, if they approve of his suit, signify their consent by preparing a dress for the youth, which they carry to his house, and put upon his person. The young man's friends then prepare presents for the girl's family, into which he goes to reside, serving his father-in-law for a year, during which he gives him all the produce of his hunting. At the end of this period the youth takes his wife home to his own house, and treats her as he pleases, his power over her being unlimited. This is the custom of the Potowatomies. Other tribes have modes of courting and marrying which are very different; but among all the Indians, the presenting of gifts to the girl's father is an essential feature of the transaction, and shows that the wife is considered as procured by purchase. Deformed children, and lame or decrepit old persons, are sometimes destroyed; but the practice is uncommon. Incest and unnatural vices are practised in some tribes, but they are always viewed as matters of reproach. The Indian funerals are conducted with much decorum. The deceased is dressed in his best clothes, and laid in a grave, in a vertical, horizontal, or inclined position, according to his own previous directions, with his mocassins, knife, money, and silver ornaments beside him, and a small quantity of food near his head. Some prefer having their bodies sewed up in a blanket, and suspended from the branches of a tree. In this position the corpse is frequently visited by the friends of the deceased, until they observe that it is in a state of decay. They then shake hands with it and bid it farewell; but this does not prevent them from paying a yearly visit to the spot, and leaving some food at the place. It is usual to mark the graves with a post, on which figures are carved expressive of the nature of the pursuits and achievements of the deceased.

Clothes. Some nations of Indians wear little or no clothing; but the general dress of the men in the temperate and cold parts of the country, previous to the arrival of the Europeans, consisted of three articles: a cloak of buffalo-skin hanging from the shoulders, a piece of skin used as an apron, and a pair of mocassins or loose boots, made of undressed skin also. The women wore a long robe of the same material, which was fastened round the waist; but among the tribes living near the whites, coarse woollens are now frequently substituted for the hides of wild animals, except for the mocassins. Houses. The habitations of the Indians are huts or cabins, generally of a circular form and small size, but sometimes of 30 or 40 feet in diameter, formed by stakes fixed in the ground, and covered with

Aborigines. the bark of trees. Sometimes the spaces between the stakes are filled up with twigs, grass, and mud, and the roof is covered nearly in the same way. A hole in the top serves for the escape of the smoke, and the skins of wild beasts form the beds and seats. When they go to a distance to hunt, they erect for temporary use large tents, which are covered with skins. On the west side of the Mississippi, where the ground is open, many of the tribes make use of horses, which are seldom employed amidst the woods covering the territories east of that river. The custom of painting their bodies is nearly universal. They introduce the colours by making punctures on their skin; and the extent of surface which this ornament covers is proportioned to the exploits they have performed. Some paint only their arms, others both their arms and legs, others again their thighs; while those who have attained the summit of warlike renown have their bodies painted from the waist upwards. This is the heraldry of the Indians, the devices of which are probably more exactly adjusted to the merits of the persons who bear them than those of more civilized countries. Besides these ornaments, the warriors also carry plumes of feathers on their heads, their arms, or ancles. Their arms are the tomahawk, the war-club, knife, the bow and arrow; and, since they had intercourse with Europeans, many of them have muskets. Each tribe or community is governed by a chief and council, who are elective; but in matters of importance the whole warriors are consulted; and Mr Keating informs us that questions are not decided by the votes of a majority, but the resolution adopted must have the consent of every individual warrior. Their assemblies are conducted with much formality and decorum. The eldest chief commences the debate, which is often carried on by set speeches, abounding in bold figures and metaphors, and bursts of a rude but impassioned eloquence. The young are permitted to be present, and to express their approbation by cries, but not to speak. In their wars the object commonly is, to secure the right of hunting within particular limits, to maintain the liberty of passing through their accustomed tracts, and to guard from infringement those lands which they consider as their own tenure. War is declared by sending a slave with a hatchet, the handle of which is painted red, to the nation they intend to break with. They generally take the field in small numbers. Each warrior, besides his weapons, carries a mat, and supports himself till he is near the enemy by killing game. From the time they enter the enemy's country, no game is killed, no fires lighted, or shouting heard, and their vigilance and caution are extreme. They are not even permitted to speak, but must communicate by signs and motions. Having discovered the objects of their hostility, they first reconnoitre them, then hold a council; and they generally make their attack just before day-break, that they may surprise their enemies while asleep. They will lie the whole night flat on their faces without stirring, and, at the fit moment for action, will creep on their hands and feet till they have got within a bow-shot of those they have doomed to destruction. On a signal given by the chief warrior, which is answered by the yells of the whole party, they start up, and, after discharging their arrows, they rush upon their adversaries, without giving them time to recover from their confusion, with their war-clubs and tomahawks. If they succeed, the scene of horror which follows baffles description. The savage fury of the conquerors, the desperation of the conquered, the horrid yells of both, and their grim figures besmeared with paint and blood, form an assemblage of objects worthy of pandemonium. When the victory is secured, they select a certain number of their prisoners to carry home: they kill the rest in cold blood, take their scalps, and then march off with the spoil. The prisoners destined to death are soon led to the place of execution, where they are stripped, have their bodies blackened, and are bound to a stake. In this situation, while the burning faggots embrace his limbs, and the knives of his revengeful enemies are inflicting a thousand tortures, it is common for the warrior to recount his exploits, boast of the cruelties he has committed upon his enemies, and to irritate and insult his tormentors in every way. Sometimes it happens that this has the effect of provoking one of the spectators to dispatch him with a club or tomahawk. Sometimes the male adult prisoners are given as slaves to women who have lost their husbands in the war, and by whom they are often married. The women taken are distributed among the warriors; the boys and girls are considered as slaves.

Subsistence. Nearly all the Indian tribes raise maize, beans, and pumpkins, by the labour of their women, but only to a small extent, and as a resource against famine, their chief reliance being upon the chase. The buffaloes which wander over the prairies of the west, in herds of tens of thousands, are their great support; but deer, bears, and in time of need otters, beavers, foxes, squirrels, and even the most disgusting reptiles, are devoured. And last and worst, there is the horrid banquet of human flesh, which is still in use among some tribes, and to which, at one period of their history or another, perhaps few or none of them have been strangers. The fact has been doubted; but the decided testimony given by Major Long and his party, who all started on their journey with a disinclination to admit it, must be considered as setting the question at rest. After alluding to the incredulity which many felt on the subject, the narrator says,—"With such feelings the gentlemen of the expedition first heard the reports of the anthropophagy of the Potowatomies, and yielded but an unwilling ear to every thing that could induce a belief in the existence of this disgusting trait in the character of the North-West Indians. Truth compels them, however, to assert, that the reports which they have received on this subject were so frequent, so circumstantial, and derived from such respectable sources, that any concealment of it, or any apparent incredulity on their part, would be a dereliction of duty. Even the most incredulous of the party, or those disposed to entertain the most favourable opinion of the Indians, were at last compelled to acknowledge that all doubt on the subject had been removed from their minds."[1] The practice seems to have its origin sometimes in famine, which drives the Indians to this resource, and sometimes in hatred or revenge towards a hostile tribe; for it is only enemies that are thus devoured; and the Indians have a superstitious idea, that the flesh of a brave man, when eaten, especially the heart, imparts a portion of his courage to the individual who consumes it. We have described the manners and dispositions of these nations at some length, because the lights and shadows of savage life, its grand features and marked peculiarities, in that state in which a brutal ferocity has not obliterated every generous quality, are more strongly depicted in their character than in that of any other American race. For the sake of distinction, they may be denominated the Allegany Indians.

[1] *Narrative of Major Long's Expedition to St Peter's River*, vol. i. p. 101. Philadelphia, 1824.

Aborigines. The Caribs, who have been compared to them, had the same courage and fierceness, but were more gross and brutal; and the Araucanians, who surpassed all the independent tribes of America in intrepidity, intelligence, and generosity, had a slight tincture of civilisation. In speaking of those other nations which make the most considerable figure in the new continent, our limited space will not permit us to do more than to describe very briefly the leading traits of their character.

American civilisation. It has been generally admitted by physiologists, that the temperate regions of the globe are best fitted to develope all the powers of our nature; and it is a fact in accordance with this opinion, that among the aborigines of America, civilisation followed very closely the chain of the Andes, and was found either upon their sides or the table-land of their summits, where the elevation of the ground moderates the heat of the tropical sun, and produces a climate analogous to that of Central and Southern Europe. This civilisation did not exist merely at the two distant and isolated points of Mexico and Peru, but presented itself at intermediate places, and may be said to have formed a continuous line from lat. 35. N. to lat. 35. S., with few interruptions, except at those parts where the mountainous chain disappears, or sinks down to a trifling elevation. Some large buildings near the Rio Gila, in lat. 33. N., with fragments of porcelain, indicate the existence of a people here who had some knowledge of the arts. These were most probably a branch of the Aztecks or Toltecks, who afterwards occupied Mexico, as the annals of this country tell. Though some pursued their march southward, it may be reasonably supposed that a part remained in the district; and the Indians living here, who cultivate corn, weave cloth, and live in villages consisting of houses built of solid materials, sometimes two stories in height, may either be their descendants, or have borrowed from them the improvements they possess. Next in order as we proceed southward, are the various nations of Mexico, of whose condition we shall speak by and by. In Chiapa were the Zapotecks, in Yucatan the Mayas, in Guatemala the Quiches and Kachiquels, all nearly as much advanced in civilisation as the Mexicans, and probably of the same primitive stock. From this point, where the Andes lose their elevation, or break into isolated cones, no distinct traces of civilisation appear till we enter the southern continent. Here were found the Muyscas or Moscas, on the table-land of Bogota, a nation consisting of several tribes, who worshipped the sun and practised some of the useful arts. To these succeeded the nations of Peru, living under the Incas, whose dominion extended from the equator to the 35th degree of south latitude. Beyond this boundary were the Chilian tribes, who, though inferior to the Peruvians, had made some advances beyond the rudeness of the savage state. It is proper to mention that some of the nations named were extinct before the arrival of the Spaniards; but the degree of civilisation they had attained is attested by the monuments they have left behind them. There were no other tribes in the new continent which had made any progress in social improvement. We would not except the Guaranis of Brazil, and a few others, who derived their subsistence chiefly from agriculture, but were in other respects savages. We place among the exceptions, however, the extinct race of the Allegewis, or whatever was the name of the people, who erected the military works existing between the Ohio and the northern lakes; but they also, it must be remembered, inhabited a temperate climate, though not a mountainous country. It may be affirmed, then, as a general proposition, that from 35° of north to 35° of south latitude, the sides and summits of the Andes were the exclusive seats of American civilisation. We admit that some of the tribes in Chiapa, Oaxaca, and Yucatan, inhabited low districts; but they were still near the Cordillera, and may be fairly considered as offsets from the nations dwelling upon it. The fact is important, as marking the effect of climate on the active energies of our species. There is no doubt that, with the improved arts of modern times, civilisation can subsist under the burning sky of the torrid zone, but not in such vigour as in countries which enjoy a more moderate temperature. Perhaps it will be found that the moral and physical powers of man attain their highest perfection in those regions where he is accompanied by *wheat* and the *vine*. The zone occupied by the former extends from the 30th to the 57th or 58th parallel; and within the tropics the corresponding climate is found on the flanks or summits of mountains, from 4500 to 10,000 feet above the level of the sea.

Mexico. It is remarkable that the Mexican annals reach to a more remote date than those of any of the nations of northern Europe, though they were preserved merely by an imperfect species of hieroglyphics, or picture-writing. We do not pretend to enter into the question which may be raised, both as to the authenticity of the records themselves, and their susceptibility of a correct interpretation. It is enough that they have received credit from Humboldt, Vater, and other men of learning and judgment who have examined into their nature and origin. From the annals thus preserved, we learn that several nations belonging to one race migrated in succession from the north-west, and settled in *Anahuac* or Mexico. The Toltecks, the first of these, left their original seat, far to the west, in 544 of our era, and after a long journey invaded Mexico, then occupied by wandering hordes, in 648. This people, who penetrated to Nicaragua, if not to South America, were nearly destroyed after the lapse of some centuries; but were followed by the Chichimeks, a half-savage tribe, about 1170, and these a few years afterwards by the Anahuatlels, or seven tribes, including the Acolhuans, Tlascalteks, and the Aztecks or proper Mexicans. All these people spoke dialects of one language, and had similar arts, customs, and institutions. The town of Mexico or Tenochtitlan was founded in 1325, and the series of Mexican kings which commenced in 1352 was continued through eight monarchs to Montezuma. The monarchy was small at first, and passed through many vicissitudes; but it was gradually enlarged, especially by the policy and enterprise of the later princes of the line. When Cortes arrived, it embraced what are now the provinces of Vera Cruz, Oaxaca, Puebla, Mexico, and part of Valladolid, a surface of 130,000 square miles; but within this were comprehended three small independent states, Tlascala, Cholullan, and Zapeaca. The pastoral state, which forms the intermediate stage between savage and civilized life, had never existed in Mexico; for the native wild ox had not been tamed, and the use of milk as food was unknown. The Mexican nations derived their subsistence from agriculture, which, however, was conducted in the rudest manner, with very imperfect instruments. They cultivated maize, potatoes, plantains, and various other esculent vegetables. They raised cotton, and understood the art of spinning and weaving it into cloth, of a texture which excited the admiration of the Spaniards. They had no iron, but showed considerable skill in fashioning the gold, silver, and copper found in a native state, into domestic utensils and ornamental articles. In some of their buildings the stones were hewn into regular forms, and accurately joined; and from the ruins of the palace of Mitla, in Oaxaca, still existing, it appears that they had the art of designing ornaments like arabesques, in paste, Aborigines. with great neatness, and attaching them to the walls; but solid structures of masonry evincing any considerable skill are extremely rare in the country. Their carvings in wood were tolerably well executed, but the figures were disproportioned and uncouth. The same remark applies to their hieroglyphical drawings, which were far inferior in taste and design to those of the Hindoos, Japanese, and Thibetians. For paper they employed sometimes the large leaves of the aloe, sometimes cotton cloth, or the skins of deer dressed. Their books consisted of strips or webs of such materials, composed of pieces neatly joined, one or two feet broad and twenty or thirty long, which were divided into pages by folding them in a zig-zag manner; and two pieces of thin deal attached to the outermost folds served as boards, and gave these manuscripts, when closed, an appearance very much like our old folios in wooden binding. The written language of Mexico contained a few real hieroglyphics or symbols, purely conventional, to designate such objects as water, earth, air, day, night, speech, and also for numbers; but it was essentially a system of *picture-writing*, in which objects were represented by coloured figures having a resemblance more or less exact to themselves. With all its necessary imperfections, this instrument was familiarly employed to a prodigious extent in deeds and instruments for effecting the transmission and sale of property. The government kept couriers for conveying intelligence from all parts of the empire; and the capital was watched and cleaned by a sort of police establishment. This is the bright side of Mexican civilisation. On the other hand, it must be kept in view, that the Mexicans had no tame animals, no made roads, no money to serve as a universal medium of exchange in commercial transactions. The government was originally a perfect feudal monarchy, in which all power was monopolized by a numerous nobility and the priesthood. The great mass of the people were serfs, attached to the soil, and transferred with it from owner to owner by descent or purchase. The peasants or slaves of a nobleman were allowed a certain portion of land, which they cultivated in common for their subsistence: the rest of their labour belonged to their lord. The country swarmed with beggars, and thousands were swept off every few years by famine. As among the ancient Egyptians and the Chinese, immutable custom, regulating every act of civil and common life, chained up the course of improvement, and spread a languid monotony over society. The crown was elective, and the powers of the monarch small, till the privileges of the nobles were destroyed by the policy and ambition of Montezuma. The religion of the Mexicans breathed a savage spirit, which sinks them, in a moral point of view, far below the hordes of wandering Indians. Their deities, represented by mis-shapen images of serpents and other hideous animals, were the creation of the darkest passions of the human breast, of terror, hatred, cruelty, revenge. They delighted in blood, and thousands of human sacrifices were annually offered at their shrines. The places of worship, called Teocallis, were pyramids composed of terraces placed one above another, like the temple of Belus at Babylon. They were built of clay, or of alternate layers of clay and unburnt bricks, but in some cases faced with slabs of polished stone, on which figures of animals are sculptured in relief.[1] One or two small chapels stood upon the summit, inclosing images of the deity. The largest known, which is composed of four stories or terraces, has a breadth of 480 yards at the base, and a height of 55. These structures served as temples, tombs, and observatories; and it is remarkable that their sides are always placed exactly in the direction of the meridian. This leads us to the most interesting fact connected with Mexican civilisation, we mean the perfection of their calendar. The civil year was composed of 365 days, divided into 18 months of 20 days, and 5 supplementary days. The Mexicans had besides a ritual or religious year for the regulation of their festivals; and, by means of a cycle of 52 years, and a very complicated method of computation, the religious and civil periods were connected with one another, and the civil year made to correspond with the natural by the intercalation of 13 days at the end of the cycle. The month was divided into four weeks of five days, but each day of the month had a distinct name; and Humboldt has given strong reasons for believing that these names were borrowed from an ancient zodiac formed of 27 or 28 lunar Houses, which was made use of from the remotest antiquity in Tartary, Thibet, and India. The calendar of the Mexicans bespeaks a degree of scientific skill, and an accuracy of observation, which are not easily reconciled with their semi-barbarous habits, their general ignorance in other things, and the recent date of their civilisation according to their own accounts. It is here, indeed, and not in their language, that we find distinct traces of their connection with Asiatic nations. The character of the Mexicans is probably the same at this day as before the conquest, which, we are disposed to think, made less change in the situation of the people than is often supposed, though it annihilated the rank and privileges of the nobles. The Mexican Indian is grave, suspicious, and taciturn; quiet and placid in his external deportment, but rancorous in his spirit; submissive to his superiors, harsh and cruel to those beneath him. His intellect is limited, and chiefly developes itself in imitative labours and mechanical arts. Slow, cautious, and persevering, he loves, both in his acts and thoughts, to travel in a beaten track. The people, though speaking many different languages, have nearly the same physical character. The Mexicans have olive complexions, narrow foreheads, black eyes, coarse glossy black hair, and thin beards. They are of the middle size, and well-proportioned in their limbs. A person with any defect or deformity is rarely seen amongst them. They are healthy, and live to an advanced age, when life is not shortened by drunkenness. The Tolteck and Azteck races, when they established themselves in the country, diffused their own language partially from the lake of Nicaragua to the 37th parallel. They reclaimed, by degrees, many of the neighbouring savage tribes to a settled mode of life, and spread a feeble degree of civilisation over a mixed mass of nations, speaking, according to Clavigero, 35 languages, of which Humboldt tells us that 20 still exist. The Azteck language is one of the most copious and polished of the American tongues, and abounds in words of the immoderate length of 12 or 15 syllables. It is uncertain what was the number of subjects over whom Montezuma ruled. The ruins in the valley of Tenochtitlan, on which the capital stands, show that it must have been more populous before the conquest than now; but the population at present is diffused over an incomparably wider space; and, upon the whole, there are no good grounds for believing that the number of civilized Indians was much greater when Cortes landed, than in 1803, when it amounted to 2,000,000.

[1] Robertson was mistaken in believing that the Teocallis were in all cases mere masses of earth, without masonry. See Humboldt's *Researches*, vol. i. p. 111, English translation.

Aborigines.

The civilisation of Mexico, as well as Peru, owed its existence to one single cause,—the patient, submissive, and superstitious character of the people, which fitted them to be beasts of burden, under an aristocracy of priests and nobles, who were led, perhaps, partly by lights derived from abroad, partly by the instinct of self-interest, to devise means for holding the mass of the community in subjection. Many of the nations which continued savage, such as the Algonquins and Iroquois, were probably equal to the Mexicans in intellect; but their propensity to superstition was less, and their energy of character was too great to permit of their being enslaved by their chiefs. It is chiefly in the variety of their primitive character that we must seek for the cause of the diversity of manners and institutions we find among the American nations.

Peru.

The ancient empire of Peru, more extensive than that of Mexico, embraced the whole sea-coast from Pastos to the river Maule, a line of 2500 miles in length. Its breadth is uncertain; but as it included both declivities of the Andes, it must have extended in some cases to 500 miles, and the entire surface of the empire probably exceeded 500,000 square miles. It is plain, however, from the imperfect history of the Incas which has been preserved, that within this space there were many districts where their authority was feeble, and others inhabited by tribes which were entirely independent. One part of the country, besides, consisted of a sandy desert, while the most elevated tracts were uninhabitable from cold. It must not therefore be supposed that the capacity of the country to support population was commensurate with the extent of its surface. Still the magnitude of the Peruvian empire, in the midst of an immense multitude of independent savage communities, so extremely minute, that a hundred of them might have been planted without crowding, in one of its provinces, is an extraordinary phenomenon. The creating and maintaining of such an empire is a proof that the Peruvians had made no trifling progress in the useful arts and in the science of government. To keep in subjection so many remote provinces, there must have been an efficient military force, rapid means of communication, considerable revenues, an organized magistracy capable of understanding and executing the plans of rulers, who had sufficient political skill and knowledge of human nature to adapt their institutions and arrangements to the wants, habits, and character of a great variety of dissimilar nations, spread over a territory reaching as far as from Lisbon to the banks of the Wolga. It is clear that the ruling tribe, which was able to extend its dominion, and to a considerable extent its language, over a space of 2500 miles, must have possessed a marked superiority of some kind over the hordes that surrounded it. We must remember, besides, that the Peruvians lay under the disadvantage of being destitute of even such an imperfect instrument of communication as the hieroglyphical language of the Mexicans, and that they were extremely deficient in military spirit. Indeed it is one of the most singular facts connected with the history of America, that by far the largest empire it contained was formed by the most unwarlike people in it. The dominion of the Incas was founded entirely on policy, superstition, and the arts. It could only be by the intelligence and skill which civilisation developes, that the Peruvians conquered tribes superior to themselves in courage; and it was by policy and superstition that the Incas tamed the rudeness of savage tribes, and held distant countries in subjection. Robertson justly observes, that the Peruvians "had advanced far beyond the Mexicans, both in the necessary arts of life, and in such as had some title to the name of elegant." In two points only were they inferior; in their calendar or mode of computing time, and in their want of such a substitute for writing as the Aztecks possessed in their hieroglyphics.

Arts in Peru.

Agriculture was conducted with greater care and success in Peru than in Mexico. The lands capable of cultivation were divided into three shares. One was consecrated to the service of religion, the erection of temples, and the maintenance of priests; the second was set apart as a provision for the support of the government; and the third and largest share, which was reserved for the people, was parcelled out, not among individuals, but among the hamlets and villages, according to the number and rank of the inhabitants; and a new division was made every year to meet any change that might arise in the circumstances of the parties. The members of each little community went to the fields under overseers, and cultivated the land by their joint labour. The produce was distributed among the families and individuals according to their wants, while the evils of famine were provided against by storing up the corn in granaries. The Peruvians having no draught animals, and no ploughs, turned up the earth with wooden mattocks; but their skill and care were exemplified in irrigation, which they practised extensively, and in their employing the dung of sea birds as manure, of which great stores exist on the islands near the coast. Their masonry was superior to that of the Mexicans. Like the ancient Egyptians, they understood mechanics sufficiently to move stones of vast size, even of 30 feet in length, of which specimens are still existing in the walls of the fortress of Cusco. They had the art of squaring and cutting blocks for building with great accuracy; and they did not effect their purpose, as Dr Robertson supposes, merely by chipping the stones, or rubbing them together so as to fit the surface of the one to that of the other, without regard to symmetry of form. It is now known that they had hard chissels, made of copper, with a mixture of 6 per cent. of tin; a proof of considerable skill in the working of metals. With these they hewed the stones into parallelopipeds, which were disposed in "courses as regular," says Humboldt, "as those of Roman workmanship." They are joined with such nicety, that the line which divides the blocks can scarcely be perceived; and the outer surface is in some cases covered with carving. The palaces or lodges of the Incas, of which there are many remains, had doors with slanting sides like the Egyptian; sloping roofs, which, it is supposed, were covered with rushes or stone slabs; no windows, but niches symmetrically distributed.[1] Ancient stone structures, which are so rare in Mexico, are pretty abundant in Peru; a fact for which we can only account by the difficulty with which the Mexicans erected buildings, in consequence of their inferiority in the art of masonry. The architecture of the Peruvians, like every thing else connected with their social state, displays a remarkable uniformity, not only of style, but of plan. "It is impossible," says Humboldt, "to examine a single edifice of the time of the Incas, without recognising the same type in all the others which cover the ridge of the Andes, along an extent of 450 leagues."

Roads.

The ancient public roads of Peru are justly considered as striking monuments of the political genius of the go-

[1] See Humboldt's account of the ancient buildings of Callo and Cunnar, vol. i. and ii. of his *Researches.*

Aborigines.

vernment. One of these extended along the sides of the Andes from Quito to Cusco, a distance of 1500 miles. It is about forty feet broad, and paved with the earth and stones which were turned up from the soil; but in some marshy places it is formed, like the old Roman roads, of a compact body of solid masonry. A tolerably level line is preserved, by filling up hollows, cutting down small eminences, and winding round the sides of large ones. At proper distances zambos or storehouses were erected, for the accommodation of the Inca and his messengers. A similar road was made along the coast in the low country.

Bridges.

Fissures a few yards in breadth were passed by bridges formed of beams laid horizontally; and an invention, at once bold and ingenious, afforded the means of crossing deep ravines, or the channels of rivers, which happened to intersect the route. This consisted of a suspension bridge, perfectly analogous in its principle to those recently introduced in Britain. It was formed of half a dozen of cables of twisted osiers, passed over wooden supports, and stretched from bank to bank; then bound together with smaller ropes, and covered with bamboos. Humboldt passed over one of these pendulous bridges, of 120 feet span; and Mr Miers crossed one of 225 feet span, over which loaded animals might travel.[1] In low grounds the rivers were crossed on rafts with a mast and sail, which, by a particular contrivance, could be made to tack and veer. In this respect the Peruvians were a stage in advance of all the other American races, who had nothing superior to the canoe with paddles. The Peruvians manufactured a rude species of pottery: they understood the art of spinning, and, in an imperfect degree, that of weaving. They procured native gold by washing the gravel of rivers, and silver, and perhaps copper, by working veins downward from the outcrop. They knew how to smelt and refine the silver ore; and they possessed the secret of giving great hardness and durability to copper by mixing it with tin. Their utensils and trinkets of gold and silver are said to be fashioned with neatness and even taste. On the other hand, they had no money, no knowledge of iron or glass; and they were ignorant of the mode of mortising or joining beams, and of casting arches. They had no animals fitted for draught; but the llama, a small species of camel, which they had tamed, was employed to some extent as a beast of burden.

Laws and customs in Peru.

The political organization of Peru, which was artificial in a high degree, reminds one, in some of its features, of the old system of the Saxons in England, but bears a more general resemblance to that of the ancient Egyptians. The mass of the people were in a state of servitude, except a small number, who were free; above these in rank were the Curacas, or chiefs of districts, who formed a sort of nobility; and above the whole, the family of the Incas, the members of which, by intermarrying only with themselves, formed a numerous and distinct caste. For the purposes of police and civil jurisdiction, the people were divided into parties of ten families, like the tythings of Alfred, over each of which was an officer. A second class of officers had control over five or ten tythings, a third class over fifty or a hundred. These last rendered account to the Incas, who exercised a vigilant superintendence over the whole, and employed inspectors to visit the provinces, as a check upon maladministration. Each of these officers, down to the lowest, judged, without appeal, in all differences that arose within his division, and enforced the laws of the empire, among which were some for punishing idleness, and compelling every one to labour. It is probable that the tythings and hundreds, as in England, would lose their numerical signification in course of time, and become mere local allotments. In the hamlets and villages, a person mounted a tower every evening, and announced where and how the inhabitants were to be employed next day. The taxes were paid in the produce of the fields; and magazines for receiving them were established in every district. Such is the account given by Acosta and Garcilasso of the civil institutions of Peru, which may be correct with regard to the oldest possessions of the Incas near Cusco, where their power had been long established; but it is not probable that such a complicated system was ever fully in operation in the more distant parts of the empire.

Government.

The government of Peru was a theocracy. The Inca was at once the temporal sovereign and the supreme pontiff. He was regarded as the descendant and representative of the great deity the sun, who was supposed to inspire his counsels, and speak through his orders and decrees. Hence even slight offences were punished with death, because they were regarded as insults offered to the divinity. The race of the Incas was held sacred. To support its pretensions, it was very desirable that it should be kept pure and distinct from the people; but human passions are often too strong for the dictates of policy; and though the marriages of the family were confined to their own race, the emperor, as well as the other males of the blood royal, kept large harems stocked with beauties drawn from all parts of the empire, and multiplied a spurious progeny, in whom the blood of the "children of the sun" was blended with that of the "children of the earth." Among a simple-minded and credulous people, the claims of the Incas to a celestial origin seem to have been implicitly believed. They were blindly obeyed, and treated with a respect bordering on adoration, by the nobles as well as the common people. The Peruvians worshipped the sun, the moon, the evening star, the spirit of thunder, and the rainbow; and had erected temples in Cusco to all these deities. That of the sun, which was the most magnificent, had its walls covered with plates of gold. The sacrifices consisted of the objects most prized by the people, of grain and fruits, of a few animals, and of the productions of their own industry. Sabeism, as it is the most rational of all the forms of idolatry, so it is generally the most mild; and doubtless this results from the tendency which it has to fix the thoughts on the marks of beneficence and wisdom which are displayed in the works of nature. The Peruvian temples were accordingly never polluted, like those of Mexico, with the blood of human victims; and the Incas even went farther, and signalized their zeal against such horrid rites, by suppressing them in all the countries they conquered. Though their history exhibits some bloody deeds, the general character of their government was the reverse of cruel. The severe punishments prescribed by their laws were rarely inflicted, and rebellion was scarcely known in their dominions. The Inca not only assumed the title of the father of his people, but the vices as well as the merits of his government sprung partly from the attempt made to construct the government on the model of paternal authority, and partly from the blending of moral and religious injunctions with civil duties. Hence the idle pretension of the state to reward virtuous conduct, as well as to punish crimes; hence too the plan of labouring in common, the extinction of

[1] Humboldt's *Researches*, vol. ii. p. 72. Miers' *Travels*, vol. i. p. 334.

Aborigines. individual property, the absurdities of eating, drinking, sleeping, tilling, building, according to fixed universal rules; in fine, that minute and vexatious regulation of all the acts of ordinary life, which converted the people into mere machines in the hands of an immense corps of civil and religious officers. Such a system may have served to reclaim some tribes from the savage state; but it must have stifled the seeds of improvement, and left the mass of the people more stupid and imbecile than it found them. The government was as pure a despotism, probably, as ever existed; but its theocratical character, no doubt, helped to mitigate the ferocity of its spirit. Superstition and force are the two bases on which tyranny rests in all countries; and in proportion as it is firmly seated on the one, it stands less in need of the support of the other. The Inca had so completely enslaved the minds of his subjects, and the apparatus he wielded for directing and controlling their acts was so perfect, that he was able in a great measure to dispense with those terrific examples of cruelty and bloodshed, by which the pure military despot operates on the fears of those who live under his authority.

Origin of Peruvian laws.

This system of the Peruvian monarchs, by which the people were kept in a state of perpetual tutelage, merits the greater attention, because it is precisely that which the Jesuits employed, in Paraguay and other districts, to reduce the natives to a settled mode of life; and it seems in fact to be the only method by which a semblance of civilisation can be introduced amongst the American nations. Two things must be supposed to account for its prevalence: first, a certain amount of timidity, passiveness, and superstition, in the body of the people, implying weak passions, but not necessarily smallness of intellect; and, secondly, a few minds of a higher class, to give an impulse to the rest, and to control and regulate their acts. In the case of Peru did these ruling intellects spring from the body of the people, and, after striking out new lights in morals and legislation for themselves, devise a complex and artificial system for establishing their power over the minds of the rest, by the help of superstition and force? Or were they strangers from another country, and imbued with the principles of a higher civilisation? If we may believe the Peruvian annals, the latter was the case. About the year 1100 of our era, or perhaps a century later, Manco Capac, with his wife and sister Mama Ocello, appeared as strangers on the banks of the lake Titiaca. They were persons of majestic appearance, and announced themselves as "children of the sun," sent by their beneficent parent to reclaim the tribes living there from the miseries of savage life. Their injunctions, addressed to a people who probably worshipped the god of day, were listened to by a few, who settled around them, and founded Cusco. By degrees, other tribes were induced to renounce their wandering habits. Manco Capac instructed the men in agriculture and the arts, and Mama Ocello taught the women to spin and to weave. Laws, institutions, and religious rites, were added. The form of a civilized society arose, which was gradually extended by persuasion or conquest; the Incas having always planted their arts and religion wherever they established their authority. Huana Capac, the twelfth in succession from the founder of the dynasty, occupied the throne when the first party of Spaniards visited Peru in 1527; and the empire was then still in a state of progress; for this prince had conquered Quito at no distant date, and nearly doubled the extent of his dominions.

Such is the account which the Peruvians give of the origin of their civilisation, which we should be disposed to reject as a fable, if there were not peculiar circumstances which give it some credibility. First, their institutions, taken in the mass, do not present what may be called the American type. The mild and paternal character which they display, the injunction to "love one another" raised to the rank of a positive precept, the preference of the useful arts to war, all breathe a spirit, not only foreign to the genius of the American tribes, but exactly opposed in character to any thing which a native self-taught legislator was likely to produce. Secondly, the artificial and systematic form of the Peruvian institutions renders it improbable that they were developed by the natural action of political causes, but strongly favours the idea, that they were framed by a few designing heads, as an instrument to tame and govern a patient, feeble, and credulous people, of rude or savage habits. A small number of Jesuits were led, by a sagacious study of the savage character, to devise a system extremely similar in its nature, which worked admirably. These missionaries were the Manco Capacs of Paraguay; and, like the Incas, might, in the course of two or three centuries, have extended their theocracy over as large a space as Peru, if their situation had permitted them to employ force. Thirdly, a million of native Peruvians yet survive, the living descendants of those who built the temples of Cusco; and their extreme stolidity, apathy, and feebleness of character, sufficiently testify that the chances were nearly as great against a legislator like Manco Capac arising amongst them, as against the Jews in the time of Augustus producing a being like Jesus Christ. They have the weakness and passiveness which fit them to receive an impression from superior directing minds; but they discover no trace of the intelligence, energy, and originality which must have been united in the persons who planned and carried into effect the political system of the Incas. We admit that oppression may have degraded their character; but it cannot have entirely changed it. Look at the Greeks of this day, who have been enslaved for a much longer period.

If, then, the civilisation of Peru was exotic, whence was it derived? To us it appears most probable, that the legislators of Peru were either Chinese, or persons who had received at second-hand a knowledge of the arts and institutions of China; and our opinion is grounded on traits of resemblance in the manners, laws, arts, and institutions of the two nations, which, in our opinion, are too numerous, striking, and peculiar, to be the effect of chance. We shall mention some of the most prominent.

Peruvians and Chinese compared.

1. The first and most obvious resemblance is in the singularly artificial frame of society in both countries. In China, as in Peru, the legislation is *directive* as well as punitive, and is distinguished by that minute and elaborate system of regulation, inspection, and control, which interferes with the most trifling actions of ordinary life, and reduces the mass of the people to the condition of automata, moved and guided in every thing by the rulers. China, says Mr Barrow, is a great school, in which the magistrates are the masters, and the people the scholars. It might be more correctly compared to a large monastic establishment, in which each person has his place and his duty assigned to him, and all his acts directed by superiors, whose wisdom and authority he is not permitted to question. The Chinese have the same immense multitude of civil officers which the Peruvians had, and the same chain of subordination from the emperor down to the petty constable. In China this system was undoubtedly the growth of many centuries; but it was too artificial to occur to the thoughts of a cazique, educated amongst a tribe of savages on the sides of the Andes. 2. In China, as in Peru, the emperor assumes the title of the "father

Aborigines.

of his people;" and his government is modelled upon this figure of speech. He affects to be sprung from progenitors who *descended from heaven*, like the children of the sun; and he unites the character of supreme pontiff with that of temporal prince. There are vestiges, too, of the worship of the heavenly bodies in China.[1] 3. The Chinese emperor extends an ostentatious patronage to agriculture, by celebrating an annual festival in its honour; on which occasion he proceeds to the field in great pomp, and takes a part in the labour of cultivating the ground with his own hands. This singular custom existed in Peru, where the Incas went through an annual ceremony perfectly similar. How foreign was such an institution to the spirit of the American tribes! 4. In China agriculture is in a rude state, and exhibits proofs of intelligence and skill only in two things—the use of manures, and a laborious system of irrigation. Precisely the same circumstances characterized the agriculture of Peru. 5. The internal taxes of China, like those of Peru, are paid in kind (maize, rice, silk, cotton, &c.), and stored in public magazines or granaries. 6. The Chinese government maintained public roads, even in those provinces where neither carriages nor beasts of burden were used, of course for the use of pedestrians; and storehouses or places of refreshment were built upon them at proper distances.[2] The Peruvians constructed roads on precisely the same plan, and for the same purposes; and this was done by no other people in America. 7. The Chinese do not inter the bodies of the dead, but lay them on the ground, and raise a tumulus or conical heap of earth over them. Such was also the practice in Peru. The only barbarously cruel rite practised in Peru, that of immolating the Inca's domestics at the obsequies of their master, was brought into China by the Tartars.[3] Its existence is an anomaly in each case; for the genius of both nations was peaceful and mild. 8. The architecture of the Chinese displays little taste, but is distinguished by two peculiarities—the power shown of cutting and moving immense masses of stone,[4] and the uniformity of style which pervades their structures, of every size and description. "All the buildings," says Mr Barrow, "from the meanest hut to the viceroy's palace, are upon one plan." Humboldt remarks the same adherence to a single model among the Peruvians; and the walls of Cusco show that they were acquainted with the method of moving stones of prodigious size. The Chinese were fond of covering their walls with carving; and examples of the same practice occur in Peru. If any of the Peruvian buildings had remained entire with their roofs on, it would perhaps have been found, that the type or primary architectural form employed in the two countries was not very dissimilar; and some allowance should be made for the circumstance, that Peru must have borrowed her models from China 700 or perhaps 1000 years ago. 9. The Peruvians made coarse pottery; and all the world knows that this is an art in which the Chinese excel. The Peruvians were the only American nation who had made any progress in the art of fusing and alloying metals, in which the Chinese have long been distinguished by their skill. 10. The Peruvians had dramas and dramatic spectacles. Where could a people so uninventive have caught the idea of such entertainments, if not from China, where they have been long familiar to the people? There were mimics and buffoons in Mexico, but nothing, we believe, to which the term drama could be applied. 11. But perhaps the most remarkable coincidence is found in an invention entirely confined to the two countries. We have described the suspension bridges made of ropes, employed by the Peruvians in crossing deep ravines. Now it is singular that bridges of the very same description, some of chains, and *some of ropes*, are found in the south of China, and nowhere else except in Thibet, which has interchanged arts and customs with China from time immemorial. This single fact we would consider as a proof of communication between the two countries. The Peruvians made their ropes of twisted osiers, and the Chinese had ropes also of this description.[5] 12. From what people nearer than the Chinese could the Peruvians borrow the idea of rafts with a mast and sail? These rafts, supporting covered huts, may be considered as literal copies of some that are used in China; and the peculiar mechanism employed in lieu of a rudder is no doubt borrowed from the paddles attached to the Chinese boats, fore and aft.[6] 13. The Chinese in ancient times made use of quippus or knotted cords to facilitate calculation. Is it not probable that this invention had passed from them to the Peruvians, the Mexicans, the Kaluschi, and other American nations who employed it? It would be easy to trace similar analogies in many other customs, laws, and institutions of the two nations. Both had nunneries or religious societies of women, who lived under a vow of celibacy; both had a class of literary men (the Havaracs and Amantas, or poets and philosophers, in Peru), patronised by the government; both divided the year into twelve months, and placed the beginning of it in January (a coincidence the more remarkable, as the year of the Mexicans and other northern nations consisted of 18 months); both were strangers to the use of milk, cheese, and butter.[7] These facts may suffice, for we have not room for lengthened inquiries; neither are we anxious to press our argument beyond its proper limits. Our position is, not that the Peruvians are descended from the Chinese, but simply that Peru had been inoculated with civilisation by persons who derived their ideas from China. If it is asked why these persons did not import from China the use of letters, the method of casting arches, and many other arts practised there, our answer is, that no individual, and still less any casual assemblage of individuals such as the purposes of trade or navigation might bring together, possesses a knowledge of every art and science which exists in his country. How many men are there in England at this day, who could not even carry the knowledge of the alphabet to another country? We must remember, too, that all the arts existing in China do not exist in every province of it, and have not always existed in those provinces where we now find them.[8] As to the means of

[7] Mr Barrow, in the article CHINA, written for this work, is our authority for this fact, which is the more remarkable, as the Mongols, the neighbours and conquerors of the Chinese, had the use of all the three articles immemorially.

[8] The uniformity and unchangeableness of customs in China have evidently been much exaggerated. The empire is formed of

Aborigines. communication, it is evident that the trade-wind renders Peru almost unapproachable from Eastern Asia, between the parallels of 30° north and 30° south latitude. But beyond these limits the west winds prevail, and hence China, in point of facility of access, is nearer to Peru than the Society or Marquesas Islands. The Chinese have long exposed themselves to the casualties of a maritime life, in vessels of large size, provisioned for many months; and at this day they perform voyages of 3000 or 4000 miles, to Ceylon and Polynesia.

The Quichua language, or that of Peru, was spread, by the care of the Incas, over all the countries which they conquered, so far at least as to be understood, if not spoken, by the great variety of tribes subject to their sway. It is understood at present as far as Santiago del Estero, 1200 miles of direct distance south-east from Cusco. This single fact proves both the long duration of their power, and the efficiency of their internal administration. It is said to be the most rich, polished, and harmonious of the South American languages, abounding in vowel sounds, but wanting those corresponding to the Spanish consonants b, d, f, g, l, x, v. Like all the other American tongues, it wants terms for abstract and universal ideas, such as *time*, *space*, *being*, *substance*, *matter*, *body*, and even such as *virtue*, *justice*, *liberty*, *gratitude*. There are five dialects of the Quichua, which are spoken in Peru proper, and in Quito, New Granada, and a considerable part of La Plata, and not only by the Aborigines, but by many Spaniards of the higher classes. The Peruvians had no alphabetic writing. They possessed a very rude species of hieroglyphics, of which little use was made, and the quippus or knotted cords of various colours; but whether these last were employed to record events, or were merely instruments of calculation, is a question which we must confess our inability to solve. The history of Peru, as it has reached us, seems to have been preserved entirely by tradition, aided perhaps by popular songs.

The Peruvians, according to Mr Stevenson, are of a copper colour, with a small forehead, the hair growing on each side from the extremities of the eye-brows; they have small black eyes, a small nose, a moderately sized mouth, with beautiful teeth; beardless chin (except in old age), and a round face. Their hair is black, coarse, and sleek, the body well proportioned, the feet small, the stature rather diminutive. Their intellectual qualities, according to M. Ulloa, are of the lowest order. The most prominent trait in their character is an imperturbable and incurable apathy. Though half-naked, they are as contented as the Spaniard in his most splendid raiment. Gold and silver have so little influence over them, that the greatest recompense will not induce them to perform the slightest service voluntarily. Neither power nor dignity moves them; and they receive with the same indifference the office of alcalde and that of executioner. They are habitually slow in their motions, and extremely indolent. When employed at any piece of labour, if the master withdraw his eye for a moment, they cease to work. They are timid, shy, secretive, and always grave, even in the dances, which are their favourite pastime. The love of intoxicating liquors is deeply rooted in their nature. They prepare a fermented beverage called chicha, from maize, by a process known to them before the conquest, and at their festivals drink till their senses fail them, day after day. This bestial habit, however, is common to all the American nations, and is confined to the men, for the women are in general strictly sober. The Peruvians are a gentle and mild people; they are fond of their dogs, and breed up hogs, geese, and chickens, for which they have so tender a regard, that they will often neither kill nor sell them. Their huts, says Mr Stevenson, consist of stones laid upon one another without any cement or mortar, thatched over with long grass or straw, affording no defence either from the wind or the rain. One small room contains the whole family; their bed a sheep-skin or two; their furniture one or two earthen pots. The principal food of the Peruvians is maize; but they raise also potatoes, wheat, beans, camates, yucas, pumpkins, and other vegetables. Christianity, imposed upon them in dogmas, by priests who take no pains to enlighten them, has scarcely gained admission to their understandings, and has no hold on their affections. They attend divine service from the dread of chastisement, and give an outward assent to whatever they are taught, but without any real religious impression being made upon their minds. They meet death with the same stupid indifference as the ordinary accidents of life, and rather decline than seek the assistance of a priest in their last hours. It ought not to be forgotten, however, that the intellectual torpor which the Peruvians display may be attributed in part to the deadening and debasing effects of three centuries of brutal oppression. They still cherish in secret a strong veneration for their ancient faith and their native government, which displays itself even in the large towns. The story of Manco Capac (whom, since numbers of our countrymen appeared in Peru, they affect to call an Englishman) and Mama Ocello, the wealth, power, and beneficence of the Incas, are still fresh in their memories, and are handed down from father to son with a degree of fond admiration which three centuries of humiliation and misfortune seem only to have rendered more intense. The barbarous murder of the Inca Atahualpa by Pizarro is annually represented in the form of a tragedy. "In this performance," says Mr Stevenson, "the grief of the Indians is so natural, though excessive, their songs so plaintive, and the whole is such a scene of distress, that I never witnessed it without mingling my tears with theirs. The Spanish authorities have endeavoured to prevent this exhibition, but without effect. The Indians in the territory of Quito wear black clothes, and affirm that it is mourning for their Incas, of whom they never speak but in a doleful tone."

The oppression of the *mita*, or forced labour in the mines, with the introduction of the small-pox and the use of spiritous liquors, has destroyed prodigious multitudes of the Indians since the conquest. What their number was before that event it is impossible to tell; but, judging from the extent of the Inca's dominions, he probably had not less than three or four millions of subjects. A pretended Spanish account, assigning a population of eight millions to Peru shortly after the conquest, is known to be fictitious. According to General Miller, there were 998,000 Indians in Peru about 1826; but he does not include those in Quito or Bolivia.[1]

Chili. In Chili there were several tribes who possessed near-

---

an assemblage of small states, conquered one after another, each of which must have had its peculiar laws, manners, and superstitions; and common sense tells us, that to blend these into one perfectly homogeneous mass, must have required a much longer period than has elapsed since the empire attained its present magnitude. It would be easy, too, to find instances of the Chinese having changed their customs, both in matters of business and matters of domestic economy.

[1] In this account of the Peruvians we have chiefly followed Garcilasso, Acosta, Frezier, and Ulloa, of whose statements a copious digest is given by Prevost, in the 13th volume of his *Histoire Générale des Voyages*. We have also taken some facts from Humboldt's

Aborigines.

ly all the arts known to the Peruvians, but were distinguished from them by a finer physical constitution, and an unconquerable spirit. When the Spaniards arrived, Chili, according to Molina, was inhabited by fifteen tribes independent of each other, who were spread over the country on both sides of the Andes, from latitude 30° to the Straits of Magellan. They all spoke dialects of one language, which is described as rich, harmonious, abounding in compound words, and having, like the other American tongues, very complicated grammatical forms. It has no affinity to the Quichua or Peruvian. The inhabitants of the plains are a stout people, of middle stature; those of the mountains are tall; and one tribe, the Tehuels or Patagonians, surpass in size every other nation in the world. All the tribes inhabiting the plains, except those of the extreme south, now make use of horses. The complexion of the Chilian tribes is, like that of the other American nations, a reddish brown; but one tribe is said to be of a clear red and white. They do not paint their bodies. The Chilians lived partly by hunting, but chiefly by agriculture, before they had any intercourse with Europeans. They cultivated maize, magu, guegen, tuca, quinoa, the potato, pumpkins, and some species of pulse; and to these they added, as food, the flesh of a small rabbit, and of the Chilihueque or Araucanian camel, of whose wool they are said to have manufactured cloth. Like the Peruvians, they understood the use of manure, practised irrigation with considerable skill, and turned up the ground with a wooden spade or mattock. They boiled their grain in earthen pots, or brayed it into meal after roasting it in hot sand; of the meal they made puddings or bread, which they knew how to leaven, and various species of fermented drink. They had gold, silver, copper, tin, and lead, procured probably by washing; but they had few or no edge-tools of metal, as those found are almost always of basalt. They made baskets and mats, extracted salt from sea-water, and were able to give various dyes to their cloths. They used *quippus* or knotted cords for calculation, and, according to Mr Stevenson, for the transmission of intelligence and for recording events. They lived in villages formed of houses standing at a distance from one another, under hereditary chiefs, but whose power was limited. It is remarkable that the Chinese mode of catching wild ducks on the rivers, by covering the fisher's head with a gourd, was practised in Chili.

Araucanians.

The Araucanians, the most intelligent, improved, and warlike of the Chilian tribes, occupy about 200 miles of the sea-coast, between the 37th and 39th parallels. They are of ordinary stature, but vigorously formed; bold, hardy, hospitable, faithful to their engagements, generous to a fallen enemy, ardent, intrepid, and enthusiastic lovers of liberty. Their vices are drunkenness, and a contempt of other nations, springing from pride. Their government, in the regularity of its form, and its sub-division of authority, has an outward resemblance to the Peruvian; but the spirit of the two systems differs as widely as the genius of the two nations. Araucania contains four tetrarchies, under four toquis or princes, who are independent of one another, but confederated for their joint security against foreign enemies. Each tetrarchy is divided into five provinces, ruled by five chiefs called *Apo-Ulmen;* and each province into nine districts, governed by as many *Ulmen,* who are subject to the Apo-Ulmen, as the latter are to the toquis. These various chiefs (who all bear the title of ulmen, as our nobility of all orders are barons) compose the aristocracy of the country. They hold their dignities by hereditary descent in the male line, and in the order of primogeniture. The supreme power of each tetrarchy resides in a diet or great council of the ulmen, who assemble annually in a large plain, like the Poles and Germans in old times; but as the people are all armed, and have a high love of liberty, no resolution of the diet is of any avail if it has not their hearty concurrence. The chiefs, indeed, are little more than leaders in war; for the right of private revenge, which is fully admitted, limits their authority in judicial matters; and they receive no taxes. Their laws are merely primordial usages. The Araucanians can raise altogether 6000 or 7000 men, besides a body of reserve. When war is declared by the great council, messengers bearing "arrows dipt in blood" are sent to all parts of the country, to summon the men to arms. Unlike many barbarous nations, which are immovably attached to their ancient customs, the Araucanians were not slow in copying the military arts and tactics of the Spaniards. Their troops now consist of infantry and cavalry; the former armed with pikes or clubs, the latter with swords and lances. The infantry are formed into regiments of ten companies, each company containing a hundred men. When they take the field, they carry parched meal with them for provisions; they station sentinels, send out scouts, and have advanced guards preceding their main body. When necessary for their security, they dig ditches, and plant stakes along their sides, and throw up mounds of earth. They advance to battle in lines well formed, and fight with intrepidity. Their history affords a brilliant example of what a brave nation, animated by an enthusiastic love of liberty, can accomplish under the greatest disadvantages. After resisting the best troops and the best generals of Spain for two hundred years, they at last compelled their proud enemies to acknowledge their independence. The Araucanians were indebted for their success to a deliberate species of courage, to which even the bravest of the North American tribes are strangers; and they combined with it a degree of sagacity and intelligence, which led them to adapt their mode of fighting to the new circumstances in which they were placed. Experience having taught them the inefficiency of their old missiles when opposed to musket balls, they soon laid aside their bows, and armed themselves with spears, swords, or other weapons fitted for close combat. Their practice was to advance rapidly within such a distance of the Spaniards as would not leave them time to reload after firing. Here they received without shrinking a volley, which was certain to destroy a number of them, and then rushing forward in a close column, fought their enemies hand to hand. In this way they gained many victories, and impressed the Spaniards with such a respect for their courage, that an individual of this nation made their achievements the subject of an epic poem. Combining the moral, intellectual, and physical qualities of the Araucanians, they were certainly the finest native race in the new world. They had nearly all the germs of civilisation which belonged to the Mexicans and Peruvians; without the ferocity of the former, the apathy of the latter, or the slavish habits common to both; and without having their minds stupified by that grovelling superstition which the rulers of these two nations seem to have considered as the only secure foundation of their authority. In true courage, in manliness and energy

*Researches*, Balbi's *Ethnographical Atlas*, and W. B. Stevenson's *Narrative of Twenty Years' Residence in South America*, a useful work, but in which the author has shown rather too great an anxiety to exalt the character of the Indians.

Aborigines.

of character, they take precedence of all the American nations.

The Araucanians believe in a supreme being, and in many subordinate spirits, good and bad. They believe also in omens and divination, but they have neither temples nor idols, nor religious rites; and discover upon the whole so little aptitude for the reception of religious ideas, that the Catholic missionaries who are settled among them have had very little success in imbuing their minds with a knowledge of Christianity. They believe in a future state, and have a confused tradition respecting a deluge, from which some persons were saved on a high mountain. They divide the year into twelve months of 30 days, which have significant names, and add five days by intercalation. They esteem poetry and eloquence, but can scarcely be induced to learn reading or writing. Chess, a game of Chinese origin, is said to have been known among them from time immemorial;[1] and it may be further observed, that the numbers 5 and 9, employed in their geographical and civil divisions, are favourite numbers in China.

The other Chilian tribes are all much behind the Araucanians in civilisation; but some, as the Puelches and the Tehuels, surpass them in strength and stature. Part of them live on horse flesh, part by keeping sheep and cattle, and part by hunting. Some of these tribes paint their faces.[2] With regard to the height of the Patagonians, M. Lesson, an eminent French naturalist, has collected the authorities on the subject, in a note published by Balbi in his Ethnographical Atlas; and they appear to us to remove every rational doubt as to the fact of a race of men existing there, whose average stature is about six feet, and among whom men seven feet high are perhaps as common as men of six feet two or three inches in England. We cannot help regarding the scepticism in which many writers have indulged upon this question, as unphilosophical. The diversities of size in the human race are innumerable, and stature, like other physical qualities, is hereditary. We form in our minds, indeed, an idea of a standard size for man; but this is merely the mean of all the varieties which come under our notice; and till we know all these, our estimate cannot have any exactness. There are scarcely two nations perhaps whose average height is the same, and who can pretend to such a knowledge of the causes producing these varieties as to fix their precise limits? That individuals seven feet high, free of weakness or defect, have existed among ourselves, is a proof that there is nothing in such stature inconsistent with the physical laws on which human life depends. And since nobody denies that the dwarfish size which we witness occasionally in our own country, as a deviation from the common type, becomes generic and universal among the Laplanders and Esquimaux, why should the natural causes which produce tall men at intervals among ourselves not be rendered equally fixed and permanent in other cases? But the chief source of the incredulity of many persons is obvious. Only one of the fifteen tribes who inhabit the south extremity of the American continent is distinguished by the very tall stature which is ascribed to the Patagonians; and as these tribes probably migrate from place to place, from the coast, for instance, to the interior, and *vice versa*, a navigator touching at a bay where some of his precursors profess to have met with the giants, may find no inhabitants at all, or only men of ordinary size, and in either case may attribute to false reports what is really the consequence of a change of habitation.

Patagonians.

Guaranis.

Of the numerous nations which inhabited Brazil, there is only one to whom we can afford any special notice in this article. The Guaranis had at one time formed a numerous people, which seems to have been spread over a larger surface than any other now existing in America. Tribes, or remnants of tribes, whose relationship to the Guaranis is attested by the strong evidence of their language, are found diffused over the wide space between the Orinoco and the embouchure of the Plata, over more than the half of South America. They are met with among the Andes of Peru, in the province of Chiquitos, in Mattogrosso, in Paraguay, in Minas Geraes; and the Omaguas, in the province of Quito, who, from their nautical habits, and the influence they obtained on the upper part of the Amazon, have been called the Phœnicians of the new world, are believed to be of the same race. They constituted the bulk of the native population of Brazil when the Portuguese gained possession of it, but were divided into many distinct tribes, quite independent of one another, and living, not in contiguity, but mixed with other nations. They are of low stature, two inches shorter than the Spaniards, according to Azara, of a square form, fleshy, and ugly. Their colour has a strong shade of the copper red, while that of the other Brazilian tribes inclines generally to the tawny or black. Their character, like their physical form, resembles that of the Peruvians. They are patient, torpid, silent, downcast in their mien, mild, and passionless. Nearly all the Indians whom the Portuguese have civilized or converted belong to this race. It is difficult to account for their dissemination through the southern continent, amidst nations much more brave and powerful than themselves. May we suppose that, like the subjects of the Incas, they had been at one time the dominant tribe of an extensive empire, which derived its force from union and civilisation? But if such a state did exist, its date cannot be very ancient; for the identity or close resemblance of the dialects spoken by the scattered portions of the Guaranis, shows that their dispersion from a common point did not happen at a very remote period.[3] Yet no memorial of its existence survives, either in traditions or monuments. The supposition, therefore, that the Guarani tribes are the remnants of a once powerful and united people, is scarcely admissible; and Azara thinks it more probable that they have crept gradually from north to south. Their dispersion is the more remarkable, as they are not a wandering but an agricultural people. They live in the woods, or in small open spaces in the forests; cultivate maize, beans, gourds, yams, mandioc; and eat also wild honey, and the flesh of monkeys and various small quadrupeds.

Paraguay Indians.

The Indians whom the Jesuits civilized and collected into communities in the celebrated settlements of Paraguay belonged chiefly to the nation of the Guaranis. These missionaries are said to have borrowed the plan of the theocracy which they established here from that which the Incas had introduced into Peru. There is no doubt that the spirit of their system was the same; and, considering that they were precluded from any other means of extending and supporting their authority than persuasion, their success was remarkable. The settlements were commenced about 1610, and were gradually extended over the country watered by the Parana and Uruguay, between the 27th and 30th degrees of south

Aborigines.

latitude, till the order of the Jesuits was suppressed in 1767. The plan of the government may be called *parochial*, for it was administered entirely by the parochial clergy. The Indians were collected into villages. Each village had its church, and its curate, who was assisted by one, two, or more priests, according to the number of Indians under his charge. The curate and assistant priests were nominated, not by the Spanish authorities, but by the father superior, also a Jesuit, who exercised a vigilant superintendence over the whole. Indians were appointed in each village with the titles of regidors and alcaldes; but they were merely instruments in the hands of the curate and his assistants, in whom all power was lodged. The curate gave his whole attention to religious offices, saying mass in the church, and visiting the sick; while the assistant priests managed all secular matters, directing the labour of the Indians who cultivated the ground, and training others to the crafts of the weaver, mason, carpenter, goldsmith, painter, and sculptor; for the fine arts were by no means neglected. Private property did not exist. The produce of the labour of the community was stored in magazines, from which each family was supplied according to its wants, special provision being made for aged persons, widows, and orphans. The surplus was sold by agents at Buenos Ayres, and the proceeds employed in paying the taxes to the king, in procuring ornaments for the churches, and various articles which the colonists could not manufacture for themselves. The religious instruction was of the most simple kind; but the service of the church was conducted with a well-trained choir, a pompous ceremonial, and every accessory calculated to strike the senses. The punishments were mild, and they were always accompanied with such admonitions as a parent would address to a child whom he was chastising. Crimes, in truth, were rare. The Indians, who regarded their spiritual chiefs with the veneration due to beneficent beings of a superior order, scarcely felt humbled in confessing their misdeeds; and offenders may have solicited correction, as Raynal says, for the quieting of their consciences. The incursions of the Portuguese compelled the Jesuits to take means for repelling force by force. All the male Indians of the proper age were accordingly armed with muskets, and disciplined as a militia. In 1732, according to Dobrizhoffer, the thirty villages or parishes under the care of the missionaries contained a population of 141,000 souls. The Jesuits had another establishment of the same kind among the Chiriguas, a branch of the Guaranis, in the province of Chiquitos, containing 30,000 or 40,000 Indians; a third, of smaller size, in the province of Moxos; a fourth in California; and probably others. After the suppression of the order, all these were committed to the care of friars of other descriptions; and we believe they have universally fallen into a state of decay. The social system established in Paraguay was the most effectual ever contrived for reclaiming the Indians from their savage mode of life; but even its success shows how hopeless the attempt is to raise the American tribes to the rank of thoroughly civilized nations. The Jesuits were able to introduce settled habits and a slight knowledge of religion and the arts among the Indians only by means of the personal ascendency they acquired over them. It was a few superior minds gaining the respect and confidence of a horde of savages, then employing the influence they acquired to lead them as children; giving them such portions of instruction as taught them to trust implicitly in their guides, working alternately on their fears, their pride, their kind affections, but never fully unveiling to them the springs of the machinery by which they were governed. The incurable indolence of the savages rendered it necessary to prescribe the labour as task-work, and to carry it on under the constant inspection of the missionaries. The plan of cultivating the ground in common, and of storing the produce in magazines, out of which the wants of each family were supplied, was resorted to as a check upon their improvident habits. In short, the eye and the hand of the missionaries were everywhere; and the social system was held together entirely by their knowledge and address. When these were withdrawn, the fabric soon fell into ruins, and the Indians relapsed into their idolatry and savage habits, just as boys drop their tasks the moment they are liberated from school.

Conversion and civilisation of the Indians.

We have dwelt a little upon this topic, because we think the experiment made by the Jesuits in Paraguay and Chiquitos is almost an *instantia crucis* with regard to the capacity of the American tribes for receiving Christianity and civilisation. From the moment that the Europeans landed in the new world, benevolence has been at work to instruct some portions of these tribes in religion and the arts; and flattering accounts have been published from time to time of the success of those humane persons who dedicated their lives to the task. But, after three centuries of incessant exertion, what is the result? Is there one tribe that exhibits the steady industry, the provident habits, the spirit of improvement, and the rational views of religion, which are to be found in any parish of England? We cannot find that there is. Many tribes, living near the whites, have adopted their habits and ideas to a certain extent, but merely under the influence of imitation. While missionaries and teachers are among them, every thing wears a favourable aspect; but their civilisation is never self-sustained. It is created by the agency of men of higher natural endowments; and when this is removed it moulders away, because it has no foundation in their character. Many parties of Indians, remnants of tribes once powerful, have lived peaceably on reserves of land, inclosed amidst the population of the United States, for more than a century. No situation can be imagined better fitted to promote their improvement; but in no one instance, so far as we know, have they melted into the mass of the white population, or risen to any thing near their level in knowledge and the useful arts. They live in huts in no material degree better than the wigwams of their wandering brethren. They are generally honest, but drunken, indolent, and ignorant, though teachers and missionaries are employed by the government to instruct them. Basket-making is almost the only trade they ply, and in their habits and character they may be aptly compared to the gypsies of Europe, who exist in the midst of civilisation, without partaking of its spirit or its benefits. It should be observed that there is not the same reluctance in the whites to mingle their blood with the red men, as with the blacks.[1] Much has been recently said of the progress made by the Cherokees; but we suspect that what is witnessed there is but a flimsy veil of improvement, spread over habits which are essentially savage. We are convinced, in short, that the Indian is truly the man of the woods; and that, like the wild animals he lives upon, he is destined to disappear before the advancing tide of civilisation, which falls upon him like a blight, because it supplies new food to nourish his vices, while it demands intellectual and moral faculties in which he is deficient, and renders useless

[1] See, on the habits and character of the Indians, Cooper's *Notions of the Americans*. vol. ii. letter 17.

Aborigines.

those qualities which predominate in his character. We would not discourage the attempt to meliorate the lot of the Indians; but this will succeed best when it is grounded on a true knowledge of their natural capacities. Some of them are much more susceptible of moral and religious improvement than others; but, to instruct and reclaim them effectually, our belief is, that the system of the Jesuits is the only one that holds out a chance of success. They must not merely be taught and preached to, but they must be retained in a state of pupilage, trained to their duties, controlled and directed in all their proceedings by intellects superior to their own; and there are many tribes too ferocious and intractable for even this method of tuition. We do not maintain that the character of the Indian nations is indelible; but to effect any considerable change in it, the lapse of a longer period would be required than the existence of these tribes is likely to extend to. Neither do we think that there is any thing in the extinction of these people by natural means which humanity should mourn over. In every state of life man has but a brief span of existence allotted to him. Successive generations fall like the leaves of the forest; and it should be remembered that the extinction of a race of men by natural causes, means merely its non-renewal, or the suspension of those circumstances which enabled it to continue its existence.

To complete our general view of the aboriginal races, a few particulars remain to be mentioned. Many of the tribes who inhabit the Pampas of South America make use of horses. Dobrizhoffer enumerates eight equestrian tribes in the province of Chaco, on the west side of the river Paraguay, who are generally distinguished by tall and vigorous forms, and a bold and active character. The Abipones and Mbayas are the most celebrated of these. The woods of Brazil are too dense for equestrians; but horses are used by a few hordes in the great plain of the Mississippi and in the north of Mexico. The American tribes in general either kill their prisoners or adopt them; but a few retain them as slaves, and compel them to work. The Guaycurus of Brazil are an example. The food of different tribes is extremely various. Maize, beans, pumpkins, and mandioc, are raised in small quantities by some; natural fruits, berries, bulbous roots, and bananas, are gathered by others. Those who dwell on the sides of rivers live greatly on fish; in the plains, buffaloes, horses, and sheep, are killed. In the forests of Brazil, monkeys, pigs, armadillos, pacas, agoutis, and tapirs, are the favourite food; but birds, turtles, deer, and the coati, are also taken; and in an emergency the Indians do not scruple to feed on serpents, toads, and lizards, the larvæ of insects, and other disgusting substances.[1] Salt is used where it can be easily obtained, and some season their food with capsicum. Some roast their meat, others boil it; and not only several savage tribes, but even the civilized Peruvians, ate their flesh raw. The Ottomaques, a tribe near the Orinoco, eat a species of unctuous clay; and this strange diet, which no doubt owed its introduction to the stern monitor, famine, is probably not extremely rare; for Drs Spix and Martius noticed a similar practice in Brazil, and Captain Franklin found the same food in use among an Indian tribe near the Frozen Ocean. The clay is stated by this traveller to have a milky and not disagreeable taste.[2] A great proportion of the tribes in Brazil and the basin of the Orinoco, and some in all parts of America, indulge in the horrid banquet of human flesh. Shame, in our sense of the term, is nearly a stranger to the breasts of these savages. In the warm regions of Brazil, men and women go entirely naked, except in the neighbourhood of the Portuguese settlements, where some wear a band of cloth round the loins.[3] In such situations, where the want of shelter is little felt, their dwellings are often nothing more than a sort of arbour formed by interlacing the open space between two or three trees with twigs, and covering it with leaves so as to form a screen on the windward side, while it is left entirely open on the other. The manufacture of bows and arrows, war-clubs, baskets, mats (which, swung from a tree, serve them both as seats and hammocks), and in some cases a coarse pottery, comprises the sum of their practical skill in the arts. It has long been the practice of bands of Portuguese, consisting chiefly of outlaws and vagabonds, to make marauding expeditions among the Indians living near the great rivers, and to carry them off and sell them clandestinely for slaves. This infamous trade is carried on in despite of the orders of the government, which has issued many decrees for the protection of the Indians, and, besides employing missionaries to convert them, enjoined the governors of provinces to furnish them with hoes and other agricultural implements. Wherever the negroes are introduced in great numbers, as in the Capitanias of Santa Paulo and Rio Janeiro, and in the whole of the West India islands, the red men rapidly disappear, the former being more intelligent, more tractable in their habits, and more active and industrious. The negroes are indeed a superior race to the Indians; and the existence of one or two hundred blacks, as slaves, among some thousands of the Cherokees, does not detract from the accuracy of this opinion. Missions for the conversion of the Indians have been supported for more than two centuries by the governments of Spain and Portugal. They are thinly spread over those parts of Mexico, La Plata, Peru, Brazil, and Colombia, which are still occupied by the savages; but there are extensive districts in all these provinces in which they have never been established, owing to the fierce character of the tribes, or the remote and inaccessible nature of the country. A mission consists in general of one or two friars or priests, who settle among the savages, learn their language, and, besides teaching them the elements of Christianity, always endeavour to instruct them in the more simple and useful arts, and to train them to settled habits. We have seen many scattered notices of these establishments, but we have not met with any work that gives a distinct account of them collectively to a recent period. We believe, however, that many of them have been abandoned, owing to the failure of the funds with which they were supported; and that the success of the others has been extremely trifling. The late revolutions in these countries, by liberating the Indians from their ancient state of tutelage under the whites, has in many cases broken up the little settlements which the missionaries had formed. This has been the result even in Brazil, where the political changes have been least felt.[4]

Origin of American population.

The problem as to the source whence America derived its population presents no difficulty now, when the contiguity of the old and the new continent at Behring's Straits is known. The breadth of the sea here (latitude 66°) is only forty-five English miles; the transit across is facilitated by two islands placed almost exactly midway between Asia and America; and in severe winters a firm body of ice joins the two continents. The climate, though rigorous, does not prevent the country on each side from

Aborigines.

being inhabited. The Aleutian Isles, besides, at the latitude of 53°, which run in a line like the piers of an immense bridge, from one continent to the other, present such easy means of communication, that few savage tribes a little familiar with sea-life could be long in Kamtschatka without threading their way across the Pacific to the peninsula of Alyaska. Indeed, if a doubt could exist, we have positive proof that America received part of its population from the north-east extremity of Asia; for the Esquimaux, living on the east side of Behring's Straits, speak a language which is radically the same with that of the Tschutskoi on the opposite shores. Two other questions however present themselves. Did all the tribes which inhabit America pass into it through this one channel? And from what nation or nations of the old world are these tribes descended? Now, it appears to us probable, that inhabitants may have been conveyed to America by other routes besides that of Behring's Straits and the Aleutian Isles. We may form some idea of the chances of human beings from other climes being cast on the shores of America, from the countless accidents which must have scattered inhabitants over the thousands of islands on the Pacific Ocean. Take the case, for instance, of Easter Island, which is within the zone of variable winds for half of the year, and is 1500 miles from the nearest known land whence it could receive inhabitants. This island is a mere speck in the ocean, 10 miles in diameter; and supposing that it could be seen by an Indian in his canoe from a distance of 25 miles on each side, a space of 60 miles in the circumference of a circle of 1500 miles radius would thus represent the probability of a canoe carried away by a storm coming within sight of it. If then we suppose the wind to blow from any westerly point between north and south, we shall find that the probability of a drifted canoe reaching the island is only as 1 to 75. If we add the chances of the isle being passed in the night-time, when it could not be seen, the probability will be only as 1 to 150. But, further, to plant a breeding population on the isle, the canoe must have carried women in it; and as the savages have not women with them in their canoes perhaps more than once in three or four of their voyages, the probability is thus diminished to 1 in 500. In other words, the peopling of an island in such a situation as Easter Island may be considered as representing the result of 500 accidents, in which canoes were drifted to sea and wrecked. This single example may give us an idea of the myriads of casualties which must have been instrumental in dispersing the human species over the isles of Polynesia,—casualties so numerous and so various, that they may be compared to the chance sowing of the volatile seeds of plants by the winds. If we neglect distance, it will be seen at once that the probability of a canoe reaching any land in such circumstances, is in proportion to the angle the land subtends on the horizon. In the extra-tropical regions the prevailing winds are from north-west to south-west. The part of South America accessible with such winds from Gambier's Islands subtends an angle of about 40°, or ten times as great as the angle subtended by a space of 25 miles on each side of Easter Island from the same station. If we throw *distance* out of view, therefore, the chances of a boat drifted with any wind between north-west and south-west reaching the coast of Peru or Chili, would be ten times as great as of its reaching Easter Island. But from this latter well peopled island the accessible coast of Peru subtends an angle of 60°, and the chances are so much higher in proportion. Easter Island is about 2800, and Gambier's Island 3600 miles from the American coast; and the question is, whether, of many hundred canoes drifted off in this direction in the lapse of ages, it is improbable that one or two carrying persons of both sexes might reach America. We may allow an unrigged boat to make 100 miles a day with a strong wind. From 28 to 36 days, then, would suffice for the voyage; and though savages often go to sea with little provisions, we must remember that they have a horrid resource in their cannibal habits. There are besides, we think, well-attested cases of the South Sea Islanders surviving a storm which has kept them a month at sea. Many of these islanders have boats capable of carrying 20 or 30 persons; and their ferocious wars are continually creating emergencies which compel crowds of males and females to take suddenly to the water to save their lives.

We have referred to Easter Island merely as an example, to illustrate causes which have been in operation in all parts of the maritime world. Setting aside Behring's Straits and Greenland, there are four points from which, according to the principles we have explained, there is a possibility that inhabitants might be transported to America. These are, first, Gambier's Isles and Easter Island, of which we have already spoken. Secondly, Southern Africa: from Congo, Benguela, and the Cape, to the coast of Brazil, the distance is from 3700 to 4100 miles; and a boat abandoned to itself, favoured at once by the tropical current, which sets north-westward, and by the trade-wind, might perform the voyage in 30 or 40 days. Thirdly, the north-west coast of Africa, and the Canary and Cape Verd Islands. From the latter (which were inhabited when discovered by the Portuguese) the distance to Brazil is only about 2000 miles, and the motion of a boat would be aided both by the trade-wind and the returning great current of the North Atlantic. The voyage might occupy from 20 to 30 days. The possibility of men being carried to America is shown by the stern of a vessel, such as the American nations could not build, which Columbus found on one of the Caribbean Islands on his second voyage.[1] It is true that both Madeira and the Azores, though nearer the old world, were uninhabited when discovered in the 15th century; but we must remember that these isles are but specks in the wide ocean, compared with America; and, further, that the mariners accidentally cast upon them might have no females with them, and would find none there. The Azores had been the residence of some luckless shipwrecked Europeans, as the figures found carved on the rocks proved. The fourth channel through which inhabitants might reach America is the Sandwich Islands. The distance is 3000 miles; and when the sun is at the southern tropic, it is probable that the western winds may blow for a time in their vicinity.

In a comprehensive view of all the causes which, in the lapse of ages, have contributed to spread the human race over the new world, the conjectures we have hazarded are not without value. There are, for instance, two parts of the new continent in which nations almost black are found, namely, California and Paraguay. In the latter

[1] Washington Irving's abridged *Life of Columbus*, p. 130. Vater has discussed this subject in his *Untersuchungen über Amerikas Bevolkerung aus dem alten Continent*: Leipsic, 1810. We have not been able to procure a sight of the work; but we find, from the introduction to the section on the American languages in the *Mithridates*, that he speaks in decided terms of the possibility, or rather the probability, of the western coasts of Europe and Africa contributing, as well as the east coast of Asia, to people the new continent.

Aborigines.

the Charruas, Minuanes, Bohanes, and Yaros, are of this complexion,[1] and seated amidst tribes of a much lighter hue. Is it unreasonable to suppose, that a few persons belonging to a South African tribe had been cast ashore at an early period on the north banks of the Plata, the district to which the natural motion of the winds and waves would most readily waft them, and had grown up into a tribe before they mixed with any other race? The Californians may be descended from the Papuas or black race inhabiting New Guinea, and who are supposed to constitute the swarthy people of the Sandwich Isles.[2] At any rate it is remarkable that the only race of a very dark complexion in North America should be found exactly at the part of the coast nearest to these isles, and to which the agency of the extra-tropical wind would conduct any object left to its guidance. We admit, however, that they might come from the Kurile Isles, where the same black race is found. By the mixture of persons belonging to tribes of this hue with others of the copper colour, the varieties of complexion found among the American nations may be accounted for. It affords a slight corroboration of this idea, that among the scanty affinities traced between the languages of the old and new world, there are some few which connect certain American dialects with that of Congo. The superior intelligence, great stature, light complexion, and personal beauty of some of the Chilian tribes, on the other hand, favour the supposition that they are of the same race with the tall, fair, handsome people of the Society and Marquesas Isles, who have displayed so great an aptitude for civilisation.[3] That individuals of European birth also had been carried to America by the accidents of maritime life, is rendered probable by physical causes; and it is singular that traditions, describing the arrival of a white or bearded man from an unknown country, and his teaching them to build houses and cultivate the ground, are preserved in three other parts of America besides Peru. Such is the Quetzalcoatl of the Mexicans, the Bochica of the Muyscas in New Granada, the Camararu of the Brazilians, who were all said to come from the east.[4] Manco Capac alone, the Peruvian legislator, made his appearance on the west coast of the continent. The story of a sword with a legible Greek inscription being found under the soil at Monte Video in 1826, is, we fear, a fiction. (*Bulletin Historique*, Août 1828.)

Affinity of Mexicans and Asiatics.

Attempts to trace the descent of the American tribes from any particular people of the old world have not succeeded. We except the Esquimaux, who are distinct from all the other nations of the new continent, and clearly of the same race with the Tschutsko of north-eastern Asia. Many analogies, however, in the physical character of the people, their rites, monuments, and superstitions, establish a connection between the Mexicans and some Asiatic nations. A general resemblance has been observed between the American nations and some tribes of Mongols and Mantchous, in the form of the skull, the brown colour of the skin, the thinness of the beard, and the oblique position of the eye. Humboldt has shown that the Mexican calendar is identical in its principles, which are very artificial and complicated, with that which was in use among the Chinese, Japanese, Thibetians, Hindoos, and Tartars; and he has rendered it probable that the names of their days are borrowed from an extinct zodiac of 27 or 28 houses anciently familiar to the same nations. The cosmogony of the Mexicans has too many analogies with that of the Jews to admit of the coincidence being accidental. Their traditions speak of the serpent woman or the mother of mankind falling from a state of innocence, of a great inundation from which a single family escaped, of a pyramid raised by the pride of man, and destroyed by the anger of the gods; they practised the ceremony of ablution upon children at their birth; they had the rite of confession for penitents; and religious societies like those of monks existed among them. Now, we know that the Nestorians about the seventh century carried the rites and doctrines of Christianity into China and Tartary, where they were found by Carpini, Rubruquis, and Marco Polo, in the thirteenth, mixed with many strange corruptions. There is little doubt that the traditions and customs alluded to reached Mexico through this channel. Further, a species of picture-writing like the Mexican was practised in China about the year 1325. Vestiges of the same art are found among the Kaluschi or Yucuatl, tribes inhabiting the north-west coast between the latitudes of 50° and 60°, and whose languages bear a resemblance to that of the Mexicans. Finally, the records of this people speak distinctly of their ancestors migrating from a distant country in the north-west; and the traditions of the Muskogees, Chickasas, Mohicans, Iroquois, and the tribes of Cinaloa, point to the same region as their original seat.[5] The facts, taken collectively, leave no doubt that more than one of the American nations were somehow connected with the people of eastern Asia; but they scarcely authorize the conclusion, that the one were a colony directly sent off from the other. The Chinese, Mongols, Tartars, and Mantchous, have cultivated the cerealia, employed horses, and tamed cattle, from very remote times. It was scarcely possible that such necessary arts should be entirely lost by a colony sprung from any of these people; yet the Mexicans were unacquainted with wheat, oats, and barley; they had no horses (which a migrating Tartar tribe might probably have carried across Behring's Straits); and they had never attempted to tame the native ox of America, nor to use the milk of its female. There is perhaps only one hypothesis by which these diverging facts can be reconciled. Tribes belonging to the races of eastern Asia had separated from them while they were still living in the state of hunters, and, crossing Behring's Straits, had spread themselves by degrees over America. Among some of these tribes, dwelling probably north of Columbia River, a few emigrants from China, Japan, or Chinese Tartary, at a comparatively late period, had been thrown by some of the accidents to which a seafaring life is liable, and bringing with them picture-writing, the art of building and weaving, a few mystical rites and traditions, and the calendar which was in use in their native country, had established their influence among the savages by address or force, and sown the seeds of civilisation. After social life had made a few advances, the increasing numbers and power of the people would enable them to send off several swarms in succession to the eastward, and dispossess the earlier and ruder inhabitants of Anahuac and the plains of the Mississippi. The Toltecks were perhaps the first of these colonists; the Hurons, Iroquois, Chichi-

America. mecks, and Aztecks (all of whom had hieroglyphics), must have been separated from the parent stock at a later period, probably two or three centuries after the Nestorians had spread some knowledge of the Christian rites and the Hebrew cosmogony among the people of eastern Asia. To all appearance there was no race in America anterior to the Toltecks who possessed any germs of civilisation; for the military works in Ohio can scarcely be referred to a period farther back than 800 or 1000 years from the present day. But for 2000 or 3000 years anterior to this the new continent had been overrun by tribes of hunters. This, we think, is clear; for while the analogies of physical character observed in the American nations, and in the structure of their dialects, show, on the one hand, that nine-tenths of them had sprung from one tribe, or a few tribes of one stock; the existence of 500 of these varieties of speech proves, on the other hand, that a very long period must have elapsed to admit of the subdivision of one, two, or even half-a-dozen of mother tongues into such a prodigious number of dialects. That the original seat of Tolteck and Azteck civilisation was not in Asia, but in the north-west parts of America, results, we think, from the non-existence of the cerealia and of tame cattle in the new world; and that the glimmering of knowledge which these people possessed had been kindled by the arrival of a few chance emigrants, perhaps at different periods, from China, Japan, or Chinese Tartary, seems equally certain, from the resemblances formerly noticed in the calendars, the superstitions, and the cosmogonical traditions of the Asiatic and American races.

Indian Antiquities. In the great valley of the Mississippi and its mighty tributaries, the Ohio and Missouri, are the remains of the works of an extinct race of men, who seem to have made advances in civilisation far beyond the races of *red men* then discovered by the first European adventurers. These remains consist chiefly of tumuli and ramparts of earth, inclosing areas of great extent, and much regularity of form. Some of them recal the barrows of Europe and of Asia, or the huge mounds and ramparts of Mesopotamia, as displayed at Babylon and Nineveh; while others remind us of the ruined hippodromes and amphitheatres of the Greeks and Romans. In that part of North America, the barrows are usually truncated cones; but in advancing farther south, they often assume the figure of four-sided pyramids in successive stages, with flattened tops, like the *Teocallis*, or temples of Mexico and Yucatan. The earliest accurate notice of them, published in England, is contained in the *Letters from America* of Adam Hodgson, in 1820 and 1821, published in 1829. Since that time they have been admirably described, and many of them delineated in the splendid work, *The Smithsonian Contributions to Knowledge*, vol. i.; from the researches of Messrs Squier and Davis, which appeared in 1848, at New York.

The barrows and ramparts are constructed of mingled earth and stones; and from their solidity and extent, must have required the labour of a numerous population, with leisure and skill sufficient to undertake combined and vast operations. The barrows often contain human bones, and the smaller tumuli appear to have been tombs; but the larger, especially the quadrangular mounds, would seem to have served as temples to the early inhabitants. These barrows vary in size, from a few feet in circumference and elevation, to structures with a basal circumference of 1000 or 2000 feet, and an altitude of from 60 to 90 feet, resembling, in dimensions, the vast tumulus of Alyattes near Sardis. One in Mississippi is said to cover a base of six acres. The ramparts also vary in thickness, and in height from 6 to 30 feet, and usually inclose areas varying from 100 to 200 acres. Some contain 400; and one on the Missouri has an area of 600 acres. The inclosures generally are very exact circles or squares, sometimes a union of both; occasionally they form parallelograms, or follow the sinuosities of a hill; and in one district, that of Wisconsin, they assume the fanciful shape of men, quadrupeds, birds, or serpents, delineated with some ingenuity, on the surface of undulating plains or wide savannahs.

These ramparts are usually placed on elevations or hills, or on the banks of streams, so as to show that they were erected for defensive purposes, and their sites are judiciously chosen for this end. The area inclosed, therefore, bears no proportion to the relative labour bestowed on such ramparts: thus, in Ohio, an area of not more than 40 acres is inclosed by mounds of a mile and a half in circumference; and on the little Miami, in the same state, is found an inclosure fully four miles round, that contains an area of about 100 acres.

These remains are not solitary and few, for in the state of Ohio they amount to at least 10,000.

The inclosures in the form of animals are more rare than those now noticed, and seem nearly confined to Wisconsin. One of those represents a gigantic man with two heads, the size of which may be estimated, by the body being 50 feet long, and 25 feet across the breast. Another on a slope near Bush Creek, represents a tolerably designed snake, with an oval ball in its mouth; the undulating folds of its body and spiral of its tail extending to a length of 700 feet. The forms of quadrupeds and birds are also characteristically represented in these works. Those that have been explored contain human bones; and though the Indians deposit their dead within them occasionally, they have no tradition of their having belonged to their ancestors. The most probable supposition respecting them is that of Mr R. C. Taylor, that each was the sepulchral monument of a different tribe, who have all disappeared from America.

The question immediately suggests itself, to what people must we ascribe those vast works? They can scarcely be the works of the ancestors of the red men discovered by Europeans in North America. Neither can we ascribe them to the early Greenland and Iceland colonists, who never seem to have passed westward of the Alleganies. We can scarcely attribute them to the somewhat apocryphal followers of the Welsh Madoc. Can their authors be the people obscurely mentioned in the Icelandic *sagas*, as the inhabitants of *New Iceland?*

A curious tradition of the present Iriquois records, that when the *Lenni Lenapi*, the common ancestors of the Iriquois and other tribes, whose language is still widely spread among the Indians, advanced from the north-west to the Mississippi, they found on its eastern side a great nation more civilised than themselves, who lived in fortified towns and cultivated the ground. This people at first granted the Lenni Lenapi leave to pass through their territories to seek an eastward settlement; but treacherously attacked them while crossing the river. This conduct gave rise to inveterate hostilities, that terminated in the extermination or subjugation of their opponents, and the establishment of the red men in those regions. This not improbable, though imperfect account of such rude communities, where neither letters nor hieroglyphics existed, is probably all that we shall ever learn of the people who executed those works that now excite our surprise.

As we advance southward, we find proofs of still greater refinement on the table-land of Anahuac or Mexico; and on descending into the humid valleys of Central America, the peninsula of Yucatan, and the shores of Honduras, we find striking remains of the semi-civilisation of the races that inhabited those countries before the Spanish invasion. The barbarous policy of Cortez and other invaders, was to eradicate every trace of the former grandeur of the native races, thereby to inure them to a degrading servitude. The systematic destruction of the native works of art and gorgeous buildings in Mexico was relentlessly carried on for ages, to the infinite regret of the modern ethnographical inquirer. Little positive information on these subjects can be gleaned from the early Spanish historians of the conquest; and it was not until the publication of Humboldt's *Researches*, that Europe knew anything of the state of the Great Mexican pyramid, or of the wonderful remains of Palenque and Papantla.

In the middle of the last century, however, some Spanish adventurers penetrated with difficulty the dense forests of the Mexican province of Chiapas, in which they discovered the remains of an ancient city, of which all memory had been lost, and to which they gave the name of PALENQUE, from a poor adjacent village. Stimulated by their report, the Spanish government some years afterwards despatched two intelligent travellers to explore those wilds; but the report of Del Rio and Du Paix, from the commotions that agitated Europe and convulsed Spain, remained unpublished until a few years ago. It has since appeared with very interesting designs of the ruins they explored. Our knowledge of such remains, however, has been greatly enlarged by the labours of an enterprising North American traveller, Mr Stephens, given to the world in four volumes, entitled *Incidents of Travel in Central America, Chiapas, and Yucatan*, 1838, and *Incidents of Travel in Yucatan*, 1842. This gentleman has discovered, in the almost impenetrable forests of those regions, the remains of no less than 44 towns, some of them with extensive and highly decorated structures. These exhibit walls of hewn stone, admirably put together with mortar, often enriched by sculptures in bold relief, and hieroglyphical inscriptions, exactly resembling the Azteck MSS. in the museums of Europe, and in the publications of Humboldt; well-executed *vaulted* roofs, and obelisks covered with mythic figures, and pictorial or hieroglyphical inscriptions. These curious remains have been concealed for ages by a luxuriant tropical vegetation, so dense that they seem to have been unknown to people living within half a mile of their site.

The most conspicuous ruins seem to have been temples or palaces, and almost invariably have a pyramidal form, in several stages, with wide intervening terraces, the ascent to which is by grand flights of steps. The chambers in those buildings have generally a length disproportioned to their width; they have no windows, but receive their light from the doors; just as the rooms do at this day in Barbary and some other eastern countries. The apartments are in two parallel rows, a narrow corridor or series of chambers runs along the front, and the apartments behind this receive their light only from the front rooms into which they open. Yet these interior apartments are often richly decorated with sculptures, ornamented with stuccos, and gaily painted red, yellow, white, and black.

The ruins of Palenque, as may be seen in the researches of Humboldt, have the characters just mentioned. They are covered with hieroglyphics, and sculptures in relief, with ornamental cornices. The largest building stands on a terrace, faced with stone, measuring 310 by 260 feet; the building itself is 200 by 180 feet; its walls are 25 feet high. The stone has been originally covered with painted stucco; fronts the east, and contains 14 doors, separated by piers ornamented with stucco figures. In this building some of the figures are erect, while others sit cross-legged, in what we term the oriental fashion; one statue, $10\frac{1}{2}$ feet high, was found at Palenque; and two fragments of two *torsos* and a head were also discovered that exhibited a severe but fair style of sculpture, that recals somewhat of the early style of Greek art.

The ruins at Copan, in Honduras, are of vast extent. Here a pyramidal structure remains, with an elevation of 150 feet measured along its slope, and this appears to be a principal temple, included with several smaller structures within a *sacred inclosure*, in the manner of the temples of ancient Egypt. On its walls are many skulls of a quadrumanous animal, well executed in high relief; a large figure of a baboon was discovered among the ruins, bearing no inconsiderable resemblance to the cynocephalus of the Egyptians. Here also several sculptured obelisks occur, from 11 to 13 feet in height, and from 3 to 4 feet wide, which, as well as the walls of the temple, were highly ornamented with sculptures in bold relief.

The similarity between the ruins at Copan and Palenque, and the identity of the hieroglyphic tablets in both show that the former inhabitants of Chiapas and Honduras had the same *written* language, though the present Indians of those provinces do not understand each other.

At Labphak, but more especially at Uxmal, both in Yucatan, are very magnificent ruins of the same kind. Several sculptured obelisks are here, also bearing on their principal face a figure of some deity probably, with a benignant countenance represented in full, and the hands applied to the breast. The other sides of the obelisks are covered with hieroglyphical tablets, proving that the same race once inhabited the plains of Honduras, and the tableland of Anahuac. The principal building at Uxmal seems to have been a very magnificent pyramid in three stages or terraces, faced with hewn stone, and neatly rounded at the angles. The first terrace is 575 feet long, 15 feet broad, and 3 feet high, serving as a sort of plinth to the whole; the second terrace is 545 feet long, 250 feet wide, and 20 feet high; the third terrace is 360 feet long, by 30 feet wide, and 19 feet in height. From the centre of the second terrace, the upper part is gained by a vast flight of well-constructed steps 130 feet wide. This leads to the temple, the façade of which is no less than 322 feet long, but has not had a greater elevation than 25 feet; yet its grandeur is enhanced by the rich sculpture that covers the upper part above a fillet, or cornice, that surrounds the whole building at about half its elevation. The interior consists of two parallel ranges of chambers, 11 in each row. The front apartments are entered by 11 doorways, enriched with sculpture, this gave sufficient light to those rooms; but the posterior row receives no light except what enters by their doors from the exterior rooms. The roofs here, unlike those of Palenque and Copan, are not stone arches, but are supported on bearers of a very hard wood that must have been brought from a distance of some hundred miles; and these beams too are covered with hieroglyphics. The flat roof of this building has been externally covered with a hard cement. In a building placed on a lower level, is a rectangular court, which has been once wholly paved with well-carved figures of tortoises in demi-relief. These are arranged in groups of four, with their heads placed together; and from the dimensions of the court, this *sala de las Fortugas* must have required 43,660 of such carved stones for its pavement.

The ruins of Chichen, also in Yucatan, extend over an area of two miles in circumference. One of the best preserved buildings with an ambit of 638 feet, is constructed in three terraces, which give it an apparent altitude of 65 feet. The buildings here, on the second terrace, have the façades highly sculptured, both above and below the horizontal fillet; and the doorways are enriched with mouldings, and *truss*-like ornaments supporting a drip-stone. The staircase here is 56 feet wide. The front apartments are 47 feet long and only 9 wide. There are three doors in the front, and in the central apartment are nine niches. The roofs are stone arches; and all has been once painted of various

America.

colours. A curious adjoining structure consists of two parallel stone walls, 274 feet long, and 30 feet apart. The walls are 30 feet thick. It has been conjectured to have been connected with the celebration of some public games, like the *palæstræ* of the Greeks.

In several of the ruins now noticed are found buildings to which there is no access. They have doorways, but these seem to have been walled up when the buildings were erected. Their use is unknown; they are named *casas cerradas*, or "shut up houses." Their interior does not differ from the other apartments above described.

It is worthy of notice, that the builders of those cities took great pains to supply them with one of the prime essentials of human comfort—abundance of good water, by means of wells and cisterns of excellent construction.

The remains, in all the 44 ancient towns visited by Stephens, have a similar character; so that we can have no hesitation to ascribe them to the same nation, or to kindred races of men, who had certainly attained no inconsiderable civilisation, although unacquainted with the use of iron, or even of bronze. They seem to have been farther advanced in the arts than even the inhabitants of the table-land of Mexico at the period of the Spanish conquest. Can we assign these ruins to the *Toltecks*, a people whom the Mexican annals represent as inhabiting the table-land before the Azteck invasion.

America discovered by Norwegians.

The discovery of a continent so large that it may be said to have doubled the habitable world, is an event so much the more grand and interesting, that nothing parallel to it can ever occur again in the history of mankind. America had of course been known to the barbarous tribes of eastern Asia for thousands of years; but it is singular that it should have been visited by one of the most enterprising nations of Europe five centuries before the time of Columbus, without awakening the attention of either statesmen or philosophers. Iceland was discovered about 860, and colonized by the Norwegians in 874. About 50, or, according to other accounts, 100 years later, the same people planted colonies in Greenland. Into the disputes respecting the situation of these colonies we have not room to enter. Sir Charles Giescke, a good authority, states that their ruins exist near the southern point of the peninsula. It is obvious that the same adventurous spirit which enabled these northern mariners to discover the southern extremity of the country, would not permit them to stop short without visiting what is now known to be the most habitable part of it—the western coast; and the fact has been established by an inscription in *Runic* characters, found on a stone four miles beyond Upernavik, at the 73d parallel, intimating that "Erling, the son of Sigvat, and Enride Oddsoen, had cleared that place and raised a hillock on the Friday after Rogation day." The marking of the date is indistinct, but it is supposed by Professor Rask, the translator, to be either 1135 or 1170; and the Runic characters show at any rate that it was anterior to the Reformation, when this mode of writing was prohibited.[1] Whoever looks at the map of Greenland, and reflects on the fact that the Norwegians must have been ascending through Davis' Straits as high as the latitude mentioned, annually, perhaps for two or three centuries, will admit that, with half the spirit of enterprise which had carried them so far, the discovery of some portion of the west coast of these straits was almost unavoidable. Now, the position and direction of this coast once known, it required no great effort to trace it southwards to Labrador and Newfoundland. We mention these particulars, because Mr Murray, one of the few who now deny the discovery of America by the Norwegians, grounds his disbelief chiefly on the hypothesis that the colonies and the navigation of this people at the period alluded to were confined to the east coast of Greenland.

In 1001 an Icelander sailing to Greenland, was driven away by a tempest far to the south-west, where he saw a level country covered with wood. The wind abating, he turned his course homeward, and on his arrival gave such a flattering account of the country he had seen, as induced Lief, the son of the founder of the Greenland colony, to undertake a voyage thither. Lief and Biorn, who sailed together, first reached a rocky island, to which they gave the name of Helluland; then a low country, thickly wooded, which they called Markland; and some days afterwards they found trees loaded with fruits on the banks of a river. They spent the winter in the country; and one of them, who was a German, having found wild vines growing, they called it Vinland. They had some intercourse, and traded for furs, with a people who came in leathern boats, and were called *Skrælings*, from their dwarfish size. A colony was planted and remained for many years in the country, the situation of which is indicated by a fact casually mentioned, that the sun remained nine hours above the horizon at the shortest day. It should of course have been under the 41st parallel; and this is the actual latitude of Rhode Island, the country which every collateral circumstance would lead us to fix upon as the seat of the colony. The Skrælings were of course the Esquimaux.[2] The *vine* appears to be the fox grape (*Vitis vulpina*), which grows wild in that part of America. Only a few unimportant particulars respecting the settlement are preserved; but it was probably abandoned or destroyed, like the Greenland colonies, of which it was an offset. The account, though meagre, is distinct and consistent. Its authenticity can scarcely be disputed; and it is almost equally obvious that the country it refers to under the name of Vinland is in the vicinity of Rhode Island. A conclusion resting on such strong grounds scarcely requires to be supported by the high authority of Humboldt and Malte-Brun. That the colony disappeared, and that the discoveries made were not prosecuted farther, are not circumstances which will shake the credit of the narrative in the minds of those who know the numerous reverses which befell the early colonies in New England and other parts of America. The hostilities of the Skrælings was no doubt the principal cause of the abandonment of the colony. The Norsemen describe Vinland as a rich country, with a delightful climate. Helluland, Markland, and Vinland, were no doubt regarded as countries either connected with or similar to Greenland, the flattering descriptions of which given by the first discoverers were sadly belied by later experience.[3] The interest excited by the obscure accounts

[1] Ferussac, *Bulletin des Sciences Historiques*, Juillet 1828.

[2] See the curious works of Torfæus called *Vinlandia Antiqua*, Hafn, 1705; and the valuable *Antiquites Americanæ*, published at Copenhagen in 1827. Also Humboldt's *Cosmos*, vol. ii. p. 233; Sabine's Transl. 1848.

[3] M. Rafn, a Dane, who has been engaged in researches respecting these early voyages, announces that he has ascertained, from original documents, various facts previously unknown; among others, that America (first discovered in 985) was repeatedly visited by the Icelanders in the 11th, 12th, and 13th centuries; that the embouchure of the St Lawrence, and in particular the bay of Gaspe, was their principal station; that they had penetrated along the coast as far south as Carolina; and that they introduced a knowledge of Christianity among the natives. The announcement is contained in a letter addressed to a person in Washington, and published in Nile's *Register* (Baltimore), in November 1828. But M. Rafn has since found reason to change his opinion as to the site of the Icelandic colony; and he now considers that it was at the mouth of the River Taunton, which falls into the sea in Narragansit Bay, at the north end of Rhode Island.

of these countries was probably such as the announcement of a new island eastward of Spitzbergen would produce at the present day. No reasonable doubt can exist, however, that the north-eastern portions of America (considering Greenland as a distinct country) were familiarly known to the Norwegians in the eleventh century.

The obscure allusions of Aristotle, Plato, and Seneca, to a country hid in the Western Ocean, must have derived fresh importance from the discovery of the Canary Isles, Madeira, and the Azores, in the early part of the fifteenth century. The love of maritime adventure was excited by these events; and among the active spirits who were attracted to nautical life by the career of distinction which was then opened up, was Christopher Columbus. Our limits do not permit us to enter into details respecting this great man, an outline of whose life will be found under the proper head. Having received a learned education, the study of the geographical systems then in vogue impressed him with a strong conviction that a voyage to India by a course directly westward was quite practicable, with the degree of nautical science which his contemporaries possessed. From the old and imperfect maps of Ptolemy, he was led to believe that the parts of the globe known to the ancients embraced 15 hours, or 225 degrees of longitude, which exceeds the truth by more than one third. The discovery of the Azores on the west side had lengthened the space by one hour; and the accounts gleaned by Marco Polo in Asia, induced him to think that the isles connected with this continent stretched out so far to the eastward that their distance from Europe could not be great. Columbus was, however, without the fortune necessary to fit out ships; and when he attempted to interest some of the princes of those times in his project, he encountered neglects and difficulties which would have exhausted the patience of any mind less ardent than his own. At length, after many delays and discouragements, Ferdinand and Isabella of Spain supplied him with three small vessels, two of them only half-decked; and in this little armament, accompanied by 120 men, he set sail from the port of Palos on the 3d of August 1492. He proceeded first to the Canary Isles, where he was detained three weeks in repairing one of his vessels. On leaving these isles he entered on an unknown sea, where all was chaos and mystery. The trade-wind, however, bore him steadily along, and the labour of the ships proceeded cheerfully, till the increasing length of the voyage, the failure of prognostics which had from time to time kept alive the hopes of the crew, and various circumstances interpreted by their superstition as evil omens, produced a mutinous spirit, which all the address and authority of Columbus would not have been able to quell, had the discovery of land happened one day later than it did. Columbus, says Humboldt, on sailing westward of the merdian of the Azores, through an unexplored sea, sought the east of Asia by the western route, not as an adventurer, but according to a preconceived and stedfastly pursued plan. He had on board the sea chart which the Florentine astronomer, Toscanelli, had sent him in 1477. If he had followed the chart, he would have held a more northern course, along a parallel of latitude from Lisbon. Instead of this, in the hope of reaching Zipangu (Japan), he sailed for half the distance in the latitude of Gomera, one of the Canary Islands. Uneasy at not having discovered Zipangu, which, according to his reckoning, he should have met with 216 nautical miles more to the east, he after a long debate yielded to the opinion of Martin Alonzo Pinzon, and steered to the south-west. The effect of this change in his course curiously exemplifies the influence of small and apparently trivial events on the world's history. If Columbus, resisting the counsel of Pinzon, had kept his original route, he would have entered the warm current of the Gulf Stream, have reached Florida, and thence perhaps been carried to Cape Hatteras and Virginia. The result would probably have been, to give the present United States a Roman Catholic Spanish population, instead of a Protestant English one, a circumstance of immeasurable importance. Ponzen was guided in forming his opinion by a flight of parrots towards the south-west. Never, says the Prussian philosopher, had the flight of birds more important consequences. It may be said to have determined the first settlements on the new continent, and its distribution between the Latin and Germanic races. It was on the 12th of October that the western world revealed itself to the wondering eyes of Columbus and his companions. What a triumph for this extraordinary man, who had treasured in his breast for twenty years, amidst neglect, discouragement, and ridicule, the grand truth, which his own incomparable skill, wisdom, and firmness, had now demonstrated in the eyes of an incredulous world! The spot which he first touched was Guanahani, or San Salvador, one of the Bahama Islands, 3650 English miles from Teneriffe. After spending nearly three months in visiting Cuba, Hispaniola, and other isles, he returned to Spain. He made three other voyages, and in the second coasted along a part of South America, which he rightly judged to be a continent, from the volume of water poured into the sea by the Orinoco; but he died ignorant of the real extent and grandeur of his discoveries, still believing that the countries he had made known to Europe belonged to that part of Eastern Asia which the ancients called India. Hence the name of West Indies, which the tropical islands and part of the continent have ever since received.

Discoveries and colonies.

We should extend this article to an unreasonable length were we to describe in detail the discoveries and settlements made by the several nations of Europe in America. We shall therefore confine ourselves to a very brief chronological notice of the more important events.

1495. The first place in which the Spaniards established their power was the large island of Hayti or Hispaniola, which was inhabited by a numerous race of Indians, of a mild and gentle character, a third part of whom are said to have perished within two or three years after the Spaniards conquered them.

1497. John Cabot, in the service of Henry VII. of England, discovered Newfoundland, and coasted along the shores of North America to Florida.

1500. Cabral, a Portuguese, visited the coast of Brazil, and discovered the mouth of the Amazon. It was probably colonised before 1515, as the first cargo of wood was sent from it to Portugal in that year.

1508. Vincent Pinzon is said to have entered the Rio de la Plata. It was in the same year that the Spaniards, finding the aborigines too weak for the labour of the mines in Hayti, first imported negroes from Guinea, and thus laid the foundation of a traffic which continues to this day to disgrace the civilisation of Europe.

1511. Diego Columbus conquered the island of Cuba, with 300 soldiers, of whom he did not lose one.

1513. Balboa crossed the isthmus of Darien with 290 men, and discovered the South Sea.

1519. Hernando Cortes sailed from Cuba with 11 ships and 550 men, and landed on the coast of Mexico, which had been discovered in the previous year. The conquest of the empire was finished in 1521 by 950 Spaniards, assisted by a vast number of the Indians of Tlascala.

1531. Peru invaded by Pizarro, and conquered in little more than one year, with a force of 1000 men.

1534. James Cartier, a Frenchman, discovers the Gulf of St Lawrence.

1535. Mendoza, a Spaniard, with 2000 followers, founds Buenos Ayres, and conquers all the country as far as

Colonies

Potosi, at which silver mines were discovered nine years after.

1537. Cortes discovers California.

1541. Chili conquered; Santiago founded; Orellana sails down the Amazon to the Atlantic from the sources of the Rio Napo.

1578. New Albion on the north-west coast of America discovered by Sir Francis Drake.

1586. The Spaniards found St Thomas's Island, in Guiana.

1587. Davis' Straits and Cumberland Islands discovered by John Davis.

1604. De Monts, a Frenchman, founded the first settlement in Nova Scotia, then called Acadie.

1607. After many ineffectual attempts during more than twenty years, the first permanent settlement of the English in North America was made this year, on the banks of James' River, in Virginia.

1608. Quebec founded by the French, who had had a small neglected colony in Canada since 1542.

1611. Newfoundland colonized by the English; a Dutch colony established at Hudson's River. New York was founded in 1614.

1618. Baffin penetrates to the 78th degree of latitude, in the bay which bears his name.

1620. The first English colony established in New England at Plymouth. It was in this year that the first negroes were imported into Virginia. They were brought by a Dutch vessel.

1635. A French colony established in Guiana.

1655. Jamaica conquered by the English.

1664. The Dutch colonies on Hudson's River capitulate to the English.

1666. The Buccaneers begin their depredations on the Spanish colonies.

1682. William Penn establishes a colony in Pennsylvania. La Salle takes possession of Louisiana, in the name of the French king.

1698. A colony of 1200 Scots planted at Darien, and ruined in the following year, in consequence of the miserable jealousy of the English.

1733. Georgia colonized by the English.

1760. Canada, and all the other French settlements in North America, conquered by the English.

We must pause at this point to give a very short account of the colonial system introduced by the principal European nations who occupied extensive tracts of the new world. The English settlements extended from the 31st to the 50th degree on the east coast, and were divided into 15 or 16 provinces. The colonists had carried the love of liberty characteristic of their countrymen with them; and after many struggles with their British rulers, all the provinces, with one or two exceptions, were permitted to enjoy a form of government extremely popular. The executive power was vested in a governor appointed by the king. He was assisted by a council, which sometimes conjoined the functions of a privy council and a house of peers. The people were represented by a house of assembly, consisting of persons chosen by the freeholders in the country parts, and the householders or corporations of towns. The governor could levy no money without the consent of the house of assembly: the British parliament, however, claimed, but scarcely ever exercised, the privilege of imposing taxes upon the colonists, without consulting them. Against this assumption of power the local legislatures always protested as an infringement of their rights. The vessels of foreign states were not permitted to trade with the colonies; but the colonists were allowed to trade in their own ships with one another, with the mother country, and, to a limited extent, with foreign states. Their taxes, which were always small, were all consumed in defraying internal expenses; and, compared with any other people in the new world, they enjoyed an unexampled degree of commercial and political liberty. It was the growing prosperity of the colonies, and the increasing debt of the mother country, which induced the British ministers, for the first time, in 1764, to attempt raising a revenue in America, for purposes not colonial. The experiment was made by imposing a stamp-duty on newspapers and commercial writings. The sum was trifling; but the Americans, long-sighted and jealous of their rights, saw in it the introduction of a principle which deprived them of all security for their property. The people declared themselves against it as one man, in local assemblies, and by petitions and publications of all kinds. The ministers became uneasy, and repealed the tax; but, as a salvo to the pride of the mother country, a declaratory act was passed, asserting her right "to bind the colonies in all cases whatsoever." The idea of raising a revenue in America was not renounced, but another mode was to be tried. Duties were laid on glass, colours, paper, and tea, and were met by an opposition in the colonies still more zealous and determined. The British ministers, irritated, but wavering in their purpose, dropped all the taxes but that on tea, and commenced at the same time a series of alarming innovations. They closed the port of Boston, changed the charter of the province, placed judges and juries on a footing to render them more subservient to the views of the government, and introduced a strong military force to overawe the people. On the other side, the colonists passed resolutions not to import or consume any British goods, and hastened to supply themselves with powder and arms. Blood was at length drawn in April 1775, at the village of Lexington; and in the following year the American congress published their celebrated declaration of independence. We shall not enter into the details of the war, which was closed in 1782. Suffice it to say, that, on the part of the Americans, it rested on high grounds; it was a war to vindicate a principle—for the practical grievance was admitted to be slight; and it was conducted with a regard to humanity, of which there are few examples in history.

British colonies.

Spanish colonies.

The Spanish possessions in America, before the revolution, formed nine distinct governments, all constructed on the same plan, and independent of one another. Four of these, of the first rank, were vice-royalties, viz. Mexico, Peru, La Plata, and New Granada; and five were captain-generalships, viz. Yucatan, Guatemala, Chili, Venezuela, and the island of Cuba. The government was vested in the viceroy or captain-general, who was held to represent the king, and to enjoy all his prerogatives within the colony. But in these countries, as in others where the supreme power is apparently unlimited, it was indirectly restrained by the influence of the courts of justice, corporations, and other public bodies. The royal audiencias or supreme courts, consisting of Spaniards nominated by the crown, had extensive judicial powers, and were independent of the viceroys. The cabildos or municipalities, and the fueros or corporations (similar to our guilds), also possessed considerable privileges, which derived security and importance from long prescription. Lastly, the clergy, who were numerous and rich, necessarily possessed great influence among a superstitious people. The vices inherent in the colonial system existed in their utmost rankness in the Spanish American dominions. There was tolerable security for all classes except the miserable Indians, who were regarded and

Colonies.

treated precisely as beasts of burden, out of whose toil and sufferings a provision as ample as possible was to be extracted, first to supply the wants of the royal treasury, and next to feed in idleness, and to satisfy the cupidity of a countless shoal of public officers and priests. Edicts were indeed issued for the protection of the Indians, and persons appointed to enforce them; but these were feeble correctives to the evils rooted in the system, and not unfrequently increased their weight. The Indians, after the conquest, were at first slaves; they paid a capitation tax to the crown, and their labour was entirely at the disposal of their lord. This system was modified from time to time; but all the changes introduced down to the revolution did not release them from their state of vassalage. They still continued subject, in a less or greater degree, to the performance of compulsory labour, under the orders of persons over whom they had no control. This was an enormous grievance; but, what was equally bad, being held incompetent in law to buy or sell, or enter into any pecuniary engagement beyond the value of a few shillings, without the agency of white men, the swarm of public functionaries had an unlimited power of interfering in their concerns, of vexing, harassing, and plundering them, under the forms of law. The memoir of Ulloa, long buried amidst the Spanish archives, with various other documents published since the revolution, depicts acts of extortion, perfidy, cruelty, and oppression practised upon the Indians which have rarely been paralleled. Men rose to affluence in offices without salaries; and the priests rivalled the laymen in the art of extracting money from those whom they ought to have protected. As the sole aim of the Spaniards in the colonies was to enrich themselves, so the government at home made all its acts and regulations subordinate to the grand object of raising a revenue. Spain retained in her hands the whole trade of the colonies, and guarded her monopoly with the most severe penalties. The price of all European commodities was enhanced three, four, or six fold, in America. The colonists were not allowed to manufacture or raise any article which the mother country could supply; they were compelled to root up their vines and olives; and for a long period one colony was not even permitted to send a ship to another. To support such a system it was necessary to keep the people in profound ignorance, and to cherish prejudices and superstition. The schools were extremely few, and permission to establish them was often refused, even in towns where the Spaniards and Creoles were numerous. The importation of books, except books of Catholic devotion, was rigorously prohibited. Even the more grave and dry sciences, such as botany, chemistry, and geometry, were objects of suspicion. And the more effectually to crush all mental activity, natives of America could rarely obtain leave to go abroad, to seek in foreign countries what was denied them in their own. On the other hand the priests, sharing in the spoil, filled the minds of the people with childish superstitions, as a means of confirming their own power; and employed the terrors of religion to teach them patience under oppression. To create a race of servants devoted to its purposes, the court bestowed all offices, from the highest to the lowest, on natives of the peninsula exclusively. The wisdom of the plan seems questionable; but that it was adhered to with wonderful pertinacity is certain. "It was the darling policy of Spain," says Mr Ward, "to disseminate through her American dominions a class of men distinct from the people in feelings, habits, and interests, taught to consider themselves as a privileged *caste*, and to regard their own existence as intimately connected with that of the system of which they were the principal support." With all those means and appliances, it is extraordinary that Spain should have been able to uphold, for three centuries, a system in which the interests of so many millions of human beings were so habitually and unrelentingly sacrificed. It was the course of events, much more than its own inherent weakness, which ultimately caused its subversion.[1]

Revolutions.

Revolution in Chili and La Plata.

After the seizure of Ferdinand, and the elevation of Joseph Buonaparte to the throne of Spain, orders were dispatched to all the colonies with the view of securing their obedience to the new dynasty. The men in office were generally disposed to submit, but the treacherous conduct of the French excited a universal hatred of their cause among the people; and when the regency established in Spain presented the semblance of a patriot government, the loyalty of the Americans blazed forth, and poured large contributions of money into the hands of Ferdinand's adherents. The weak and suspicious conduct of the regency, however, and its subserviency to the grasping spirit of the merchants of Cadiz, at length alienated the colonists, and roused them to take measures for their own security. But the diversity of views and interests among the colonists rendered the course to be adopted a matter of some delicacy. Ferdinand, being a prisoner, was, politically speaking, a nonentity. Napoleon's brother was clearly an usurper, odious to, and rejected by, the mass of the Spanish people. The regency, shut up in Cadiz, without troops or revenue, was but a phantom; and the little power it had was so employed as to raise doubts whether its members were not secretly in league with the enemy. In these circumstances, when the only government to which the colonists owed allegiance had fallen into abeyance, the wisest course they could have pursued was to declare themselves independent. This would at once put a stop to the machinations of France, which they dreaded, and prevent the regency from compromising or sacrificing their interests by its weakness or treachery. The Spaniards, however, who occupied all public situations, were averse to a change which they foresaw must lead to the downfall of their power. This was perfectly understood by the other classes; and in the first movements which took place in the different colonies, nothing was said derogatory to the supremacy of Spain, though independence was clearly aimed at. By spontaneous efforts of the people "juntas of government" were formed, at Caraccas in April 1809, at La Paz in Upper Peru in July, at Quito in August, at Santa Fe and at Buenos Ayres in May 1810, and at Santiago in Chili in September the same year. In 1810, also, the first insurrection broke out in Mexico. The colonists unluckily had been too long the slaves of superstition and tyranny to be fit for conducting so bold an experiment; and after a struggle, which was generally short, but almost everywhere bloody, the juntas were all put down except in Colombia and Buenos Ayres. But in the stir and tumult of the contest, old prejudices had received a shock, and the seeds of political change had struck their roots too deep in the soil to be eradicated. A desultory war was carried on for six years between Buenos Ayres and Upper Peru, with little advantage on either side. At length, in 1817, the former state, which had assumed the style of an independent republic four years before, sent an army across the Andes to Chili, under General San Martin, and

[1] *Mexico*, by H. G. Ward, Esq. vol. i. chap. i. 2d edition. *Memoirs of General Miller*, vol. i. chap. i. 1828.

Revolutions.

defeated the Spaniards at Chacabuco. A second victory, gained at Maipo in April 1818, led to the entire subversion of the Spanish power in this colony. The war was now transferred to Peru, where the Spaniards continued to lose ground, till the decisive battle of Ayacucho put an end to their power in December 1824. Rodil and Olaveta, with the obstinacy of their nation, held out for some months longer, when every chance of success was gone; but after the surrender of Callao in January 1826, the Spanish flag no longer waved on any spot in the land of the Incas.

Colombia.

In New Granada and Venezuela the struggle was more bloody, variable, and protracted than in any other part of South America. As this portion of the dominions of Spain was comparatively easy of access, and from its central position was in some measure the key to the whole, she made immense efforts for its preservation. No less than ten thousand troops were sent out to it within the course of one year. The patriots, on the other hand, possessed advantages here, in the greater intelligence of the population, and the easy intercourse with the West Indies. From 1809, when juntas were established in Caraccas and Quito, to the surrender of Porto Cabello in 1823, the vicissitudes of the war were numerous and extraordinary. The patriots were repeatedly on the eve of a complete triumph, and as often the state of their affairs seemed nearly hopeless. But the spirit of resistance never was entirely subdued. The cause was rooted in the hearts of the people, and was insensibly gaining ground even during its reverses. To attempt the faintest outline of the military operations would lead us beyond our proper limits. It is enough to state, that the decisive victory of Carabobo, gained by the patriots in 1819, gave them an ascendency which they never afterwards lost; but the Spaniards, according to their custom, continued to maintain the contest as long as they had a foot of land in the country, and were only finally expelled in 1823.

Mexico.

In Mexico the revolutionary movement began at Dolores in 1810, and soon wore a very prosperous appearance; but the weakness or false pride of the Creoles, who were cajoled into the ranks of their oppressors the old Spaniards, armed against the patriots those who should have been their firmest supporters; and by one or two mischances, the force of the independent party was ruined in November 1815, when Morelos, their able leader, was taken prisoner and executed. For six years after this period many guerilla bands maintained themselves in the provinces, and greatly annoyed the Spaniards; but they did not act in concert, and no congress or junta professing to represent the Mexican people existed. Even during this interval the desire for independence was making great progress among the population; but the establishment of a constitutional government in Spain in 1820, and its extension to the colonies, gave a new aspect to the affairs of Mexico. The viceroy Apodaca, while outwardly yielding obedience to the new system, was silently taking measures to effect its overthrow; but mistaking the character of the agent he employed, this person, the celebrated Iturbide, turned his own arms against him, proclaimed a constitution, under the name of "the three guarantees," and put an end to the dominion of Spain in 1821, almost without bloodshed. Iturbide, who had nothing in view but his own aggrandizement, called a congress, which he soon dissolved, after getting himself proclaimed emperor. His usurpation kindled a spirit of resistance. He was exiled in 1823, made a new attempt on the liberties of his country in 1824, was taken prisoner, and expiated his crimes by a military death within a few weeks after he landed.[1]

Guatemala.

Guatemala was the last portion of the American continent which threw off the Spanish yoke. In 1821 the persons in office assembled and formed a junta. Divisions arose, which were fomented by the intrusion of a Mexican army sent by Iturbide. This force, however, was beaten, and an elective assembly called, which declared the country independent, and established a constitution in July 1823. Spain now retains none of her possessions in the new world but Cuba and Porto Rico.

Cruelty of the Spaniards.

It is impossible for any one to read the narrative of the wars produced by these revolutions, without having a conviction forced upon him, that the Spaniards rank far below all the Christian nations of Europe, not excepting the Russians, in those moral qualities which are the surest tests of civilisation, a respect for human life, and a strict regard to engagements, whether binding on the honour or the conscience. The executions in cold blood, the countless massacres, the treachery, perfidy, and contempt of the most solemn oaths and engagements, of which they were guilty, in every colony, and almost in every district, are, we believe, without a parallel in the modern civilized world, and strongly remind one of the barbarous and exterminating hostilities of the Jenghis Khans and Tamerlanes of Asia. The Indians were destroyed by thousands on the slightest provocation; and even the officers of European birth who fell into the hands of the Spaniards, were either shot or brutally treated, long after the period when any pretext existed for disregarding the rules of civilized war. More blood, we are satisfied, was shed by Morillo alone in one year, in the single state of Venezuela, than in the thirteen North American states during the seven years of their revolutionary struggle. The patriots, bred in the same school, were too often equally culpable. General Miller estimates the number of human beings destroyed by the sword in Spanish America between 1810 and 1825 at one million! This is probably an exaggeration; but it merits attention, as showing the opinion formed by an observer, who, though a partisan, is both candid and well informed.[2]

Brazil.

The government of Brazil was conducted by the Portuguese on a system extremely similar to that of the Spanish colonies. The monopoly which the mother country retained of the commerce of the colony was equally rigorous; the restrictions on its internal industry as severe; and the same means were employed to keep the people in a state of pupilage and ignorance. Down to 1806 a single printing press had never existed in Brazil. In 1807, when the emperor Napoleon had resolved to possess himself of Portugal, and if possible to get the royal family into his power, the king, seeing no other means of escaping from the clutches of his enemy, embarked with his suite in several ships, and sailed for Brazil, where he arrived in January 1808. He was received with joy by the colonists, who anticipated great benefits from his residence, of which they were not disappointed. One by one the fetters of colonial dependence fell off. Within a few months printing presses and newspapers were established, the ports were open to the trade of all

New States.

nations, and the people were invited and encouraged to prosecute all those branches of internal industry from which they had till now been interdicted. To crown and secure these advantages, Brazil was declared an independent kingdom in 1815, subject to the crown of Portugal, but entitled to its separate administration and its own laws. The revolutionary spirit pervading the Spanish colonies now found its way into Brazil, and produced an insurrection at Pernambuco in 1817. It was soon subdued, but received a new impulse from the constitutional systems suddenly introduced into Spain and Portugal in 1820. To quiet the popular feeling, it was announced that the Portuguese constitution would be extended to Brazil. Before this had been done, however, the old king had sailed for Europe, leaving his son Don Pedro to rule in his absence. The people now discovered, or believed, that the object of the king was to degrade Brazil again to the rank of a colony, and to restore the old system in all its rigour. Meetings were held and resolutions adopted, to maintain the independence of the country at all hazards; and the patriots, gaining confidence by degrees, called loudly for the establishment of a legislature, and besought Don Pedro to put himself at the head of the independent government. Ambition or policy induced Pedro to listen to the solicitation: in 1822 he was proclaimed emperor, and had his own title and the independence of Brazil acknowledged by his father three years afterwards. A representative system was at the same time introduced. An unlucky war now arose with Buenos Ayres, which weakened both countries; but it was at length terminated in 1828, by the recognition of the disputed territory as an independent state, under the title of the Banda Oriental.

Having finished this brief notice of the series of revolutions which broke the fetters of America, we shall now give a very short sketch of the new political order of things which has arisen out of these changes, referring for a detailed account of the several states to the articles appropriated to them in the different volumes of the present work.

America, with its isles, embraces at present (1853) twenty-two independent states, and various colonies belonging to seven European powers. The states are, 1. Brazil; 2. Venezuela; 3. New Granada; 4. Ecuador or Quito; 5. Peru; 6. Bolivia or Upper Peru; 7. Chili; 8. La Plata, or the Argentine Republic; 9. Uruguay; 10. Entre Rios; 11. Paraguay; 12. Patagonia; 13. Costa Rica; 14. Mosquitia; 15. Guatemala; 16. Honduras; 17. Nicaragua; 18. San Salvador; 19. Mexico; 20. United States; 21. Hayti; 22. Dominica. The colonies belong to Russia, Britain, Denmark, Sweden, Holland, France, and Spain. Patagonia is merely the geographical name of a district occupied by independent tribes of Indians; Mosquitia, or the Mosquito coast, is a small Indian state ruled by a native king; and Hayti is a Negro state ruled by a black emperor. For detailed accounts of these various states and colonies, we refer to the articles under the proper heads. At present, we must confine ourselves to a brief notice of the more important ones.

Brazil is the largest state in South America, and enjoys the greatest combination of natural advantages. It is bounded on the south, west, and north, by La Plata, Paraguay, Uruguay, Bolivia, Peru, Ecuador, New Granada, Venezuela, and Guiana. Embracing an area of 3,000,000 English miles, it is nearly as large as Europe, and is capable of supporting a much greater population. Its climate is probably cooler and more salubrious than that of any other extensive tropical country; and every part of its soil is rich and fruitful, as its magnificent forests and the exuberance and boundless variety of its vegetable productions attest. Its commercial advantages are admirable. No country in the new world has the same facilities for carrying on intercourse with Europe, and with all its neighbours. The Amazon, with its numerous branches, the Parana, the Tocantin, the St Francisco, and other streams, supply the most remote parts of the interior with easy means of communication with the sea. Brazil possesses iron, copper, and probably all the other metals; but her mines of gold and diamonds are remarkably rich. Her most valuable productions for exportation are, cotton, sugar, coffee, hides, tobacco, vanilla, dyewoods, aromatic plants, timber, &c. Her commerce is much greater than that of all the Spanish colonies put together. The Brazilians are lively, irritable, hospitable, but ignorant, superstitious, and rather inclined to indolence. Their recent acquisition of independence, however, has worked like a charm, and produced an extraordinary change in their industry, opinions, and modes of thinking. Lancasterian and other schools are spreading in all directions; the press brings forth new publications; and 25 journals existed in 1828, in a country where the art of printing was unknown in 1807. According to the constitution introduced by Don Pedro, the legislature consists of a senate of 52 members, who hold their places for life, and a house of representatives of 107, elected by the people for three years; upon the acts of both of which bodies the emperor has a negative. The members of the lower house are chosen by elections of two stages. The householders of a parish meet and appoint one elector for every hundred of their number, and the electors thus chosen meet in districts and choose the deputies. The debates are conducted with open doors, and with much boldness and freedom, according to Mr Walsh.

The population of Brazil amounted to 3,671,558, according to returns published in 1818, and procured probably for the purpose of taxation. This was exclusive of the wandering Indians. In 1823 it was estimated at 4,000,000 by Humboldt. M. Schœffer, a German, carries it to 5,700,000, but a more recent estimate (1848) reduces it to 5,000,000, including 3,500,000 slaves, and 500,000 free persons of colour, but excluding the savage tribes.

Brazil, unlike the Spanish American provinces, has remained subject to its ancient sovereign; and its government, from being colonial, has become imperial and independent, without any violent revolution. The result has been greatly in favour of the peace and prosperity of the country. See BRAZIL.

The portion of South America next to the isthmus includes the states of Venezuela, New Granada, and Ecuador. From 1820 it formed one state under the name of Colombia, till 1831, when a separation took place; but for the sake of brevity, we shall here speak of the three together. The territories of these three states are bounded on the south by Peru, on the south-east and east by Brazil and Guiana, on the other sides by the sea, and embrace an area of 1,020,000 square English miles. The soil is fruitful, and the climate salubrious, except along the coast and in a few other low situations. The eastern part consists chiefly of the llanos or steppes of the Orinoco, which are very hot; the western, of the mountain ridges of the Andes, which support tracts of table-land where the blessings of a temperate climate are enjoyed, and the cerealia of Europe can be successfully cultivated. The tropical vegetation extends to the height of 4000 feet; from 4000 to 9000 is the region where wheat, barley, and leguminous plants thrive. Above the level of 9000 feet the climate becomes severe; and at 15,700 feet vegetation ceases. The situation of New Granada is highly favourable for commerce. It has excellent ports on both seas; and being mistress of the isthmus of Panama, it has superior facilities for establishing a communication from the one to the other. The Orinoco and the Amazon afford the

New States.

inmost districts of Venezuela and Ecuador the advantages of water-carriage to the ocean. The Cassiquiari, an intermediate channel, by which the Orinoco *anastomoses* or connects with the Amazon (a remarkable hydrographical phenomenon), is within the limits of Venezuela. The territory contains much gold and silver; the former in alluvial deposits: it has mines of copper and mercury also, with platinum, iron, and coal. Its tropical productions are similar to those of Brazil; but it has as yet cultivated few articles for foreign markets, and its exports are inconsiderable. The civilised population of this country is chiefly located in the districts near the coast, and in the high valleys or table-land of the Andes. Its amount, according to the Almanac de Gotha, is,

| | |
|---|---|
| Venezuela | 986,000 |
| New Granada | 2,138,000 |
| Ecuador | 665,000 |
| | 3,789,000 |

It is always of importance to know in what proportions the different races are blended; but on this subject we have data only for New Granada, whose inhabitants are thus classified:

| | |
|---|---|
| Whites | 13 per cent. |
| Mestizoes (from whites and Indians) | 23 |
| Indians (civilised) | 26 |
| Mulattoes | 32 |
| Negroes, free or slaves | 5 |

The governments of all the three states are republican. See VENEZUELA, NEW GRANADA, and QUITO (or ECUADOR).

La Plata.

La Plata, or the Argentine Republic, is, in point of natural advantages, the second state of importance in South America. It is bounded on the west by Chili; on the north by Bolivia, Paraguay, Entre Rios, and Uruguay; on the east and south by the sea. It embraces an area of 950,000 square miles, if we include in its territories Tucuman, Salta, Santiago del Estero, and Jujuy, which scarcely acknowledge its authority. Nearly the whole territory of this republic consists of open plains destitute of timber, called *pampas*, extending from the Atlantic and the river Paraguay to the Andes. The eastern part of these plains exhibits a vigorous growth of herbage, intermixed with a forest of gigantic plants 9 or 10 feet high, which have been called thistles, but are now known to be artichokes: in the middle they are covered with grass; and the western division, which extends to the foot of the Andes, consists of barren sandy plains, thinly sprinkled with shrubs and thorny trees. The openness and dryness of the country, however, render it healthy; and by the Parana, the Paraguay, and their branches, it possesses a great extent of natural inland navigation. It has mines of gold, silver, copper, lead, and probably iron; but its mineral riches have been greatly diminished by the separation of Potosi, Cochabamba, La Paz, and other provinces, now forming part of Bolivia. The force of this republic lies almost entirely in the wealth, intelligence, and commercial spirit of its capital, Buenos Ayres, which contains 80,000 souls, including a large proportion of foreigners. A small number of *estancias*, or grazing farms, are sparingly diffused over its boundless plains, the proprietors of which keep multitudes of horses and mules, flocks of sheep, and vast herds of cattle; the latter being chiefly valued for their skins. These people are a bold, frank, hardy, half-civilised race, who live isolated in the wilderness, and scarcely acknowledge any government. Since the separation of Bolivia, the population probably does not exceed 750,000. See PLATA, LA; and for the three small states formed out of the north-eastern portion of its territory, see PARAGUAY, ENTRE RIOS, and URUGUAY.

Chili.

Chili extends along the coast of the Pacific, from 25° to 44° of south latitude: its length is 1300 miles; its breadth varies from 30 to 120; and its surface, exclusive of Araucania and the district beyond the 44th parallel, is 66,960 square miles, according to Mr Miers. The country consists properly of the western slope or declivity of the Andes; for the branches of the mountains, running out in tortuous directions from the main trunk, reach to the sea-shore. It enjoys an excellent and healthful climate; severe cold is unknown in the inhabited parts, and the heat is seldom excessive. The useful soil bears a small proportion to the entire surface of the country, consisting merely of the bottom of the valleys. It has rich mines of gold, silver, and copper in the northern provinces; but very few of them can be worked, in consequence of the absolute sterility of the adjacent country. Its two northern provinces, occupying 450 miles of the coast, are nearly perfect deserts. The soil continues extremely dry, and yields nothing without irrigation, till we reach the latitude of 35°; and it is believed that not one-fiftieth part of the country is fit for cultivation. But south of the river Maule the land is covered with fine timber, and bears crops of wheat and other grain, without the aid of any other moisture than what is supplied by the atmosphere. This is in truth the fine and fruitful part of Chili; and the project was once entertained of selecting its chief town, Conception, for the seat of the government. Chili has no manufactures, and is unfavourably situated for commerce. It has no navigable rivers, while its mountainous surface is an obstacle to the formation of roads; and its communications with all other parts of the world are circuitous and difficult. A representative constitution was established in Chili in 1823. An enumeration dated 1844 makes the population 1,080,000. See CHILI.

Peru.

Peru is a continuation of the country which forms Chili, consisting of the western declivities of the Andes, from the 4th to the 22d degree of south latitude, with the addition of a considerable tract on the east side of the mountains, between the 4th and 15th parallels. There are few countries in the world which have a more singular physical character than the western part of Peru. It is a belt or zone of sands, 1700 miles in length, and from 7 to 50 in breadth, with inequalities of surface which might be called mountains, if they were not seen in connection with the stupendous back ground of the Andes. This long line of desert is intersected by rivers and streams, which are seldom less than 20 or more than 80 miles apart, and on the sides of which narrow strips of productive soil are created by means of irrigation. These isolated valleys form the whole habitable country. Some of the large rivers reach the sea; the smaller are either consumed in irrigating the patches of cultivated land, or absorbed by the encompassing desert, where it never rains, where neither beast nor bird lives, and a blade of vegetation never grew. No stranger can travel from one of these valleys to another without a guide, for the desert is trackless; and the only indications of a route are an occasional cluster of bones, the remains of beasts of burden that have perished. Even experienced guides, who regulate their course by the stars, the sun, or the direction of the wind, sometimes lose their path, and they almost inevitably perish. Of a party of 300 soldiers thrown ashore by a shipwreck in 1823 on one of these desert spaces, nearly a hundred expired before they reached the nearest valley. Ignorance and wonder have been busy with this singular region: legends are current, which tell that descendants of the ancient Peruvians have lived in some of these mysterious valleys, hid from the knowledge of their merciless invaders, since the days of the Incas. We have no reason to believe that more than one acre in a hundred of maritime Peru will ever be available for the sustenance of mankind. The country has two advantages—its mines of the precious metals, and a temperate and delightful climate, in consequence of the absence of rain,

New States.

and the fogs which intercept the solar heat. It can never be rich in the proper sense of the term, or make much progress in the improvements which depend upon a dense population. Like Chili, it has no navigable rivers—and nature has deprived it of the means of forming good roads. There are indeed few countries in the world whose natural advantages have been so much overrated as Peru; and it requires little sagacity to discover that its future career cannot correspond with its past celebrity. The districts east of the Andes, which have a hot climate, accompanied with a rich soil, will ultimately be the most valuable part of the country; but their secluded situation, and want of communication with other countries, must keep them long in a backward state. The government is republican. Peru comprehends a surface of 350,000 square miles; the capital, Lima, contains 70,000 inhabitants; and the entire population of the state is given as under by General Miller:—

| | |
|---|---|
| Whites | 240,819 |
| Indians | 998,846 |
| Mestizoes | 383,782 |
| Free Mulattoes | 69,848 |
| Slaves | 43,628 |
| | 1,736,923 |

A more recent account makes it 1,374,000. See PERU.

Bolivia.

Bolivia, or Upper Peru, lies eastward of Lower Peru, and is bounded on the south by the Argentine Republic, and on north and east by Brazil. It is of an irregular form, and comprehends a space of 480,000 square miles. The climate is pleasant and healthful, the soil is generally dry, and in the eastern parts, as well as the elevated table-land, its aridity produces barrenness. Nature, however, as a compensation for its other disadvantages, has bestowed upon it some of the richest mines in the world. The country was erected into an independent state only in 1825, and named Bolivia in honour of its liberator Bolivar. It has a small strip of barren territory on the shores of the Pacific Ocean, between the 22d and 25th parallel; but it is, properly speaking, entirely an inland country, and more deficient in the means of communicating with foreign nations than any other state in America. See BOLIVIA.

Guatemala.

Guatemala or "Central America" originally occupied all the narrow part of the continent, from the 83d to the 94th degree of west longitude, extending 800 miles in length, and covering a space of 130,000 square miles. The surface of the country is hilly, and in most parts mountainous; the climate warm and very moist. The mineral wealth of the country is not great; but this is compensated by the richness of its soil, and its excellent commercial position. It was a federal republic, but its five provinces have now become independent states. Humboldt estimated the population of the five states at 1,600,000. According to a statement furnished to Mr Thomson, a former British envoy, by the government, it was 2,000,000; while Mr John Baily, whose work on "Central America" was published in 1850, reduces it to 1,437,000, viz.:—

| | |
|---|---|
| Guatemala | 600,000 |
| St Salvador | 280,000 |
| Honduras | 236,000 |
| Nicaragua | 226,000 |
| Costa Rica | 95,000 |
| | 1,437,000 |

The proportions of the different races have been estimated as follows:—

| | Humboldt. | Thomson. |
|---|---|---|
| Whites and Creoles | 20 | 20 |
| Mixed classes | 28 | 40 |
| Indians | 52 | 40 |

Mexico.

Mexico is the most populous and powerful of all the new states erected in America since the commencement of the present century. Previous to the late war with the United States it embraced an area of 1,600,000 square miles, which was reduced to 1,000,000 by the cession of the northern provinces in 1848. About three-fourths of the surface consists either of mountains or table-land, raised from 5000 to 10,000 feet above the sea. Owing to this extraordinary elevation, even those parts of the country which lie within the torrid zone (the low ground on the coast excepted) enjoy a dry, cool, and salubrious atmosphere; but this advantage is counterbalanced by the insufficient supply of moisture, and the rapid evaporation resulting from the same cause, which render the soil generally rather arid, and in many parts absolutely barren; by the smallness of the rivers, and the almost entire absence of inland navigation; and by the obstacles which the steep and rugged ascents from the coast present to land-carriage. The republic is besides almost destitute of ports on the Atlantic side. Mexico is extremely rich in the precious metals; and there are few regions upon which nature has lavished so great a variety of vegetable productions, or where plants fitted to the coldest and the hottest climates may be seen so nearly in juxtaposition. The low ground on the east coast is admirably calculated for raising sugar; and no country is more favourably situated for growing the other great articles of West India produce: coffee, cotton, cocoa, indigo, and tobacco. The raising of *bread-stuffs*, as they are termed by the Anglo-Americans, wheat, maize, and barley, with potatoes, the cassava root, beans, pumpkins, fruit, &c., for domestic consumption, will necessarily be the chief branch of industry on the table-lands. The mines have never employed above 30,000 labourers; and their superior productiveness depends chiefly on two circumstances—the great abundance of the ore, which is only of poor quality, and the comparative facility with which they can be worked, owing to their being generally situated in fertile districts, where, provisions, wood, and all materials can be easily procured.

Mexico has her full share of the ignorance and superstition which belonged to Old Spain; and these evils, with her internal dissensions, and her rapacious, immoral, and intolerant clergy, are great obstacles to her improvement. That excessive inequality of fortune which corrupts both extremes of society was nowhere in the world more prevalent than in Mexico. Individual proprietors possessed immense tracts of land and boundless wealth, while all the great towns swarmed with beggars, and thousands fell a sacrifice to famine from time to time. The Mexican constitution, which is federal, and almost a literal copy of that of the United States, was established in 1824. The distinction of *castes*, which was maintained in the greatest rigour under the colonial system, has now disappeared, and power and office are open, not only legally but practically, to men of all colours. The African blacks formed an extremely small proportion of the Mexican population at all times; and since the revolution slavery has ceased. The number of inhabitants was estimated at 6,800,000 by Humboldt in 1823, and classed as follows:—

| | Numbers. | Proportions. |
|---|---|---|
| Whites | 1,230,000 | 29 per cent. |
| Mixed races | 1,860,000 | 27 |
| Indians | 3,710,000 | 54 |

Mr Ward states that very few of the whites, so called, are free of a mixture of Indian blood; and now when the odious distinctions founded on complexion are abolished, they readily acknowledge it. Mr Ward estimated the population at 8,000,000 in 1827, and, since the loss of the northern provinces, we find it put down at 7,200,000. See MEXICO.

Mines.

We have said nothing respecting the produce of the gold

New States.

and silver mines in the different parts of America, because our object was to bring the information on this subject into one short general statement. The following table, given by Humboldt, exhibits the average produce of all the gold and silver mines in the new world about 1803.

| | Pure gold marks. | Pure silver marks. | Value of both in dollars. |
|---|---|---|---|
| Mexico | 7,000 | 2,338,220 | 23,000,000 |
| Peru | 3,400 | 611,090 | 6,240,000 |
| Chili | 12,212 | 29,700 | 2,060,000 |
| La Plata | 2,200 | 481,830 | 4,850,000 |
| Colombia (New Granada) | 20,505 | | 2,990,000 |
| Brazil | 29,900 | | 4,360,000 |
| | 75,217 | 3,460,840 | 43,500,000 |
| In English money | | | L.8,700,000 |

The Spanish mark, in which the quantity is expressed in the first two columns, is valued at 145·82 dollars in gold, and at 9·4 dollars in silver. This branch of industry has been injured more deeply than any other during the late wars. The great exertions required to maintain the mines free of water, the amount of capital necessary to keep them working, and the facility with which violent hands could be laid upon their produce, all rendered these establishments extremely liable to suffer from domestic convulsions. Mr Ward computes, that in the 15 years between 1810 and 1825, the annual produce of the Mexican mines did not exceed 10,000,000 of dollars, or about *two-fifths* of their average annual produce during the 15 years preceding. In Brazil, the washings have probably experienced no interruption. Humboldt computes the whole produce of the American mines from 1492 to 1803 to be 5,706,000,000 dollars, or L.1,255,000,000, of which only 4½ per cent. was retained in America, and 5,445,000,000 dollars (L.1,197,900,000), or 95½ per cent., was remitted to Europe.

A great auriferous deposit was discovered in Upper California in the end of 1847, just before its formal cession to the United States. It is situated in the valley of the Sacramento River, and its principal branch the Joaquin, and is believed to extend over a range of country 200 miles in length or more. The gold is found in its virgin state in small grains, in three different situations; *firstly*, in sand and gravel beds; *secondly*, among decomposed or disintegrated granite; and *thirdly*, intermixed with a friable talcose slate standing in vertical strata, and containing white quartz, interlaminated or in veins. The largest pieces of gold are found in and near the talcose slate rocks, over which the streams flow; but the finer particles and scales have been carried down by the water to the lowest part of the valleys. It was known before that gold existed in the country; but the wonderful richness of the deposit was only discovered in 1847, in making a mill-race on American Fork, a small branch of the Sacramento. It soon became widely known, and attracted multitudes of persons, first from the neighbouring districts, and by and by from all parts of the world. The population, which was estimated at 15,000 in 1848, had increased to 92,000 in 1850, and in December 1852 was found to be 305,000. As to the produce of the Californian "diggings," we find that an officer of the United States Treasury department estimated the value of the gold obtained down to the commencement of 1852 at 150,000,000 dollars, or L.30,000,000, and the annual produce 64,500,000 dollars, or about L.13,000,000, but for 1852 it was expected to be L.15,000,000. The annual supply of the precious metals from the new world appears therefore to have been nearly doubled by the Californian "diggings."

The estimate just mentioned forms part of a statement prepared by an officer of the Treasury at Washington, in answer to a demi-official inquiry as to the total produce of the gold and silver mines of the world (except Australia) since 1492. It forms a proper supplement to Humboldt's tables.[1]

*Estimate of the precious metals from* 1492 *to* 1852.

| | | |
|---|---|---|
| America, exclusive of the United States | | $6,877,833,800 |
| California, received at Mint | $98,408,000 | |
| California, foreign exports, manufactured, &c. | 51,592,000 | |
| Other United States gold at Mint | 15,855,000 | |
| Ditto not brought to Mint | 1,145,000 | |
| Total United States | | 167,000,000 |
| Total America | | $7,044,833,800 |
| Europe and Asia, exclusive of Russia | | 1,755,000,000 |
| Russia | | 213,581,000 |
| Total production, 1492 to 1852 | | $9,013,414,800 |
| In English money | | L.1,800,000,000 |

The present annual product of the precious metals, the writer estimates as follows:—

| | |
|---|---|
| All South America | $30,710,000 |
| Add for any probable increase, according to the best authorities | 3,290,000 |
| Hungary, Saxony, and Northern Asia | 4,000,000 |
| Russia, at the highest estimate of late years | 20,000,000 |
| Africa and South Asia (a rough estimate) | 1,000,000 |
| Carolina, Georgia, &c. | 500,000 |
| California | 64,500,000 |
| Total | $124,000,000 |
| In English money | L.24,800,000 |

United States.

The United States were colonised a century later than Spanish America; but their brilliant and rapid progress shows in a striking light how much more the prosperity of nations depends on *moral* than on *physical* advantages. The North Americans had no gold mines, and a territory of only indifferent fertility, covered with impenetrable woods; but they brought with them intelligence, industry, a love of freedom, habits of order, and a pure and severe morality. Armed with these gifts of the soul, they have converted the wilderness into a land teeming with life, and smiling with plenty; and they have built up a social system so pre-eminently calculated to promote the happiness and moral improvement of mankind, that it has truly become the "envy of nations." The republic is bounded on the north by Canada, on the south-west by Mexico, and on the other sides by the sea or the Indian lands. It now consists of thirty-two sovereign states, and of three *territories*, which will be converted into *states* as soon as each acquires a population of 60,000 souls. The extent of the country, if we include the Indian lands stretching west to the Pacific Ocean, over which it claims a right of pre-emption, embraces an area of 3,260,000 square miles. The agriculture of the United States partakes to some extent of a tropical character. The sugar-cane is cultivated in Louisiana, Florida, and other states, as high as the latitude of 31½°. Cotton is raised in all the southern states within the 37th parallel, and tobacco

[2] Hunt's *Commercial Magazine* (New York) for 1852, p. 91.

New States. in those within the 41st. Wheat succeeds in the middle and northern states, and maize thrives in every part of the union. Agriculture is conducted with considerable skill; but the "high farming" practised in England would not pay in America, where money is of much value, and land of little. Scarcely any portion of the soil is rented in the United States: the farmers are almost universally proprietors; and when their property is extensive, which rarely happens, it is soon broken into small occupancies, under the law of equal division. The Americans are making considerable progress in manufactures, particularly in those of cotton. The mechanical skill which has been developed in England, by centuries of progressive industry, is rapidly transplanted to the United States by crowds of emigrants; while the increasing use of machinery is depriving England of the superiority derived from her cheap labour. In the useful arts generally America is on a level with France and England; in the fine arts and the sciences she is much behind. The internal commerce of the United States is conducted with extraordinary spirit. The capital expended on roads, canals, harbours, bridges, and other public works, appears scarcely credible to those who reflect on the short term of the republic's existence. The extent of her foreign trade and the amount of her shipping, place her next to Great Britain on the list of commercial nations.

| | |
|---|---|
| The population of the United States in 1850 was by census | 23,191,000 |
| In 1800 it was | 5,306,000 |
| Increase in 50 years | 17,885,000 |

If the rate had been uniform for the half century, the annual increase must have been 2·996 per cent.; but at present (1852) the immigrants from foreign countries amount to fully 300,000, or three-sevenths of the annual increase, only the other four-sevenths being due to the natural growth of the population. The whites numbered 19,557,271 in the census; the free coloured population 429,710; and the slaves 3,204,093.

In Florida and South Carolina the slaves are rather more numerous than the whites, but they are less numerous in the other states. Slavery does not exist in the states of Maine, Massachusetts, New Hampshire, Vermont, Rhode Island, Connecticut, New York, Pennsylvania, New Jersey, Indiana, Illinois, Ohio, Wisconsin, Iowa, and California; and it is verging towards extinction in Delaware and Maryland. The slaves multiply as fast as the whites, a proof that their treatment is incomparably more mild than in the West Indies, where their numbers constantly diminish.

The American government is a pure representative democracy, in which the people are recognised as the fountain of all power; and the sole object of all its mechanism is to give effect to their deliberate opinions. The federal and state governments are constituted on the same plan. The legislature consists in every case of two bodies, a house of representatives chosen for one or two years, and a senate for a period varying from two years to six; but both always by popular election, except in the case of the federal senate, which is chosen by the legislatures of the twenty-four states. The president holds his office for four years, but is occasionally re-elected for four years more. While the politicians of Europe, bred in the schools of monarchy and aristocracy, have been predicting anarchy and confusion as the result of these republican institutions, their solid excellence has been quietly developing itself, in the cheering spectacle which the United States present of perfect order, security, and contentment, combined with growing intelligence, prosperity, and unrivalled liberty.

There is no national church in America, and yet religion is in a flourishing condition in all the populous parts of the country. The most numerous denominations are, the Presbyterians, Independents, Baptists, and Methodists.

The characteristic facts in the condition of America are, the non-existence of titles, of privileged classes, of corporations in our sense of the term, of a landed aristocracy, of mendicity except to a very limited extent, and of an endowed church; the cheapness and efficiency of its government, the universality of education, the omnipresence of its periodical press, the high feeling of self-respect which exists in the very humblest classes, and the boundless spirit of enterprise which pervades society from top to bottom. The higher classes are less polished than in England, the middle are perhaps less carefully instructed; but the American people, taken collectively, are better educated, and have more intelligence and manliness of character, than any other nation in the world. The master evils of the republic are its insecure and ever fluctuating paper currency, and the negro slavery, which blackens and benumbs all the southern states.

British America. The portion of the American continent claimed by the British is bounded on the south by the territories of the United States, on the north by the Polar Sea, on the west by the Russian territories, from which it is divided by the meridian of 141° west. It contains an area of 2,600,000 square miles, of which about one-half may be habitable, and one-seventh part tolerably fertile; but the districts which have been marked out into counties or townships, and in which settlements are begun, form a very small portion of this immense region. Of these the latest return (1851) is as follows:—

| | Area, square miles. | Population. |
|---|---|---|
| Lower Canada | 250,000 | 904,000 |
| Upper Canada | 105,000 | 952,000 |
| New Brunswick | 27,700 | 211,473 |
| Nova Scotia / Cape Britain | 18,742 | 276,117 |
| Prince Edward's Island | 2,134 | 62,348 |
| Newfoundland | 35,913 | 100,000 |
| Vancouver | 16,000 | 11,463 |
| | 455,493 | 2,517,401 |

See Canada, &c.

Russian America. Russian America comprises the north-west angle of the continent, as far as the 141st meridian west from London, with a narrow strip of coast reaching as far south as $55\frac{1}{2}$° of north latitude. It occupies a surface of about 500,000 square miles, of which the useful soil probably does not constitute a tenth part. The Russians have merely a number of posts or factories stationed along the coast for conducting the trade in furs, which gives these possessions their only value. New Archangel, in latitude 57·3° and longitude 135·20° west, is the head establishment. It is a fortress, with a small garrison and 40 pieces of cannon. Owing to the rigour of the climate, this portion of America can never support more than a very limited population.

Hayti. Hayti, called formerly Hispaniola and St Domingo, was a colony belonging partly to France and partly to Spain, till 1791, when the blacks rose in arms, killed a number of whites and expelled the rest. The attempt of England in 1793, and of France in 1801, to conquer the island, both failed, and Hayti has at length been acknowledged as an independent state by all the great powers, including France. The island, which contains about 26,000 square miles, is remarkably fertile; but its climate, like that of the West Indies generally, is rather unhealthful. The population, Colonies.

which before the revolution was estimated at 600,000, is now said to amount to 900,000 or 1,000,000, and it is almost entirely composed of blacks and mulattoes. The island formed one state till 1843, when the eastern or Spanish portion revolted, and established its independence. It is now (1852) the republic of "Dominica," ruled by a president, while the western portion, retaining the name of Hayti, constitutes an empire under Faustin I. After long negotiations, the French government agreed in 1838 to acknowledge the independence of Hayti, on condition of the latter paying 60,000,000 of francs, by small annual instalments continued for 30 years. The money was destined chiefly to indemnify the French proprietors who were chased from the island in 1791.

West Indies.

The multifarious nature of the subject prevents us from attempting any description of the West India colonies, insular and continental. The islands have been variously denominated, but the most convenient division seems to us the following:—1. The Great Antilles, comprehending Cuba, Hayti, Jamaica, and Porto Rico; 2. The Small Antilles, extending in a semicircle from Porto Rico to the coast of Guiana; 3. The Bahama Isles, about 500 in number, but only a small number of which are inhabited.

The British colonies are 18 in number, viz., 15 *insular*, Jamaica, Antigua, Barbadoes, Dominica, Grenada, Montserrat, Nevis, St Kitts, St Lucia, St Vincents, Tobago, Tortola, Trinidad, Bahamas, Bermuda; and 3 *continental*, Demerara, Berbice, Honduras. The colonies contained a population of 972,000 in 1851, of whom probably four-fifths were persons of colour.

The Almanac de Gotha assigns to Cuba a population of 898,752 in 1851 and to Porto Rico 288,000. Other authorities make it considerably greater. According to a recent Spanish writer, the different classes stand thus in Cuba:—Whites and Creols 42 per cent., slaves 43, free persons of colour 15 per cent.

The French colonies in the West Indies include Martinique, Guadaloupe, and some smaller isles, and on the continent Guiana. According to a recent authority, the population of these colonies in 1841 was 277,000, of whom 183,780 were slaves.

The Dutch have Surinam on the continent, with the islands of Curaçoa, St Eustatius, and St Martin. The collective population of these possessions, according to the Almanac de Gotha for 1853, was 90,581, of whom probably three-fourths are slaves.

The Danes have the small islands of Santa Cruz, St Thomas, and St Martin, containing a population of 39,614 in 1850, of whom five-sixths are slaves. St Bartholomew, another of the lesser Antilles, belongs to Sweden.

Humboldt gave the following estimate of the entire population of America in 1823:—

| | Number. | Proportion. |
|---|---|---|
| Whites | 13,471,000 | 38 per cent. |
| Indians | 8,610,000 | 25 |
| Negroes {Slaves 5,000,000 / Free 1,433,000} | 6,433,000 | 19 |
| Mixed races | 6,428,000 | 18 |
| | 34,942,000 | |

Putting together the populations assigned to the several states in the preceding pages, the total amount for 1850 is 52,800,000, and the increase since 1823 is almost entirely confined to the United States.

The black population of America, including negroes and mulattoes, forms three groups, the centres of which are in the southern parts of the United States in the West India islands, and in the eastern parts of Brazil:—

Population.

| | |
|---|---|
| In the United States (slaves and free) | 3,624,000 |
| In West Indies | 2,400,000 |
| In Brazil | 2,800,000 |
| | 8,824,000 |

The number of blacks in all the other parts of America probably does not amount to 100,000. Slavery brings two evils with it, which strike at the roots of national prosperity; it produces an aversion to labour in the free population, and it renders person and property insecure. We may therefore safely predict, that the countries where the African race most abound will be the most unimproved and backward part of the American continent a century hence.

Increase of population.

One of the most interesting questions connected with America relates to the increase and probable amount, at a future period, of its inhabitants. It was the astonishing progress of the United States that first clearly unfolded the principles on which the multiplication of human beings depends. We now know with certainty that a prosperous community, possessing abundance of unoccupied land, will double its numbers in 25 years, without any aid from emigration; and as the scale ascends in a geometrical ratio, a short time necessarily produces a wonderful change. It is to be observed, however, that the civilised white population of the United States, possessing the advantages of superior industry, order, and forethought, naturally increases faster than the other classes. It increases at the rate of 3 per cent. per annum. The inhabitants of Spanish and Portuguese America, composed of men in whom Indian and European blood are mingled, possess a far lower degree of civilisation, and the principle of growth operates among them much more feebly. In the thirty years which have elapsed since they achieved independence, the addition to their numbers has been extremely small, probably not exceeding one-fifth. Even if their governments were becoming less anarchical, their low intellectual and moral character is a formidable obstacle to their progress, and we doubt whether under the most favourable circumstances they will double their numbers in less than a century. Let us assume, however, that they multiply at the rate of one per cent. per annum, and in this case they will double their numbers in 75 years. Experience shows that the independent indigenous tribes moulder away whereever they come into juxtaposition with the civilised races. As for the black population, it does not maintain its numbers in the West Indies, nor probably in Brazil, while in the United States it grows rapidly. At present we shall throw it out of our estimate, as it forms only one-sixth of the whole; and taking the other portions of the civilised or settled population as given above, let us count forward, and take a conjectural peep into the future of the New World.

The problem is, what will be the number of the inhabitants of the new continent two or three centuries hence, and of what races will it consist? Setting aside the negroes to simplify the question, and the savages, who will gradually disappear, it is evident that the soil of America is destined to be occupied by two races, who may be designated as the Anglo-Saxon and the Spanish-Indian. In the latter the Indian blood greatly predominates, for the Creoles or pure progeny of the Spaniards probably do not constitute more than 20 per cent. of the population, while the civilised Indians may amount to 50, and the Mestizoes to 30.

| | |
|---|---|
| The whites in the United States were in 1850 | 19,500,000 |
| The population of British America, | 2,500,000 |
| | 22,000,000 |
| The population of Spanish and Portuguese America, exclusive of slaves, was in round numbers, | 20,000,000 |

Population.

The Anglo-Saxon population in America increases at 3 per cent. annually, and doubles its numbers in 25 years.

| | |
|---|---|
| Its amount in 1850 was | 22,000,000 |
| In 1875 it will be | 44,000,000 |
| In 1900, | 88,000,000 |
| In 1925, | 176,000,000 |

A population of 176,000,000 spread over the territories of the United States and Canada, would only afford an average of 40 persons to each square mile, about 1-7th part of the density which England now exhibits, and could occasion no pressure. But let us suppose the rate of increase after 1925 to fall to 2 per cent., the period of doubling will then be 35 years.

| | |
|---|---|
| In 1960 the number will be | 352,000,000 |
| In 1995 do. do. | 704,000,000 |

Suppose the rate again to decline to $1\frac{1}{2}$ per cent., which scarcely exceeds that of England and Prussia, the period of doubling will then be 50 years.

| | |
|---|---|
| In 2045 the number will be | 1,408,000,000 |
| In 2095 do. do. | 2,816,000,000 |

Let us now compare with this the growth of the Spanish-Indian population, doubling its numbers in 75 years.

| | |
|---|---|
| Its present amount is | 20,000,000 |
| In 1925 it will be | 40,000,000 |
| In 2000 do. | 80,000,000 |
| In 2075 do. | 160,000,000 |
| In 2095 (interval of 20 years) | 200,000,000 |

It hence appears that, supposing both races to have free space for expansion, the Anglo-Saxon population in 240 years from the present time will amout to 2816 millions, while the Spanish-Indian population will only have multiplied to 200 millions, or *one-fourteenth part* of the other. It will be shewn by and by on probable grounds, that the new continent if fully peopled could support 3600 millions, and there would consequently be room enough for both; but long before this density is attained, the two races will inevitably come into collision. In new settlements, where the best lands are invariably first occupied, and the inferior neglected, the population is always thinly diffused. The Anglo-Saxons will therefore crowd to the richer fields of the south, while millions of acres of their own poorer lands are still untenanted. For we may rest assured that before cultivation is extended to the third-rate soils on the north side of the boundary, means will be found to appropriate the first-rate soils on the south side. These may be acquired by purchase like the lands of Louisiana, or by conquest like those of New Mexico and California, but in one way or another they will be acquired. Nearly twenty years ago M. de Tocqueville calculated that along the great space from the Gulf of Mexico to the Canadian Lakes the whites were advancing over the wilderness at an average rate of 17 miles per annum, and that enlightened observer was powerfully impressed by the grandeur and solemnity of this deluge of men, for ever swelling and flowing onward, to the west, the south, and the north, as "driven by the hand of God." Since he wrote the rate of progress has perhaps doubled, and every year will quicken its pace. If, then, we take a glance at the state of America at any future period, say 240 years hence (A.D. 2095), we must take the ratio of increase of the two civilised races as the prime element of our calculation. We may assume that the whole continent from Behring's Straits and Hudson's Bay, to Cape Horn, will be divided between the two races in some such proportion as their rate of growth indicates,—it may be 10, 15, or 20 to 1. Supposing them to maintain a separate existence, the weaker race will probably be driven, like the Welsh before the English, into the mountainous and inhospitable regions. On the other hand, it is possible, and not improbable, that the smaller population may be absorbed into the mass of the greater, be incorporated with it, and adopt its language. The result, like other things in the womb of time, may be modified by causes yet unseen; but in whatever shape it may present itself, there is little risk in predicting that the Anglo-Saxon race is destined by its superior intelligence and energy, to rule the new world from end to end. American statesmen now speak of the whole continent as the heritage of their people. Even thirty years ago the government of the United States formally announced that it would resist by force any attempt of a European power to plant a *new* colony on the Western continent.

America.

The problem as to the future fate of the negroes in the United States is one of difficult solution, and the difficulty arises mainly from the fact that they multiply as fast as the whites. If, like the blacks of Brazil or Cuba, their numbers constantly fell off, or even continued stationary, while the whites increase as they now do, the result would be, that in a century the negroes would form only a 50th or a 100th part of the population, a proportion quite insignificant. That they do increase at three per cent. per annum, in spite of hard labour, poor fare, and exposure to the elements in a subtropical climate, while among the working-classes of Britain the rate is little more than one per cent., and among those of France only the half of one per cent., is a result which could not have been anticipated. An explanation of the anomaly is not easily found; but there are two circumstances to which a certain influence may be attributed: *1st*, The disgraceful practice of breeding slaves for sale (as horses are raised for the market) is now established in the Southern States, and prevails extensively; *2dly*, The strict discipline maintained on slave-estates, with its attendant regular habits and enforced sobriety, will prevent, or greatly lessen, the mortality arising from intemperance, which operates so fatally on the Indian tribes, and to a great extent also on the free negroes. De Tocqueville informs us that the mortality is greater among the free negroes than among the slaves, and that, in the ten years ending 1831, the proportion of deaths in Philadelphia, was twice as great among the blacks as among the whites.

It thus appears that a part of the increase among the negroes is not natural but factitious, and that slavery as it exists in the United States, both multiplies the number, and lengthens (comparatively) the lives of those who are subject to it. It follows that the emancipation of the blacks, which Jefferson declared to be "as certain as any thing in the book of fate," will, when it takes place, check their increase, and may even positively reduce their number, as freedom in juxtaposition with the Europeans is daily thinning the number of the Indians. The proprietors of the Southern States are as sensible of the evils of slavery as those of the northern; and emancipation would come much sooner if a dread were not felt of filling the country with a demoralised population, such as the liberated negroes are found to be. To meet the difficulty the colony of Liberia was established on the west coast of Africa in 1820, and two or three thousands of the free blacks have since then been sent thither. Its affairs have been conducted with good order, and it has even been found instrumental in checking the slave trade on the shores of Africa. But the free negroes have shewn little desire to return to the land of their ancestors, and the expense of conveying them across 5000 miles of ocean is a serious objection. Cuba seems destined to fall into the hands of the Americans at no distant day, and from its great extent could afford room for all the blacks, bond and free, in the United States. Perhaps a new Liberia might be planted there with better hopes of success. As for the amalgamation of the two races, to which some look forward, the most enlightened observers deem it all but impossible.

Useful soil in New and Old Continents.

Paradoxical as the fact may appear, we are satisfied that

America.

the new continent, though less than half the size of the old, contains at least an equal quantity of useful soil, and much more than an equal amount of productive power. America is indebted for this advantage to its comparatively small breadth, which brings nearly all its interior within reach of the fertilizing exhalations of the occan. In the old continent, owing to its great extent from east to west, the central parts, deprived of moisture, are almost everywhere deserts; and a belt round the western, southern, and eastern shores, comprises nearly all that contributes to the support of man. How much fruitful land, for instance, is there in Continental Asia? If we draw a line from the Gulf of Cutch (near the Indus) to the head of the Yellow Sea, we cut off India and China, with the intervening Birman empire, and the southern valleys of Thibet; and this space, which comprises only about one-fifth of the surface of Asia, embraces five-sixths of its productive power. Arabia, Persia, Central Thibet, Western India, Chinese and Independent Tartary, are deserts, with scattered patches of useful soil not amounting to the twentieth part of their extent. Siberia, or northern Asia, is little better, owing to aridity and cold together. Anatolia, Armenia, the Punjab, and a narrow strip along the western shores of the Pacific Ocean, north as far as the 60th parallel, compose the only valuable agricultural territory beyond India and China. Europe, which is merely the western margin of Asia, is all fruitful in the south; but on the north its fruitfulness terminates at the 60th or 62d parallel. Africa has simply a border of useful soil round three-fourths of its sea-coast, with some detached portions of tolerably good land in its interior. Of the 31,000,000 of square miles which these three continents occupy, we cannot find, after some calculation, that the productive soil constitutes so much as one-third, and of that third a part is but poor.

Now, in estimating the useful soil in America, we reject, 1. all the region northward of the latitude of 53°, amounting to 2,600,000 square miles; 2. a belt of barren land about 300 miles broad by 1000 in length, or 300,000 square miles, lying on the east side of the Rocky Mountains; 3. a belt of arid land of similar extent situated on the east side of the Andes, between 24° and 40° of south latitude; 4. the desert shore of Peru, equal to 100,000 square miles; 5. an extent of 100,000 square miles for the arid country of Lower California and Sonora; and, 6. an extent of 500,000 square miles for the summits of the Andes and the south extremity of Patagonia. These make an aggregate of 3,900,000, square miles; and this, deducted from 13,900,000, leaves 10,000,000 square miles as the quantity of useful soil in the new world.

Ratio of fertility to latitude.

Now, what relation does the fruitfulness of the ground bear to the latitude of the place? The productive powers of the soil depend on two circumstances, heat and moisture; and these increase as we approach the equator. First, the warm regions of the globe yield larger returns of those plants which they have in common with the temperate zones; and, next, they have peculiar plants which afford a much greater portion of nourishment from the same extent of surface. Thus, maize, which produces 40 or 50 for one in France, produces 150 for one on an average in Mexico; and Humboldt computes that an arpent (five-sixths of an acre), which will scarcely support two men when sown in wheat, will support fifty when planted with bananas. From a consideration of these and other facts, we infer that the productive or rather nutritive powers of the soil, will be pretty correctly indicated by combining the ratios of the heat and the moisture, expressing the former of these in degrees of the centigrade scale. Something, we know, depends on the distribution of the heat through the different seasons; but as we do not aim at minute accuracy, this may be overlooked.

| Latitude. | Annual rain, inches. | Mean annual heat. | Product. | Ratio. |
|---|---|---|---|---|
| 60 | 16 | 7 | 112 | 4 |
| 45 | 29 | 14 | 406 | 15 |
| 0 | 96 | 28 | 2688 | 100 |

Thus, if the description of food were a matter of indifference, the same extent of ground which supports four persons at the latitude of 60°, would support 15 at the latitude of 45°, and 100 at the equator. But the food preferred will not always be that which the land yields in greatest abundance: and another most important qualifying circumstance must be considered,—it is labour which renders the ground fruitful; and the power of the human frame to sustain labour is greatly diminished in hot climates. In the torrid zone, in low situations, we doubt if it is possible for men to work regularly in the fields for more than five hours a day, or half the daily period of labour in England. On these grounds, and to avoid all exaggeration, we shall consider the capacity of the land to support population as proportional to the third power of the cosine (or radius of gyration) for the latitude. It will therefore stand thus in round numbers:—

| | | | | | |
|---|---|---|---|---|---|
| Latitude, | 0° | 15° | 30° | 45° | 60° |
| Productiveness, | 100 | 90 | 65 | 35 | $12\frac{1}{2}$ |

In England the density of population is above 300 persons per square mile; but England is in some measure the workshop of the world, and supports, by her foreign trade, a greater population than her soil can nourish. In France the density of population is about 160; in Germany it varies from 100 to 200. Assuming, on these grounds, that the number of persons whom a square mile can properly sustain, without generating the pressure of a redundant population, is 150 at the latitude of 50°, we have 26 as the sum which expresses the productiveness of this parallel. Then taking, for the sake of simplicity, 35 as the index of the productiveness of the useful soil beyond 30° in America, and 85 as that of the country within the parallel of 30° on each side of the equator, we have about 4,000,000 square miles, each capable of supporting 200 persons, and 5,700,000 square miles, each capable of supporting 490 persons. It follows, that if the natural resources of America were fully developed, it would afford sustenance to 3,600,000,000 of inhabitants, a number nearly five times as great as the entire mass of human beings now existing upon the globe! The novelty of this result may create perplexity and doubt on a first view; but we are satisfied that those who investigate the subject for themselves will be satisfied that our estimate is moderate. But, what is even more surprising,—there is every probability that this prodigious population will be in existence within three or at most four centuries. We are quite aware of the objections which may be raised to this conclusion, but they all seem to us to admit of an answer. In particular, we would observe, that the expense and difficulty of transporting men from situations where they are redundant, to others where vacant space exists, which is so much felt in the Old World, will be incredibly facilitated by the employment of steam-navigation upon the innumerable rivers which are ramified over four-fifths of the New Continent.

The imagination is lost in contemplating a state of things which will make so great and rapid a change in the condition of the world. We almost fancy that it is a dream; and yet the result is based on principles quite as certain as those which govern the conduct of men in their ordinary pursuits. Nearly all social improvements spring from the reciprocal influence of condensed numbers and diffused intelligence. What, then, will be the state of society in America two centuries hence, when two thousand millions of civilised men are crowded into a space *comparatively* so narrow, and when this immense mass of human beings speak only two languages, perhaps only one! Such a state of things may be said to undo the curse of Babel, and restore the great mass of mankind to their pristine facility of intercourse; for the languages spoken by the communities of Europe and Asia will be as unimportant then, in the general scale of the globe, as the dialects of Hungary, Finland, and Bohemia, are in Europe at this day. History shows that wealth, power, science, literature, all follow in the train of numbers, general intelligence, and freedom. The same causes which transferred the sceptre of civilisation from the banks of the Euphrates and the Nile to Western Europe, must, in the course of no long period, carry it from the latter to the plains of the Mississippi and the Amazon. When we reflect on these changes, which are not more extraordinary than they are near and certain, the conviction is forced upon us, that society, after all its advances, is yet but in its infancy; that the habitable world, when its productive powers are regarded, may be said hitherto to have been an untenanted waste; and that we have at present only an imperfect glimpse of the state of things under which the true destiny of man, and the grand scheme of providence in this lower world, is to receive its full development. We are quite aware that some will smile at these speculations; but if any one suspects us of drawing on our fancy, we would just request him to examine thoroughly the condition and past progress of the North American republic. Let him look at its amazing strides in wealth, intelligence, and social improvement; at its habits of order, combined with an indomitable love of liberty; at its marvellous instinct of self-government, which has made the founding of a new state in the wilderness as easy and peaceful an undertaking as the building of a house or the planting of a vineyard; let him look at the prodigious growth of its population; and let him answer the question, "what power can stop the tide of civilisation which is pouring from this single source over an unoccupied world?" Let him trace the laws on which this progress depends, and let him then apply them to unfold the future history of society in the new continent.

Proposed canal at Isthmus.

The project of joining the Atlantic and Pacific Oceans by a canal carried across the narrow part of the American continent, has often excited the attention of statesmen and commercial men. This canal, if executed upon a scale sufficient to admit vessels of 300 or 400 tons, would have a powerful influence upon the fate of America. For all the purposes of commercial intercourse it would bring the east and west sides of the continent within one-third part of their present distance from one another; and would be of even more advantage to the New World than the discovery of the passage to India by the Cape has been to the Old. It has also been proposed to accomplish the same object by a boat canal, or by a railroad, and four different routes have been recommended. A digest of the surveys and explorations connected with these, and an estimate of their comparative merits, has been published in the *Journal of the Geographical Society* (vol. xx. 1851), by Captain Fitzroy, R.N. From this our materials are derived.

1. The Isthmus of Tehuantepec, at $94\frac{1}{2}°$ west longitude. The distance from sea to sea in a straight line is 140 English miles, the surface has few great inequalities, and the lowest summit level is about 700 feet above the sea. The climate is said to be rather better than at the parts of the isthmus farther eastward, and there is a settled population, though not very numerous, from whom labour might be obtained. On the other hand, there is no port at either end of the line, the rivers are small, and barred at their mouths by sand-banks, and the length of the route, as well as the elevation of its summit level would render the execution of a railroad or a canal too expensive to permit the hope of even a moderate remuneration for the outlay. The project however, has found warm support in the United States, as it would render available by far the shortest maritime route to California. A survey has been made, and a cession of the necessary quantity of land has, we believe, been obtained.

2. The Nicaragua route, at 11° of north latitude. The first portion of this is the river San Juan, which flows from the Lake of Nicaragua, and after a course of 80 miles falls into the Caribbean Sea. It is of considerable depth, but is obstructed by rapids, and the port at its mouth, now called Greytown, is only capable of receiving small vessels. The lake is 90 or 100 miles long, 30 or 40 broad, and 125 feet above mean tide level at Greytown. Its depth varies from 2 fathoms to 40, but much of it has never been sounded, and recent surveys show shallows at both ends. From this lake to the Pacific six different routes have been traced, and some of them surveyed. One through the Lake Managua (which is 28 feet higher than Nicaragua Lake), westward to the Bay of Fonseca, would require 90 or 100 miles of canal, and the whole length of inland navigation from Greytown would exceed 300 miles; another route from the same lake to Realejo is 40 miles shorter; and a third to Tamarinda a good deal shorter still, but both the latter want good ports at their termini on the Pacific. A fourth route goes direct from the south-west side of Nicaragua Lake to San Juan del Sur; it is only 10 to 12 miles in length, but requires a tunnel (for ships) 1 or 2 miles long, and the port at its mouth is very small. A fifth runs from the same lake a little farther east to the Bay of Salinas, a distance of 15 miles, half of which is by the River Sapoa, and now navigable for boats; and the summit level is only 130 feet above the lake, and twice as much above the Pacific. It is believed there would be a sufficient supply of water from the stream, and the canal would further have the advantage of a good port. Captain Fitzroy seems to think this one of the most promising lines, but it has not yet been carefully surveyed. Of the sixth proposed route, running from the east end of the lake to the Gulf of Nicoya, neither the precise length nor the nature of the intervening country is known. Of the whole district Captain Fitzroy says, that though insufficiently explored, "enough is known to discourage any attempt to construct either canal or railway, unless the Sapoa track (the fifth) should prove to be as eligible as Dr Oersted believes. Even then there will be the disadvantages of so inferior a harbour as that of Greytown, and the difficulties of the river, which must be cleansed from its numerous obstructions, though renewed annually by floods." He considers the climate pestilential, particularly in the low grounds on both sides of the river, which holds its course amidst forests, swamps, and mud banks. Mr Squier, however, an intelligent American, in his work on Nicaragua (New York 1852) thinks the climate comparatively good. In reference to a canal there is a physical evil not to be overlooked, namely, the volcanic eruptions which shake the soil, and might desturb the levels; and there is a moral one still more serious, arising from the frequent insurrections and political revolutions, which makes property insecure, and may render engagements with the government mere waste paper. The latter evil applies to the whole isthmus, but more especially to this district, touching as it does the territories of three states (Nicaragua, Costa Rica, and Mosquito) which are often at war with one another.

3. The Panama line, at 79° and 80° of west longitude. The extreme narrowness of the isthmus here, called attention to it as an eligible point for establishing a communication between the two seas, before any other locality was thought of. Numerous explorations have been made; four routes have been pretty carefully surveyed, those of Loyd, Morel, Garella, and Hughes; and along the last of these a railway is now in course of construction. It commences on the Atlantic at Limon or Navy Bay, from which the direct

America. distance to Panama, according to Captain Fitzroy, is (33 geographical) 38½ English miles. It passes by Gorgona, and is to be carried 42 miles over elevations of nearly 300 feet, through a tunnel, and over large viaducts and bridges, terminating a little westward of Panama. The port of Chagres is unfit for large ships. Limon Bay, which is large, and has a good depth of water, is exposed to strong north winds. A breakwater, to protect it from these, has been proposed, but is impracticable on account of the vast sum it would cost. But Captain Fitzroy thinks that a large wet dock or basin might be excavated between Manzanilla Island and the mainland, at the terminus of the railroad, and might serve as the first step towards an artificial harbour, to which Limon Bay would be accessory as a useful roadstead. "On the opposite coast, near Panama, a spacious and tolerably sheltered anchorage, with access to works carried out into the sea, may be found in the bay, but not very near the city." A ship canal here, whether at the elevation of the railroad (300 feet), or at the lower level proposed by Garella, of 150 feet, would require works on a gigantic scale; for his plan includes a tunnel *for ships*, 125 feet in interior height, 97 feet wide, and nearly three miles long, with about 33 locks. Without some better security than can now be obtained, it is not probable that any private company will risk the capital necessary for the execution of such works. Morel, in his survey, professes to have found a valley or tract of low ground between the Trinidad, a branch of the Chagres, and the Caymito, which falls into the Pacific 10 miles west of Panama, of which low ground the summit level is only 40 feet above the sea. This, unluckily, is contradicted by other authorities; but if such a low summit level exist, a channel navigable by the largest ships might possibly be made from sea to sea without a lock. The portion of the railroad now in progress is the southern half, extending from Panama to Gorgona, and was expected to be finished in 1853. On the north side, the river Chagres is made use of as far as navigable.

4. The Atrato and Cupica line commences on the Atlantic side in the Gulf of Darien, at 77° of west longitude. It has not been surveyed, but the nature and form of the ground are well known, and its suitableness for a canal was pointed out by Humboldt 40 years ago. The route extends from the inner part of the Gulf of Darien up the river Atrato, thence westward along its branch, the Naipi, and through a low tract of ground to the river Cupica, which falls into the Pacific. The whole length of the proposed line is estimated at 114 miles. For two-thirds of this distance, or 76 miles, the rivers are said to be navigable by ships, for 19 miles more by loaded boats, and it is supposed that a canal might be cut through the remaining 19 miles without any extraordinary difficulty. The proprietor of an estate on the Naipi told Mr Watts, the British vice-consul at Carthagena, that he was in the habit of crossing to the Bay of Cupica, and the rise between the bay and the river was gradual, and only about 150 feet in the whole. That the ground is really low, is proved by the fact that the launch of a Chilian frigate, carrying 15 men, was drawn over it in 10 hours, the men having to cut the bush as they advanced. The canal and river communication along this line would have the benefit of a good port at each extremity. Dr Cullen, an intelligent Scotsman who has travelled over it, recommends it strongly; and Captain Fitzroy is inclined to think that it will be found preferable to every other for a great ship canal.

Animals. The opinion entertained in the infancy of natural history, that all the larger animals had spread from one common centre to the different countries where we find them, is, we believe, now abandoned by all scientific writers. It is found that every region of the globe, separated from others by well-marked boundaries, or by contrasted climates, has plants and animals peculiar to itself. The vast multitude of facts now ascertained respecting the distribution of animals can be explained on no hypothesis but one. We are forced to infer, that after the last catastrophe which destroyed the living beings inhabiting the earth, a great variety of new animal tribes were created; that each was placed on the spot to which its powers and functions were best adapted; and that from this as a centre it was left to spread by such means of locomotion as nature had provided it with. Some birds, for instance, strong of wing, and some few quadrupeds of migratory habits, are diffused from the west coast of Europe to the east coast of Asia; while many others, which, from their mode of life or their small size, were ill fitted for travelling, are confined within a very narrow space. Where wild animals resembling each other, exist in regions distinct and entirely separated, it is found that they are not of the same species, but are corresponding species belonging to the same genus. The horse, the ox, the antelope, the elephant, and the rhinoceros of Asia, are distinct species from those of Southern Africa, where the same genera exist. This hypothesis, as Dr Prichard remarks, does not contradict the testimony of the Scriptures; it merely assumes that there were animals created subsequent to the deluge in various parts of the earth, of which it was not necessary for the sacred historian to speak.

The American animals belonging to the Cuvierian Division of *Vertebrata* are very numerous. It is true that some of the larger quadrupeds have no living types in the New World. There are none to compare in size with the elephant, the rhinoceros, the hippopotamus, the giraffe, or the camel; but fossil remains of the mastodon, megatherium, and megalonyx will vie in size with the largest quadrupeds of the Old World.

In the class of Mammifera, America is very rich, as the following synopsis of the species in each order will show:—

| | |
|---|---|
| Quadrumana, | 59 |
| Carnivora, | 89 |
| Marsupialia, | 21 |
| Rodentia, | 71 |
| Edentata, | 16 |
| Pachydermata, | 6 |
| Ruminantia, | 22 |
| Cetacea, | 18 |
| | 302 |

Some of these are common to the Old and the New Worlds, and a few have been introduced by Europeans; but several, which were at one period considered as identically the same in both continents, have by more recent investigations been found to be only allied species. Some of the larger animals of Eastern Asia and North-Western America, as the reindeer, make annual migrations over the Arctic Seas from one continent to the other; and many of the mammals inhabiting the sea no doubt may be considered as identical. We shall here note the more important American vertebrate animals under the *orders* to which they belong, attaching to each *genus* the number of American *species*, and of the more important mention the specific names.

| Quadrumana.—*Apes.* | Species. |
|---|---|
| *Mysetes*, Howler, | 7 |
| *Pithecia*, Saki, | 10 |
| *Ateles*, Sapajou, | 10 |
| *Cebus*, Capuchin, | 12 |
| *Nocthorus*, | 3 |
| *Callithrix*, | 17 |
| | 59 |

America.

CARNIVORA.

| | |
|---|---|
| *Cheiroptera*, Bat, | 12 |
| *Erinaceus*, American hedgehog, | 1 |
| *Sorex*, Shrew, | 3 |
| *Scalops*, Shrew-mole, | 5 |
| *Talpa*, Mole, | 1 |
| *Ursus*, Bear, | 5 |
| Grizzly bear. Black bear. White bear. Cordillera bear. Barren ground bear. | |
| *Procyon*, Racoon, | 2 |
| *Nasua*, Coati, | 3 |
| *Meles*, Badger, | 2 |
| *Gulo*, Wolverine, | 1 |
| *Viverra*, *Putorius*, } Weasel, | 13 |
| *Mephites*, Skunk, | 5 |
| *Lutra*, Otter, | 5 |
| *Canis*, Dog, | 4 |
| Common dog. Maned wolf. Gray wolf. Mexican wolf. | |
| *Vulpes*, Fox, | 7 |
| Arctic fox. Gray fox. Black fox. Bald fox. Virginian fox. Chilé fox. Silvery fox. | |
| *Felis*, Cat, | 11 |
| Puma. Guigna. Jaguar. Colorolo. Ocelot. Bay lynx. Black jaguar. Canadian lynx. Jaguarondi. American serval. Margay. | |
| *Phoca*, Seal, | 8 |
| *Trichecus*, Walrus, | 1 |
| | 89 |

MARSUPIALIA.

| | |
|---|---|
| *Didelphis*, Opossum, | 21 |

Of which the chief are Virginian, Palmated, Crab-eating, Mexican, Short-tailed, Merian, and Murine.

RODENTIA.

| | | |
|---|---|---|
| *Sciurus*, Squirrel, | | 10 |
| *Arctomys*, Marmot, | | 4 |
| *Mus*, Mouse, | | 20 |
| Viz.:—Echymys, | 5 | |
| Mouse, | 8 | |
| Merion, | 3 | |
| Lemming, | 1 | |
| Economic rat, | 2 | |
| Musk rat, | 1 | |
| *Castor*, Beaver, | | 2 |
| *Hystrix*, Porcupine, | | 3 |
| *Lepus*, Hare, | | 17 |
| *Hydrochœrus*, Water hog, | | 1 |
| *Cavia*, Cavy, | | 6 |
| *Cœlogenus*, Paca, | | 1 |
| *Lagostomus*, Viscacha, | | 1 |
| *Lagotis*, Chincha, | | 2 |
| *Callomys*, Chinchilla, | | 1 |
| *Atrocoma*, | | 2 |
| *Auromys*, | | 1 |
| *Pœphagomys*, | | 1 |
| *Octodon*, | | 1 |
| | | 73 |

EDENTATA.

| | |
|---|---|
| *Bradypus*, Sloth, | 3 |
| *Dasypus*, Armadillo, | 10 |
| *Myrmecophaga*, Ant-eater, | 3 |
| | 16 |

Besides the living Edentata, America affords the vast fossil skeletons of the Megatherium and Megalonyx.

PACHYDERMATA.

| | |
|---|---|
| *Sus*, Boar (imported), | 1 |
| *Dicoteles*, Peccari, | 2 |
| *Tapirus*, Tapir, | 1 |
| *Equus*, Horse (imported), | 2 |
| | 6 |

Besides these living Pachydermata, America abounds with the fossil bones of animals rivalling the elephant of the Old World in size, viz., the Mastodon giganteum, and Mastodon Andium. The skeletons of the former occur in vast quantity in the frozen mud of the islands of Escholtz Bay, within Behring's Straits.

RUMINANTIA.

| | |
|---|---|
| *Auchenia*, Llama, | 3 |
| Guanaco. Vicuña. Alpaca. | |
| *Cervus*, Deer, | 10 |
| Wapiti deer. Rufous deer. Virginian deer. Guiana deer. Marsh deer. Wandering deer. Prairie deer. Simple-horned deer. Forest deer. Rein deer. | |
| *Alces*, Elk, | 1 |
| Moose deer or Carabou. | |
| *Antilope*, Antelope, | 2 |
| Prong-horned antelope. Palmated antelope. | |
| *Ovis*, Sheep, | 2 |
| Mountain sheep. Common sheep (imported). | |
| *Capra*, Goat, | 1 |
| *Bos*, Ox, | 3 |
| Bison. Common ox (imported). Musk ox. | |
| | 22 |

CETACEA.

| | |
|---|---|
| *Manatus*, Manati, | 3 |
| Northern manati. Broad-nosed manati. Southern manati. | |
| *Delphinus*, Dolphin, | 7 |
| Common dolphin. Beaked dolphin. Porpesse. Deductor. Grampus. Fitzroy's dolphin. Beluga. | |
| *Monodon*, Narwal, | 1 |
| *Physeter*, Cachalot, | 2 |
| Sperm cachalot. Blunt-headed cachalot. | |
| *Balæna*, Whale, | 5 |
| Greenland whale. Broad-nosed whale. Razor-back or physalis. Beaked whale. Finner or boops. | |
| | 18 |

Birds.

The birds of America are very numerous in almost every great family. The researches of Wilson, Charles Buonaparte, Audubon, Richardson, and Dekay, have beautifully illustrated the ornithology of North America; while those of Azara, Humboldt, Swainson, Waterton, Edmondstone, and Darwin, have thrown great light on that of South America. The North American species of birds already described amount to between 560 and 600; the species of South America are at least as numerous; so that we may fairly estimate the ornithology of America to include 1100, or perhaps 1300 species; and some genera are wholly peculiar to the New World,—as the genera of humming birds, toucans, aracaris, pauxis, crax, penelope, tinamous, and the wild turkey.

Reptiles.

The serpents of America are very numerous, amounting to 80 innocuous A, and to 12 or 13 venomous snakes B. In the work of Schlegel we find the following genera of both kinds.

A. Tortrix 1; calamaria 7; coronella 6; xenodon 5; heterodon 3; lycodon 4; coluber 8; herpetodryas 12; psammophis 2; dendrophis 3; dryiophis 3; dipsas 11; tropidonotus 3; homalopsis 6; boa 5.

B. Elaps 3; trigonocephalus 5; crotalus 4.

Of these the genera heterodon, and crotalus or rattlesnake are entirely peculiar to America, and the latter are by far the most deadly of serpents. The reptilia of North America have been well described by Dekay and Holbrooke. These authors mention the following, *Testudinata*, or tortoises; chelonia, or turtle, 3; sphargis, or leatherback turtle, 1; trionyx, or soft tortoise, 4; chelydra, or half-defended tortoise, 3; emys, or fresh water tortoise, 19; chelys 2; terrapin 3,—in all 35.

They give the North American saurians as, crocodile 2; alligator 1; anolis 1; scinks 4; agama 4; tropidolepis 2; ophisaurus 1; leptophis 1,—in all 16. Of the *Ranidæ* there are of rana, frog, 13; bufo, toad, 5; hyla, tree frog, 8,—in all 26.

The fishes of America are most numerous. The fresh waters abound with *Siluridæ;* the seas with chætodons, diodons, all of the strangest forms. We shall only mention one other American fish, the *amblyopsis spelæus* of Dekay, a small fish absolutely destitute of eyes. It is found in the vast mammoth cave of Kentucky. It belongs to Agassiz's family of *cyprinodotes*, but was at first considered as allied to the *Siluridæ*. It is worthy of remark, that the same cavern is inhabited by several minute animals also without eyes; as if nature had in an especial manner adapted them for a subterranean life, in which eyes would have been useless.

It is remarked by Azara, that single species of wild animals are diffused over a much wider surface in the New World than in the Old. The jaguar and tapir, for instance, are found from the banks of the Plata to those of the Rio del Norte in Mexico. This circumstance strengthens the conclusion, that America derived its human inhabitants from the old continent, and remained, of course for a much longer period, entirely in possession of the animal tribes; and further, that the former civilisation (such as it was) arose only at a late period.[1]

Changes in European animals.

The European animals which have been naturalised in America are the cow, horse, ass, hog, sheep, goat, dog; and these have multiplied to such a degree as to exceed the native quadrupeds greatly in numbers. The warm climate of the tropical parts of America has produced considerable changes in the habits and physical qualities of most of these species. The hog, which generally wanders in the woods, and lives on the wild fruits and roots found there, has lost in a great measure its domestic habits, and assumed the character of the wild boar. The black cattle also, roaming at large in a country entirely uninclosed, are found to fall off unless they receive a certain quantity of salt in their food, which in some cases they procure from plants, in others from brackish water. By distributing salt to them at a certain regular hour, they are taught to assemble at the owner's residence, and are thus kept from becoming wild. In Europe the constant practice of milking cows has enlarged the udder greatly beyond its natural size, and so changed the secretions, that the supply does not cease when the calf is removed. In Colombia, where circumstances are entirely different, nature shows a strong tendency to resume its original type. A cow gives milk there only while the calf is with her. It must be allowed to suck during the day, and the fluid is procured only by separating them during the night, and milking the cow in the morning before the calf visits her. The ass has undergone little alteration in America, and it has nowhere become wild. It is otherwise with the horse. Numbers of these animals in a wild state exist in Colombia, and many other parts of America, both South and North, where they wander over the plains and savannahs in troops. It is observed that the colour of the animals living in this state returns to that bay chesnut which is considered as characteristic of the natural wild horse. It is worthy of notice, that the amble, the pace to which the domestic horse in Spanish America is exclusively trained, becomes in the course of some generations hereditary, and is assumed by the young ones without teaching. The sheep thrives and multiplies in the temperate parts of the New World, and shows no tendency to withdraw from the protection of man; but in the warm regions it undergoes a remarkable change. If the lamb be shorn at the usual time, its wool is of the same description as in Europe, and it will grow again in the same way; but if it be suffered to remain on the animal's body after the proper season for cutting, it thickens, felts together, and detaches itself, and then is succeeded by a short close shining hair, very like that of the goat in the same climate. The goat in Colombia has the size of its udder contracted, and undergoes a change similar to that which is experienced by the cow.[2] (C. M.)

---

AMERICA, United States of. See United States.

AMERIGO VESPUCCI. See Vespucci.

AMERSFOORT, a town of Holland, in the province of Utrecht, 12 miles E.N.E. of the city of that name, and situated on the river Eem, which here is navigable. In 1850 it contained 12,360 inhabitants. The chief buildings are the town-house, and the great church dedicated to St George. It has a court of primary jurisdiction, a college, and an industrial school. Woollen, cotton, silk, glass, and tobacco, are manufactured here; and the transit trade is very considerable.

AMERSHAM, or Agmondesham, an ancient market and borough town of Buckinghamshire, in the hundred of Burnham, pleasantly situated in a valley between richly-wooded hills, through which the river Colnes flows. It consists chiefly of two streets, crossing each other; and at the point of intersection stands the church, a very handsome building, containing several beautiful monuments. The town has

---

[1] *Azara*, French translation. Preface, p. 50.

[2] *Sur les Changemens survenus*, &c., par M. Roulin, en *Bulletin des Sciences Naturelles*, Avril 1829.

some manufactories of cotton goods and black lace. It formerly returned two members to parliament. The population in 1851 amounted to 2093. It has a free grammar school, with three exhibitions at Oxford.

AMES, Fisher, an eminent American statesman and writer, son of Nathaniel Ames, a physician, was born at Dedham, in Massachusetts, on 9th April 1785. After practising the law for some little time, he abandoned that profession for the more congenial pursuit of politics, and in 1788 became a member of the Massachusetts convention for ratifying the constitution. In this assembly he bore a conspicuous part, and in the next year, having passed to the house of representatives in the state legislature, he distinguished himself greatly by his eloquence and forensic talents. During the eight years of Washington's administration he took a prominent part in the national councils; and on the retirement of that eminent man from office, he returned to his residence at Dedham to resume the practice of the law, which the state of his health, after a few years, obliged him to relinquish. But Ames was not idle: he continued his literary labours, and published numerous essays, chiefly in relation to the contest between Great Britain and revolutionary France, as it might affect the liberty and prosperity of America. Four years before his death, he was chosen president of Harvard College, an honour which his broken state of health obliged him to decline. After suffering for two years from extreme debility, he expired on the 4th July 1808, having acquired the admiration and respect of his countrymen by the brilliancy of his talents and his private virtues. His writings were collected and published, with a memoir of the author, in 1809, by the Rev. Dr Kirkland, in one large octavo volume.

Ames, *Joseph*, author of a valuable work on the progress of printing in England, called *Typographical Antiquities*, which is often quoted by bibliographers. He was born in 1689, and died in 1759. The best editions of his work are those published with the additions of Herbert and of Dibdin.

Ames, *William*, D.D., a learned Independent divine, was born in 1576, and educated at Christ's College, Cambridge. In the reign of King James I., he left the university, in order to avoid expulsion for nonconformity, and retired to the Hague, where he had not been long before he was invited to accept of the divinity chair in the university of Franeker, in Friesland, which he filled with great ability for above twelve years. He removed from thence to Rotterdam on account of his health; and there he continued during the remainder of his life. His controversial writings, which compose the greater part of his works, are chiefly against Bellarmine and the Arminians. He also wrote, 1. *A fresh Suit against Human Ceremonies in God's Worship*; 2. *Lectiones in Psalmos Davidis*; 3. *Medulla Theologiæ*; and several pieces relative to the sciences. He died of an asthma, at Rotterdam, in November 1633.

AMESBURY, a market-town in the hundred of the same name, in the county of Wilts, 77 miles from London, and 7 from Salisbury. It is situated in a narrow valley on the river Avon, on Salisbury plain. It is an ill-built town, but contains the beautiful house built by Inigo Jones for the Duke of Queensberry. At Milston, in this neighbourhood, Addison was born. Near the town stands the druidical monument of Stonehenge. Population in 1851, 1172.

AMETHYST, a transparent gem of a purple colour, which seems composed of a strong blue and a deep red; and, according as either of these prevails, affording different tinges of purple, sometimes approaching to violet, and sometimes even fading to a pale rose colour. Though the amethyst is generally of a purple colour, it is nevertheless sometimes found naturally colourless, and may at any time be easily made so by putting it into the fire; in which pellucid or colourless state it so resembles the diamond, that its want of hardness seems the best way of distinguishing it. Some derive the name *amethyst* from its colour, which resembles wine mixed with water; while others, with more probability, think it got its name from its supposed virtue of preventing drunkenness,—an opinion which, however imaginary, prevailed to that degree among the ancients, that it was usual for great drinkers to wear it about their necks. Be this as it may, the amethyst is scarcely inferior to any of the gems in the beauty of its colour. The *common amethyst* is a variety of quartz; the *oriental amethyst* is a variety of spinelle. Its most common form is a six-sided prism, terminated by a flat and short pyramid of the same number of sides. The amethyst is found in the East and West Indies, Siberia, and in every part of Europe; the oriental being so hard and bright as to equal any of the coloured gems in value. The common amethysts, however, fall infinitely short of these; all the European ones, and not a few of those brought from the East and West Indies, are a mere variety of rock crystal.

*Counterfeit or Factitious Amethyst.* Spars and crystals tinged red and yellow, &c., are sold for amethysts. The false ones come from Germany, are tinged by vapours in the mines, and contain lead and manganese.

Amethysts may be counterfeited by glass, to which the proper colour or stain is given. There were fine ones made in France about the year 1690, which may even impose on connoisseurs, unless the stone be taken out of the collet.

Amethyst, in *Heraldry*, a term for the purple colour in the coat of a nobleman, in use with those who blazon with precious stones instead of metals and colours. This, in a gentleman's escutcheon, is called *Purpure*; and in those of sovereign princes, *Mercury*.

AMETHYSTINE is applied, in *Antiquity*, to a kind of purple garment dyed of the hue of amethyst. In this sense amethystine differed from *Tyrian* as well as from *hyacinthine* purple, being a kind of medium between them.

AMHARA, one of the great divisions of Abyssinia, including the whole country north of the upper basin of the Blue River, and separated on the north-east from Tigré by the Tacazze. The province of Amhara Proper is in the south-east of this territory, and constitutes a state or kingdom still nominally subject to the head of the royal family, who is however a mere puppet in the hands of his temporary minister, with a paltry pension. The great lake of Dembea lies in the centre, surrounded by the plain of Dembea, which has been called the granary of the country, on account of its fertility and the blandness of its climate. The language is the Amharic, a branch of the Semitic stock.

AMHERST, Jeffrey, *Lord*, was born in 1717 in Kent. He served in the Duke of Cumberland's campaigns in Germany, and afterwards with distinction in the military operations that wrested Canada from the French. He was governor of Virginia in 1763, and of Guernsey in 1770. He was created a baron in 1776, while he was commander-in-chief in England, which office he retained till the dissolution of Lord North's administration in 1782. He was again appointed commander-in-chief in 1793, an office which he resigned on account of his age in 1795. He died in 1797. Amherstburgh in Upper Canada was named after this able officer.

Amherst, a seaport-town of Eastern India, situate in a district of the same name, in the province of Tenasserim, at the mouth of the Saluen or Martaban River. It was founded by the English in 1826, on the restoration of the town of Martaban to the Burmese, and named in compliment to the governor-general of India, who projected its erection. The proclamation inviting the natives to people the town was well adapted to the character and capacities of those whom it addressed. "The inhabitants of the towns and villages who wish to come shall be free from molestation, extortion, and oppression. They shall be free to worship as usual, temples, monasteries, priests, and holy men. The people shall go and come, buy and sell, do and live as they please, conforming to the laws. In regard to slavery, since all men, common people or chiefs, are by nature equal, there shall be under the English government no slaves. Whoever desires to come to the new town, may come from all parts and live happy; and those who do not wish to remain may go where they please without hinderance." Batteries erected on the heights protect both town and harbour. The latter is spacious and secure, with a depth of three fathoms at low tides; but it is difficult of access, especially during the south-west monsoon. Teak forests abound in the neighbourhood, and the timber they furnish forms a principal article of export. Distance east from Rangoon 100 miles; from Moulmein south 30 miles. Lat. 16. 4. N. Long. 97. 40. E. (E. T.)

AMHERST, a small town in the county of Hampshire, Massachusetts, U. S., North America, 90 miles west of Boston. It is chiefly noted for its literary institutions, which consist of a college, an academy, and a classical institution. Its college was opened in 1821, and in 1850 had 166 students. Population about 2500. This is the name of several other places in the United States.

AMHERSTBURG, in Essex county, Upper Canada, is in Lat. 42. 5. N. Long. 83. 10. W. It is on the north shore of Lake Erie, near the River Detroit. It has a garrison and some redoubts.

AMHURST, NICHOLAS, an English poet and political writer of the eighteenth century, was born at Marden in Kent, and entered of St John's College, Oxford; from which he was expelled for irregularity of conduct and libertine principles. Retaining great resentment against the university on this account, he abused its learning and discipline, and some of the most respectable characters in it, in a poem published in 1724, called *Oculus Britanniæ*, and in a book entitled *Terræ Filius*. He published a Miscellany of Poems, sacred and profane; and *The Convocation*, a poem in five cantos, which was a satire on the Bishop of Bangor's antagonists. But he is best known for the share he had in the political paper called *The Craftsman;* though, after being the drudge of his party for nearly 20 years, he was utterly forgotten in the famous compromise of 1742. He died in that year of a broken heart, and was indebted to the charity of his booksellers for a grave.

AMIANTHUS, or ASBESTUS; *Asbeste*, Haüy. The general composition of this substance may be stated as a silicate of magnesia, lime, and protoxide of iron. It occurs in highly delicate fibres, often thinner than a hair, longitudinally cohering, and easily separated. The finest varieties are of a brilliant silky white, and flexible. The Tarentaise in Savoy, and the island of Corsica, are cited as the localities affording the most perfectly fibrous white and silky varieties; and it occurs so abundantly in the last, that Dolomieu was enabled to use it in place of hay for packing his specimens. Anciently it was woven into napery and towels, which, when foul, were thrown into the fire, from whence they came out perfectly clean. Amianthus cloth was sometimes employed by the ancients to preserve the bones of the dead in the funeral pile.

AMICABLE BENCHES, in *Roman Antiquity*, were, according to Pitiscus, lower and less honourable seats allotted for the *judices pedanei*, or inferior judges, who, upon being admitted to the emperor's council, were dignified by him with the title *amici*.

*AMICABLE Numbers* denote pairs of numbers, of which each is mutually equal to the sum of all the aliquot parts of the other. So the first or least pair of amicable numbers are 220 and 284; all the aliquot parts of which with their sums, are as follows, viz.:

Of 220, they are 1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110, their sum being - - - - - - - 284
Of 284, they are 1, 2, 4, 71, 142, and their sum is 220

The second pair of amicable numbers are 17,296 and 18,416, which have also the same property as above.

And the third pair of amicable numbers are 9,363,584 and 9,437,056.

These three pairs of amicable numbers were found out by F. Schooten (sect. 9 of his *Exercitationes Mathematicæ*), who, it is said, first gave the name of *amicable* to such numbers, though such properties of numbers, it seems, had before been treated of by Rudolphus, Descartes, and others.

To find the first pair, Schooten puts $4x$ and $4yz$, or $a^2x$ and $a^2yz$ for the two numbers, where $a=2$; then making each of these equal to the sum of the aliquot parts of the other, gives two equations, from which are found the values of $x$ and $z$, and consequently assuming a proper value for $y$, the two amicable numbers themselves $4x$ and $4yz$.

In like manner for the other pairs of such numbers; in which he finds it necessary to assume $16x$ and $16\,yz$ or $a^4x$ and $a^4yz$ for the second pair, and $128x$ and $128yz$, or $a^7x$ and $a^7yz$ for the third pair.

Schooten then gives this practical rule, from Descartes, for finding amicable numbers, viz., assume the number 2, or some power of the number 2, such that if unity or 1 be subtracted from each of these three following quantities, viz.—

From 3 times the assumed number,

Also from 6 times the assumed number,

And from 18 times the square of the assumed number, the three remainders may be all prime numbers; then the last prime number being multiplied by double the assumed number, the product will be one of the amicable numbers sought, and the sum of its aliquot parts will be the other. That is, if $a$ be put = the number 2, and $n$ some integer number, such that $3a^n-1$, and $6a^n-1$, and $18a^{2n}-1$, be all three prime numbers; then is $\overline{18a^{2n}-1}\times 2a^n$ one of the amicable numbers, and the sum of its aliquot parts is the other. On this subject see Euleri *Opuscula varii Argumenti*, tom. ii. p. 23–107.

AMICTUS, among *Ecclesiastical Writers*, the uppermost garment anciently worn by the clergy; the other five being the alba, cingulum, stola, manipulus, and planeta. The amictus was a linen garment, of a square figure, covering the head, neck, and shoulders, and buckled or clasped before the breast. It is still worn by the religious abroad. Its English name is *Amice*.

AMICUS CURIÆ, a law term, to denote a bystander who informs the court of a matter in law that is doubtful or mistaken.

AMIDA, a god worshipped by the Japanese, who has many temples erected to him in the Island of Japan, of which the principal is at Jeddo. The Japanese have such a confidence in their idol Amida, that they hope to attain eternal felicity by the frequent invocation of his name. One of the figures of this idol is preserved at Rome.—See *Kampfer*, 243.

AMIENS, an arrondissement in the department of the Somme, in the north of France. Its extent is 719 square miles, or about 460,035 English acres. It comprehends thirteen cantons, viz., Amiens, Conti, Corbi, Hornoy, Moliens-Bibame, Oisemont, Piquigny, Poix, Soins, and Villers-Bocage, with 249 communes or parishes. In 1851 it contained 189,968 inhabitants.

AMIENS, a city, the capital as well of the department of the Somme as of the circle of its own name. It is a fortified place with a strong citadel, on the Somme, which receives here the waters of the Seille, and passes through the town in three branches. It has access to the sea, but only for small craft. It is a well-built ancient town, containing a cathedral, fourteen churches, and two hospitals. The population in 1851 amounted to 49,139. The cathedral is a venerable object, both for its beauty and extent. The town-house is a large, handsome stone building, and contains a fine collection of pictures of the French school. Amiens is the seat of the prefect, of a bishop, and of the departmental courts of justice. There is a commercial board, a society of agriculture, a botanic garden, a lyceum, a theatre, and a library. Amiens was always a manufacturing city. Though it suffered much during the revolution of 1789, it has since revived; and at present produces considerable quantities of woollen cloths, cassimeres, and worsted stuffs. There are also some moderate establishments for making cotton goods, the yarn of which, for all but the finer kinds, is spun in the city. It has also trade in tanning and in soap making. This city is distinguished as the birthplace of Peter the Hermit, the preacher of the first crusade, and of Voiture the poet, as well as for the treaty of peace of 1802. Long. 2. 23. E. Lat. 49. 53. N.

AMILCAR, the name of several Carthaginian captains. The most celebrated of them is Amilcar Barcas, the father of Hannibal. See HAMILCAR.

AMILICTI, in the *Chaldaic Theology*, denote a kind of intellectual powers, or persons in the divine hierarchy. The amilicti are represented as three in number, and constitute one of the triads in the third order of the hierarchy.

AMINTA, in *Literary History*, a beautiful pastoral comedy composed by Tasso, the model of all dramatic pieces wherein shepherds are actors. Guarini's *Pastor Fido* and the *Fili de Sciro* of Bonarelli are only copies of this excellent piece.

AMIOT, PERE, a learned Jesuit, born in 1718 at Toulon. He was sent to Pekin in 1751, and continued to reside there until his death in 1794. He obtained the favourable notice of the emperor Kien Lung; which, with his profound knowledge of the Chinese and Mantcheou languages, enabled him to collect and transmit to Europe more information on China than all his predecessors. His researches have enriched all the memoirs on that singular people during the last century.

AMISUS, in *Ancient Geography*, the chief city of the ancient kingdom of Pontus. It was built by the Milesians, and peopled partly by them and partly by a colony from Athens. Under the kings of Pontus it became a very flourishing city. Mithridates Eupator made a large addition to the town, which he called Eupatoria, and made it his residence alternately with Sinope. It was taken by the Roman general Lucullus in the Mithridatic war, and afterwards by Pharnaces son of Mithridates. Julius Cæsar, after defeating Pharnaces, restored it to its ancient liberty. Amisus is now called Samsoon.

AMITERNUM, an ancient city of the Sabines, situated near the sources of the Aternus. Its site is now occupied by the modern village of Vittorino, where numerous remains are still to be seen. This was the birthplace of the historian Sallust.

AMITTERE LEGEM TERRÆ, among *Lawyers*, a phrase importing the loss of liberty of swearing in any court; the punishment of a champion overcome or yielding in battle, —of jurors found guilty in a writ of attaint,—and of a person outlawed.

AMLWCH, a seaport borough in the hundred of Twrcelyn, in the island of Anglesey, North Wales. It has a harbour cut out of the rock with great labour and cost, capable of containing 30 vessels of about 200 tons burden. It rose rapidly after the discovery of the copper mines of Pary's Mountain, but since the ore there has been exhausted it has declined. It is 261 miles from London, and 15 from Beaumaris. Population in 1851, 3169.

AMMA, among *Ecclesiastical Writers*, a term used to denote an abbess or spiritual mother.

AMMA, an ancient Greek land measure, equal to 60 feet.

AMMAN, JOHANN CONRAD, a physician, and one of the earliest writers on the instruction of the *deaf and dumb*, was born at Schaffhausen, in Switzerland, in 1669. In 1687 he graduated at Basle; and as his religious principles did not permit him to settle in his native country, he retired to Holland, where he appears to have devoted his time and attention chiefly to the cure of the defects and imperfections of speech. He first called the attention of the public to his method, in a paper which was inserted in the *Philosophical Transactions;* and which appeared in a separate form in the year 1692, under the title, *Surdus Loquens, sive Methodus quâ qui surdus natus est loqui possit;* and afterwards, with much additional matter, in 1702 and 1728, under the title, *Dissertatio de Loquela, quâ non solum vox humana et loquendi artificium ex originibus suis eruuntur, sed et traduntur media, quibus ii qui ab incunabulis* SURDI ET MUTI *fuerunt, loquelam adipisci, quique difficulter loquuntur, vitia sua emendare possint.* In this work, which Haller terms "*vere aureum*," he develops, with great ability, the mechanism of vocal utterance, and describes the process which he employed in teaching its use to the unfortunate class of persons committed to his care. This consisted principally in exciting the attention of his pupils to the motions of his lips and larynx while he spoke, and then inducing them by gentle means to imitate these movements, till he brought them to repeat distinctly letters, syllables, and words. As his method was excellent, we may readily give him credit for the success to which he lays claim. In a long course of practice, he says that he never failed in his endeavours but in two instances; one of which was that of a girl who was an idiot, and the other that of a Jew, from whose father he foresaw that he would not get any thanks for his trouble. The edition of *Cælius Aurelianus*, which was undertaken by the Wetsteins in 1709, and still ranks as one of the best editions of that author, was superintended by Amman. (T. M.)

AMMAN, *Paul*, a physician and botanist, was born at Breslau in 1634. In 1662 he received the degree of doctor of physic from the university of Leipsic, and in 1664 was admitted a member of the society *Naturæ Curiosorum*, under the name of *Dryander*. Shortly afterwards he was chosen extraordinary professor of medicine in the above-mentioned university; and in 1674 he was promoted to the botanical chair, which he again, in 1682, exchanged for the physiological. He died in 1691. Paul Amman seems to have been a man of an acute mind and extensive learning; but a restless and irritable disposition led him to engage too much in controversy, and to indulge in a degree of raillery in his writings, which the nature of the subjects hardly warranted. By his first work, which was published in 1670, under the title *Medicina Critica, seu Centuria Casuum in Facultate Lipsiensi resolutorum variis discursibus aucta*, he drew down upon himself the displeasure of the faculty, who had certainly no cause to rejoice at this exposure of their decisions. In the *Parænesis ad docentes occupata circa Institutionum medicarum Emendationem*, which appeared three years afterwards, and in the *Irenicum Numæ Pompilii cum Hippocrate*, which he published in 1689, he showed his independent turn of thinking, by boldly attacking the systems of Galen and Hippocrates, and the abuses to which the implicit adoption of them had given rise. But it is chiefly on his botanical writings that his fame ought to rest. The *Supellex Botanica, et Manuductio ad Materiam Medicam*, which he committed to the press in 1675, contains a full but somewhat prolix catalogue of the plants of the botanic garden of Leipsic and its environs, with their synonyms; followed by a brief introduction to the study of the *Materia Medica*, which exhibits an accurate knowledge of the science he was then employed in teaching. His next publication was entitled, *Character Naturalis Plantarum;* to the second edition of which, in 1685, he prefixed a dissertation on the true classification of plants. In this work he adopted the arrangement of Morison, endeavouring to show, as the title imports, that the genera of plants were only to be distinguished by their parts of fructification, and illustrating his method by the description of 1476 different genera and species, in alphabetical order. An enlarged edition of this book was published by Daniel Nebel in 1700, with the addition of the characters of Tournefort and Hermann. For a complete list of Paul Amman's writings, see Haller, *Bibl. Med.*, and Eloy, *Dict. Hist.* (T. M.)

Amman, or *Ammant*, in the *German* and *Belgic Polity*, a judge who has the cognizance of civil causes. It is also used among the French for a public notary, or officer, who draws up instruments and deeds.

AMMANATI, Bartolomeo, a celebrated Florentine architect and sculptor, of the time of Michael Angelo, who was much employed both at home and in Rome. The beautiful and stable bridge over the Arno, *Ponte della Trinita*, is one of his celebrated works. The three arches are elliptic, very light, and elegant, yet have resisted the utmost fury of the river which has swept away several other bridges at different times. He was born in 1511, and died in 1592, at the age of 81. His wife, daughter of Giov. Antonio Baltiferi, an elegant and accomplished woman, published a volume of poems that are highly esteemed in Italy.

AMMIANUS Marcellinus, a Roman historian of the fourth century, was born in the city of Antioch, in Syria. Having served several years in the early part of his life in the army, he was afterwards promoted to the honourable station of *protector domesticus*. In the year 350 he entered the service of Constantius, the emperor of the East, and under the command of Ursicinus, a general of the horse, he served during several expeditions. According to his own modest relation, it appears that he acquired considerable military fame, and that he deserved well of his sovereign. He attended the emperor Julian in his expedition into Persia, but history is silent respecting his having obtained any higher military promotion than that which has already been mentioned. He was either in the city or the vicinity of Antioch when the conspiracy of Theodorus was discovered, in the reign of Valens, and was an eye-witness of the severe torments to which many persons were exposed by the emperor on that account.

But his lasting reputation was not to be acquired from military exertions. He left the army and retired to Rome, where he employed his time and talents in writing a history of that empire, comprising a period of 282 years. Though a Greek by birth, he wrote in the Latin language; but, according to the remark of Vossius, his Latin shows that he was a Greek, and also a soldier. His history extended from the accession of Nerva to the death of Valens; and the work was originally divided into thirty-one books. Of these the first thirteen have perished, and the eighteen which remain commence with the seventeenth year of the reign of Constantius, and terminate at the year 378. But there are several facts mentioned in the history which prove that the author was alive in the year 380. Of this number are the accession of Theodosius to the eastern empire, the character of Gratian, and the consulate of Neothorius. Some have reckoned the style harsh and redundant, but this may easily be excused, from his education and military life; and the valuable information communicated abundantly compensates for that defect. Candour and impartiality are leading features in his history. Gibbon appears to have fairly estimated his character, when he says that he is "an accurate and faithful guide, who composed the history of his own times without indulging the prejudices and passions which usually affect the mind of a contemporary."

There is a difference of opinion as to whether he was a Christian or a pagan. But the respectful manner in which he speaks of pagan deities, and of the advantage of heathen auguries to foretell future events, renders it abundantly evident that he was a heathen. The favourable account which he gives of the religion, manners, and fortitude of Christians, is the result of his candour and impartiality as an historian. The work of Ammianus has passed through several editions, of which the best are the Leyden edition of 1693, and those of Leipsic, published in 1773 and 1808.

AMMIRATO, Scipio, an eminent Italian historian, born at Lecce in Naples in 1531. After travelling over great part of Italy without settling to his satisfaction, he was engaged by the great duke of Tuscany to write the *History of Florence*, for which he was presented to a canonry in the cathedral there. He wrote other works while in this station, and died in 1600.

AMMODYTES, a genus of Mamacopterygious fishes; of which our sand eel, *A. Tobianus*, is one.

AMMON, or Ammonium, the ancient name of the celebrated oasis (Siwah) on the west of Egypt, containing the oracle of the god Ammon. Arrian calls it a *place*, in which stood the temple of Jupiter Ammon, entirely surrounded by sandy wastes. Pliny states, that the oracle of Ammon was 12 days' journey from Memphis, and among the *Nomi* of Egypt he reckons the *Nomos Ammoniacus;* Diodorus Siculus says that the district where the temple stood, though surrounded with deserts, was watered by dews which fell nowhere else in all that country. It was agreeably adorned with fruitful trees and springs, and full of villages. In the middle stood the Acropolis or citadel, encompassed with a triple wall; the first and inmost of which contained the palace; the others the apartments of the women, the household, and children, as also the temple of the god, and the sacred fountains for lustrations. Without the Acropolis stood, at no great distance, another temple of Ammon, shaded by a number of tall trees; near which there was a fountain, called that of the sun, or *Solis Fons*, because subject to extraordinary changes according to the time of the day; morning and evening warm, at noon cold, at midnight extremely hot. A kind of fossil salt was said to be naturally produced here. It was dug out of the earth in large oblong pieces, transparent as crystal. It was thought to be a present worthy of kings, and was used by the Egyptians in their sacrifices. From this our sal-ammoniac has taken its name. The observations of Brown and Hornemann prove that the oasis of Siwah is the district in which this celebrated oracle was situated. Pliny places it at 12 days' journey from Memphis, and Hornemann reached Siwah in 12 days from Cairo. These travellers found an old building 32 feet long, 15 broad, and 18 high, formed of large stones, and with some hieroglyphics upon it. This is most probably the ancient sanctuary of Ammon, which was placed in an inclosure, and surrounded by an outer wall. Near this old building is a spring, which still preserves, in popular opinion, the qualities attributed by the ancients to the Fountain of the Sun, and which, in fact, belong to all deep-seated cold springs. Our modern travellers found also the salt incrustations, the numerous date-trees, and the sea-shells and fossil wood in the neighbouring desert, which Strabo and other ancient writers notice. Arrian and Diodorus describe the district as having a breadth of 40 or 50 stadia, with which Brown's estimate of 4 to 6 English miles nearly agrees. Hornemann makes the circumference 50 miles, but he includes some patches of habitable land near it, but not contiguous to it.

Ammon, or Hammon, in *Heathen Mythology*, the name of the Egyptian Jupiter, worshipped under the figure of a ram. See Amon.

Ammon, or Ammonius, *Andreas*, an excellent Latin poet, born at Lucca in 1477, was sent by Pope Leo X. to England, in the characters of prothonotary of the apostolic see, and collector-general of that kingdom. He was a man of singular genius and learning, and soon became acquainted with the principal literati of those times; particularly with Erasmus, Colet, and others, for the sake of whose company he resided some time at Oxford. The advice which Erasmus gives him, in regard to pushing his fortune, has a good deal of humour in it, and was certainly intended as a satire on the artful methods generally practised by the selfish and ambitious part of mankind. "In the first place," says he, "throw off all sense of shame; thrust yourself into every one's business, and elbow out whomsoever you can; neither love nor hate any one; measure everything by your own advantage; let this be the scope and drift of all your actions. Give nothing but what is to be returned with usury, and be complaisant to every body. Have always two strings to your bow. Feign that you are solicited by many from abroad, and get everything ready for your departure. Show letters inviting you elsewhere, with great promises." Ammon was Latin secretary to Henry VIII., but at what time he was appointed does not appear. In 1512 he was made canon and prebendary of the collegiate chapel of St Stephen, in the palace of Westminster. He was likewise prebendary of Wells; and in 1514 was presented to the rectory of Dychial in that diocese. About the same time, by the king's special recommendation, he was also made prebendary of Salisbury. He died in the year 1517, and was buried in St Stephen's chapel in the palace of Westminster. He was esteemed an elegant Latin writer, and an admirable poet. The epistles of Erasmus to Ammon, abounds with encomiums on his genius and learning. His works are, 1. Epistolæ ad Erasmum, lib. i.; 2. Scotici Conflictus Historia, lib. i.; 3. Bucolicæ vel Eclogæ, lib. i. Basil, 1546, 8vo; 4. De Rebus Nihil, lib. i.; 5. Panegyricus quidam, lib. i.; 6. Varii Generis Epigrammata, lib. i.; 7. Poemata Diversa, lib. i.

AMMONIA, or Volatile Alkali. See Chemistry.

Ammonia, a name of Juno in Greece. It is also used in ancient authors for the country of Lybia.

AMMONIAC, a concrete, gummy, resinous juice brought from the East Indies, usually in large masses, composed of little lumps or tears, of a milky colour, but soon changing, upon being exposed to the air, to a yellowish hue. We now know that the plant which affords this juice is *Dorema ammoniacum*. It is one of the Umbelliferæ (*Pent. digyn.*), and grows on an arid soil in the province of Irak in Persia, 42 miles from Ispahan. It grows also near Herat in Khorassan, and on the north-western slopes of the Himalayas. The plant is said also to grow in Nubia, Abyssinia, and the interior parts of Egypt. It is brought to the western parts of Europe from Egypt, and to England from the Red Sea, by ships trading to the east. Such tears as are large, dry, free from little stones, seeds, or other impurities, should be picked out, and preferred for internal use: the coarser kind is purified by softening it in hot water and colature, and then carefully inspissating it; unless this be skilfully done, the gum will lose a considerable portion of its more volatile parts. There is often vended in the shops, under the name of strained gum-ammoniacum, a composition of ingredients much inferior in virtue. Ammoniac has a nauseous, sweet taste, followed by a bitter one; and a peculiar smell, somewhat like that of galbanum, but more grateful; it softens in the mouth, and grows of a whiter colour when chewed. Thrown upon live coals, it burns away in flame. It is partially soluble in water and in vinegar, with which it assumes the appearance of milk; but the resinous part, amounting to about one-half, subsides on standing. It is of considerable use in the *Materia Medica* as an antispasmodic.

Ammoniac, *Sal*, a saline substance, formerly much used in dyeing and some other arts. At present not much of it is employed in this country, most of the sal-ammoniac manufactured in Great Britain being sent to Russia.

Sal-ammoniac is usually in the form of a hard, white cake, opaque, or only slightly translucent. Its taste is cooling, saline, and rather disagreeable; though it has been occasionally employed as a seasoner of food. Its specific gravity is 1·441, according to the mean of the experiments of Wallerius, Watson, and Kirwan. It requires rather more than three times its weight of cold water to dissolve it. The primary form is considered to be the cube; but it crystallises also in octahedrons, and in a figure bounded by 24 trapeziums, formed by replacing the angles of the cube by three triangular faces. These, when they increase very much, cause the faces of the cube to disappear, and thus form a 24-sided figure, known in mineralogy by the name of *leucite* crystal. A hundred parts of alcohol, of the specific gravity 0·834, dissolve $1\frac{1}{2}$ part of this salt. When exposed to a moist atmosphere, it gradually absorbs water, and deliquesces, though very slowly. When heated, it sublimes unaltered in a white smoke, having a peculiar smell, very characteristic of sal-ammoniac. If a cold body be presented to this smoke, the sal-ammoniac condenses on it, and forms a white crust. When thus sublimed, it has the property of carrying along with it various bodies, which, when heated by themselves, are perfectly fixed.

If quicklime or potash be triturated with sal-ammoniac, a strong smell of ammonia exhales. If sulphuric acid be poured upon it, vapours of muriatic acid are separated in abundance. If equal bulks of muriatic acid gas and ammoniacal gas be brought into contact, they immediately combine and condense into sal-ammoniac. These facts, which are well known, show us that sal-ammoniac is a salt composed of muriatic acid and ammonia. The composition of this salt seems to have been first discovered by Tournefort in 1700. The experiments of Geoffroy junior in 1716 and 1723 were still more decisive, and those of Duhamel, in 1735, left no doubt upon the subject. Various experiments have been made by modern chemists to determine the proportions of the constituents of this salt. Dr Thomson first pointed out a process by synthesis, which has the advantage of being very simple, and at the same time rigidly accurate. He observed, that when muriatic gas and ammoniacal gas, both as dry as possible, are brought in contact with each other, they always combine in equal volumes; therefore sal-ammoniac is composed of 100 measures of muriatic acid gas, united with 100 measures of ammoniacal gas. Now, 100 inches of muriatic acid gas weigh 40·011 grains, and 100 cubic inches of ammoniacal gas weigh 18·3837 grains. Hence sal-ammoniac is composed of

| | | |
|---|---|---|
| Muriatic acid ............... | 40·011 | or 4·625 |
| Ammonia ................... | 18·3837 | or 2·125 |

But 4·625 is the weight of an atom of muriatic acid, while 2·125 is the weight of an atom of ammonia. Hence, it is evident that sal-ammoniac is a compound of

| | |
|---|---|
| 1 atom muriatic acid ..................... | 4·625 |
| 1 atom ammonia ......................... | 2·125 |
| | 6·750 |

and that an integrant particle of it weighs 6·750.

Ammoniac. But there is another way in which the composition of this salt may be viewed. Muriatic acid is a compound of chlorine and hydrogen. It has been shown, that most of the substances hitherto called *muriates* are in fact *chlorides*, or combinations of chlorine with the metallic bases of the alkalies, earths, or metallic oxides respectively. Thus, *common salt* is a *chloride of sodium*, or a compound of chlorine and sodium; *horn silver* is a *chloride of silver*, or a compound of chlorine and silver. If a hole be dug in a piece of sal-ammoniac; if this hole be slightly moistened by breathing on it; if a globule of mercury be put into it, and this globule be subjected to the action of a tolerably powerful galvanic battery, the mercury speedily acquires the consistence of butter, and swells up so as to amount to nearly four times its original bulk. In short, it is converted into an amalgam. Ammonia itself may be substituted for sal-ammoniac; but the experiment, in that case, is attended with greater difficulty. In this case the ammonia is evidently altered by the galvanic energy, and one of its constituents has combined with the mercury, and converted it into an amalgam. If the amalgam be put under water, it is speedily reduced to the state of pure mercury, while in the mean time ammonia and hydrogen gas are evolved. The same thing happens if the amalgam be put into a glass tube without any water. It would appear from this, that, by the galvanic energy, ammonia has been united to hydrogen, and converted into a substance which is capable of amalgamating with mercury.

Now, no instance can be produced of any substance uniting with mercury, and forming an amalgam which retains the metallic lustre, except a metal. Hence we are entitled to infer, that the mercury in the preceding experiment has united with a metal, and that the compound of ammonia and hydrogen is a metal. This supposed compound of ammonia and hydrogen has received the name of *ammonium*.

Ammonia itself has been shown to be a compound of

| | |
|---|---|
| 1 atom azote | 1·75 |
| 3 atoms hydrogen | 0·375 |
| | 2·125 |

while muriatic acid is a compound of

| | |
|---|---|
| 1 atom chlorine | 4·5 |
| 1 atom hydrogen | 0·125 |
| | 4·625 |

Were the atom of hydrogen in the muriatic acid to combine with the ammonia and convert it into *ammonium*, then ammonium would be a compound of

| | |
|---|---|
| 1 atom azote | 1·75 |
| 4 atoms hydrogen | 0·50 |
| | 2·25 |

The integrant particle of it would weigh 2·25. We might conceive sal-ammoniac to be a compound of

| | |
|---|---|
| 1 atom chlorine | 4·5 |
| 1 atom ammonium | 2·25 |
| | 6·75 |

According to this view, it would be a *chloride of ammonium*. The atomic constituents are the same according to both views; the only difference lies in the way in which these atoms are united. If sal-ammoniac be a muriate of ammonia, then one atom of hydrogen is united with one atom of chlorine, constituting muriatic acid, while three atoms of hydrogen are united with one atom of azote, constituting ammonia. If it be a chloride of ammonium, then four atoms of hydrogen are united to one atom of azote, constituting ammonium, an integrant particle of which is united to an atom of chlorine. It is impossible to determine, in the present state of chemical knowledge, which of these views is the true one. We have no other evidence of the existence of ammonium than the amalgam formed with mercury by means of sal-ammoniac and the galvanic battery, and the resolution of this amalgam into mercury, ammonia, and hydrogen. But this curious experiment is not easily explained upon any other supposition.

Ammoniac.

The name *ammoniacus sal* occurs in Pliny, lib. xxxi. cap. vii. He tells us that it was applied to a kind of fossil salt found below the sand, in a district of Cyrenaica, from which circumstance its name was derived. It was similar in appearance to the *alumen scissile*, had a disagreeable taste, but was useful in medicine. The general opinion is, that the sal-ammoniac of the ancients was the same as that of the moderns; but the imperfect description of Pliny is far from being sufficient to decide the point. The native sal-ammoniac of Bucharia, as described by Model and Karsten, and which was analyzed by Klaproth, has no resemblance to the salt described by Pliny. The same remark applies to the sal-ammoniac of volcanoes. Dioscorides, in mentioning sal-ammoniac (book v. chap. cxxvi.), makes use of a phrase quite irreconcilable with the description of Pliny, and rather applicable to rock-salt than to our sal-ammoniac. Sal-ammoniac, he says, is peculiarly prized if it can be easily split into rectangular fragments. Finally, we have no proof whatever that sal-ammoniac occurs at present, either near the temple of Jupiter Ammon, or in any part of Cyrenaica. These circumstances induce us to conclude that the term *sal-ammoniac* was applied as indefinitely by the ancients as most of their other chemical words. It may have been given to the same salt which is known to the moderns by that appellation, but was not confined to it.

The name *sal-ammoniac* is derived, according to some, from the temple of Jupiter Ammon, in the neighbourhood of which it was found; according to others, from a district of Cyrenaica called Ammonia; but according to Pliny, from the sand in which it occurred,—the Greek name for sand being *αμμος*.

But whether our sal-ammoniac was known to the ancients or not, there can be no doubt that it was well known to the alchemists. Albertus Magnus, in his treatise *De Alchymia*, informs us, that there were two kinds of sal-ammoniac, a natural and an artificial. The natural was sometimes white, and sometimes red; the artificial was more useful to the chemist. He does not tell us how it was prepared, but he describes the method of subliming it, which can leave no doubt that it was real sal-ammoniac. In the *Opera Mineralia* of Isaac Hollandus the father, addressed to his son, there is likewise a description of the mode of subliming sal-ammoniac. There can be no doubt, then, that true sal-ammoniac was known in the thirteenth century. Basil Valentine, in his *Currus Triumphalis Antimonii*, describes some of the peculiar properties of sal-ammoniac in a still less equivocal manner, if possible; but, after the two older writers already quoted, his evidence is unnecessary.

Sal-ammoniac occurs native in Bucharia, and probably in other parts of the world. It is found also in small quantities near volcanoes, being formed during the extraordinary convulsions of these mountains. This fact seems in corroboration of an opinion advanced by some mineralogists, that the principal fuel of volcanoes is pit-coal, and that they are always moistened with sea-water; for sal-ammoniac is sublimed in small quantities during the burning of London bricks, the sand of which is brought from the sea-shore, while the fuel is pit-coal.

Ammoniac. In the Latin, English, and French chemical books published in the seventeenth and the beginning of the eighteenth century, the name of this salt is usually written *sal-armoniac.* This we conceive to be an old German word; for Agricola has given us an alphabetical catalogue of all the Latin technical terms which he uses in his works, with a German translation of each. Now, the German translation which he gives of *sal-ammoniacus* is *sal-armoniac.* The present German name for this salt is *salmiak.*

Egypt is the country where sal-ammoniac was first manufactured, and from which Europe for many years was supplied with it. This commerce was first carried on by the Venetians, and afterwards by the Dutch. Nothing was known about the method employed by the Egyptians till the year 1719. In 1716 Geoffroy junior read a paper to the French academy, showing that sal-ammoniac must be formed by sublimation; but his opinion was opposed so violently by Homberg and Lemery, that the paper was not printed. In 1719 M. Lemaire, the French consul at Cairo, sent the academy an account of the mode of manufacturing sal-ammoniac in Egypt. The salt, it appeared, was obtained by simple sublimation from soot. In the year 1760 Linnæus communicated to the Royal Society a correct detail of the whole process, which he had received from Dr Hasselquist, who had travelled in that country as a naturalist. This account is published in the 51st volume of the *Philosophical Transactions*, 1760, p. 504. Almost the only fuel used in Egypt is the dung of cattle. This is collected during the first four months of the year, when the cattle feed on spring grass, which in Egypt is a kind of clover. It is dried, and sold to the common people as fuel. The soot from this fuel is carefully collected and sold to the sal-ammoniac makers, who only work during the months of March and April; for at other periods of the year the dung of their cattle is not fit for their purpose. An oblong oven is built of bricks and moist dung, as long again as broad, and of such a size that the outside or flat part of the top of the arch may hold fifty glass vessels, ten in length, and five in breadth, each vessel having a cavity left for it in the brick work of the arch. These glass vessels are globular, with a neck an inch long and two inches wide. In general they are about eighteen inches in diameter. Each vessel is coated over with a fine clay found in the Nile, and afterwards with straw. They are filled two thirds with soot, and put into their holes at the top of the oven. At first a gentle fire is raised, and the temperature is gradually increased to the highest degree, at which it is kept for three days. A smoke with a sourish smell, not unpleasant, issues first from the glasses, then the salt sublimes, and coats the upper part of the vessel.

It was long supposed that camels' urine and camels' dung were essential for the success of the above process; but this is a mistake. The dung of black-cattle, horses, sheep, goats, &c. are all used promiscuously. The dung of these animals contains the sal-ammoniac ready formed. This depends upon the food which the animals live on, and accordingly it is only fit for the purpose at one season of the year. The soot contains the sal-ammoniac likewise ready formed, and merely mixed with a quantity of charcoal, oil, &c. from which it is freed by sublimation. Chaptal informs us that he found sal-ammoniac in the soot obtained by burning the dung of cattle that had fed on the saline plants in the marshes near the Mediterranean. Thus the Egyptian method of obtaining sal-ammoniac is the simplest possible.

The first attempt to manufacture sal-ammoniac in Europe was made by a Mr Goodwin, a chemist of London, about the beginning of the eighteenth century. We do not know his process accurately; but he appears to have used the mother ley of common salt and putrid urine as ingredients. Dossie, in his *Institutes of Experimental Chemistry*, gives it as his opinion, that the salt obtained by this process was not sal-ammoniac, but sulphate of ammonia, and even describes a process for subliming that salt. But he must have been mistaken; for sulphate of ammonia, as appears from the experiments of Hatchett, is entirely decomposed when we attempt to sublime it. Goodwin's process, however, whatever it was, did not succeed, and was speedily abandoned. In the year 1740 a patent was taken out for making sal-ammoniac by a London manufacturer. The process was nearly the same as Goodwin's, and was equally unsuccessful. The first successful manufacture of sal-ammoniac in this country was established in Edinburgh by Dr Hutton and Mr Davy. We do not know in what year the manufactory was begun; but as the plan was concerted while these gentlemen were students at the university of Edinburgh, the establishment of the work cannot have been far from the year 1760. From the university of Edinburgh, Dr Hutton went to Paris. During his absence Mr Davy began the manufactory, and on his return admitted him as a partner. This original manufactory existed in Edinburgh till within these few years. The low price of sal-ammoniac during the war with Russia induced the proprietors to abandon it, as was the case with almost all the sal-ammoniac works in Britain.

Sal-ammoniac was first manufactured in France by Baumé, who established a work about the year 1760; but whether it was posterior or anterior to the work of Hutton and Davy, we do not know. Manufactories of it were afterwards established in Germany, Holland, and Flanders.

Various modes were followed in Europe to procure this salt. But the theory (if we can apply the term here) of most of the manufacturers was the same. They formed a sulphate of ammonia, which they mixed with common salt. A double decomposition took place. The sulphuric acid of the sulphate united with the soda of the common salt, and formed Glauber's salt, which was obtained in great abundance by crystallization, and sold as a medicine. The muriatic acid and ammonia, uniting together, formed sal-ammoniac, which was sublimed. When the British government imposed a heavy duty on Glauber salts, the manufacture of sal-ammoniac in this country received so severe a blow, that it is not likely ever to recover it. We shall give a short sketch of the processes followed in different manufactories, in order to afford a more distinct idea of the method of procuring this salt.

Before the French revolution, several manufactures of sal-ammoniac existed in Flanders, which deserve to be described; first, because they were in some measure an imitation of the original Egyptian method. Bricks, or rather balls, were formed of the following materials: twenty-five parts of pounded pit-coal, five parts of soot, two parts of clay, and as much of a saturated aqueous solution of common salt as was sufficient to convert the whole into a paste; this paste was moulded in an iron mould, and the balls suffered to dry. These were burnt in a brick furnace, along with a quantity of dry bones, the proportion of which does not appear to have been accurately determined. The furnace communicated by an aperture, two inches wide, into a vaulted brick chamber above. From the top of this chamber there was a communication, likewise two inches wide, with a horizontal gallery, which terminated in a perpendicular chimney. The fire was kept up with these materials for five or six months, and then allowed to go out. By the combustion of the pit-coals, soot, and bones, a quantity of carbonate of ammonia is formed. The common salt is decomposed by the clay, and muriatic acid disengaged. This acid coming in contact with the carbonate of ammonia, decomposes it, and sal-ammoniac is formed. The sides and roof of the vaulted chamber are found coated with this impure sal-ammoniac, which is carefully removed. The bottom of the chamber, and the horizontal gallery above, contain likewise sal-ammoniac, but so much loaded with bitumen, that it requires to be burnt a second time before the sal-ammoniac can be extracted. The impure sal-ammoniac is put into egg-shaped clay vessels, twenty inches long and sixteen in diameter. Each is filled to within three inches of the top. The lower part of these vessels is exposed to a graduated heat for forty-eight hours, while the upper part, being left in the air, is comparatively cool. The oily matter is first driven off, and then the sal-ammoniac is sublimed in a cake in the upper part of the vessel. The charcoal, and any other fixed matter present, remains at the bottom. Finally, the clay vessels are broken, and the cakes of sal-ammoniac taken out. There is a small hole in the upper part of the clay vessels, and care is taken to keep this hole open during the whole process, to prevent the vessels from bursting. Fifteen parts of the sooty matter taken from the vaulted chambers yield about five parts of sal-ammoniac. (*Journal des Mines*, No. X. p. 3.)

The original process of Baumé was to distil animal substances, in order to procure from them carbonate of ammonia. With this salt he decomposed the muriate of magnesia, which exists in considerable quantity in the mother ley of common salt, when that substance is procured from sea-water; the liquid containing the sal-ammoniac was evaporated, and the sal-ammoniac sublimed. This process was speedily abandoned, and another substituted in its place by MM. Leblanc and Dizé. They brought into contact, in a leaden chamber, vapours of ammonia and of muriatic acid. The ammonia was procured by distilling animal substances, and the muriatic acid by decomposing common salt by means of sulphuric acid. But this method, though it yielded a very pure sal-ammoniac, was speedily abandoned on account of its expense.

The process of Hutton and Davy was to procure ammonia, which they did chiefly from soot. This they converted into sulphate of ammonia. The sulphate was mixed with common salt, and thus two salts were procured; Glauber's salt, which they obtained by crystallization, and sal-ammoniac, which was sublimed.

Almost all the manufactures of sal-ammoniac, whether in Britain, France, or Germany, were similar in principle to that of Hutton and Davy. The only difference consisted in the means employed to procure the sulphate of ammonia. We shall describe a manufacture, formerly existing in London, in which the methods employed were both scientific and economical.

The material from which the ammonia was extracted was bones. These were collected in the streets and from dunghills, chiefly by old women. The bones were bruised and boiled, in order to extract the fat which they contained, which was sold to the soap-makers. They were then put into iron cylinders eight feet long and three feet in diameter, placed horizontally over a fire-place, so that they could be made red-hot. At one end of the cylinder was a mouth, about fourteen inches in diameter, by which the bones were introduced. This mouth was accurately shut by a cover, and made air-tight by means of lute. From the other end of the cylinder proceeded a cast-iron pipe, from six to eight inches in diameter, and twenty feet long, terminating in one or more oblong leaden receivers, which were kept cool by water placed in a leaden vessel, the bottom of which formed their cover, the juncture being secured by lute. Of these receivers there were commonly two to each still, or three to two stills. Every receiver was about twelve feet long, one foot deep, and fourteen inches wide; and the refrigeratory that covered it held about four inches in depth of water. At the end most remote from the still was a pipe, fitted with a wooden plug, for the purpose of drawing off the condensed liquor; and above this was a hole through which the gas and uncondensible vapour passed off into the open air.

A single charge of each still yielded about 36 pounds of impure alkaline liquor, and about 30 pounds of black fetid oil floating on its surface. This latter being skimmed off, the ammonia was saturated with sulphuric acid, either by means of the mother liquor from the green vitriol makers, or still more economically by means of calcined and pulverized gypsum. In this last case the materials were mixed, and left in contact for some hours. A double decomposition took place; the sulphuric acid of the gypsum uniting with the ammonia, while the carbonic acid of the carbonate combined with the lime of the gypsum. The solution of sulphate of ammonia thus produced was mixed with common salt, by which Glauber's salt and sal-ammoniac were formed, and separated from each other.

For this purpose the liquid, clarified by subsidence and decantation, was transferred into oblong leaden boilers, about nine feet long, three wide, and nine inches deep. Two thirds of the length of these boilers were set upon iron plates heated by a fire beneath; the remaining part was supported by flat tiles, and defended from the heat by a solid brick work. As the water evaporates, the Glauber's salt begins to crystallize. It is swept from time to time to the cool extremity of the boiler, whence it is shovelled into baskets placed over the end of the boiler, that the liquid which drains off may not be lost. The evaporation is continued till feathered crystals of sal-ammoniac begin to appear on the surface. The liquid is then run into coolers, and deposits little else than sal-ammoniac till the temperature sinks to 70°. The crystals must now be removed, that they may not be mixed with the Glauber's salt, which begins at that temperature to be deposited. The sal-ammoniac thus obtained is first drained in baskets, and then exposed to heat in a kind of oven, till the water of crystallization is driven off. It becomes spongy, friable, of an ash-colour, mixed with small white filaments.

This salt is introduced, while still hot, into globular grey earthen jars, fitted with a cover (with a hole of about half an inch diameter in its centre), luted on with a mixture of clay and horse-dung. These are set in earthen pots over a strong fire, in a furnace of either a circular or oval form, and capable of containing from six to eighteen, surrounded with sand up to the edge of the pot, and also having about $2\frac{1}{2}$ inches of sand on the cover, confined by an iron ring about three inches deep, and two inches less in diameter than the cover, in order that the luting, should it give way, may be repaired without suffering the covers to be cooled by the removal of the sand; for, during the sublimation, their temperature should be about 320°. These earthen vessels may be filled with the dried salt to within two inches of the top. It may be gently pressed in, but not rammed close. The fire, which has been lighted some time before, is now to be raised gradually till the iron pots are of a pretty strong red heat all

Ammonites. round. They are so placed in the furnace that the upper part is first heated, the bottoms resting on solid brick work. At first a quantity of aqueous vapour, carrying with it a portion of the salt, escapes through the hole in the cover. The hole must be left open as long as any moisture exhales. This is known by bringing a cold smooth iron plate near the hole, in order to condense the sublimate. When the water is gone, the salt attaches itself to this plate in the form of a dry semi-transparent crust. The hole is now to be stopped up with lute, and more sand put upon the cover. The heat is to be kept up till it is judged that most of the sal-ammoniac, but not the whole, has sublimed. The time requisite for this, depending on the furnace, can only be learned by experience. If the heat be continued too long, the cake of sal-ammoniac acquires a yellow colour, and a scorched, opaque, crackled appearance, which, injuring its saleability, ought to be avoided. When the lute gives way, and requires repairing during the process, the appearance of the cake of sal-ammoniac is injured. On this account glass vessels would be preferable to those of clay. But in this country the expense of glass is so great, on account of the high duty laid upon it, that manufacturers are scarcely able to use it in those cases where the vessels must be broken at the end of every process, as is the case in the sublimation of sal-ammoniac. (Aikin's *Dictionary of Chemistry*, article Sal-Ammoniac.)

One process more deserves to be mentioned, on account of its ingenuity and simplicity. It was the invention of Mr Astley, who secured the exclusive privilege by a patent, and had a manufactory at Borrowstowness on the Frith of Forth, and another at Portobello, near Edinburgh. He mixed together animal matters (chiefly woollen rags) with what in Scotland is called *spirit of salt.* It is the mother ley that remains after all the crystals of common salt that can be got have been separated from seawater. It consists chiefly of muriate of magnesia. This mixture was burnt in furnaces, and the produce received in small chambers placed over the furnaces. This produce contained abundance of sal-ammoniac, which was obtained pure by sublimation. We conceive the theory of this process to be, that carbonate of ammonia is formed by the combustion of the animal matter. This carbonate immediately decomposes the muriate of magnesia, and sal-ammoniac sublimes. In principle, therefore, it does not differ from Baumé's original process, though in point of economy it is probably greatly superior to it. We have little doubt that Baumé's method yields a greater return from the same quantity of materials; but this is probably much more than counterbalanced by the much greater expense attending his process. Nothing can demonstrate this more clearly than the circumstance that his method was abandoned in France as too expensive, though labour be much cheaper in that country than in this, while Mr Astley manufactured his sal-ammoniac with profit in the neighbourhood of Edinburgh. (T. T.)

AMMONITES, a fossil genus of spiral chambered shell, containing numerous species approaching nearest to the living nautilus.—See Von Buch, *Ann. de Sciences Nat.;* Sowerby's *Conchology;* D'Orbigny, *Palæont. Franc.*

AMMONITES, the descendants of the younger son of Lot (Gen. xix. 38). They originally occupied a tract of country east of the Amorites, and separated from the Moabites by the river Arnon. It was previously in the possession of a gigantic race called Zamzummins (Deut. ii. 20). The Israelites, on reaching the borders of the Promised Land, were commanded not to molest the children of Ammon, for the sake of their progenitor Lot. Nevertheless, frequent wars were carried on between Israel and the Ammonites up to the time of Judas Maccabæus (B.C. 164), who fought many battles with the Ammonites, and took Jazer, with the towns belonging to it. Justin Martyr affirms that in his time the Ammonites were numerous (*Dial. cum Tryph.* § 119). Origen speaks of their country under the general denomination of Arabia. Josephus says that the Moabites and Ammonites were inhabitants of Cœle-Syria (*Antiq.* i. 11, § 5).

Ammonitis — Ammonius.

Their national idol was Molech or Milcom, whose worship was introduced among the Israelites by the Ammonitish wives of Solomon (1 Kings xi. 5. 7).

AMMONITIS, in *Ancient Geography*, a country of Arabia Petræa, occupied by the children of Ammon, whence the appellation. It was a small district, situated among the upper branches of the river Jabbok, eastward of the Dead Sea.

AMMONIUS, surnamed SACCAS, from his having been in his youth a porter, was born in Alexandria about the end of the second century. He was one of the most celebrated philosophers of his age; and, adopting with alterations the Eclectic philosophy, laid the foundation of that sect which was distinguished by the name of the *New Platonists.*

This learned man was born of Christian parents, and educated in their religion, the outward profession of which, it is said, he never entirely deserted. As his genius was vast and comprehensive, so were his projects bold and singular: he attempted a general coalition of all sects, whether philosophical or religious, by framing a system of doctrines which he imagined calculated to unite them all, the Christians not excepted, in the most perfect harmony. In pursuance of this design, he maintained that the great principles of all philosophical and religious truth were to be found equally in all sects; that they differed from each other only in their method of expressing them, and in some opinions of little or no importance; and that, by a proper interpretation of their respective sentiments, they might easily be united into one body. Accordingly all the Gentile religions, and even the Christian, were to be illustrated and explained by the principles of this universal philosophy; and the fables of the poets and priests were to be removed from Paganism, and the comments and interpretations of the disciples of Jesus from Christianity. In conformity to this plan, he insisted that all the religious systems of all nations should be restored to their original purity, and reduced to their primitive standard, viz., the ancient philosophy of the east, preserved uncorrupted by Plato: and he affirmed that this project was agreeable to the intentions of Jesus Christ, whose sole view in descending upon earth was to set bounds to the reigning superstition, to remove the errors that had blended themselves with the religions of all nations, but not to abolish the ancient theology from which they were derived. He therefore adopted the doctrines which were received in Egypt concerning the universe and the Deity, considered as constituting one great whole; concerning the eternity of the world, the nature of souls, the empire of Providence, and the government of the world by dæmons. He also established a system of moral discipline, which allowed the people in general to live according to the laws of their country and the dictates of nature, but required the wise to exalt their minds by contemplation, and to mortify the body, so that they might be capable of enjoying the presence and assistance of the dæmons, and of ascending after death to the presence of the Supreme Parent. In order to reconcile the popular religion, and particularly the Christian, with this new system, he made the whole history of the heathen gods an allegory; maintaining that they were only celestial ministers, entitled to an inferior kind of worship. He acknowledged also that Jesus Christ was an excellent man, and the friend of God; but alleged that it was not his design entirely to abolish the worship of dæmons, and that his only intention was to purify the ancient religion. This system, so plausible in its first rise, but so comprehensive and complying in its progress, has been the source of innumerable errors and corruptions in the Christian church. At its first establishment it received some countenance from Athenagoras, Pantænus, and Clemens the Alexandrian, and all who had the care of the public school belonging to the Christians at Alexandria. It was afterwards adopted with various degrees of assent by Longinus, the celebrated author of the treatise on the Sublime, Plotinus, Herennius, Origen, Porphyry, Iamblichus the disciple of Porphyry, Sopater, Edisius, Eustathius, Maximus of Ephesus, Priscus, Chrysanthius the master of Julian, Julian the Apostate, Hierocles, Proclus, and many others, both Pagans and Christians. Ammonius opened his school A.D. 193, and died A.D. 243.

His opinions may be gathered from the writings and disputations of his disciples. The only work of his now extant is a *Diatessaron*, or Harmony of the Gospels, which is preserved in the Latin version of Victor, bishop of Capua (who wrongly ascribed it to Tatian), and of Luscinius.

AMMUNITION, a general name for all warlike provisions, but more particularly powder, ball, &c.

AMNESTY, in matters of policy, denotes a pardon granted by a prince to his rebellious subjects, usually with some exceptions: such was that granted by Charles II. at his restoration. The word is formed from the Greek ἀμνηστία, the name of an edict of this kind published by Thrasybulus, on his expulsion of the tyrants out of Athens. An amnesty marks the pre-existence of revolution or rebellion, and those countries are happiest where it is least known. Many amnesties have been granted in France and other parts of Europe during the past half century, but since the Jacobite insurrections none has been deemed necessary in Britain. The latest act of amnesty is the 20th Geo. II. c. 52, "An Act for the King's most gracious general and free pardon." A similar act was passed after the rebellion of 1715. In both instances, however, punishments had been extensively inflicted before the passing of the amnesty, and acts of forfeiture were passed against those persons conspicuous in the insurrections who could not be apprehended and brought to trial. The old treason law of England contained a general principle of amnesty honourable to the humanity of its authors, exempting from punishment those charged with treason against a king *de jure*, unless he were king *de facto*. This was pleaded by Sir Harry Vane when he was brought to trial at the Restoration; but the plea was met by the discreditable quibble that Charles II. was king not only *de jure* but *de facto* from the time of his father's death, though he was "kept out of the exercise of his royal authority by traitors and rebels."

AMNIOS, or AMNION, a thin pellucid membrane, which surrounds the fœtus in the womb. See ANATOMY.

AMOEBÆUM, in *Ancient Poetry*, a kind of poem representing a dispute between two persons, who are made to answer each other alternately: such are the third and seventh of Virgil's Eclogues.

AMOL, or AMUL, a city of Persia, in the province of Masenderan, on the Heras, about 12 miles above its entrance into the Caspian, and over which there is a bridge of 12 arches. The population in winter is about 40,000, but a great number of these are shepherds, who leave the city in summer to tend their flocks. Here is a magnificent mausoleum erected by Shah Abbas to a former sovereign; and in its vicinity are many mounds and Persian remains.

AMOMUM, an aromatic genus of plants, natives of hot climates, especially the East Indies. See BOTANY.

AMON, or AMUN, or AMMON, the name of an Egyptian god, in whom the classical writers unanimously recognise their own Zeus and Jupiter. The primitive seat of his worship appears to have been at Meroë, from which it descended to Thebes, and thence, according to Herodotus (ii. 54), was transmitted to the oasis of Siwah and to Dodona; in all which places there were celebrated oracles of this god. His chief temple and oracle in Egypt, however, were at Thebes, a city peculiarly consecrated to him, and which is probably meant by the No and No Amon of the prophets. He is generally represented on Egyptian monuments by the seated figure of a man with a ram's head, or by that of an entire ram, and of a blue colour. In honour of him, the inhabitants of the Thebaid abstained from the flesh of sheep, but they annually sacrificed a ram to him and dressed his image in the hide. A religious reason for that ceremony is assigned by Herodotus (ii. 42); but Diodorus (iii. 72) ascribes his wearing horns to a more trivial cause.

As for the power which was worshipped under the form of Amon, Macrobius asserts (*Saturnal.* i. 21) that the Libyans adored the setting sun under that of their Ammon; but he points to the connection between the ram's horns of the god and Aries in the zodiac.

The etymology of the name is obscure. Eustathius says that, according to some, the word means *shepherd*. Jablonski proposed an etymology by which it would signify *producing light;* and Champollion, in his latest interpretation, assigned it the sense of *hidden*. There is little doubt that the pointed Hebrew text correctly represents the Egyptian name of the god, and, besides what may be gathered from the forms of the name in the classical writers, Kosegarten argues that the enchorial Amn was pronounced Amon, because names in which it forms a part are so written in Greek, as Ἀμονρασόνθηρ. Moreover, Ἀμῶν and Ἀμοῦν are found in Iamblichus and Plutarch; and the latter expressly says that the Greeks changed the native name into Ἄμμων.

AMON, fourteenth king of Judah, reigned two years, and was assassinated B.C. 642.

AMONEBURG, a small town of Hesse-Cassel, on the river Ohm, 8 miles east of Marburg. Pop. 1200.

AMONTONS, GUILLAUME, a celebrated French experimental philosopher, was the son of an advocate who had left his native province of Normandy, and established himself at Paris, where the subject of this memoir was born in 1663. The exertions of genius frequently take a particular direction from accidental circumstances. A severe illness with which Amontons was afflicted in his early youth, had the effect of rendering him almost entirely deaf, and consequently of secluding him in a great measure from the ordinary commerce and amusements of society. Being compelled by this accident to depend for his enjoyments on the resources of his own mind, he began to take great pleasure in the construction of machines of various kinds, and in the study of the laws of mechanics; a path of inquiry which he pursued through life with unremitting ardour and distinguished success. One of the first objects which engaged his attention was the discovery of the perpetual motion; an attempt which, though necessarily unsuccessful, was productive of greater advantage to him than it has usually been to those who have pursued that vain chimera.

Amontons directed his views in a particular manner to the improvement of instruments employed in physical experiments; a subject which requires the finest applications of mechanical principles, and which till that time had not met with a due share of attention. In 1687, before he had attained his 24th year, he presented to the Academy of Sciences an hygrometer of his own invention, which was received with approbation by that learned body. In 1695 he published the only work which he has given to the world. It was dedicated to the academy, and entitled *Remarques et*

*Expériences Physiques sur la Construction d'un Nouvel Clepsydre sur les Baromètres, les Thermomètres, et les Hygromètres.* After Huygens' beautiful application of the pendulum to the regulation of the motion of clocks, any attempt to revive the clepsydra, an incommodious instrument, and not susceptible of much accuracy, might seem to subject its author to the imputation of not sufficiently appreciating the great importance of a discovery which has so completely changed the face of astronomical science; but the object of Amontons was to produce an instrument capable of measuring time on board ship, in circumstances where the motion of the vessel rendered such timekeepers as were then known useless. The machine which he constructed is said to have been extremely ingenious, and probably differed entirely from those of the ancients, among whom the clepsydra was in common use.

In 1689 Amontons was admitted into the Academy of Sciences, the memoirs of which he enriched with many important contributions. The first paper which he presented after his admission was one on the theory of *Friction*, a subject then involved in great obscurity, and on which his inquiries tended to throw considerable light. After that appeared, in succession, an account of a New Thermometer, and of numerous Experiments made with the Barometer, relative to the nature and properties of Air,—a detailed account of all which is given in the history of the academy. By his countrymen he is generally regarded as the inventor of the telegraph; and he had the honour of exhibiting the methods by which he proposed to accomplish the object in view, before some members of the royal family. It appears, however, from a paper read by Dr Hooke to the Royal Society in 1684, that that ingenious philosopher had brought the telegraph, in theory at least, to a state of far greater maturity than Amontons, and nearly 20 years earlier. The experiments of the latter were made about the year 1702. It may be regarded as a curious fact in the history of inventions, that although the great importance of telegraphic communication is obvious, and the method of accomplishing it was clearly explained by Hooke, and its practicability demonstrated by Amontons, it continued to be regarded as a mere *jeu d'esprit*, and was not regularly applied to useful purposes till nearly a century afterwards, at the time of the French Revolution. Amontons died in 1705, aged 42.

AMORBACH, a city of the kingdom of Bavaria, in the circle of Lower Franconia, 24 miles south of Aschaffenburg. It is situated at the junction of the rivers Mudau and Bill, and has a castle, the residence of the princes of Leiningen, and once a very rich Benedictine abbey, two churches, a chapel, an almshouse, and manufactures of cloth, paper, &c. Pop. 2900.

AMORGO, an island in the Archipelago, south-east of Naxos, in Lat. 36. 48. N. Long. 26. 0. E. It is about 36 miles in circumference, and has a small town of the same name, with an excellent harbour, Port Anna, on its north-east coast. It is mountainous, and produces wine, oil, wheat, barley, &c. Pop. 3000. The poet Simonides was born here.

AMORITES, the descendants of one of the sons of Canaan, the most powerful and distinguished of the Canaanitish nations. We find them first noticed in Gen. xiv. 7, "the Amorites that dwelt in Hazezon-tamar," afterwards called Engedi, a city in the wilderness of Judea not far from the Dead Sea. In the promise to Abraham (Gen. xv. 21), the Amorites are specified as one of the nations whose country would be given to his posterity. When the Israelites were about to enter the Promised Land, the Amorites occupied a tract on both sides of the Jordan. They were under two kings—Sihon king of Heshbon, and Og king of Bashan, who "dwelt at Ashtaroth" (Deut. i. 4). Before hostilities commenced messengers were sent to Sihon, requesting permission to pass through his land; but Sihon refused, and came to Jahaz and fought with Israel; and Israel smote him with the edge of the sword, &c. (Num. xxi. 24). Og also gave battle to the Israelites at Edrei, and was totally defeated. Still, after repeated severe defeats, the Amorites, by means of their war-chariots and cavalry, confined the Danites to the hills, and would not suffer them to settle in the plains: they even succeeded in retaining possession of some of the mountainous parts. "The Amorites *would* dwell in Mount Heres in Aijalon, and in Shaalbim, yet the hand of the house of Joseph prevailed, so that they became tributaries. And the coast of the Amorites was from *the going up to Akrabbim* (*the steep of Scorpions*), from the rock and upwards" (Judges i. 34–36).

AMORPHOUS (α, priv., and μόρφη, form), a term of frequent use in physical science, to denote the absence of determinate form.

AMORTIZATION, in *Law*, the alienation of lands or tenements to a corporation or fraternity and their successors. See MORTMAIN.

AMOS, one of the twelve minor prophets, and a contemporary of Isaiah and Hosea. He was a native of Tekoah, about six miles south of Bethlehem, inhabited chiefly by shepherds, to which class he belonged, being also a dresser of sycamore-trees. The period during which he filled the prophetic office was of short duration, unless we suppose that he uttered other predictions which are not recorded. It is stated expressly that he prophesied in the days of Uzziah, king of Judah, and in the days of Jeroboam, the son of Joash, king of Israel, two years before the earthquake (Amos i. 1). As Jeroboam died in the fifteenth year of Uzziah's reign, this earthquake, to which there is an allusion in Zechariah (xiv. 5), could not have happened later than the seventeenth year of Uzziah: and as Uzziah and Jeroboam were contemporaries for about fourteen years, from B.C. 798 to 784, the latter of these dates will mark the period when Amos prophesied.

The allusions in the writings of this prophet are numerous and varied; they refer to natural objects, to historical events, to agricultural or pastoral employments and occurrences, and to national institutions and customs.

Some peculiar expressions occur; such as "cleanness of teeth," a parallelism to "want of bread," iv. 6.; and in the orthography there are a few peculiarities.

The canonicity of the Book of Amos is amply supported both by Jewish and Christian authorities. Philo, Josephus, and the Talmud include it among the minor prophets. It is also in the catalogues of Melito, Jerome, and the sixtieth canon of the Council of Laodicea. Justin Martyr, in his *Dialogue with Trypho* (§ 22), quotes a considerable part of the fifth and sixth chapters. There are two quotations from it in the New Testament: the first (v. 25, 26) by the proto-martyr Stephen, Acts vii. 42; the second (ix. 11) by the apostle James, Acts xv. 16.

AMOUR, GUILLAUME DE ST, a canon of Beauvais in the thirteenth century, who distinguished himself greatly by his defence of the privileges of the university of Paris against ecclesiastical encroachments.

AMOUR, or AMUR, a great river of Chinese Tartary, which has its rise in the central deserts of northern Asia, among the mountains of Daouria, in about Long. 109. E. and Lat. 49. N. It has a winding course; flowing first in a northerly direction; and afterwards making a long detour towards the east; then turning to the north, it falls into the sea of Okhotsk, in about Lat. 53. N., opposite to the middle of the island or peninsula of Saghalien. This river is called Amur by the Russians, after the confluence of the Argun and the Schilka; and still higher up the Schilka is formed by the union of the Onon and Ingoda. It is called Schilka by the Tungoose; Saghalien Oula, or Black Mountain River, by the Tartars; and Ghelon Kiangh, or the Dragon River, by the Chinese. It was first known to the Russians in 1639; and they resolved to annex to their empire the territory through which it flows, on account of the valuable furs with which it was known to abound. Many sanguinary conflicts accordingly took place between them and the Chinese, which ended in a treaty in 1689, by which the Russians abandoned their settlement on its banks, from which they were wholly excluded until the year 1847, when the navigation of this river was by treaty again opened to them. The river, which pours out an immense body of water, is navigable for large vessels as far as the Russian town of Nertschink, 1500 miles from the sea, though its stream is rapid, and it is annually frozen for some time. The length of its course is upwards of 2200 miles.

AMOY, a commercial city and seaport of China, in the province of Fokien, on a small island of the same name, in Lat. 24. 10. N. and Long. 118. 13. E. The city is neither clean nor well built, but it has many public buildings and shops. It is commanded by a citadel on a height, with fortifications. Amoy was captured by the British in 1841; and is one of the five Chinese ports opened up to British commerce by the treaty of 1842. Its harbour is deep, commodious, and safe, so that vessels on entering do not require the assistance of pilots. The traffic of Amoy is very considerable: in 1847, 117 vessels entered its harbour, with an aggregate burden of 16,494 tons; and the value of its imports, by British ships, during the same year was L.179,758, by foreign vessels L.75,976; of its exports in British vessels L.7139, in foreign vessels L.8568. Its principal exports are crockery-ware, umbrellas, tea, sugar, sugar-candy, paper, tobacco, camphor, and grass-cloth. Population in 1847, 250,000.

AMPERE, Andre Marie, professor of mathematical analysis in the Polytechnic School of Paris, and one of the most distinguished philosophers of this century, was born at Lyons in 1775. Among his numerous publications, on various branches of knowledge, he is best known by his Electro-Magnetico-Dynamic papers, which were afterwards embodied in two volumes entitled *Recueil des Observations Electro-Dynamiques*, Paris, 1824–26. His mechanical invention is there exhibited in the various beautiful contrivances by which he demonstrated the force and direction of electro-magnetic currents, and his sagacity by the philosophical spirit with which he explained the phenomena. His speculations *On the Application of the Calculus of Variations to Mechanical Problems*, as well as his first publication in 1820, *Considerations on the Mathematical Theory of Games of Chance*, are specimens of refined and profound speculation. He also showed an early interest in the Chemical Theory of Definite Proportions. In 1824 he published a remarkable paper *On the Surface-curve of Luminous Waves;* and about 1830, a good *Essay on the Philosophy of the Sciences.* Besides these larger works, he was the author of several papers in *Le Journal de l'Ecole Polytechnique*, and in *Memoires de l'Institut.*, on mechanical philosophy and natural history. Ampere died at Paris in 1836, at the age of 61. (T. S. T.)

AMPHIARAUS, in *Pagan Mythology*, a celebrated prophet, who possessed part of the kingdom of Argos. He was believed to excel in divining by dreams, and is said to have been the first who divined by fire. Amphiaraus, knowing by the spirit of prophecy that he should lose his life in the war against Thebes, hid himself in order to avoid engaging in that expedition; but his wife Eriphyle, being prevailed upon by a present, discovered the place in which he had concealed himself, so that he was obliged to accompany the other princes who marched against Thebes. This proved fatal to him; for the earth being split asunder by a thunderbolt, both he and his chariot were swallowed up in the opening. Amphiaraus, after his death, was ranked among the gods; temples were dedicated to him; and his oracle became very famous, as well as the sports instituted in his honour.

AMPHIBIA, a term in *Zoology* bestowed on different groups of animals, and with a considerable variety of signification. When rigorously interpreted, it applies to very few animals, as, with rare exceptions, naturalists know of no species which are strictly amphibious; that is to say, possessed of the power of performing the vital act of respiration either in air or water. When intended, however, merely to express the habit of existing alternately for a time in either of these elements, the term *amphibious* applies to various groups, which have little in common with each other. Hence the artificial mode of arrangement adopted by Gesner and the older naturalists, who, taking into consideration chiefly the habitations of animals, bestowed the name of amphibia on beavers, otters, frogs, and other incongruous genera. Linnæus applied the name, in his earlier works, to a class composed of reptiles and chondropterygious fishes; but he afterwards restricted it to reptiles alone possessed of cold red blood and a simple circulation. The amphibia of Baron Cuvier, again, are such of the mammalia or mammiferous quadrupeds as are enabled by their motive organs to dwell in water as well as on the land; for example, seals, sea lions, the walrus, &c. In his system they occupy an intermediate station between the feline and marsupial or pouched animals. They pass the greater portion of their time at sea, and seldom come ashore except to suckle their young, or dry their moistened furs by exposure to sun and air. Their power of sustaining without injury a long-continued submersion does not, however, result from a continuance of the *foramen ovale*, by which it was supposed that the blood of these creatures passed from one chamber of the heart to another, without the necessity of being propelled through the lungs. Seals do not differ in that respect from other animals.

Buffon was of opinion that the newly born young of all mammiferous quadrupeds might be submerged in a nourishing fluid without depriving them of life, because their circulation at that early period was supposed to resemble that of amphibious reptiles. Experiments, however, on this subject would no doubt have accorded perfectly with those of Le Gallois, instituted with a view to ascertain the possibility of dividing the spinal marrow without the production of death. It is singular that Daubenton, his skilful and laborious coadjutor, did not remind Buffon that the fœtus, while suspended in the liquid of the amnios, receives oxygenated blood from the mother, whilst after birth a necessity ensues for the vital act of respiration being performed by the individual itself. It is also known that the *foramen ovale* does not exist at the period of birth, except in such species as are destined to enjoy a continuance of that peculiarity of structure; from which we may infer that a primordial disposition of organs is of greater importance, and less easily alterable, than many modern physiologists are accustomed to suppose.

The principal characteristic of reptiles in general consists in this, that only a portion of the blood is transmitted through the lungs, the remainder being projected by the heart directly to the other parts of the body, without being specially subjected to the influence of the respiratory organs; whereas in the higher classes, such as man, the rest of the mammalia, and birds, the whole of the blood must pass by the lungs before it is retransmitted to the more distant parts of the circulating system. The respiration of animals, or the process by which the blood is oxygenated, becomes weaker and less frequent in proportion to the diminution which takes place in the quantity of blood transmitted to the lungs, compared with that which passes directly from the heart; and as it is respiration which warms the blood, and produces in the fibres their susceptibility of nervous irritation, it follows, as observed by Cuvier, that the blood of reptiles is cold, and their muscular strength much less than that of birds or quadrupeds. The seat of their sensations is also much less centralised than in the last-named classes; and hence many of them exhibit life and motion long after their heads have been severed from their bodies.

A truly amphibious animal, according to the proper meaning of the term, ought to possess the power of breathing under water like a fish, and of respiring the atmospheric air like a land animal. According to this interpretation, neither seals nor beavers, nor even whales, are truly amphibious; for they cannot sustain their existence under water except by aid of a certain portion of air which they have inspired at the surface. In like manner, neither the frog nor the tadpole is amphibious (unless it may be for a short time at a certain intermediate period of life); for the former only seeks the water as a place of temporary resort, in which, however, it cannot breathe; and the latter is entirely aquatic, being unprovided with lungs, and consequently unable to respire, except through the medium of water. A frog can therefore only be said to be amphibious in as far as it possesses, at two distinct periods of its life, the faculty of living first in the water and then on the land; but its habit of life is by no means optional, and the change of structure, both in the respiratory and digestive system, as it passes from the immature to the adult state, is among the most extraordinary in the whole range of the animal economy. Born with gills, and destitute of external members, its form and functions are rather those of a fish than of a reptile; but as it advances in growth, the four limbs become developed, the tail decreases and finally disappears, the jaws are formed, the gills are absorbed, and their uses are supplied by lungs. It can no longer breathe under water.

Among the many wonderful anomalies with which the kingdom of nature presents us, there exist, however, certain truly amphibious animals, classed under the genera of *Proteus* and *Siren*, both of which are provided at one and the same time with the gills of a fish and the lungs of a terrestrial creature; but their habits and propensities are decidedly aquatic. The former inhabit the subterranean waters of Carniola; the latter (of which there are several species) occur among the marshes and rice-fields of South Carolina. For an account of these singular animals see the article REPTILIA. (J. W.)

AMPHIBOLE and AMPHIBOLITE, augite and hornblende. See MINERALOGY.

AMPHIBOLOGY, in *Grammar* and *Rhetoric*, a term used to denote a phrase susceptible of two different interpretations. Amphibology arises from the order of the phrase, rather than from the ambiguous meaning of a word. Of this kind was that answer which Pyrrhus received from the oracle: *Aio te, Æacida, Romanos vincere posse;* where the amphibology consists in this, that the words *te* and *Romanos* may either of them precede, or either of them follow the words *posse vincere*, indifferently.

AMPHIBRACHYS, in *Greek* and *Latin Poetry*, the name of a foot consisting of three syllables, whereof that in the middle is long and the other two short; such are the words ăbīrĕ, ămārĕ.

AMPHICOME, in *Natural History*, a kind of figured stone, of a round shape, but rugged, and beset with eminences, celebrated on account of its use in divination. The word is originally Greek, αμφικομη, *q. d. utrinque comata*, or hairy on all sides. This stone is also called *Erotylus*, Ερωτυλος, *Amatoria*, probably on account of its supposed power of creating love. The amphicome is mentioned by Democritus and Pliny.

AMPHICTYONY, in *Greek Antiquity*, was an association of several tribes for the purpose of insuring the observation of the law of nations towards one another, and of protecting the temple of the deity whose worship formed the outward bond of union among the several tribes. It is acknowledged on all hands, and admitted by the ancients themselves, that the name is formed from ἀμφί and κτίζω, or rather κτίω, whence its meaning is "the dwellers around" (a common centre). According to this etymology, the name ought to be spelt *Amphictiony;* but in deference to the ancient legend, which connects the institution with the mythical hero Amphictyon, the spelling *Amphictyony* still prevails; although there were Greek amphictyonies with which that hero neither had, nor could have had, any connection whatever. There is positive evidence that several associations of this kind existed in Greece at a very early period; and they are of special interest to the philosophic historian, because they are the first symptoms of civilisation and humanity, and do great honour to the age in which they originated; but what that age was, and what the circumstances were which occasioned the formation of such confederacies, are questions concerning which we have no historical information. Tradition, indeed, connects the institution with the Attic king Amphictyon; but it was in all probability not formed till after the period of the Doric migration, when the affairs of Greece became gradually settled.

The most important of these confederations was the *Amphictyony of Delphi, or Thermopylæ.* It has been supposed that this was a confederation of the Hellenes against the Pelasgians; but this opinion is sufficiently refuted by the fact, that among its members we find both Hellenes and Pelasgians. The names of the twelve tribes forming this Amphictyonic league are not the same in all authorities. Harpocration, with whom Libanius and Suidas on the whole agree, mentions the Ionians, Dorians, Perrhæbians, Bœotians, Magnetes, Achæans, Phthians, Malians, Dolopians, Ænianians, Delphians, and Phocians. Æschines has no more than eleven, and instead of the Achæans, Ænianians, Delphians, and Dolopians, he only gives the Thessalians, Œteans, and Locrians; while lastly, Pausanias's list contains only ten names, viz., the Ionians, Dolopians, Thessalians, Ænianians, Magnetes, Malians, Phthians, Dorians, Phocians, and Locrians. The differences in these lists have been accounted for by the assumption that they refer to different times, but we have no evidence of any members of the confederacy having ever dropped off before the sacred war, after which the Phocians were excluded for a short time. Hence we have to supply two tribes for the list of Pausanias, and one for that of Æschines; for it must be observed that the number twelve was unalterably fixed. The tribe wanting in Æschines are the Dolopians, and those which must be added to the list of Pausanias are the Perrhæbians and Bœotians. The Œteans, mentioned by Æschines alone, are the same as the Ænianians whom he omits, and who dwelt around Mount Œta. The Achæans and Phthians, moreover, are the same, and should have been recorded as the Phthian Achæans. The Delphians also did not at first form members of the league, but rose to that rank only in later times, and instead of these two names the Thessalians and Locrians have to be entered in the list of Harpocration. Hence the Delphic Amphictyony consisted of the Ionians, Dolopians, Thessalians, Ænianians (Œteans), Magnetes, Malians, Phthian Achæans, Dorians, Phocians (including the Delphians), Locrians, Bœotians, and Perrhæbians, who were Pelasgians. All these nations dwelt, in the earliest times, in and about Thessaly, while afterwards we find them more scattered over different parts of Greece; and this circumstance alone shows, that the formation of the league must belong to a very early period.

All the twelve members of this confederacy, though some were very insignificant, and were even treated by others as subjects, had equal rights at the meetings, and the vote of the smallest tribe was as weighty as that of the most powerful. The objects of the league are distinctly expressed in the oath which the Amphictyons had to take, and which is preserved in Æschines' oration 'De Falsa Legatione.' This oath bound the Amphictyons not to destroy any of the Amphictyonic towns, not to turn away its running waters either in time of war or in time of peace; and if any one should attempt to rob the temple of Delphi (the common centre of the confederacy), to employ their hands, feet, tongue, and their whole power, to bring him to punishment. The humanising influence which this and other enactments of the confederacy were intended to exercise, is perceptible in the part relating to war. The framer of the law evidently regarded war only as an unavoidable means of settling disputes between two states; but it was to be carried on only for the purpose of bringing the dispute to a decision, and not for destruction and devastation. Another enactment probably was that the inhabitants of a conquered city should not be sold as slaves. But the chief care of the Amphictyons appears to have been to watch over the temple, to punish those who were guilty of a crime against it, and to reward those who did anything to increase its splendour and glory. In later times the political influence of the league generally lay dormant, until it was exercised by some powerful state or individual for selfish purposes.

The Amphictyons had regularly two meetings every year in the spring at Delphi, and in the autumn at Anthela, near the pass of Thermopylæ. At Delphi the deputies met in the temple of Apollo, and at Anthela in that of Demeter. This circumstance of the two places of meeting, and of the two divinities with which the Amphictyony was connected, renders it highly probable that, in the form in which we know it, it was a union of originally two distinct Amphictyonies, each of which had its own religious centre. The deputies of the several states who met at these places are called *Pylagoræ* (Πυλαγόροι, or αι), and *Hieromnemones* (Ἱερομνήμονες). The difference between these two classes of deputies has been the subject of much discussion among the learned; but if we admit that our Amphictyony was a union of two, the Pylagoræ were probably the deputies sent to Thermopylæ, and the Hieromnemones those sent to Delphi, the former, after the union, taking precedence at the meetings at Thermopylæ, and the latter at those of Delphi. The deputies sent to these annual meetings were appointed by lot in their respective states; and each state had two votes. The meetings, however, were attended not only by the deputies but by thousands of others who flocked to Delphi or Thermopylæ for religious and mercantile purposes, or only for the sake of amusement. This occasioned popular meetings (ἐκκλησίαι) distinct from those of the regular deputies. But we cannot suppose that all the Greeks indiscriminately were allowed to take part in those popular assemblies, which must have consisted of visitors from the states which were members of the Amphictyony.

The constitution of the confederacy and the number of its members remained, as far as we know, unaltered until the time of the sacred war; after the termination of which, in B.C. 346, the Phocians were excluded from the league. The same was the fate of the Lacedæmonians, who had supported the Phocians. The vacancy was filled up by the admission of the Macedonians to the league. The Phocians, however, were afterwards restored to their position, because they had distinguished themselves by their valour during the invasion of the Gauls under Brennus. At the time of the Ætolian ascendency in Greece, the Ætolians appear to have usurped the power of the Amphictyons. Strabo speaks of the Amphictyons as broken up in his own time; and although their name occurs even at a much later time, yet they cannot have exercised any influence on the affairs of Greece. The whole institution died away into the same obscurity in which its origin is buried.

Amphictyony.

Wise and humane as were the objects of the Amphictyons, yet, wherever they actively interfered in the affairs of Greece during the historical period, we find that they were more powerful for evil than for good; and the holy wars which were carried on by them in the defence of the Delphic temple, and the honour of its god, contributed not a little to the demoralisation of the Greeks.

The very first time that the Amphictyons interfered in the affairs of Greece, we find them acting in direct opposition to the spirit of their institution. We allude to the Crissæan or first sacred war, which broke out in B.C. 594 and lasted till B.C. 585. The inhabitants of Crissa (or Cirrha) on the Corinthian Gulf, were charged with extortion and violence towards the strangers who landed at their port, or passed through their territory on their way to Delphi. For this the Amphictyons declared war against Crissa, and it was vigorously carried on, in the name of the league, by the Thessalians and Cleisthenes, the tyrant of Sicyon. They even pretended to have the sanction of Apollo to dedicate the Crissæans and their territory to the god, to enslave them, and make their land a waste for ever. The war is said to have been terminated by a stratagem of Solon, who poisoned the waters of the river Pleistos, from which the town was supplied. When the town was taken, the vow of the Amphictyons was literally carried into effect: Crissa was razed to the ground, its harbour choked up, and its fertile plain changed into a wilderness. Such was the terrible vengeance taken by a body of confederates, whose original object was to prevent those very things which they now perpetrated to uphold the honour of the deity presiding over them. The second sacred war, which likewise lasted for ten years, from B.C. 355 to 346, was carried on with unparalleled exasperation for a period of ten years, and nearly all the Greeks took part in it. The Thebans had set their hearts upon conquering Phocis, but screened their designs behind a charge preferred against the Locrians, alleging that they had robbed the temple of Delphi, because they had taken into cultivation a tract of land belonging to the Delphic temple. The Amphictyonic council, before which the charge was brought, condemned the Phocians to pay a heavy fine, and to destroy the crops of the sacred fields. No sooner was this verdict pronounced than the Thebans, Thessalians, Locrians, and Œteans took up arms to execute it. The Phocians were joined by Athens and Sparta, and took possession of the temple of Delphi and its treasures, which they were obliged to employ in defraying the expenses of the war. The war was carried on with unexampled cruelty; for even the surrender of the dead for burial was refused, and all Phocian captives were put to death. This war also afforded Philip of Macedonia an opportunity to interfere in the affairs of Greece, being invited by the Thessalians to co-operate with them against the Phocians. Philip and his Macedonians acted as the champions of the god, and defeated the Phocians in a bloody battle near Magnesia. Three thousand captive Phocians were put to death. The latter, however, remained undaunted until at length they were compelled by treachery to surrender. The Amphictyons now excluded them for ever from the league, their arms and horses were to be delivered up, their towns to be destroyed, and the people were henceforth to live in small villages, and to pay annually to the god sixty talents (about L.15,000) until the temple should be completely indemnified. Macedonian and Theban troops carried the judgment into execution: twenty-two towns disappeared from the face of the earth, and the otherwise fertile country remained for many years a wilderness. A third sacred war was decreed against the town of Amphissa, because its inhabitants had taken into cultivation the plain of Crissa; but in reality the war was brought about by the venal creatures who endeavoured to promote the ambitious schemes of Philip of Macedonia, who was bent upon making himself master of Greece. This war broke out in B.C. 338, and its unfortunate consequences led to the catastrophe which deprived Greece of her independence in the battle of Chæronea. Such is a brief outline of the history of the Delphic Amphictyony, which not only itself violated its first principles, but is not known to have ever raised its voice to condemn the wanton destruction of other Amphictyonic towns, such as Platææ and Thebes.

Other confederations of a similar kind were,—

1. The *Amphictyony of Calaurea*, connected with the temple of Poseidon, in the island of Calaurea. This Amphictyony consisted of the towns of Hermione, Epidaurus, Ægina, Athens, Prasiæ, Nauplia, and the Minyan Orchomenos. Sparta and Argos became members of it at a late period, after having contrived to get Nauplia and Prasiæ excluded. This circumstance shows that this confederation was in all probability formed before the Doric migration.

2. *Amphictyony of Onchestos*, in the territory of Haliartus in Bœotia, was likewise connected with the temple of Poseidon. As at all other Amphictyonies, the meetings of the members were celebrated with various religious rites, solemnities, and public games. We do not know the nations that constituted this league.

3. *Amphictyony of Amarynthos*, in Eubœa, connected with the temple of Artemis. We know that the two towns of Eretria and Chalcis were members of it, and that there existed an ancient treaty, by which these two cities pledged themselves not to use against each other any missiles thrown from afar. The meetings were celebrated with splendid festivals.

4. *Amphictyony of Delos*, connected with the temple of Apollo, was a league formed among the inhabitants of the Cyclades and the Ionians in the neighbourhood. Its institution was ascribed to Theseus. The solemnities connected with its meetings gradually fell into disuse, until they were revived and increased in B.C. 426, when the island of Delos was purified by the Athenians. The Athenians, after this time, regularly sent an annual embassy to Delos, and they also retained for themselves the superintendence of the temple and the administration of its treasures. (L.S.)

AMPHIDRYON, in *Ecclesiastical Writers*, denotes the veil or curtain which was drawn before the door of the *bema* in ancient churches.

AMPHILA, a wide bay in the Red Sea, encumbered with thirteen small uninhabited islets. Lat. 14. 30. N. Long. 41. E.

AMPHILOCHIA, in *Ancient Geography*, was a small district at the eastern end of the Ambracian Gulf. Its chief town was Argos, surnamed *Amphilochicum*, to distinguish it from the greater Argos.

AMPHILOCHIUS, bishop of Iconium in the fourth century, was the friend of St Gregory Nazianzen and St Basil. He assisted at the first general council of Constantinople in 381, presided at the council of Sidæ, and was a strenuous opposer of the Arians. He died in 394. His works were published in Greek and Latin at Paris, in 1644, by Francis Combefis.

AMPHILOCHUS, son of Amphiaraus and Eriphyle, was believed to have been a celebrated diviner. He had an altar erected to him at Athens, and an oracle at Mallos in Cilicia, which city was said to have been founded by him and Mopsus. The answers of this oracle were given by dreams; and the party inquiring used to pass a night in the temple, that night's dream being the answer.

AMPHIMACER, in *Ancient Poetry*, a foot consisting of three syllables, whereof the first and the last are long, and that in the middle short: such is the word cāstĭtās.

AMPHION, in *Greek Mythology*, the son of Zeus by Antiope, and the husband of Niobe, was a famous musician of antiquity, at the magical sounds of whose lyre the stones began to move, and formed themselves into walls around Thebes, after his conquest of that city. He was killed by Apollo for assaulting his temple; or, as some report, he destroyed himself in despair at the slaughter of his children by that god. See NIOBE.

AMPHIORCIA, or AMPHOMOSIA, in *Grecian Antiquity*, the oath taken in court by the plaintiff and the defendant, that they would speak the truth. The judges also took this oath, that they would administer the laws with impartiality.

AMPHIPOLIS, an Athenian colony, built on the site of the Thracian city Ἐννέα Ὁδοί, *the nine ways*, 497 years B.C. It was on the east bank of the river Strymon, near its origin from the lake Cercinitis. Its importance arose from its site on a navigable river, and its vicinity to the gold mines of *Mons Pangæus*. It is now Jeni Keni.

AMPHIPROSTYLES, in the architecture of the ancients, a temple which had columns in the front, and as many in the aspect behind, but none on the sides. See ARCHITECTURE.

AMPHISCII, among *Geographers*, a name applied to the people who inhabit the torrid zone. The Amphiscii, as the word imports, have their shadows one part of the year towards the north, and the other towards the south, according to the sun's place in the ecliptic. They are also called *Ascii*.

AMPHISSA, in *Ancient Geography*, the chief town of the Locri Ozolæ, about seven miles west of Delphi. The modern town of Salona occupies its site.

AMPHITHEATRE, in *Ancient Architecture*, a building of an elliptic form, of two or more stories of open arcades, with a number of interior galleries and arched passages, which served both as a communication and support to several rows of seats which rose above each other, and were arranged round a large space called the *arena*. The derivation of the word *ampitheatre* indicates that it is a place where the spectators, circuitously arranged, saw the performance equally well on all sides.

The history of amphitheatres is of considerable importance, in consequence of its connection with ancient manners. These structures owed their origin to the barbarity of the ancients, and their ruin to the humanity of the moderns. They are the production of Roman invention in the last ages of the republic. The Romans were immoderately fond of every amusement of a bloody and horrible nature. Their rulers encouraged this general feature in the Roman character, to rouse and foster that martial spirit which rendered them masters of the world. After the Samnite wars had extended the Roman sceptre over the whole peninsula of Italy, the first gladiatorial conflicts were exhibited in Rome in the year B.C. 260. Lucius Metellus brought into the circus the elephants which were part of the spoil of the Carthaginians, in the year 252, and this proved the introduction of wild beasts into the spectacles of Rome. This addition was equally agreeable to the Roman taste; and those who courted the popular favour vied with each other in entertaining the people in this barbarous manner. This soon gave birth to a profession of men denominated *gladiators*, who were trained to the combat, and for reward slaughtered one another in the arena, whilst every savage animal which the wilds of Asia or Africa produced added to the horrors of the scene.

In the days of Pompey and Cæsar these barbarous amusements were given with an astonishing profusion. In the games given by Pompey, the elephants attempted to break down the barrier between them and the people: this circumstance, and the form of the circus not enabling all the spectators to have a full view, induced Cæsar to alter the original form, and construct edifices where the people might be entertained without danger or interruption. Amphitheatres were suited to this purpose; they were therefore adopted, and became the common place for the exhibitions both of gladiators and wild beasts.

It is supposed that the first amphitheatre was composed of those singular machines, formed by Caius Curio, for the games which he presented among the funeral honours of his father. Caius constructed, in a semicircular form, two contiguous wooden theatres, moveable on wheels, first placed back to back; and the people having been amused in these the one-half of the day, they were then wheeled round, forming one spacious theatre, where the gladiators contended during the remainder of the day. Pliny is the only writer who makes mention of this amphitheatre; and from his account it is difficult to ascertain whether this was the first idea of an amphitheatre, or whether the previous sight of one had suggested this huge and wonderful structure. It is said that Julius Cæsar, a few years after, formed a hunting theatre of wood; and, in consequence of the circular position of the seats, it obtained the name of an *amphitheatre*. This appears to have been of a very superior kind, and in great estimation.

In the reign of Augustus, Statilius Taurus erected one of stone, but it seems to have been seldom used; and, from its being consumed by fire in the time of Nero, it is evident that it was not wholly of stone. These wooden buildings appear to have been generally temporary, but a few of them permanent, from the endowment bestowed upon them. The politic spirit of Augustus induced him to erect several of these; and Caligula began one, which he left unfinished. Nero formed a large and spacious one, the building of which is said to have occupied a year. Herod of Judæa erected amphitheatres both in Jerusalem and in Cæsarea. During the reign of Tiberius, one was built at Fidenæ, which Tacitus informs us fell while the games were performing, killing or injuring about 50,000 persons. There was another at Placentia, reported to have been the most spacious in Italy; but it was destroyed by fire in the contest between Vitellius and Otho.

The unfortunate accidents which happened to these wooden buildings led to the construction of others of a more strong and durable nature, where the crowd might be entertained without danger. This honour was reserved to Vespasian and Titus. In his eighth consulate the former began the amphitheatre, which the latter finished during his reign. It is said that the expense of this building would have erected a metropolis, and it is deservedly esteemed one of the most celebrated edifices of ancient times. Dio says that 9000 wild beasts were destroyed at the dedication of this huge building, but Eutropius restricts their number to 5000. After the hunting of these ferocious animals was ended, the arena was instantly filled with water, and sea animals were made to contend, and a sea-fight exhibited. This immense building obtained the appellation of the *Coliseum* or *Colosseum*.

This amphitheatre became the model of other amphitheatres throughout the empire. Compared with the original model, these were natural valleys, with seats formed in the surrounding heights similar to the amphitheatre at Corinth. On the declivity of two hills seats of stones were sometimes placed, and the extremes formed by regular works of stone. Of this kind was that of Gortyna in Candia. One in the vicinity of Sandwich in Kent had its benches formed of turf; and similar must have been those amphitheatres which were formed along with the camps and military stations of the Roman soldiers.

Amphitheatre.

When Christianity became the religion of the empire, it ameliorated the dispositions of the Romans, and induced them to lay aside this barbarous custom. Constantine the Great terminated the gladiatorial combats in the East during his reign; but they were not finally abolished at Rome until the beginning of the fifth century, in the reign of Honorius. The combats of wild beasts continued, however, some time longer; but during the progress of the fifth century these gradually declined, until they were finally abolished, and the amphitheatres were abandoned to the ravages of time and accident. During the middle ages they were sometimes employed for judicial conflicts, tilts, and tournaments; but these practices having been discontinued, the amphitheatres experienced universal neglect and ruin.

It is scarcely possible to give a clear idea of the manner in which such immense crowds of people were seated and arranged, and how they had a convenient entrance and exit. It has already been mentioned, that these buildings were circuitous, and that the exterior circuit was composed of two or more stories of arcades; and it may now be added, that the number of these stories varied according to the nature of the building. A corresponding number of arched passages and staircases opened upon the ground floor towards these stories, in the direction of radii towards the arena. These communications were again intersected by arched passages, which encircled the whole structure, and afforded an uninterrupted entrance to every part of the amphitheatre. Sometimes an intermediate gallery surrounded the whole in the centre of the fabric, and served as a common place of resort to all the stairs which led to the higher galleries. This was the form of one at Nismes. Sometimes each staircase had its distinct communication by itself. Such was the case with one at Verona.

The four radiating entries on the diameter were usually more capacious; and by the two principal of these the emperor, the senate, and other persons of distinction, were conducted to their seats on a place which was called the *podium*. The other two led to the arena, and by these the gladiators and beasts made their entrance. The various ranks of the people passed by the staircases, which led to their respective seats. The doors which opened from the staircases were called *vomitories*, and varied in magnitude, according to the extent of the amphitheatre and the number of exterior arches. The number of seats between the several vomitories was unequal, and seems to have been subject to no positive regulation. These benches were about one foot and eight inches in height, and about two feet four inches in breadth. A platform four feet eight inches broad was formed of one of these benches, which served as a circular communication to the whole building. These obtained the name of *precinctions*, and the boundaries on the side were called *belts*. The latter were surrounded by balustrades, to protect the persons from falling who occupied the benches in the vicinity. The podium was more spacious than the precinctions, and was a platform encircling the arena. From one precinction to the belt of another, a flight of stairs two feet six inches in breadth descended opposite to every vomitory. Small canals were cut in the tops of the benches, by which the rain and urine were conducted from bench to bench, until they reached the instruments prepared to convey them to the drains below. These stairs radiated from the highest

Amphitheatre.

bench to the podium; so that, with the precinctions, they separated the whole cavity into wedge-like divisions (*cunei*), which the people occupied according to their rank.

The amphitheatre called the *Coliseum* was of an elliptical form, whose longest diameter was about 581 Italian feet, and the shortest 481. The length of the diameter of the arena was about 285 feet, and the breadth 182, reserving a space for the seats and galleries of about 157 feet in breadth. The external circumference inclosed a superficies of above five acres and a half, and could scarcely be included in a parallelogram of seven acres. Three stories of arcades, adorned with columns of the Doric, Ionic, and Corinthian orders, and inclosed with a pilastrade of the Corinthian order, composed the external elevation. The first story rose about four feet from the ground, and the pavement supported the bases of the columns. The columns which supported the upper stories were placed upon pedestals. A stylobate supported the pilastrade, in which were the windows of an intermediate gallery, and in every second interpilaster was a window to illuminate the highest gallery. A cantaliver cornice, perforated with square holes, through which the erect pieces of wood passed that supported the awning to a range of corbels, about the centre of the pilastrade, crowned the building. These various columns, pilasters, and stories, appear to have been continued without interruption around the whole edifice. The height of the first story was about 30 feet, the second 38, and the third 38; the pilastrade about 44; and the whole, includiug the blocking course and the steps, was 157 feet in height. The external circumference of the whole building is 1641 Italian feet.—See *Marchese Guispe Melchiorri.*

An ellipsis of 80 open arches formed the exterior circuit of the ground plan; the piers, with three-quarter columns in front, of about 2 feet 10 inches diameter. The four which correspond to the four above-mentioned semi-diameters, were about 14 feet 2 inches, and 76 of the arches were about 13 feet 8 inches. These arches led to a large double corridor, that encircled the whole: this corridor is a magnificent and distinguishing feature in the Coliseum theatre. Square openings in the precinction above illuminated the interior corridor; and the corridor which was united with the wall of the podium appears to have been illuminated in a similar manner. A double corridor was seen on the floor of the second story, directly above the corridor of the lower floor, and an interior corridor which sent forth stairs leading to a range of vomitories on the one hand, and on the other hand an intermediate corridor which formed a mezzanine floor above the double corridor of the interior circuit. Here the stairs began to ascend to the next story, and square holes in the upper floor illuminated this gallery. A double corridor formed the third story, and it appears that here the stairs commenced that led to the galleries above. There were also some windows in the interior wall, and vomitories which opened to the uppermost cunei of benches. In a similar manner were other three stories constructed and filled above; the whole composing a most magnificent and spacious structure.

Justus Lipsius supposes that this amphitheatre was capable of containing 87,000 spectators on the benches; and Fontana adds 22,000 for the galleries and other passages. Upon a fair calculation it appears, that if fully crowded, it might contain about 80,000. This magnificent structure astonishes by its vast size, and the adaptation of its various parts to the intended use. When this amphitheatre was in its glory, and crowded with Romans, the sight must have been magnificent and striking. If the report be accurate that it was completed in two years and nine months, it affords an astonishing instance of Roman vigour and persevering industry. Besides former depredations, Michael Angelo removed nearly one-half of the external wall to build the Palazzo Farnese. To prevent these depredations, Pope Benedict XIV. consecrated these ruins, and erected several altars, which were much frequented on the Sundays and Fridays, before the revolution in France. To guard these relics, a hermit was stationed in a small dwelling near the centre.

Amphitrite ‖ Amphitryon.

Amusements.

The different kinds of amusement have already been cursorily alluded to. Gladiators contended together, or entered the lists with wild beasts. These wild animals were hunted or encountered, or left to devour each other, according to the humour of the times, or the taste of him who gave the entertainment. It appears also, that criminals were sometimes forced to fight with these ferocious creatures, for the entertainment of the people of Rome; and, in the dawn of Christianity, many of the Christians suffered death in this brutal manner. It is also reported, that artificial mountains were sometimes constructed with caves below, from whence these devouring animals rushed forth to attack their prey.

Information concerning the laws that regulated the amphitheatre is rather scanty; but the following are among the number. In the centre of one side of the podium was the emperor's seat, called the *suggestum*, and highly adorned. The remainder of the podium was occupied by senators; and when this space was not sufficient, several of the adjacent wedges were appropriated to the other senators and to persons of distinction. The equites, and the civil and military tribunes, had their places next assigned them. From this order both the liberti and the legati were excluded. The married men sat by themselves. The young men were also arranged by themselves, and their tutors sat near them to observe their conduct. The attendants and servants occupied the highest gallery. The vestals had special seats, and frequently the princesses and ladies of distinguished rank sat along with them. The front of the gallery was assigned to the women, who were placed on chairs; and the lowest order of the people stood behind them. It appears, also, that for the better accommodation of the people, the different tribes had particular cunei allotted to them. It is also proper to remark, that the arrangement in the different provinces was different from that of Rome, as circumstances varied. The general direction of the amphitheatre was under the care of an officer, named *villicus amphitheatri;* and different officers, who were called *locarii*, had the direction of the cunei. By carefully preventing any person from occupying a place to which he was not entitled, all confusion was prevented, and strict order maintained.

The means used by Pope Benedict to preserve the Coliseum at Rome have already been mentioned. Of one which was erected at Verona, only four arches of the external circuit remain. These consist of three stories of about 90 English feet. The building otherwise is almost entire. The whole building was erected without cement, and joined and secured by iron cramps, overlaid with lead. The superficies is about four acres and nearly one-third. One erected at Nismes has suffered much dilapidation; but the remains are yet worthy of the attention of the traveller. At Pola in Istria, there are the remains of an amphitheatre built on the declivity of a hill. It was erected of stone, with cramps of iron. The amphitheatre of Italica, 4 miles from Seville in Spain, is much ruined. The walls are immensely thick, and contain within them an arched passage 16 feet wide, into which the *vomitoria* opened. The diameter measures 300 feet by 195 feet.

AMPHITRITE (Αμφιτρίτη), in the *Greek Mythology*, the wife of Poseidon, and goddess of the sea; sometimes taken for the sea itself.

AMPHITRYON, son of Alcæus, and the father of Hercules, less known by his own exploits than from his wife Alcmena's adventure.

AMPHIUMA, a genus of Reptilia, found in North America. See REPTILES.

AMPHORA, in *Antiquity*, a liquid measure among the Greeks and Romans. The Roman amphora contained 48 sectari, equal to very nearly six gallons, and the Grecian or Attic amphora contained one third more.

AMPMHORA, a large vessel used by the ancients for preserving wine, oil, fruits, &c., and so called from its usually having an ear or handle on each side of the neck, whencc it was also called *diota*. It was commonly made of earthenware, but sometimes of stone, glass, or even more costly materials; its usual form was tall and narrow, diminishing below to a point. Homer and Sophocles mention amphoræ used as cinerary urns; and a discovery made in 1825 at Salona shows that they were sometimes used as coffins. The amphora was divided lengthwise to receive the corpse, then closed and deposited in the earth, thus preserving the skeletons entirc.—(Steinbüchel, *Alterthum*, p. 67.) The wicker baskets used in gathering the vintage were also called amphoræ.

AMPHORARIUM VINUM, in *Antiquity*, denotes that which is drawn or poured into *amphoræ* or pitchers; by way of distinction from *vinum doliare*, or cask wine. The Romans had a method of keeping wine in *amphoræ* for many years to ripen, by fastening the lids tight down with pitch or gypsum, and placing them either in a situation within reach of smoke, or under ground.

AMPHOTIDES, in *Antiquity*, a kind of armour or covering for the ears, worn by the ancient pugiles, to prevent their adversaries from laying hold of that part.

AMPLIATION, in a general sense, denotes the act of enlarging or extending the compass of a thing. On a medal of the emperor Antoninus Pius, we find the title *Ampliator Civium* given him, on account of his having extended the *jus civitatis*, or right of citizenship, to many states and people before excluded from that privilege. Indeed, it is generally supposed that this prince made the famous constitution whereby all the subjects of the empire were made citizens of Rome.

AMPLIATION, in *Roman Antiquity*, was the deferring to pass sentence in ccrtain causes. This the judge did by pronouncing the word *amplius;* or by writing the letters N. L. for *non liquet;* thereby signifying that, as the cause was not clear, it would be necessary to bring further evidence.

AMPLITUDE, in *Astronomy*, an arch of the horizon intercepted between the east or west point and the centre of the sun or a planet at its rising or setting; and which therefore is said to be either north and south, or *ortive* and *occasive.*

*Magnetical* AMPLITUDE, the different rising or setting of the sun from the east or west points of the compass. It is found by observing the sun, at his rising and setting, by an amplitude compass.

AMPSANCTI VALLIS, or AMSANCTI LACUS, a valley with a small sulphurous lake and cavern in the heart of the Hirpini, or Principato Ultra, about four miles from the town of Frigento (Ciccro, Pliny). It is now called *Moffeta* or *Mufiti*, from the goddess Mephitis, who had a temple there. The ancient poets imagined that this gulf led to hell. (Virg., *Æneid* vii. 563.) The Moffeta is thus described by Mr Swinburne: "We were led into a narrow valley, extending a considerable way to the south-west, and pressed in on both sides by high ridges thickly covered with copses of oak. The bottom of the dell is bare and arid: in the lowest part, and close under one of the hills, is an oval pond of muddy ash-coloured watcr, not above fifty feet in diameter; it boils up in several places with great force in irregular fits, which are always preceded by a hissing sound. The water was several times spouted up as high as our heads in a diagonal direction; a whirlpool being formed round the tube, like a basin, to receive it as it fell. A large body of vapour is continually thrown out with a loud rumbling noise. The stones on the rising ground that hang over the pool are quite yellow, being stained with the fumes of sulphur and sal-ammoniac. A most nauseous smell, rising with the steam, obliged us to watch the wind, and keep clear of it, to avoid suffocation. The water is quite insipid, both as to taste and smell; the clay at the edge is white, and carried into Puglia to rub upon scabby sheep, on which account thc lake is farmed out at 100 ducats a year. On a hill above this lake stood formerly a temple dedicatcd to the goddess Mephitis; but I perceived no remains of it."

AMPTHILL, a market town in the hundred of Redbourne Stoke, in the county of Bcdford. It is pleasantly situated in a valley between two gentle elevations. It is neatly built; has a free school, an alms-house for twelve persons, a new market-house, a bank, and an extensive brewery. In Ampthill Park, the fine domain of Lord Holland, a little westward of the town, a cross was erected in 1774, in memory of Catherine of Aragon, queen of Henry VIII. who resided there. Population in 1851, 1961. Market-day, Thursday.

AMPULLA, in *Antiquity*, a vessel of glass or earthenware bellying out like a jug, small-mouthed, and frequently covered with leather, used to contain unguents for the bath, perfumes, or any liquid. In reference to thc swollen shape of the ampulla, Horace applies the word to inflated language or bombast.

AMPULLA, among *Ecclesiastical Writers*, denotes one of the sacred vessels used at the altars. Ampullæ were also used for holding the oil used in chrismation, consecration, coronation, &c. Among the ornaments of churches we find frequent mention made of ampuls or vials.

*Knights of St* AMPULLA belong to an order instituted by Clovis I., king of France. At the coronation they bear up the canopy under which the ampulla is carried in procession.

AMPULLARIA, a Lamarckian genus of freshwater univalves. See CONCHOLOGY.

AMPURIAS, the capital of the territory of Ampurdan, in Catalonia, seated at the mouth of the river Llobregat, in Long. 2. 56. E. Lat. 42. 5. N.

AMPYX, or AMPYCTER (in Latin *Frontale*), a broad band or plate of gold worn upon the forehead in ancient times by Grecian ladies of rank, and sometimes enriched with precious stones. It was also used to adorn the heads of horses and elephants.

AMRAPHEL, the king of Shinar or Babylonia, confederated with Chedorlaomer, king of the Elamites, and two other kings, to make war against the kings of Sodom, Gomorrah, and the threc neighbouring cities. See Genesis xiv.

AMRIAL-CAIS, the most celebrated of the ancient Arabian poets, and a contemporary of Mahomet, whom he satirized. He was poisoned while attempting to avenge the death of his father, who had been murdered by his tribe. His poem was published at Leyden in 1748; and a translation of it by Sir William Jones appeared in 1782.

AMRITSIR in Northern India, a city in the British province of the Punjaub, situated within the Division of Lahore, and at an equal distance from the rivers Beas and Ravee. It is a populous and cxtensive place, having a circumference of eight miles; and though the streets are narrow, the houses are lofty and substantially built of brick. Its opulence, which is considerable, is not thc result of its manufactures, which, with the exception of fine shawls made in imitation of the Cashmere fabric, are confined to coarse cloths and inferior silks, but has been derived partly from an extensive transit trade carried on between Cashmere, Hindustan, and Central Asia, and partly from its reputation for sanctity, which has caused it to become a favourite resort for pilgrims. It is not impossible, however, that its trade may shortly be diverted to Shikarpore, Sukkur, and other towns on the Indus, where periodical commercial fairs, upon a large scale, have been recently established under the authority of the British Government. The remaining source of the prosperity of Amritsir is a reservoir or sacred basin constructed in the year 1581 by Ram Das, the fourth Guru or Spiritual Guide of the Seiks, immersion in which is supposed to purify from all sin. The reservoir is about 135 paces square, built of brick, in the centre of which stands a temple dedicated to Guru Govind Singh, in which is lodged under a silken canopy the book of laws written by this saint. From 500 to 600 priests are supported by the pious contributions of the devotees. Provision is made for an ample supply of water to the town by means of the Baree Doab Canal, now in course of execution. This canal issues from the Ravee above the town of Dinanuggur, and traversing the country in a south-westerly direction, rejoins the parent stream some distance above its junction with the Chenab. The total length of the canal and its branches is 450 miles, and its cost has been computed at L.527,000. A striking object in Amritsir is the fortress of Govindghur, built by Runjeet Sing in 1809. Measures have been recently resorted to by the British for adding to its security, and it is now a place of great strength. Distance east from Lahore 37 miles. Lat. 31. 40. N. Long. 74. 45. E. (E. T.)

AMRU-EBN-AL-AS, or Amer, one of the most famous of the first race of Saracen leaders, was descended of Aasi, of the tribe of Koreish, by a woman of infamous character. In his youth he indulged in poetry, and wrote satirical verses against the person and doctrine of Mahomet. His zeal in opposing the new religion prompted him to undertake an embassy to the king of Ethiopia, to stimulate him against the converts whom he had taken under his protection. It is uncertain by what arguments he was induced to change his religious sentiments; but he returned a convert to the Mahometan faith, and, along with Khaled, joined the fugitive prophet at Medina. The military talents of Amru had begun to attract general attention, when Abubeker resolved to make a new attack upon Syria, in which he obtained a high command. After several displays of his military valour and address in some successful enterprises, he rose to the elevated station of chief in Irak, when Khaled requested the attendance of all the Arabian generals before Damascus. During the caliphate of Omar he also served in Palestine, under Abu-Obeidah. While besieging Cæsarea, he held a memorable conference with Constantine, the son of the emperor Heraclius. Historians mention that their time was chiefly occupied in producing genealogical arguments to prove the affinity of the Greeks and Arabians, and the consequent rights of the latter as their descendants.

After the death of Obeidah, Amru assumed the chief command in Syria, in which he was confirmed by the khaliff, notwithstanding the opposition of Othman. An expedition against Egypt having been resolved upon, Amru wrote to the khaliff, informing him that he would instantly march into that country. During the progress of his march, attended by only 4000 Arabs, a messenger from Omar arrived with a letter, containing directions to return, if he should receive this letter in the territories of Syria; but if he should receive it in those of Egypt, he might advance, and all needful assistance would be instantly sent to him. Anticipating the contents, he hastened on to the frontiers of Egypt, and read the instructions of the khaliff. Then requesting some of the inhabitants to be brought before him, and inquiring of them in what country they were, and being informed that they were in Egypt, Amru replied, "Let us, then, continue our march." Having taken Pharma, he advanced to Misrah, the ancient Memphis, and besieged it for seven months. Although numerous reinforcements arrived, he would have found it very difficult to storm the place previous to the inundation of the Nile, if Mokawkas had not treacherously lessened the forces of the citadel, which was consequently taken by storm; and the Greeks who remained there were either made prisoners or put to the sword. On the same spot Amru erected a city named Fostat, the ruins of which are now known by the name of Old Cairo. The Coptic Christians, who composed the great majority of the Egyptian natives, and who were enemies to the Catholic Greeks, after this victory submitted to Amru, and engaged to provide quarters and support for the Mussulman army.

Amru pursued the Greeks to Alexandria, and, after an obstinate and bloody siege of 14 months, the city was taken A.D. 640. To Amru has generally been attributed the burning of the famous *Alexandrian Library*, by command of the khaliff Omar. But with this act of barbarism, so repugnant to the character of Omar and his general, he is for the first time charged by Abulpharagius, a Christian writer, who lived six centuries later. It is highly probable that few of the 700,000 volumes collected by the Ptolemies remained at the time of the Arab conquest, when we consider the various calamities of Alexandria from the time of Cæsar to those of Caracalla, Diocletian, and the disgraceful pillage of the library in A.D. 389 under the rule of a Christian bishop, Theophilus, a far less respectable character than the Arabian conquerors.—See Gibbon, *Decline and Fall of the Roman Empire*, c. 51.

In the year 663, of the Hegira 43, Amru died in his government of Egypt, highly esteemed, and much regretted by his countrymen. In a pathetic oration to his children on his death-bed, he bitterly lamented his youthful offence in satirizing the prophet, although Mahomet had forgiven the offence, and had frequently affirmed that "there was no Mussulman more sincere and steadfast in the faith than Amru."

AMRUM, an island of Denmark, in the German Ocean, between latitude 54. 38. and 54. 43. It contains about 15 square miles, with 600 inhabitants. It is in the barony of Westerlandfohr and Amrum, and the diocese of Ribe.

AMSDORFIANS, in *Ecclesiastical History*, a sect of Protestants in the 16th century, who took their name from Amsdorf, their leader. They maintained that good works were not only unprofitable, but were obstacles to salvation.

AMSTERDAM, or Amsteldamme, a great maritime and commercial city of Holland, capital of the canton and province of North Holland, standing in N. Lat. 52. 22. and in E. Long. 4. 53. It derives its name from the river Amstel, on the banks of which it is built, somewhat in the form of a half-moon or crescent, with the horns projecting into the river Y, an arm of the Zuyder Zee; while on the other sides it is surrounded by meadows, gardens, and country-houses.

Founded about the year 1203, Amsterdam, at the close of that century, was little more than a fishing village—its great advancement having taken place in the sixteenth century, when the persecutions of the Spaniards under the Duke of Alva drove great numbers of Flemish merchants and manufacturers to seek protection in Holland and in England; after which period it increased rapidly in wealth and importance, and during the succeeding century, and the first half of the eighteenth, maintained its pre-eminence as the metropolis of the commercial world. This city is said to be

Amsterdam.

8 miles in circumference, covering an area of 900 acres, and to contain upwards of 28,000 houses. It is surrounded by a deep fosse or canal 80 feet wide, and was regularly fortified in the fifteenth century; but the only remains of its defences are some picturesque *tetes de pont* on the Amstel, &c., and 26 bastions, each of which now supports a windmill for grinding corn. Its site having been originally a salt-marsh, all the buildings are supported on piles; whence Erasmus likened the inhabitants to storks, building on the tops of trees. These piles are from 50 to 60 feet in length; and after passing through a mixture of peat and sand of little consistence, at the depth of about 40 feet they enter a bed of firm clay, which forms a good foundation. When driven to the requisite depth, their ends are sawed level, and sometimes covered with thick planks, on which the masonry is constructed. Though many of the houses have declined from the perpendicular, they were considered to be quite secure against falling; yet that they are not altogether exempted from such a contingency was shown in 1822, by the sinking and total ruin of a large stack of warehouses heavily filled with corn. The streets in the oldest parts of the town are narrow and irregular, but the houses frequently present a picturesque sky-line, broken by fantastic gables, roofs, chimneys, towers, and turrets, of all forms and dimensions. Westward of the Amstel, which passes almost through the centre of the city, stands the more modern part, where the houses are often exceedingly handsome, the streets broad, and planted with rows of large trees between the houses and the canals. Three great canals, viz., Prinsen Gracht, Kieser's Gracht, Heeren Gracht, and a smaller one, Singel, extend in the form of polygonal crescents, nearly parallel to each other, and to the great fosse or canal that surrounds the city. Each of the three first mentioned has a length of about two miles, and the Kieser's Gracht is about 140 feet wide. Numerous smaller canals intersect the city, dividing it into 95 islets, and are traversed by no fewer than 290 bridges. All heavy burthens are transported by water. The grand bridge over the Amstel is 610 feet long, 65 in width, and supported on 36 piers, between 11 of which large vessels pass when the bridges are open. Near to this is the Amstel-sluice, by which the waters are confined and let off at pleasure. Besides the basins within the city, it has five large docks. Enclosed by the Oosterlijk Dok, is the Ryk's Maritime Dok, and the islet of Kattenburg, on which stand the arsenal, the admiralty offices, and the warehouses of the Dutch East and West India Companies. The principal shops are in the Kalver straat, the Nieuwe dyk, and Warmoes straat, and may vie with the richest of Paris or London. The chief promenade is the Plantaje or Park, near to which lie the Botanic and Zoological Gardens; and the old ramparts are now converted into boulevards. Of the public buildings, the principal is the palace, formerly the Stadhuis, an imposing structure built in 1648 by the architect Van Kampen, at the cost of 30,000,000 guelders, or L.864,200. It is supported on 13,659 piles, is 282 feet in length, 235 in breadth, and 116 feet in height, exclusive of a cupola 41 feet high. It was built for the public offices of the legislature, but was appropriated by Louis Napoleon for a palace in 1808. The great hall or council-chamber of the Republic is now a ballroom, one of the most magnificent in Europe, measuring 120 feet by 57, and 90 in height: the walls are encrusted with white Italian marble to the lofty cornice which divides the upper tier of windows from the square *mezzanine* or upper row of lights, and some good emblematic sculptures are placed over the doors of the principal apartments. In front of the palace stands the Beurs or exchange, a fine tetraprostyle Ionic building, serving as the front to a large quadrangle with a handsome peristyle of the same order. The Oude Kerk with its fine stained windows, its splendid organ, and its tombs, is an interesting object. It is 300 feet long, has three aisles, and a steeple 240 feet in height. The Nieuwe Kerk, which was commenced in 1408, is remarkable for its finely carved pulpit, and the elaborate bronze castings of the choir, the magnificent monument to the famous admiral De Ruiter, with numerous others; and a cenotaph to the memory of the gallant Van Speyk, who in the year 1831 blew up his ship and perished, rather than yield to the Belgic enemies of Holland.

Amsterdam in 1850 contained 224,235 inhabitants, of whom about 23,000 were Jews, who reside in a particular quarter of the city. There are about fifty places of public worship, viz. fifteen of the Reformed religion, sixteen Catholic, fifteen Jansenist, three Lutheran, two Anabaptist, one Moravian, one Scottish Presbyterian, one English Episcopal, one Greek, one Armenian, and four Jewish Synagogues. The charitable institutions, which are supported chiefly by voluntary contributions, amount to twenty-three, and are admirably adapted to their several ends. These include hospitals for the sick, the aged and infirm, the blind, the deaf and dumb, the insane, widows, orphans and foundlings, and an establishment for the reformation of drunkards; besides a noble institution for promoting the education and improvement of the poor, which has branches in every town in Holland. The beneficial results are very apparent; beggars and drunken people are rarely to be seen in the streets. Among the public institutions may be noticed the Spinhuis, for the punishment of delinquents; and the Rasphuis, at present used merely as a temporary arrest-house.

Notwithstanding the humidity of the atmosphere, and the deficiency of spring water, Amsterdam is healthy, and the people are robust; which must be ascribed very much to that great attention to cleanliness for which they are proverbially noted above any other nation; the only exception being in the Jews' quarter, which is dingy and dirty. This city has no good potable water but what is collected in tanks on the roofs of the houses, or brought from a distance in stone jars, and in large water-barges for the supply of those who do not possess tanks. Many of the poorer people dwell in cellars below the houses: another class live entirely on the canals, bringing up their families in comfortable apartments erected on the decks of their vessels. These vessels, which are of various sizes, according to the wealth of the proprietors, are employed in inland navigation, and are remarkable for their neatness and cleanliness, the whole domestic economy being conducted with a view to the comfort of the inmates. Sometimes may be seen even a little flower-garden on the deck. Like all the towns in Holland, Amsterdam is remarkably clean, and has an air of newness, though surpassed perhaps in these respects by Rotterdam and the Hague.

The chief literary institutions are the Athenæum or college with eleven professors, the society called "Felix Meritis," from the first words of the inscription on their place of meeting, the Scientific Institute, and the Royal Academy of the Fine Arts, in all of which lectures are delivered on science and literature. The collections of pictures and antiquities are of great value. The Museum or picture gallery in 1847 contained 386 fine pictures, chiefly of the Flemish and Dutch schools, including some by Wouvermans, Rembrandt, Vander Helst, Both, and Reubens, of wonderful power. The famous "Night-guard" of Rembrandt, and the magnificent "Banquet of the Civic Guard," by Vander Helst, are in this collection; which also possesses a fine collection of prints in 200 portfolios. Among the private collections those of MM. Six and Vander Hoop stand pre-eminent; the latter containing between 80 and 90 pictures of the old masters, besides many others. Amsterdam has a Dutch and also a German theatre, an Italian opera-house, and several minor theatres. Its industry comprises manufactures of woollen, cotton, and silk, gold lace, perfumery, and jewellery: the cutting of diamonds has long been extensively practised here by the Jews: there are refineries of borax, sugar, smalt, &c.; soap, oil, glass, iron, dye, and chemical works, distilleries, breweries, tanneries, tobacco and snuff factories, &c., &c. The commercial establishments are on a grand scale. The celebrated Bank of the Netherlands, founded in 1609, was dissolved in 1796; and the present bank, on the model of the Bank of England, was established in 1814. The commerce with all parts of the world is very extensive; though Antwerp, Rotterdam, and Hamburg, are powerful rivals. The prosperity of Amsterdam has been subject to vicissitudes: in 1785 the population is said to have amounted to 235,000; and in 1814, the epoch of its greatest depression, it had declined to 180,000; but the opening of the Helder Canal, in 1825, has done much to revive its commercial prosperity. This great work, which extends from Nieuwe Diep opposite the Texel to Amsterdam, a distance of 51 miles, has obviated the delays and dangers formerly encountered in the intricate navigation of the Zuyder Zee, and the formidable obstruction of a bar called the *Pampus* at the mouth of the Y, which obliged vessels to unload partially in the roadstead; but now the largest ships are brought direct to the city. See NAVIGATION, INLAND.

It may be noticed as a curious fact that there is not a water-mill in all Holland, owing to the flatness of the soil, which is in many parts, like Amsterdam, below the level of ocean; so that the utmost attention to the dikes is necessary to prevent the inundation of the country. The expense of keeping these dikes in repair is said to amount annually to a very large sum.

From 250 to 260 large ships belonging to Amsterdam trade to the East and West Indies, the Baltic, and Mediterranean, and the port is a scene of unceasing activity. The imports include sugar, coffee, tea, spices, tobacco, indigo, cochineal, cotton, hemp and flax, wine and brandy, linen, cotton and woollen stuffs, hides, hardwares, rock-salt, tin-plates, iron, timber, pitch and tar, whale-oil, dried fish, coal, &c. The chief exports are the produce of Holland: cheese, butter, &c.; madder, clover, rape, hemp, linseeds, rape and linseed oils, Dutch linen; the produce of East and West India possessions, and of other tropical countries; Spanish, German, and English wools, all kinds of grain, linens from Germany, gin from Schiedam, French, Rhenish, and Hungarian wines, brandy, &c. Amsterdam has a large transit trade, and a very considerable business in insurance and in bills of exchange. The number of vessels laden that entered its port in 1850 was 2000, and in ballast 28, the total tonnage being 348,082; the number that left the port laden was 1457, and in ballast 524, making a total of 347,253 tons.

There are two railways, one connecting Amsterdam with Rotterdam, the Hague, Leyden, and Haarlem; the other with Utrecht, Arnheim, and Prussia; and there is regular communication by steam-vessels with Kampen, Enkhuizen, Harlingen, and Hamburg.

AMSTERDAM, a small town in New York, United States, on the Utica Railway, 32 miles north-west of Albany. It contains 5333 inhabitants, principally employed in the manufacture of carpets, saws, scythes, &c.

AMSTERDAM, or *Tongataboo*, an island in the South Sea, discovered by Tasman, a Dutch navigator. Its greatest extent from east to west is about 21 miles, and from north to south about 13. It is broad at the east end, and tapers towards the west, where it turns, and runs to a point due north. It is about six leagues to the west of Middleburg. The shore is surrounded by coral rocks, and its most elevated parts are not above six or eight yards above the level of the sea. It is wholly laid out in plantations, in which are cultivated plantains in great variety, bread-fruit, shaddocks, yams, and the fruits of Taheite, with taro, and other esculent vegetables in great abundance. The people are familiar with the use of the bow and spear, and are dexterous fishermen. Their manners are licentious; but they have some commendable qualities, according to the missionaries; though other accounts represent them as cruel, treacherous, and vindictive. Long. 175. W. Lat. 21. 11. S.

AMSTERDAM, *New*, a seaport town of British Guiana, on the right bank of the Berbice River, near the confluence of the Canje. Lat. 6. 14. 51. S. Long. 57. 31. 8. W. It was founded by the Dutch in 1796; but is now the seat of the British Colonial Government of Berbice, formerly at Georgetown. It is a healthy town; the houses, which are generally built of wood, being separated from each other by trenches which fill and empty with the tide. The whole town is intersected by canals, communicating with the sea. The harbour is good, though the passage to it is impeded at low water by a sand-bar. Three strong batteries protect the entrance of the river. Pop. about 3000.

AMULET, a charm or preservative against mischief, witchcraft, or diseases. Amulets have been made of stone, metal, simples, animals, and, in a word, of everything that imagination could suggest. Sometimes they consisted of words, characters, sentences, ranged in a particular order, and engraved upon wood, &c., and worn about the neck, or some other part of the body. At other times they were neither written nor engraved, but prepared with many superstitious ceremonies, great regard being usually paid to the influence of the stars. The Arabians have given to this species of amulet the name of Talisman. All nations have been fond of amulets: the Jews were extremely superstitious in the use of them to drive away diseases; and the Mishna forbids them, unless received from an approved man who had cured at least three persons before by the same means. Among the Christians of the early times amulets were made of the wood of the cross, or ribands with a text of Scripture written on them, as preservatives against diseases.

AMURATH, or AMOURAD I., the third sultan of the Turks, and one of the greatest princes of the Ottoman empire, was the son of Orchan, whom he succeeded in 1360. After the capture of Gallipoli, he overran all Thrace or Romagna from the Hellespont to Mount Hæmus, and fixed the seat of the Turkish empire at Adrianople. He defeated the prince of Bulgaria, conquered Misnia, chastised his rebellious bashaws, and is said to have gained 36 battles. This prince, in order to form a body of devoted troops that might serve as the immediate guards of his person and dignity, appointed his officers to seize annually, as the imperial property, the fifth part of the Christian youth taken in war. These, after being instructed in the Mahometan religion, inured to obedience by severe discipline, and trained to warlike exercises, were formed into a body distinguished by the name of *Janizaries* or *New Soldiers*. The Janizaries soon became the chief strength and pride of the Ottoman armies, and were distinguished above all the troops whose duty it was to attend on the person of the sultan. The death of Lazarus, despot of Servia, who had endeavoured in vain to stop the progress of Amurath's arms, touched Milo, one of his servants, in so sensible a manner, that in revenge he stabbed the sultan in the midst of his troops, and killed him upon the spot, A.D. 1389, after he had reigned 23 years. He was the grandson of Othman, and was succeeded by his son Bajazet.—Gibbon, xi.

AMURATH II., the tenth emperor of the Turks, was the eldest son of Mahomet I. and succeeded his father in 1421. He besieged Constantinople and Belgrade without success; but he took Saloniki from the Venetians, and compelled the prince of Bosnia, and John Castriot, prince of Albania, to pay him tribute. He obliged the latter to send his three sons as hostages, among whom was George, celebrated in history by the name of *Scanderbeg.* John Hunniades defeated Amurath's troops, and obliged him to make peace with the Christian princes in 1442. These princes afterwards breaking the peace, Amurath defeated them in the famous battle of Varna, November 10. 1444, which proved so fatal to the Christians, and in which Ladislaus, king of Hungary, was killed. Amurath twice abdicated the throne, first in 1442, and again in 1444, in favour of his son. In his retreat he was the companion of Santons and Dervishes; practising their fasts and gyrations until the exigencies of the state again called the royal fanatic into the field. He afterwards defeated Hunniades, and killed above 20,000 of his men; but George Castriot, better known by the name of *Scanderbeg,* being re-established in the estates of his father, defeated the Turks several times, and obliged Amurath to raise the siege of Croia, the capital of Albania. Chagrined at his ill success, and infirm with age, Amurath died at Adrianople, February 11. 1451. It is observed to this prince's honour, that he always kept his treaties with the greatest fidelity.

Amurath III., son of Selim II., was born about the year 1545, and crowned A.D. 1573. Naturally weak and suspicious, he commenced his reign by putting to death his five brothers, the eldest of whom was but eight years old. His reign was distinguished by a series of enterprises ill planned and worse executed. He died A.D. 1595.

Amurath IV., surnamed the *Valiant,* was the son of Achmet I., and in the year 1622, at the age of 13, succeeded his uncle Mustapha. Baghdad fell into the hands of the Persians, and several other disastrous events clouded the commencement of his reign. The recovery of Baghdad being a favourite object, in the year 1637 he marched against it; and after thirty days of unremitting assault, with the expense of much blood, he took possession of the city. By pushing his men forward to the attack at the point of the scimitar, and by slaughtering 30,000 Persians in cold blood after the surrender, he displayed the brutal ferocity of his disposition. One person alone is reported to have moved his obdurate heart on the present occasion. A famous player upon the harp entreated those who were sent to massacre him to allow him to speak to the sultan previous to his death. Informed who he was, the sultan requested him to give a specimen of his skill in his profession: with this he readily complied, and touched his harp so melodiously, and sung in such pathetic strains the lamentations on the tragedy of Baghdad, intermixed with the praises of Amurath, that the hard heart of the cruel monarch being at length softened, he melted into tears, and saved both the musician and the remaining inhabitants.

The violence of Amurath soon enfeebled his constitution; and the fruits of his debaucheries and excesses were obvious even in the prime of life. At the age of 31 he fell a victim to an excess of revelling in the feast of Bairam, in the year 1640.

AMUSETTE, a small one pound cannon, well adapted from its lightness for mountainous regions, but no longer in use.

AMWELL, a large village in the hundred of Hertford, of the county of that name, 20 miles from London. It is at the head of the New River, conducted to the metropolis by Sir Hugh Middleton, between the years 1606 and 1612. The population in 1851 was 1652.

AMYCLÆ, a city of Laconia in ancient Greece, on the Eurotas, 20 miles south-east of Sparta. It was according to some the birthplace of Castor and Pollux.

Amyclæ, the name of a Grecian colony in Latium, between Cajeta and Terracina.

AMYGADALEÆ, a natural order of plants called also Drupaceæ. The bitter and sweet almond belong to this order, both being generally considered as produced by the *Amygdalus communis.*

AMYGDALOID, a compound rock of any base with many rounded nodules of other stones imbedded in it. The base is often some kind of trap, as basalt or greenstone.

AMYLINE. See Chemistry.

AMYNTAS. See Macedonia.

Amyntas, a Greek writer cited by Athenæus as the author of a work entitled Σταθμόι, *Stations.* The existing fragments prove it to have been of some value, as giving a description of the manners, customs, and natural products of Asia. The epoch of this writer is unknown.

AMYNTIANUS, a Greek historian in the reign of the emperor Marcus Aurelius, to whom he dedicated a life of Alexander the Great, of which no fragment remains. He also wrote lives of Philip, of Olympias, and of several other distinguished characters, but none of them are extant.

AMYOT, Jacques, bishop of Auxerre and grand almoner of France, was born of an obscure family at Melun, on the 30th of October 1514, and studied philosophy at Paris, in the college of Cardinal le Moine. He left Paris at the age of 23, and went to Bourges with the Sieur Colin, who presided over the abbey of St Ambrose in that city. At the recommendation of this abbot, a secretary of state took Amyot into his house to be tutor to his children. The great improvements they made under his direction induced the secretary to recommend him to the Princess Margaret, duchess of Berry, only sister of Francis I.; and by means of this recommendation Amyot was made public professor of Greek and Latin in the university of Bourges. It was during this time that he translated into French the *Amours of Theagenes and Charicled,* with which Francis I. was so pleased, that he conferred upon him the abbey of Bellosane. He also translated Plutarch's *Lives,* which he dedicated to the king; and afterwards undertook that of Plutarch's *Morals,* which he ended in the reign of Charles IX. and dedicated to that prince. Charles conferred upon him the abbey of St Cornelius de Compiegne, and made him grand almoner of France and bishop of Auxerre. He died in 1593, aged 79.

AMYRALDUS, or Amyraut, Moise, an eminent French Protestant divine, born at Bourgueil in Touraine in 1596. He studied at Saumur, where he was chosen professor of divinity; and his learned works gained him the esteem of Catholics as well as Protestants, particularly of Cardinal Richelieu, who consulted him on a plan of reuniting their churches, which, however, as may well be supposed, came to nothing. He published a piece, in which he attempted to explain the mystery of predestination and grace, which occasioned a controversy between him and some other divines. His doctrine on this head, which was adopted by numerous followers, consisted of the following particulars, viz., that God *desires* the happiness of all men, and that none are excluded by a divine decree; that none can obtain salvation without faith in Christ; that God refuses to none the *power of believing,* though he does not grant to *all* his assistance, that they may improve this power to saving purposes; and that many perish through their own fault. Those who embraced this doctrine were called *Universalists;* though it is evident they rendered grace *universal* in words, but *partial* in reality, and are chargeable with greater inconsistencies than the *Supralapsarians.* Amyraut also wrote *An Apology for the Protestants, A Paraphrase on the New Testament,* and several other books. This eminent divine died in 1664.

ANA, a Latin plural termination, appropriated to various collections of the observations and criticisms of eminent characters delivered in conversation and recorded by their friends, or discovered among their papers after their decease. Though the term Ana is but of modern origin, the species of composition to which it has been applied is not of such recent date as some persons have imagined. It appears, from D'Herbelot's *Bibliothèque Orientale*, that, since the earliest periods, the eastern nations have been in the habit of preserving the maxims of their sages. From them this practice passed to the Greeks and Romans. Plato and Xenophon treasured up and recorded the sayings of their master Socrates. From their example Arrian, in the concluding books of his *Enchiridion*, which have not descended to posterity, collected the casual observations which had dropped from Epictetus. The numerous apophthegms scattered in Plutarch, Diogenes Laertius, and other writers, evince that it had been customary in Greece to preserve the ideas delivered by illustrious characters. It appears that Julius Cæsar compiled a book of apophthegms, in which he related the *bon-mots* of Cicero; and Quintilian informs us, that a freedman of that celebrated wit and orator composed three books of a work entitled *De Jocis Ciceronis.* We are told by Suetonius, that Caius Melissus, originally the slave, but afterwards the freedman and librarian, of Mæcenas, collected the sayings of his master; and Aulus Gellius has filled his *Noctes Atticæ* with anecdotes which he heard from those distinguished characters whose society he frequented in Rome. Were the books compiled by the freedmen of Cicero and Mæcenas now extant, they might be entitled Ana; and it is certainly to be regretted that we possess no authentic record of the conversational remarks or hints which dropped from the sages, orators, or statesmen of Greece and Rome. How interesting would be a *Colloquia Mensalia* of Atticus or Cæsar!

But though vestiges of this species of composition may be traced in the classical ages, it is only in modern times that it has attained to full popularity and perfection. Literary anecdotes, critical reflections, and historical incidents, came to be mingled with the detail of *bon-mots* and ludicrous tales; so that instruction and entertainment were agreeably blended. The term Ana seems to have been applied to such collections as far back as the beginning of the fifteenth century. Thus, Francesco Barbaro, in a letter to Poggio, says, that the information and anecdotes which Poggio and Barthelemi Montepolitiano had picked up during a literary excursion through Germany, will be called *Ana:* "Quemadmodum mala ab Appio e Claudia gente *Appiana*, et pira a Mallio *Malliana* cognominata sunt, sic hæc literarum quæ vestra ope et opera Germania in Italiam deferentur, aliquando et *Poggiana* et *Montepolitiana* vocabuntur."

Poggio Bracciolini, to whom this letter is addressed, and to whom the world is indebted for the preservation of so many classical remains, is the first eminent person of modern times whose jests and opinions have been transmitted to posterity. Poggio was secretary to five successive popes. During the pontificate of Martin V., who was chosen in 1417, Poggio and other members of the Roman chancery were in the habit of assembling in a common hall adjoining the Vatican, in order to converse freely on all subjects. Being more studious of wit than of truth, they termed this apartment *Buggiale*, a word signifying a place of recreation where tales are related, and which Poggio himself interprets *Mendaciorum Officina*. At these meetings Poggio and his friends discussed the news and scandal of the day, and communicated to each other entertaining anecdotes; they attacked what they did not approve, and they approved of little; they also indulged in the utmost latitude of satiric remark, dealing out their sarcasms with such impartiality, that they did not spare even the pope and cardinals. The pointed jests and humorous stories which occurred in these unrestrained conversations were collected by Poggio, and formed the chief materials of his *Facetiæ*, first printed, according to De Bure, in 1470. This celebrated collection, which forms a principal part of the *Poggiana*, is chiefly valuable as recording interesting anecdotes of eminent men of the fourteenth and fifteenth centuries. It also contains a number of quibbles or *jeux-de-mots*, and a still greater number of idle and licentious stories. Many of these, however, are not original, some of them being taken from ancient authors, and a still greater number from the *Fabliaux* of the *Trouveurs.* Thus, the *Fabliau La Culotte des Cordeliers* is the *Braccæ Divi Francisci* of Poggio; *Le Meunier d'Aleus* is Poggio's *Quinque Ova; Du Vilain et de sa Femme* is his *Mulier Demersa;* and *Du Pré Tondu* is the *Pertinacia Muliebris* of the *Facetiæ.* On the other hand, Poggio has suggested much to succeeding writers. Hans Carvel's *Ring* is his *Visio Francisci Filelfi;* and Fontaine's fables, *Le Charlatan, Le Coq et le Renard*, and that of the *Wolf and Fox pleading before the Ape*, are from stories originally related by Poggio. The *Facetiæ* forms, upon the whole, the most amusing and interesting part of the *Poggiana* printed at Amsterdam in 1720; but this collection also comprehends some further anecdotes of his life, and a few scattered maxims extracted from his graver compositions.

Poggiana.

Though Poggio was the first person whose remarks and *bon-mots* were collected under the name of Ana, the *Scaligerana*, which contains the opinions of Joseph Scaliger, was the first work *published* under that appellation; and, accordingly, may be regarded as having led the way to that class of publications.

Scaligerana.

There are two collections called Scaligerana—a *prima* and *secunda* Scaligerana. The first was compiled by a physician named Francis Vertunien, Sieur de Lavau, who attended the family of the Messieurs Chateigner, in whose house Joseph Scaliger resided. He, in consequence, had frequent opportunities of meeting that celebrated critic, and was in the custom of committing to paper the learned or ingenious observations which dropped from him in the course of conversation; to which he occasionally added remarks of his own. This collection, which was chiefly Latin, remained in manuscript many years after the death of the compiler. It was at length purchased by M. de Sigogne, who published it in 1669, under the title of *Prima Scaligerana, nusquam antehac edita;* bestowing upon it the title *prima*, in order to preserve its claim of priority over another Scaligerana which had been published three years before, but had been more recently compiled. This second work, known by the name of *Secunda Scaligerana*, was collected by two brothers of the name of Vassan, who went to complete their studies at the university of Leyden, of which Scaliger was at that time one of the professors. Being particularly recommended to Scaliger, they were received in his house, and daily enjoyed his conversation; in the course of which, he gave them much information concerning various topics of history and criticism. The Vassans immediately wrote down what they had heard, and soon made up a large manuscript volume, in which, however, there was neither connection nor arrangement of any description. In this state the manuscript was delivered by one of the Vassans, on his retirement to a monastery, to M. de Puy; and after passing through various hands, it came into the possession of M. Daillé, who for his own use arranged in alphabetical order the articles which it contained. Isaac Vossius having come to Paris on a visit to M. Daillé, obtained the loan of the manuscript, which he transcribed, and afterwards published at the Hague, under the title of *Scaligerana, sive Excerpta ex ore Josephi Scaligeri*. This edition was full of inaccuracies and blunders; but a more correct impression was afterwards published by M. Daillé, with a preface complaining of the use that Vossius had made of the manuscript, which he declares was never intended for publication, and was not of a nature to be given to the world. Indeed most literary men in that age conceived that the *Scaligerana*, particularly the *second*, detracted considerably from the reputation of the great scholar whose sentiments they recorded. They are full of mistakes and contradictions; and Bayle has remarked, that the Vassans attribute to him observations which it is almost impossible he could have uttered. Joseph Scaliger, with more extensive erudition, but less genius than his father Julius Cæsar Scaliger, had inherited his ridiculous vanity and dogmatical spirit. He wished it to be thought that he knew every thing, and that his opinions were infallible. Conversing with two young students of a university, of which he formed the principal ornament, he would probably be but little cautious in the opinions he expressed, as his literary errors could not be detected or exposed. Unfortunately the blind admiration of his pupils led them to regard even his most absurd opinions as the responses of an oracle, and his most unmerited censures as just condemnations. The *Scaligerana*, accordingly, contains many falsehoods, with much unworthy personal abuse, of the most distinguished characters of the age. Thus, he calls Cardinal Bellarmin a mere atheist (*plane atheus*), and compares the duke of Sully to Sejanus. Indeed M. Daillé, in his preface to the *Secunda Scaligerana*, confesses that it contains "multa futilia, scurrilia, obscœna; quædam manifeste falsa. Ubique de se suisque magnifice, ne dicam thrasonice, loquitur; laudum parcus, conviciorum largus, in omnes contumeliosissime invehitur: denique, neminem sibi de manibus elabi patitur, cujus non errata, vitia, nævos etiam levissimos, acerrime insectetur, et plusquam cynica licentia arrodat."

In imitation of the *Scaligerana*, a prodigious number of similar works appeared in France towards the end of the seventeenth and beginning of the eighteenth century. At first these collections were confined to what had fallen from eminent men in conversation; but they were afterwards made to embrace fragments found among their papers, and even passages extracted from their works and epistolary correspondence. Of those which merely record the conversations of eminent men, the best known, the fullest, and most valuable, is the *Menagiana*. Menage was a person of good sense, of various and extensive information, and of a most communicative disposition. He lived during the greater part of his life in the best society. An assembly of literary characters met, during a long period of time, at his house every Wednesday; and, during his latter years, he daily received persons of that description. Much of his time was thus spent in conversation; and those of his friends who habitually enjoyed it were at pains to record his opinions, which were generally founded on a correct taste and judgment, and were always delivered in a manner the most interesting and lively. A collection of his oral opinions was published in 1693, soon after his death; and this collection, which was entitled *Menagiana*, was afterwards corrected and enlarged by M. la Monnoye, in an edition published by him in 1715. Among the most curious articles in the *Menagiana* may be numbered the dissertation on *Le Moyen de Parvenir*, a work attributed to Beroalde de Verreville; that on *Le Songe de Poliphile*; as also a letter of La Monnoye on the existence of a book supposed to have been entitled *De Tribus Impostoribus*, concerning which there has been much discussion and controversy.

Perroniana.

The *Perroniana*, which exhibits the opinions of Cardinal Perron, was composed from his familiar conversation by M. de Puy, and published by Vossius, by the same contrivance which put him in possession of the *Scaligerana*. Some parts of this collection are useful in illustrating the literary and ecclesiastical history of the age in which Perron lived; but it also contains many puerile, imprudent, and absurd remarks, which it is generally supposed he never uttered, and many of which were proved by M. Chevreau (*Chevræana*) to have been the interpolations of his friends. Some of his assertions,—as that Luther denied the immortality of the soul, and that every English peasant drinks from a silver goblet,—are evidently false. Nor can much reliance be placed on the judgment or taste of an author who has elsewhere declared that a page of Quintus Curtius is worth thirty of Tacitus, and that, next to Quintus Curtius, Florus is the greatest Roman historian. The *Thuana*, or observations of the president De Thou, have usually been published along with the *Perroniana*. This collection is not extensive, and by no means of such value as might have been expected from a man so able and distinguished.

Thuana.

Valesiana.

The *Valesiana* is a collection of the literary opinions of the historiographer Adrian Valois, published by his son. M. Valois was a great student of history, and the *Valesiana*, accordingly, comprehends many valuable historical observations, particularly on the works of Du Cange.

Fureteriana.

The *Fureteriana* contains the *bon-mots* of M. Furetiere, of the French academy, the stories which he was in the habit of telling, and a number of anecdotes and remarks found among his papers after his decease. This production, however, consists chiefly of short stories, and comprehends but few thoughts, opinions, or criticisms on books. Furetiere, it is well known, had a violent quarrel with the French Academy, of which he was a member, concerning his *Dictionnaire Universel de la Langue Françoise*. Having published a preliminary discourse, the further printing was interdicted by the French Academy, which accused him of purloining materials they had amassed for a similar work. This controversy subsisted during the rest of the life of Furetiere, who spent his concluding years in writing and publishing libels on his associates. The *Fureteriana*, accordingly, is replete with allusions to a subject with which his thoughts were so completely engrossed: in particular we find there the plan and outline of an allegorical and burlesque poem, entitled *Les Couches de l'Académie*; in which he has satirized different members of the academy, especially M. Charpentier, one of his bitterest foes, whom he has designated by the name of *Marmentier*.

Chevræana.

The *Chevræana*, so called from M. Chevreau, exhibits more research than most works of a similar description, and is probably more accurate, as it was published during the life of the author, and revised by himself. Among other interesting articles, it contains a learned and ingenious commentary on the works of Malherbe, to whom the French language and poetry were highly indebted for the perfection to which they attained.

Parrhasiana.

*Parrhasiana* is the work of Jean le Clerc, a professor of Amsterdam, who bestowed this appellation on his miscellaneous productions with the view of discussing various topics of philosophy and politics with more freedom than he could have employed under his own name. This work is not of the light and unconnected description of

Ana. most of the Ana which have been above enumerated, as it contains much learned philological disquisition, and a long dissertation on poetry and eloquence. In the first volume there is a list of his published works, and a bitter reply to all those who had censured them.

Huetiana. The *Huetiana*, which has always held a distinguished place among the Ana, contains the detached thoughts and criticisms of Huet, bishop of Avranches, which he himself committed to writing during his life. This author was well fitted to produce a valuable work in this department of literature. He enjoyed the friendship of a number of distinguished characters, and his reading was various and extensive. This collection, however, was not begun by him till he was far advanced in life. Huet was born in 1630, and in 1712 he was attacked by a malady which impaired his memory, and rendered him incapable of the sustained attention necessary for the completion of a long or laborious work. In this situation he employed himself during the concluding years of his life in throwing his detached observations on paper. These were published by the Abbé d'Olivet the year after his death, under the name of *Huetiana*,—a work which is not, like some other Ana, a succession of *bon-mots* or anecdotes, but forms a series of thoughts and criticisms on various topics of morals, philosophy, and literature, and also comprehends pretty long dissertations on the origin of rhyme, the comparative merit of the ancients and moderns, with similar topics. One of the most instructive discussions to a scholar, in this collection, is that on the Latinization of names and surnames; in which he points out and criticises the different modes of this process. His critical judgments on Montaigne, Rochefoucauld, and Tacitus, seem also well founded; and if some of his opinions in matters of taste betray singular or defective feelings, there are others which appear equally just and refined. But were there no other literary memorials of the bishop of Avranches, he certainly would not derive high reputation from the *Huetiana*. D'Alembert has treated this collection with contempt; and has selected some articles to show the bishop's incompetent judgment and frivolous taste. It may be suspected, indeed, from the circumstances in which the articles contained in the *Huetiana* were composed, that they do not always display that correct judgment which distinguishes many of the other works of this learned writer.

Casauboniana. The *Casauboniana* presents us with the miscellaneous observations, chiefly philological, of the celebrated Isaac Casaubon. During the course of a long life, that eminent commentator was in the daily practice of committing to paper any thing remarkable which he heard in conversation with his friends, especially if it bore on the studies in which he was engaged. He also made diurnal annotations on the works he was employed in reading, with which he connected his judgments concerning the author and his writings. This compilation, which was styled *Ephemerides*, together with his *Adversaria*, and materials amassed for a refutation of the *Ecclesiastical Annals of Baronius*, came, at his death, into the possession of his son Meric Casaubon, who bequeathed the whole to the Bodleian library at Oxford. These were shown to Christopher Wolfius during a visit which he paid to that university; and having been transcribed by him, were published under the title of *Casauboniana*. This collection consists of opinions concerning various eminent writers, illustrations of passages in Scripture, and philological observations and animadversions on the first thirty-four years of the *Annals of Baronius*. The materials and information which it contains are probably more accurate than is usually the case in works of the same description, as they were not communicated in casual conversation, and reported by others, but were daily committed to writing by Casaubon himself, while the works from which they were derived remained fresh in his recollection. Ana.

Besides the above, a great many works, under the title of Ana, appeared in France about the same period. Thus, the opinions and conversation of Charpentier, Colomesius, and St Evremond, were recorded in the *Carpenteriana*, *Colomesiana*, and *St Evremoniana;* and those of Segrais in the *Segraisiana*,—a collection formed by a person stationed behind the tapestry in a house where Segrais was accustomed to visit, and of which Voltaire has declared, "que de tous les Ana c'est celui qui merite le plus d'être mis au rang des mensonges imprimés, et surtout des mensonges insipides." The Ana, indeed, from the popularity which they now enjoyed, were compiled in such numbers, and with so little care, that they became almost proverbial for inaccuracy. About the middle of the eighteenth century they were sometimes made the vehicles of political squibs, as in the *Maupeouana*, and of heretical opinions, as in the *Longueruana*. Thus the evil naturally began to cure itself, and by a re-action, which is very general in regard to all productions of literature, the French Ana sunk in public esteem as much below their intrinsic value as they had formerly been exalted above it. Carpenteriana. Colomesiana. Evremoniana. Segraisiana. Maupeouana. Longueruana.

Although these connections have been chiefly formed from the oral opinions of eminent men on the Continent, particularly in France, England has also produced one or two examples of this species of composition, which are not altogether undeserving of attention. Of these, perhaps the most curious is the *Walpoliana*, which is a transcript of the literary conversation of Horace Walpole. That multifarious author was distinguished for his resources of anecdote, wit, and judicious remark, as well as for his epistolary qualifications. From his father, Sir Robert Walpole, he had learned many anecdotes concerning the political characters who figured during the period of his administration. He was himself personally acquainted with all the eminent literary characters of his own day in England; and his repeated visits to Paris, and constant correspondence with friends in that capital, supplied him with the most interesting information with regard to France. A great part of his life was devoted to conversation. While residing at Strawberry-hill, he generally rose from table about five o'clock, and taking his place on his drawing-room sofa, to which his gout in a great measure confined him, he passed the time, till two o'clock in the morning, in miscellaneous chit-chat, full of singular anecdotes, strokes of wit, and acute observations. As he possessed, and was daily communicating, such stores of instruction and amusement, it was suggested to him that he ought to form a collection of these anecdotes and observations. This he declined, but he furnished the editor of the *Walpoliana* with many anecdotes in his own handwriting. After his death, several specimens of this miscellany were published in the *Monthly Magazine;* and being afterwards enlarged by anecdotes retained in the memory of the editor, or communicated by others, were published in two volumes, under the title of *Walpoliana*. Most other works which, in this country, have been published under the name of *Ana*, as *Baconiana*, *Atterburyana*, are rather extracts from the writings and correspondence of eminent men, than memorials of their conversation. Walpoliana.

There are some works which, though they do not bear the title, belong more strictly to the class of Ana than many of those collections which are known under that appellation. Such are the *Mélange d'Histoire et de Littera-*

Ana.

*ture*, published under the name of *Vigneul Marville;* and the *Locorum Communium Collectanea, ex Lectionibus Philippi Melanchthonis*,—a work which was published as far back as the sixteenth century, and has obtained considerable reputation on account of its theological learning, and the information it communicates concerning the early state of the reformed church. But of those productions which belong to the class, though they do not bear the name, of Ana, the most celebrated are the *Colloquia Mensalia* of Luther, and Selden's *Table-Talk*, both of which merit particular notice. The first, which comprehends the conversation of Luther with his friends and coadjutors in the great work of the Reformation, was first published in 1566. Captain Henry Bell, who translated it into English in the time of the Commonwealth, informs us that, at the instigation of the pope, the emperor of Germany had promulgated an edict commanding the works of Luther to be destroyed. It was for some time supposed that all the copies of the *Colloquia Mensalia* had been burned in consequence of this order; but at length, in 1626, a German called Van Sparr, having occasion to build on the old foundation of a house in which his grandfather dwelt when the imperial edict was issued, he found lying in a deep hole, and wrapped up in a linen cloth, a printed copy of the *Colloquia Mensalia*. Captain Bell having formerly become acquainted with Van Sparr during a long residence in Germany, his friend transmitted the work to him in England, where he executed a translation of it; an undertaking to which he pretends that he was urged by the vision of an old man with a long white beard, arrayed in white, who spoke these words: "Sirrah, will you not take time to translate that book?" The extraordinary book translated by Bell, at the instance of this vision, is said to have been originally collected by Dr Anthony Lauterbach, "out of the holy mouth of Luther;" and was afterwards digested into common-places by Dr John Aurifaber. It chiefly contains observations and discussions on idolatry, auricular confession, mass, excommunication, clerical jurisdiction, general councils, and all the points agitated by the reformed church in those early periods. With such topics there is intermixed many diatribes against Antichrist and the Cardinals, and much sarcasm on popish miracles and relics. Occasionally, however, it must be confessed that our great reformer expresses a belief in superstitions fully as wild and monstrous as those which he derides, and which he was called to overthrow. Thus, he asserted that he was repeatedly kept from sleep by the devil cracking nuts in his chamber; and he affirmed that there was a child at Dessau, which had been substituted by the arch-fiend instead of one he had stolen away, and which child Luther earnestly advised the prince of Anhalt to throw into the river Moldaw.

Luther's Colloquia Mensalia.

Selden's Table-Talk.

If the collection of Selden's apophthegms and sayings, entitled *Table-Talk*, be regarded of good authority, we shall find in it a more genuine and undisguised expression of the sentiments of that eminent man, than in his more studied productions. This work was published, after the death of Selden, by Richard Milward, his amanuensis, who, in his dedication to Selden's executors, affirms that, for twenty years, he enjoyed the opportunity of daily hearing his discourse, during which long period he made it his practice, from time to time, faithfully to commit to writing "the excellent things that usually fell from him." Dr Wilkins, in his introductory discourse to the Works of Selden, has attempted to throw discredit on the genuineness of this compilation, asserting that it contains many things derogatory from Selden's erudition, and foreign from his manners and principles. It is not improbable, indeed, that the memory of the amanuensis may have occasionally failed him, and that he may have recorded sayings which inadvertently escaped his master in the heat of conversation, and such as he probably would not have deliberately maintained. But, on the whole, the work has completely an air of genuineness; and although the familiarity of his illustrations and parallels may appear to clash with the idea formed of so great a scholar, they are characteristic of a man who had been conversant with scenes of common life, no less than the speculations of the closet. That such was the usual manner of Selden's conversation, the editor of the *Table-Talk* recalls to the recollection of those friends of his patron to whom the work is dedicated; and this appeal forms a presumption of his veracity. The *Table-Talk* contains many curious facts and opinions concerning the political and ecclesiastical history of the interesting period during which Selden lived, and in the important events of which he bore a considerable share. To judge from this work, Selden had great contempt for the theologians of his day; and seems to have been of opinion that the state should invariably keep a rein on the church. He was partial to the Episcopal form of worship; but was evidently not very strict in doctrinal points, as appears from what he is reported to have said on the subject of *heresy*. In his political opinions he seems to have entertained a high respect for the sacredness of the social contract; and he justified the resistance to the Stewarts, on the ground that they had infringed and violated this compact between prince and people. Besides religious and political opinions, the *Table-Talk* contains much of a lighter description; in consequence of which, Selden has been accused of showing more laxness, in point of moral principle, than might have been expected from so grave and respectable a character. Many of those sentiments, however, which have been considered objectionable, may have been merely advanced as plausible deductions from principles assumed for the sake of argument. But whatever difference of opinion may exist with regard to the matter of the *Table-Talk*, the manner in which the sentiments are there expressed must be universally admitted to be perspicuous and agreeable. The style of Selden, in most of the works published under his own care, is harsh and obscure; but Clarendon, who differed from him so widely in political opinions, acknowledges that he was "a clear discourser, and that he possessed the faculty of making difficult things easy, and presenting them clearly to the understanding." Accordingly, this talent for elucidation shines chiefly in his *Table-Talk*, which is filled with the stores of his extensive reading, delivered without any pretensions to that order and method, the want of which has been attributed to his other productions.

Ana.

It thus appears that, although the compilations designated by the name of Ana belong more particularly to France, they have not been wholly unknown in this country. In their *Motti e Burle*, and sometimes in their novels, the Italians also have recorded the witticisms of their distinguished poets and artists. The novels of Sacchetti are full of repartees attributed to Dante and the painters Giotto and Buffalmacco. Almost every Italian biographical work of the sixteenth and seventeenth centuries, like Boswell's *Life of Johnson*, records at great length the conversational remarks of the individual whose life is detailed. Thus, Manso has dedicated one of the books of his life of Torquato Tasso to an account of the wise and witty sayings of that illustrious poet, who, towards the close of his days, had become the intimate friend of his biographer. The conversation of the poet, however, was neither gay nor brilliant. One of the characters in Gol-

Ana. doni's drama of Torquato Tasso thus contrasts his writings and conversation :

> Ammiro il suo talento, gradisco i carmi suoi ;
> Ma piacer non trovo a conversar con lui.

It also unfortunately happens that the greater part of the sayings recorded by Manso may be found in the Apophthegms of Erasmus, which were published before the birth of Tasso. Indeed Manso seems to have been aware of the want of originality in the *bon-mots* of his friend ; for, after mentioning one, he says, " questo motto fu da alcuni ad *Epitcto* attribuito." It was usual, indeed, among the biographers of those times to pillage Xenophon or Plutarch for good things to put into the mouths of their heroes ; a practice from which Machiavel could not abstain in his short account of the illiterate soldier Castruccio Castracani. In those ages of pedantry, however, it is not improbable that many sayings of the old philosophers might have been repeated as their own by the learned men of the times ; and that the Italian *literati* might occasionally attempt to make their hearers merry with the jests of Socrates or Diogenes. The genius and character of the people rendered any collection of this nature less agreeable than the Ana of the neighbouring nation. In Italy, gravity was numbered among the virtues, and, in the eulogy of an illustrious man, is always mentioned as one of his most commendable qualities. There seems, in that country, to have been no medium between the most fantastic buffoonery and a certain tragic solemnity. The Italians wanted that " mobility of imagination," that facility, rapidity, abandonment, and gaiety, which seems almost peculiar to the French, and forms the chief charm of social intercourse, as well as of those works in which it is represented ; though, no doubt, when reduced into writing, much of its grace and spirit must evaporate and disappear.

The existence of similar causes, and perhaps in a stronger degree, prevented the popularity of Ana among the Spaniards ; though they too have related the jests and opinions of the duke d'Ossuna, and of some others. Indeed, whatever may be the genius or disposition of a people, traces of this mode of composition may in some shape or other be discovered among them.

When presented in their most perfect form, which is that of the French Ana, these collections are certainly entertaining from their variety, and curious, as presenting a lively image of the distinguished characters whose sentiments they record. If men reason more correctly on paper, they usually display their feelings and convictions with more truth in unpremeditated conversation. Few are so cautious or hypocritical that they do not sometimes drop the mask in the society of their friends, and express what they think or feel, when they no longer entertain apprehensions that their sentiments will be communicated to the vulgar. In general, however, the Ana should rather be regarded as affording a notion of the spirit and turn of thinking of those whose conversation they detail, than as authorities for particular opinions. A spirit of contradiction, a wish to display ingenuity, to astonish by paradoxes, or even to support conversation, may often lead men to maintain opinions in colloquial intercourse which they perhaps never seriously held, or at least would be ready to disclaim on mature consideration. It also unfortunately happens that, in many of the Ana, those who collected the conversations which they presented to the world interpolated their own opinions; which, of course, greatly diminishes their authority as characteristical records. It has also been objected to this species of composition, that every subject is treated superficially ; but it should be recollected that the Ana do not profess to contain profound dissertations ; and in fact no one consults them with the view of being deeply informed on any topic. A better founded objection is, that many subjects are treated, not merely superficially, but inaccurately. Such compositions are liable to a double risk of error ; first, of the person who delivers opinions in the heat of discourse, or relates anecdotes from vague recollection ; and, secondly, of the person who records them, who must be liable to mistake what he has only heard in the course of conversation. From these causes, and from their wide and general circulation, many of the most current literary errors may be traced to the Ana. When read, however, with discrimination, they may prove highly useful in illustrating various points of literary history, as they certainly contain a great deal which is not to be found in the formal compositions of the learned.

Wolfius has given a history of the Ana in a preliminary discourse to his edition of the *Casauboniana*, published in 1710. In the *Répertoire de Bibliographies Spéciales, Curieuses, et Instructives*, by Peignot, there is a *Notice Bibliographique* of these collections ; but many of the books there enumerated consist of mere extracts from the writings of popular authors, and do not, therefore, belong to that class of literary works described in the preceding article. (J. C. D.)

Anabaptists. ANABAPTISTS, a name which has been indiscriminately applied to Christians of very different principles and practices, though many of them object to the denomination, and hold nothing in common besides the opinion, that baptism ought always to be performed by immersion, and not administered before the age of discretion.

The word Anabaptist is compounded of *ανα, a new*, and *βαπτιστης, a baptist ;* and in this sense the Novatians, the Cataphrygians, and the Donatists, may be considered as a kind of Anabaptists in the earlier ages, though not then denoted by this name ; for they contended that those Christians of the Catholic church who joined themselves to their respective parties should be rebaptized. But we must not class under the same denomination those bishops of Asia and Africa who, in the third century, maintained that baptism administered by those whom they called heretics was not valid, and therefore that such of them as returned into their churches ought to be rebaptized. Nor do the English and Dutch Baptists consider the denomination as at all applicable to their sect, by whom the baptism appointed by Christ is held to be " nothing short of *immersion upon a personal profession of faith ;*" of which profession infants being incapable, and sprinkling being no adequate symbol of the thing included, the baptizing of proselytes to their communion, who in their infancy had undergone the ceremony of sprinkling, cannot, it is urged, be interpreted a repetition of the baptismal ordinance.

Anabaptists, in a strict and proper sense, appear to be those who not only rebaptize, when they arrive at an adult age, persons that were baptized in their infancy, but also, as often as any person comes from one of their sects to another, or as often as any one is excluded from their communion and again received into the bosom of the church, they baptize him. And such were many of the German Baptists. But the single opinion common to all the sects to which the name of *Anabaptists* has been indiscriminately applied, is that of the invalidity of *infant baptism*, in whatever way administered ; and hence the general denomination of *Antipædobaptists*, which included Anabaptists, Baptists, Mennonites, Waterlandians, &c., as distinguished by their respective peculiarities ; though *Anabaptists* seems to have been adopted by most writers as the general term.

Anabaptists.

To the above peculiar notion concerning the baptismal sacrament, the Anabaptists added principles of a different nature, depending upon certain ideas which they entertained concerning a perfect church establishment, pure in its members, and free from the institutions of human policy.

The Anabaptists appear to have made little noise, or to have been little noticed, before the time of the reformation in Germany. The most prudent and rational part of them considered it possible, by human wisdom, industry, and vigilance, to purify the church from the contagion of the wicked, provided the manners and spirit of the primitive Christians could but recover their lost dignity and lustre; and seeing the attempts of Luther, seconded by several persons of eminent piety, prove so successful, they hoped that the happy period was arrived in which the restoration of the church to purity was to be accomplished, under the divine protection, by the labours and counsels of pious and eminent men. Others, far from being satisfied with the plan of reformation proposed by Luther, looked upon it as much beneath the sublimity of their views, and consequently undertook a more perfect reformation, or, to express more properly their visionary enterprise, they proposed to found a new church, entirely spiritual, and truly divine.

This sect was soon joined by great numbers, and (as usually happens in sudden revolutions of this nature) by many persons whose characters and capacities were very different, though their views seemed to turn upon the same object. Their progress was rapid; for, in a very short space of time, their discourses, visions, and predictions, excited commotions in a great part of Europe, and drew into their communion a prodigious multitude, whose ignorance rendered them easy victims to the illusions of enthusiasm. The most pernicious faction of all those which composed this motley multitude, was that which pretended that the founders of the new and *perfect church* already mentioned were under the direction of a divine impulse, and were armed against all opposition by the power of working miracles. It was this faction that, in the year 1521, began their fanatical work, under the guidance of Munzer, Stubner, Storck, &c.

These persons were disciples of Luther; but well knowing that their opinions were such as would receive no sanction from him, they availed themselves of his absence to disseminate them in Wittenburg, and had the address to overreach the piety of Melanchthon. Their principal purpose was to gain over the populace, and to form a considerable party. To effect this, says Bayle, they were industrious and active, each in his own way. Storck, wanting knowledge, boasted of inspiration; and Stubner, who had both genius and erudition, laboured at commodious explications of Scripture. Not content with discrediting the court of Rome, and decrying the authority of consistories, they taught, that among Christians, who had the precepts of the gospel to direct, and the Spirit of God to guide them, the office of magistracy was not only unnecessary, but an unlawful encroachment on their spiritual liberty; that the distinctions occasioned by birth, or rank, or wealth, being contrary to the spirit of the gospel, which considers all men as equal, should be entirely abolished; that all Christians, throwing their possessions into one common stock, should live together in that state of equality which becomes members of the same family; that as neither the laws of nature nor the precepts of the New Testament had placed any restraint upon men with regard to the number of wives which they might marry, they should use that liberty which God himself had granted to the patriarchs.

They employed at first the various arts of persuasion in order to propagate their doctrine. They preached, exhorted, admonished, and reasoned, in a manner that seemed proper to impress the multitude; and related a great number of visions and revelations with which they pretended to have been favoured from above. But when they saw that these methods of making proselytes were not attended with such rapid success as they fondly expected, and that the ministry of Luther and other eminent reformers was detrimental to their cause, they then had recourse to more expeditious measures, and madly attempted to propagate their fanatical doctrine by force of arms. Munzer and his associates, in the year 1525, put themselves at the head of a numerous army, composed for the most part of the peasants of Suabia, Thuringia, Franconia, and Saxony; and declared war against all laws, government, and magistrates of every kind, under the chimerical pretext that Christ was now to take the reins of civil and ecclesiastical government into his own hands, and to rule alone over the nations. But this seditious crowd was routed and dispersed without much difficulty by the elector of Saxony and other princes; and Munzer, their ringleader, ignominiously put to death, and his factious counsellors scattered abroad in different places.

Many of his followers, however, survived and propagated their opinions through Germany, Switzerland, and Holland. In the year 1533 a party of them settled at Munster under the direction of two Anabaptist prophets, John Matthias, a baker of Haerlem, and John Bockholdt, a journeyman tailor of Leyden. Having made themselves masters of the city, they deposed the magistrates, confiscated the estates of such as had escaped, and deposited the wealth they amassed together in a public treasury for common use. They made preparations of every kind for the defence of the city; and sent out emissaries to the Anabaptists in the Low Countries, inviting them to assemble at Munster, which was now dignified with the name of Mount Sion, that from hence they might be deputed to reduce all the nations of the earth under their dominion. Matthias, who was the first in command, was soon cut off, in an act of frenzy, by the bishop of Munster's army, and was succeeded by Bockholdt, who was proclaimed, by a special designation of Heaven, as he pretended, king of Sion, and invested with legislative powers like those of Moses. The extravagancies of Bockholdt were too numerous to be recited: it will be sufficient to add, that the city of Munster was taken after a long siege and an obstinate resistance; and Bockholdt, the mock monarch, was punished with a most painful and ignominious death.

It must, however, be acknowledged, that the true rise of the numerous insurrections of this period ought not to be attributed to religious opinions. The first insurgents groaned under the most grievous oppressions—they took up arms principally in defence of their civil liberties; and of the commotions that took place, the Anabaptist leaders above mentioned seem rather to have availed themselves, than to have been the prime movers. That a great part of the main body, indeed, consisted of Anabaptists, seems indisputable; and whatever fanaticism existed among them would naturally be called forth or inflamed by particular situations or circumstances, and run riot in its wildest shapes. At the same time it appears from history, that a great part also consisted of Roman Catholics, and a still greater of persons who had scarcely any religious principles at all. Indeed, when we read of the vast numbers that were concerned in those insurrections, of whom it is reported that 100,000 fell by the sword, it appears reasonable to conclude that a great majority of them were not Anabaptists.

Before concluding this article, it must be remarked, that the Baptists or Mennonites in England and Holland are to be considered in a very different light from the enthusiasts we have been describing; and it appears equally uncandid and invidious to trace up their distinguishing tenet, as some of their adversaries have done, to those obnoxious characters, and there to stop, in order as it were to associate with it the ideas of turbulence and fanaticism, with which it certainly has no natural connection. Their coincidence with some of those oppressed and infatuated people in denying baptism to infants, is acknowledged by the Baptists; but they disavow the practice which the appellation of *Anabaptists* implies, and their doctrines seem referable to a more ancient and respectable origin. They appear supported by history in considering themselves as the descendants of the Waldenses, who were so grievously oppressed and persecuted by the despotic heads of the Roman hierarchy; and they profess an equal aversion to all principles of rebellion on the one hand, and to all suggestions of fanaticism on the other. See BAPTISTS.

ANABAS, Cuvier's name for a genus of fishes that have the faculty of climbing up and living for some time out of water. See ICHTHYOLOGY, *Acanthopterygii.*

ANABASIS (ἀνάβασις), the title of the work of Xenophon describing the expedition of Cyrus the younger against his brother Artaxerxes of Persia, 401 years B.C. Major Rennell, in an elaborate memoir, has estimated the retreat of the 10,000 Greek auxiliaries of Cyrus as equal to a distance of 3465 English miles (taking the *stadia* of Xenophon at 10 to our mile), through a difficult, and to them, unknown country. Arrian's account of the expedition of Alexander the Great is likewise called *Anabasis.*

ANABATHRA, in *Ancient Writers*, denotes a kind of steps or ladder whereby to ascend to some eminence. In this sense we read of the anabathra of theatres, pulpits, &c. Anabathra appears to have been sometimes also applied to ranges of seats rising gradually over each other.

ANABATHRA is more particularly applied to a kind of stone blocks raised by the highway sides, to assist travellers in mounting or alighting, before the use of stirrups was invented. The first author of this contrivance among the Romans was C. Gracchus, brother of Tiberius.

ANABLEPS, a Cuvierian genus of Malacopterygious fishes, with a divided pupil, cornea, and iris in each eye, giving the appearance of four eyes, from which the trivial name of the only species is derived. It inhabits the rivers of Guyana.

ANABOLÆUM, or ANABOLE, in *Antiquity*, a kind of upper coat, worn over the tunica.

ANACALYPTERIA, according to Suidas, were presents made to the bride by her husband's relations and friends, when she first uncovered her face and showed herself to men. These presents were also called ἐπαύλια; for, among the Greeks, virgins before marriage were under strict confinement, being rarely permitted to appear in public, or converse with the other sex; and when allowed that liberty, wore a veil over their faces, termed Καλύπτη, or Καλύπτρα, which was not left off in the presence of men till the third day after marriage; whence, according to Hesychius, this day was also called *anacalypterion.*

ANACAMPTIC, a name applied by the ancients to that part of optics which treats of reflection, being the same with what is now called Catoptrics.

ANACARDIACEÆ, a natural order of trees with acrid resins in their bark. The cashew nut belongs to this order.

ANACHARSIS, a Scythian philosopher, who lived about 600 years before Christ. His father was one of the chiefs of his nation, and married a woman of Greece. Instructed in the Greek language by his mother, he prevailed upon the king to intrust him with an embassy to Athens. On his arrival in that renowned city, he was introduced to Solon by one of his own countrymen, named *Foxaris.* From such a well-qualified master Anacharsis rapidly acquired a knowledge of the wisdom of Greece, and the literature then in circulation. By the influence of Solon he was introduced to the principal characters of Athens, and was the first stranger who was honoured with the title of citizen by the Athenians. After he had resided several years at Athens, he travelled through different countries in quest of knowledge, and then returned to his native country inflamed with the desire of instructing them in the laws and the religion of the Greeks. But his countrymen were not prepared to profit by his instructions; and while he was performing sacrifice to the goddess Cybele, in fulfilment of a vow which he had made on his way home, he was slain by an arrow, said to have proceeded from the hand of his own brother Saulius, the king. Thus fell the Scythian philosopher, a victim to the folly and ignorance of his countrymen who wantonly rejected the wisdom and learning of Greece. His energetic mode of expressing himself gave birth to the proverbial saying "Scythian eloquence."—*Herodot.* iv. 76, *Lucian. Scyth.* ii.

ANACHARSIS, Travels of. See BARTHELEMY.

ANACHORET, in *Eccelsiastical History*, denotes a hermit or solitary monk, who retires from the society of mankind into some desert, with a view to avoid the temptations of the world, and to be more at leisure for meditation and prayer. Such were Paul, Anthony, and Hilarian, the first founders of monastic life in Egypt and Palestine.

ANACHRONISM, in matters of literature, an error with respect to chronology, whereby an event is placed earlier than it really happened. The word is compounded of the negative ἀν, and χρόνος, *time.* Such is that of Virgil, who places Dido in Africa at the time of Æneas, though in reality she did not come thither till 300 years after the taking of Troy.

ANACLASTIC GLASSES (ἀνα, and κλάσις, *a breaking*), a kind of sonorous flat-bellied phials, resembling inverted funnels, with bottoms extremely thin, and slightly convex. They have the property of emitting a vehement noise when alternately filled with air and exhausted by the mouth. In Germany, where they are chiefly made, they are called *vexier glaser, i. e.,* vexing glasses, on account of the disturbance they occasion by their resilition.

ANACLASTICS, that part of optics which considers the refraction of light, commonly called *Dioptrics.* See OPTICS.

ANACLETERIA, in *Antiquity*, a solemn festival celebrated by the ancients when their kings or princes came of age, and assumed the reins of government. This designation was more especially applied to the inauguration of the Græco-Egyptian princes.

ANACLETICUM, in the *Ancient Art of War*, a particular blast of the trumpet, whereby the fearful and flying soldiers were rallied, and recalled to combat.

ANACLETUS, or CLETUS, bishop of Rome from the year 78 to 91. Some spurious decretals are extant under his name.

ANACLETUS, anti-pope, of Jewish extraction, was elected in 1130. He maintained his position till his death, in the face of all opposition, and was succeeded by Innocent II. in 1138.

ANACLINTERIA, in *Antiquity*, a kind of pillows on the dining couch, whereon the guests used to lean. The ancient tricliniary beds had four pillows, one at the head, another at the feet, a third at the back, and a fourth at the breast.

ANACŒNOSIS (ἀνακοίνωσις), in *Rhetoric*, a figure by which a speaker applies to his opponents for their opinion on the point in debate.

ANACOLUTHON (ἀνακόλουθον), in *Rhetoric* and *Grammar*, a want of coherency or of sequence in a sentence.

ANACONDA, in *Natural History*, is a name given in the isle of Ceylon to a very large and powerful snake, the *Python Bivittatus*.

ANACREON, the celebrated lyric poet, was born at Teos, an Ionian city in Asia Minor, about the year B.C. 560. Of his personal history little is known; but it would appear that his early youth was passed at Teos; and when Ionia fell under the Persian yoke, about B.C. 540, he migrated with many of his countrymen to Abdera in Thrace. In the same year he went to Samos, in consequence of an invitation from Polycrates the tyrant, by whom he was treated with great distinction and regard, and loaded with favours, which the poet repaid by praises in many of his songs. His residence at the splendid court of Polycrates was the happiest period of his life. On the murder of his friend and patron, in B.C. 522, he was invited to Athens by Hipparchus, the son of Pisistratus, who is said by Plato to have sent a galley of fifty oars for his conveyance. (*Hipparch.* p. 228.) At Athens he became acquainted with the younger Simonides and several other poets, and enjoyed the intimacy of many illustrious persons in that city. Anacreon is said to have perished by choking on the stone of a grape, in the 85th year of his age; and judging from the second of his two epitaphs by Simonides, that event took place at Teos, whither he is supposed to have retired on the death of Hipparchus in B.C. 514. The Athenians erected on the acropolis a statue representing Anacreon in a state of bacchanalian joyousness; and his effigy appears on several coins of Teos, which are still extant. The story of his passion for Sappho involves an anachronism that would appear to render it a fiction.

The harp of Anacreon was strung to the praises of beauty, love, and wine; and we are enabled to form some estimate of his genius from the numerous fragments of his poetry that time has spared. Though he continually alludes to wine as the source of his inspiration, Athenæus (x. 429) argues, with much propriety, that the poet merely affected inebriation in the composition of his celebrated dithyrambics. Indeed, from the tenor of his writings, it has very generally been assumed that the poet himself was the votary of voluptuousness and excess: though against this most natural inference we have the testimony of many writers, who ascribe to Anacreon the highest merits, not only as a poet, but also as a man. His rejection of the munificent presents of Polycrates, as not worthy the anxieties they entailed, is a circumstance certainly in his favour; and scarcely less so is the praise of Plato, who dignifies the poet with the epithet of "wise." Simonides, also, in a fragment still extant, places his character in a very favourable light. (See *Anthol. Palat.* vii. 25.) Yet, in spite of all this testimony, when we reflect on the inherent tendency of our nature to exalt the characters of extraordinary men, though we may allow Anacreon to have possessed many merits, it is impossible, on an impartial review of his writings, to elude the conviction that he was in fact a consummate voluptuary.

Five books of Anacreon's odes were extant in the time of Plutarch and Athenæus; and these were sung on all festive occasions to music composed by the poet himself. He also wrote elegies, hymns, satires, and epigrams; of which last several are preserved in the *Anthologia Græca*. All his poems were written in the Ionic dialect; his favourite metres being the Choriambic and the Ionic a Minore. A collection of fifty-five odes ascribed to Anacreon was first published by H. Stephens at Paris, in 1554, and subsequently by Maittaire, by Spaletti with a fac-simile of the Vatican MS., by Brunck, and others. It is now universally admitted that most, if not all, of these poems are spurious. They probably were written soon after the time of Alexander the Great, and some of them even so late perhaps as the fourth and fifth centuries of our era. Though many of these poems display considerable elegance, they are deficient in that vigour and earnest tone which characterize the genuine remains: the versification is sometimes defective, and the language occasionally barbarous; not to mention that they contain ideas altogether foreign to the age of Anacreon, and afford but one solitary example of the numerous citations from this poet by ancient writers. Some valuable observations on this subject are given by Fischer in the preface to his second edition of Anacreon, published at Leipzig in 1776, which contains this collection, together with the genuine remains. The best editions are by Mehlhorn, Glogau, 1825; Fischer, 3d edition, Leipzig, 1793; Brunck, 2d edition, Strasburg, 1786; and of the separate fragments, that of Bergk, Leipzig, 1834.

ANACREONTIC VERSE, in *Ancient Poetry*, a kind of verse, so called from its being much used by the poet Anacreon. It consists of three feet and a half, usually spondees and iambuses, and sometimes anapæsts.

ANACRISIS (ἀνάκρισις), a trial or examination which the archons or chief magistrates of Athens underwent before their admission into that office. The *anacrisis* stands distinguished from the *dokimasia*, which was a second examination in the agora. The anacrisis was performed in the senate-house. The questions here proposed to them were concerning their family, kindred, behaviour, estate, &c. It is the opinion of some that all magistrates underwent the anacrisis.

ANACRISIS, among *Civilians*, an investigation of truth, interrogation of witnesses, and inquiry made into any fact, especially by torture.

ANACRUSIS (ἀνάκρουσις), in *Antiquity*, denotes a part of the Pythian song, wherein the combat of Apollo and Python is described. The anacrusis was the first part, and contained the preparation to the fight.

ANADEMA (ἀνάδημα), among the *Ancients*, denoted an ornament of the head, wherewith victors at the sacred games had their temples bound.

ANADIPLOSIS (ἀνα and δίπλοος, *double*), in *Rhetoric* and *Poetry*, a repetition of the last word of a line, or clause of a sentence, in the beginning of the next: thus,

> Pierides, vos hæc facietis maxima Gallo:
> Gallo, cujus amor, &c.
> Et matutinis accredula vocibus instat,
> Vocibus instat, et assiduas jacit ore querelas.

ANADYOMENE APHRODITE (ἀναδυομένη, *emerging*), in *Grecian Mythology*, answered to the Sea Venus of the Romans, and described that goddess as rising from the sea. The most celebrated picture in all antiquity was the Aphrodite Anadyomene by Apelles.

ANADYR, a river in North Asiatic Russia, arising from a lake between Lat. 68° and 69°, consequently within the Arctic circle. After passing southwards, a little way beyond that circle, its general course is to the east, and it discharges itself into Behring's Strait, near the promontory of Tschutskoi Nos.

ANÆSTHESIA. See CHLOROFORME.

ANAFESTO PAOLLUCIO, of Heracleia, was elected the first Doge of Venice, A.D. 697, and was succeeded in office by Marcello Tagliana in 717.—Sismondi, *Hist. Rep. Ital.* i.; Figliasi, *Mem. de' Veneti* i.

ANAGLYPH (from ἀνά and γλύφω), any work sculptured in relief on a plane or smooth surface, as exemplified in cameos. When the object or design is produced by engraving or indenting, as in seals, the work is styled *diaglyphic*, or *intaglio*.

ANAGNIA, now AGNANI, a town of Italy, once the capital of the ancient Hernici, and still containing about 6000 inhabitants. It occupies the summit of a hill, above the *Fiume Sacco*, about 35 miles E.S.E. of Rome.

ANAGNOSTA, JOHN, a Byzantine historian of the fifteenth century. He was present at the siege of Thessalonica by Amurath in 1430, of which he gives an account in his work *De Rebus Constantinopolitanorum Macedonius.*

ANAGNOSTES (ἀναγνώστης), in *Antiquity*, a kind of literary servant, retained in the families of persons of distinction, and whose chief business was to read to them during meals, or at any other time. Cornelius Nepos relates of Atticus, that he had always an anagnostes at his meals.

ANAGOGE (ἀναγωγή), among *Ecclesiastical Writers*, the elevation of the mind to things celestial and eternal. It is particularly used where words, in their natural or primary meanings, denote something sensible, but have a further view to something spiritual or invisible.

In a more particular sense, it denotes the application of the types and allegories of the Old Testament to subjects of the New; thus called, because the veil being here drawn, what before was hidden is exposed to open sight.

ANAGRAM (from the Greek ἀνά, *backwards*, and γράμμα, *letter*), a transposition of the letters of some name, whereby a new word is formed, either to the advantage or disadvantage of the person or thing to which the name belongs. Thus the anagram of Galenus is *angelus;* that of Logica, *caligo;* that of Alstedius, *sedulitas.* Calvin, in the title of his *Institutions*, printed at Strasburg in 1539, calls himself *Alcuinus*, which is the anagram of Calvinus, and the name of the great restorer of learning in the time of Charlemagne.

Those who adhere strictly to the definition of an anagram take no other liberty than that of omitting or retaining the letter H at pleasure; whereas others make no scruple to use E for Æ, V for W, S for Z, and C for K; and *vice versa.* Besides anagrams formed as above, we meet with another kind in ancient writers, made by dividing a single word into several; thus, *sus tinea mus* are formed out of the word *sustineamus.* Anagrams are sometimes also made out of several words; such as that on the question put by Pilate to our Saviour, *Quid est veritas?* whereof we have this admirable anagram, viz., *Est vir qui adest.* A work entitled *Z. Celspirii* (Christ. Serpilii) *de Anagrammatismo, Libri II.* Ratisb. 1715, 8vo, gives numerous examples of this art.

The cabalists among the Jews are professed anagrammatists; the third part of their art, which they call *themuru, i.e.*, changing, being nothing but the art of making anagrams, or finding hidden and mystical meanings in names; which they do by changing, transposing, and differently combining the letters of those names. Thus, of נח, the letters of Noah's name, they make חן, *grace;* of משיח, *the Messiah*, they make ישמח, *he shall rejoice.*

Thomas Billon, a Provençal, was a celebrated anagrammatist, and retained by Louis XIII. with a pension of 1200 livres, in the capacity of anagrammatist to the king.

ANAGROS, in *Commerce*, a measure for grain, used in some cities in Spain, particularly at Seville. It is equal to two bushels.

ANAITIS ('Ανῖατις), an Armenian divinity, whom the Greeks sometimes identified with their own Artemis and Aphrodite. From the nature of her worship, she appears to have represented the creative powers of nature. Her name is variously written—Anaitis, Anæa, Aneitis, Tanaïs, or Nanæa.—*Vide* Plin. xxxiii.

ANAK, the father of the Anakim, was the son of Arba, who gave his name to Kirjath-arba, or Hebron. (Josh. xiv. 15.) Anak had three sons, Sheshai, Ahiman, and Talmai (chap. xv. 14, and Numb. xiii. 22), all of gigantic size; their posterity were remarkable, not only for their extraordinary stature, but for their fierceness, and were called *Anakim;* in comparison with whom, the Hebrews who were sent to view the land of Canaan reported that they were but as grasshoppers. (Numb. xiii. *ult.*) Caleb, assisted by the tribe of Judah, took Kirjath-arba, and destroyed the Anakim, A.M. 2559. (Judges i. 20, and Joshua xv. 14.)

ANALECTA (ἀνάλεκτα), in literature, is used to denote a collection of small pieces; as essays, remarks, &c.

ANALEMMA, in *Geometry*, a projection of the sphere on the plane of the meridian, orthographically made by a straight line and ellipses, the eye being supposed at an infinite distance, and in the east or west point of the horizon.

ANALEMMA denotes likewise an instrument of brass or wood, upon which this kind of projection is drawn, with an horizon or cursor fitted to it, wherein the solstitial colure, and all circles parallel to it, will be concentric circles; all circles oblique to the eye will be ellipses; and all circles whose planes pass through the eye will be right lines. The use of this instrument is to show the common astronomical problems, which, if not too large, it will do, though not very exactly.

ANALEPSIS (from ἀναλαμβάνω, *to restore*), the augmentation or nutrition of an emaciated body.

ANALEPTICS, restorative or nourishing medicines.

ANALOGY (ἀναλογία), in *Philosophy*, a certain relation and agreement between two or more things, which in other respects are entirely different. There is likewise an analogy between things that have some resemblance to one another; for example, between animals and plants; but the analogy is still stronger between different species of animals.

Analogy enters much into all our reasoning, and serves to explain and illustrate. A great part of our philosophy, indeed, has no other foundation than analogy.

"It is natural to mankind," says Dr Reid, "to judge of things less known, by some similitude, real or imaginary, between them and things more familiar or better known. And where the things compared have really a great similitude in their nature, when there is reason to think that they are subject to the same laws, there may be a considerable degree of probability in conclusions drawn from analogy. Thus, we may observe a very great similitude between this earth which we inhabit, and the other planets, Saturn, Jupiter, Mars, Venus, and Mercury. They all revolve round the sun, as the earth does, although at different distances and in different periods. They borrow all their light from the sun, as the earth does. Several of them are known to revolve round their axis like the earth, and, by that means, must have a like succession of day and night. Some of them have moons, that serve to give them light in the absence of the sun, as our moon does to us. They are all, in their motions, subject to the same law of gravitation as the earth is. From all this similitude, it is not unreasonable to think that those planets may, like our earth, be the habitation of various orders of living creatures. There is some probability in this conclusion from analogy.

"But it ought to be observed, that as this kind of reasoning can afford only probable evidence at best, so, unless great caution be used, we are apt to be led into error by it."—"No author has made a more just and a more happy use of this mode of reasoning than Bishop Butler, in his *Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature.* In that excellent work, the author does not ground any of the truths of religion upon analogy, as their proper evidence; he only makes use of analogy to answer objections against them. When objections are made against the truths of religion, which may be made with equal strength against what we know to be true in the course of nature, such objections can have no weight.

"Analogical reasoning, therefore, may be of excellent use in answering objections against truths which have other evidence. It may likewise give a greater or a less degree of probability in cases where we can find no other evidence. But all arguments drawn from analogy are still the weaker, the greater disparity there is between the things compared; and therefore must be weakest of all when we compare body with mind, because there are no two things in nature more unlike.

"There is no subject in which men have always been so prone to form their notions by analogies of this kind, as in what relates to the mind. We form an early acquaintance with material things by means of our senses, and are bred up in a constant familiarity with them. Hence we are apt to measure all things by them, and to ascribe to things most remote from matter the qualities that belong to material things. It is for this reason that mankind have, in all ages, been so prone to conceive the mind itself to be some subtile kind of matter; that they have been disposed to ascribe human figure and human organs, not only to angels, but even to the Deity." (*Essays on the Intellectual Powers.*) See Locke's *Essay*, B. iv. c. xvi. § 12; Beattie *on Truth*, part i. c. 2, § 7; and Stewart's *Philosophy of the Mind*, vol. ii. chap. ii. § 4.

Analogy, in *Grammar*, is the correspondence which a word or phrase bears to the genius and received forms of any language.

ANALYSIS (from ἀναλύω, *to resolve*), in a general sense, implies the resolution of something compounded into its original and constituent parts.

Analysis, in *Mathematics*, is properly the method of resolving problems by means of algebraical equations, whence we often find that these two words, *analysis* and *algebra*, are used as synonymous. *Analysis* is divided, with regard to its object, into that of *finites* and *infinites*. *Analysis of Finite Quantities* is what we otherwise call specious arithmetic or algebra. *Analysis of Infinites*, called also the *New Analysis*, is particularly used for the method of fluxions, or the differential calculus.

Analysis, in *Mental Philosophy*, signifies the process of decompounding our thoughts into their simplest elements, or of resolving our intellectual operations into their primary principles.

Analysis, in *Physics*, and in *Chemistry*, also denotes decomposition, that is, the separation of what is complex into its constituent parts. The different meanings of the term *Analysis*, as used in mathematics and the other branches of science, are well explained in Stewart's *Philosophy of the Mind*, vol. ii. chap. iv. § 3.

ANAM, or An-nam, a large country in the south-eastern part of Asia, between China and the Gulf of Siam, 965 miles in length from north to south, with a breadth varying from about 85 miles to 400. It has a long, winding, and much indented sea-coast, affording many safe and commodious harbours. The view which the country presents from the sea is that of a varied landscape, composed of bold headlands, picturesque valleys, well-cultivated slopes, extensive down and low plains, frequently terminating in sandhills, with a distant background of lofty mountains. Along the coast are numerous groups of islands. It is all comprised in one empire; but it is made up of three distinct territories, and part of a fourth, all formerly separate independent states, namely, Tonquin, Cochin-China, Champa, or Tsiampa, and the eastern part of Cambodia, or Camboja; which see.

ANAMNESIS, ἀνάμνησις, a rhetorical figure, the calling to remembrance of something omitted.

ANAMORPHOSIS, in *Perspective Drawing*, is a deformed or distorted figure, which appears confused and unintelligible to the common unassisted view; but when seen at a certain distance and height, or as reflected from a plane or curved mirror, appears regular and in right proportion.

ANAMOUR, Cape, in Lat. 36. 3. N. Long. 32. 50. E., is the most southern point of Asia Minor. It was the ancient Anemurium.

ANANCITIS, in *Antiquity*, a kind of figured stone, otherwise called *synochitis*, celebrated for its magical virtue of raising the shadows of the infernal gods.

ANANIAS, a Sadducee, high priest of the Jews, who put to death St James, the brother of our Lord, and was deposed by Agrippa.

Ananias, a Christian belonging to the infant church at Jerusalem, who, conspiring with his wife Sapphira to deceive and defraud the brethren, was overtaken by sudden death, and immediately buried. (Acts v. 1–11).

Ananias, a Christian of Damascus who was commanded in a vision to go and visit the newly converted Saul of Tarsus. (See Acts ix. 10; xxii. 12.)

Tradition represents Ananias as the first that published the Gospel in Damascus, over which place he was subsequently made bishop; but having roused, by his zeal, the hatred of the Jews, he was seized by them, scourged, and finally stoned to death in his own church.

ANANISABTA, or Ananisapta, a magical word frequently found inscribed on coins and other amulets, supposed to have the virtue of preserving the wearer from the plague.

ANAPÆST, in *Ancient Poetry*, a foot consisting of two short syllables and one long: such is the word scŏpŭlōs. It is just the reverse of the dactyl.

ANAPHORA, in *Rhetoric*, the repetition of the same word or words in the beginning of a sentence or verse.

ANAPHRODISIA, a medical term derived from the Greek, signifying impotence.

ANARCHY, the want of government in a nation, where no supreme authority is lodged either in the prince or other rulers, but the people live at large, and all things are in confusion. The word is derived from the Greek privative α, and ἀρχή, *command, government.*

ANASARCA, an effusion of serum into the cellular tissues, occasioning a soft, pale, inelastic swelling.

ANASTASIUS I., Emperor of the East, and the successor of Zeno, was raised from obscurity to that exalted position by the Empress Ariadne, who married him on the fortieth day of her widowhood. His reign commenced auspiciously, but was afterwards disturbed by foreign and intestine wars, and by religious distractions. In the year 500 he was anathematized by pope Symmachus for his support of the Eutychians. He died in 518 at the age of nearly 90, leaving behind a name darkened by avarice, cruelty, and cowardice.

Anastasius II., whose proper name was *Artemius*, was elevated from the humble situation of a secretary to the throne of Constantinople, by the free voice of the senate and Roman people, A.D. 713. His natural talents, improved by education and daily exertion, enabled him to manage with great prudence the affairs of the empire during the time that he was secretary to his predecessor Philippicus. The Saracens had made inroads upon Asia Minor in the beginning of his reign; but he sent a strong army to the frontiers of Syria for its protection, under the command of Leo the Isaurian, a man of great military experience. These enemies of the empire also meditated the design of taking Constantinople; but the vigilance of Anastasius defeated their purpose, by providing a formidable naval force, repairing and strengthening the walls of the city, and by forcing all the inhabitants either to provide themselves with provisions for three years, or instantly to depart from the city. Disappointed in their design, the enemy's fleet sailed to Phœnicia, and the imperial fleet assembled at Rhodes to watch the motions of the enemy. But the measures of the emperor received a severe check from the conduct of the sailors, who raised a mutiny, and slew their admiral for no other cause than his honourable endeavours to maintain proper discipline in the fleet. Justly dreading severe punishment, the seamen raised the standard of rebellion, declared Anastasius unworthy to reign, and conferred the purple upon one Theodosius, a person of mean birth. Informed of this sedition, Anastasius fled from his tottering throne to Nice. The new emperor hastened to besiege Constantinople, which, after a vigorous resistance of six months, was reduced to subjection. The late emperor being assured of his life, abandoned his claim to the crown, assumed the character of a monk, and was banished to Thessalonica, having worn the purple only during the space of two years. Having, however, prevailed upon the Bulgarians to espouse his cause, he laid aside the habit of the monk for that of the warrior, and, in the year 721, in the time of the Emperor Leo, he resumed his claim to the throne. A numerous army of these barbarians hastened to the capital; but being unable to reduce it, they delivered up the unhappy Anastasius to the emperor, who put him to death, along with his principal associates.

ANASTASIUS, surnamed *Bibliothecarius*, a Roman abbot, library-keeper of the Vatican, and one of the most learned men of the ninth century, assisted in 869 at the fourth general council, the acts and canons of which he translated from the Greek into Latin. He also composed the lives of several popes, and other works: the best edition of which is that of the Vatican.

ANASTOMATICS, medicines supposed to have the power of opening the mouths of vessels, and promoting the circulation; such as deobstruents, cathartics, and sudorifics.

ANASTOMOSIS. See ANATOMY.

ANASTROPHE, in *Rhetoric* and *Grammar*, denotes the inversion of the natural order of the words: such is *saxa per et scopulos*, for *per saxa et scopulos*.

ANATHEMA (ἀνάθεμα), among *Ecclesiastical Writers*, imports whatever is set apart, separated, or divided; but is most usually meant to express the cutting off a person from the privileges of communion with the faithful. The anathema differs from excommunication in the circumstances of being attended with curses and execrations. It was practised in the primitive church against notorious offenders. Several councils also have pronounced anathemas against such as they thought corrupted the purity of the faith. There are two kinds of anathemas, the one judiciary and the other abjuratory. The former can only be denounced by a council, a pope, or a bishop; the latter makes a part of the ceremony of abjuration, the convert being obliged to anathematize the heresy he abjures.

ANATHEMA (ἀνάθημα), in *Heathen Antiquity*, was an offering or present made to some deity, and hung up in the temple. Whenever a person left off his employment, it was usual to dedicate the tools to the patron deity of the trade. Persons, too, who had escaped from imminent danger, as shipwreck and the like, or had met with any other remarkable instance of good fortune, seldom failed to testify their gratitude by some present of this kind.

ANATOCISMUS (from ἀνα and τόκος), in *Antiquity*, a kind of usury corresponding to what we call *compound interest*. This is the worst kind of usury, and has been severely condemned by the Roman law, as well as by the common laws of most other countries.

ANATOLIA. See NATOLIA.

# ANATOMY.

ANATOMY (Ανατομη), signifying literally dissection, or separation of parts by cutting, applied to organized bodies, is used to denote the artificial separation of their component parts in order to obtain an exact knowledge of their situation, shape, and structure.

A more just idea of the nature and objects of anatomy may be given by defining it as that science, the province of which is to ascertain the structure of living and organized bodies.

All the objects of the material world may be arranged in two great divisions, according as they are organized or void of organization. Inorganic bodies (*corpora bruta*) are distinguished by the homogeneous characters of their internal structure, any one portion of which, in the same mass, presents the same appearance and properties as any other. Endowed also with the general properties of matter, as weight, cohesion, impenetrability, and atomic attraction, or that resident in the constituent particles, they are subject to physical laws only. All the changes which inorganic bodies undergo consist either in mechanical changes of place or shape, or in change of chemical constitution; and the consideration of the mode in which these changes take place, of the agents by which they are effected, and the laws by which they are regulated, constitutes the sciences of MECHANICS and CHEMISTRY.

In organic bodies (*corpora organica, c. viva*), on the contrary, we recognise a peculiar structure, in which the parts, though arranged in a certain order, are heterogeneous, or consist of different kinds of matter. In other words, not only do organized bodies consist of different kinds of substance, but these component substances may be again resolved into material elements, differing from each other in mechanical, chemical, and vital properties.

Observation further shows, that organic are distinguished from inorganic bodies by the presence of a series and combination of actions and processes, which are collectively known under the abstract denomination of *Life*. Of this term, however familiar it may appear, it has been found difficult to give a satisfactory and unobjectionable definition; and physiological authors have found it requisite, in order to avoid obscurity, to define it from its tendency, its obvious effects, or, negatively, from what experience shows to ensue upon its termination. Life is an attribute of living bodies, and is known only as it manifests its presence in these; and hence, instead of saying what it is, we are compelled to specify only the circumstances which denote its existence. Attentively considered, all the varieties of organized and living bodies may be said to be distinguished from those which are inorganic by two great characters,—growth or the reproduction of the individual, and generation or the reproduction of the species. Growth, or increase of size, includes the general processes of assimilation and nutrition, with all the subordinate actions of which these are composed; and since it consists in the conversion of brute or inorganic into living or organic matter, it constitutes one of the most essential characters of life and organization. By virtue of this, living bodies are the seat of an incessant change in their interior structure; whereas inorganic bodies remain in the same state, unless from the operation of chemical laws. The formation of a new body similar to others of the same class, order, and kind, however various in its mode, is also a uniform attribute of all living and organized bodies. To one or other of these two general purposes, then, all the actions and processes of living bodies, however complex and multifarious they seem, may be ultimately referred. To these two characters of living bodies Cuvier adds a third,—death, or the termination of life; but as this is a negative circumstance, and is included in the idea of life as a process having beginning and end, it is superfluous in the general idea of the term. The knowledge of the actions and processes of living and organized bodies, and of the laws to which they are subject, constitutes the science of PHYSIOLOGY, or, as it has been also denominated, ZOONOMY (ζωη and νομος, *laws of life*,) or BIOLOGY (βιος and λογος, *doctrine of life*).

Life supposes organization or the arrangement of matter and material particles peculiar to living bodies; and, reciprocally, organization, though not the cause of life and living processes, invariably implies their existence, either present or previous. In other words, every organized body either is or must have been living; and every living body is endowed with the peculiar internal structure termed *organic*. Though it is difficult to specify by definition the characters of this structure, some idea of it may be communicated by stating, that all living bodies possess material organs of definite shape, substance, and structure, consisting of certain parts, and placed in proper positions. While it is the province of PHYSIOLOGY to study the actions and processes of living bodies, and to investigate the laws by which they are regulated, the exclusive object of ANATOMY is to distinguish and describe their constituent parts,—to determine the shape, position, and structure of their organs,—and, in short, to develope their structure. The term is not free from objection, since it literally denotes one only of the means employed to acquire the information requisite. But the objection is not obviated by the substitution of such terms as *morphology* and *organology*, in so far as the study of anatomy is not confined either to the shapes of parts or the knowledge of organs alone, but considers their position, their intimate structure, and their organization; in short, all the circumstances relating to the material constitution of living bodies.

All living and organized bodies, though agreeing in the general character of possessing organs for assimilation and nutrition, and organs of reproduction, differ nevertheless in the possession or the want of organs for two other functions, viz. those for recognising the presence of foreign bodies, or organs of *sensation*, and those for changing place, or organs of *locomotion*. The possession of these organs distinguishes those living beings denominated ANIMALS; the want of them in like manner characterizes those termed PLANTS or VEGETABLES. Upon this principle anatomy, or the science of organic structures, resolves itself into two great divisions,—ANIMAL ANATOMY, or ZOOTOMY (ζωον and τομη), the object of which is the investigation of the structure of animal bodies; and VEGETABLE ANATOMY, or PHYTOTOMY (φυτον and τομη), the object of which is to explain the structure peculiar to the vegetable tribes.

Animal anatomy, again, naturally resolves itself into several divisions, according as the object is to explain the structure of the animal kingdom at large, or that of certain classes, orders, tribes, families, or genera only. The most ordinary and convenient division, however, is into that which treats of the anatomy of the known animal tribes in general, and that which treats of the structure peculiar to the human subject. The accidental circumstance of the former being studied chiefly in comparison with the latter, the organic forms of which are regarded as the standard of reference, has given it the denomination of COMPARATIVE ANATOMY, though that of ANIMAL ANATOMY or ZOOTOMY would be more appropriate. The latter has generally been named ANATOMY simply, or the Anatomy of the Human Body, and occasionally ANTHROPOTOMY or HUMAN ANATOMY.

The connection which subsists between the latter and the several divisions of the art of healing, renders it interesting to the medical, the surgical, and the philosophical reader generally, and invests it with the highest importance to all. Comparative Anatomy, nevertheless, possesses the peculiar advantage of directing the mind of the inquirer to general resemblances, to universal facts, and to comprehensive analogies. Independent of the important services which its knowledge renders to several of the arts, it is of the greatest use in throwing light on some of the obscurest parts of physiology; by the extensive chain of analogical facts which it traces, it tends to explain difficulties in organization and function, which could not otherwise be intelligible; and by establishing the connection between external characters and habits with peculiarities of internal structure, it affords the only rational basis for the classifications and distinctions of zoology. Comparative or Animal Anatomy constitutes the great source of what may be termed the Philosophy of Animal Life.

Of the present treatise, the greater part will be devoted to the subject of HUMAN ANATOMY, or the explanation of the structure of the human frame in the healthy state. In a smaller proportion, it is proposed to give a view of the structure of animal bodies generally, with occasional observations on those peculiarities in configuration and structure which distinguish classes, orders, and genera, from each other. This will constitute COMPARATIVE ANATOMY.

The subject of VEGETABLE ANATOMY, unfolding the peculiarities of structure observed in plants, will be treated of in the article BOTANY.

Previous to entering on the subject of Animal Anatomy, however, and its two divisions, Human and Comparative Anatomy, it is requisite to take a historical view of the progress of the science from its origin to the present time.

History.

In tracing the history of the origin of anatomy, it may be justly said that more learning than judgment has been displayed. Some writers claim for it the highest anti- B.C. 1957–
quity, and pretend to find its first rudiments alternately in 1537.
the animal sacrifices of the shepherd kings, the Jews, and other ancient nations; and in the art of embalming, as practised by the Egyptian priests. Even the descriptions 1184.
of wounds in the Iliad have been supposed adequate to prove that, in the time of Homer, mankind had distinct notions of the structure of the human body. Of the first, it may be said that the rude information obtained by the slaughter of animals for sacrifice does not imply profound anatomical knowledge; and those who adduce the second as evidence, are deceived by the language of the poet of the Trojan war, which, distinguishing certain parts by their ordinary Greek epithets, as afterwards used by Hippocrates, Galen, and all anatomists, has been rather too easily supposed to prove that the poet had studied systematically the structure of the human frame.

With not much greater justice has the cultivation of anatomical knowledge been ascribed to Hippocrates, who, because he is universally allowed to be the father of medicine, has also been thought to be the creator of the science of anatomy. Of the seven individuals of the fa- 460–377.
mily of the Heracleidæ who bore this celebrated name, the second, who was son of Heraclides and Phenarita, and grandson of the first Hippocrates, was indeed distinguished

History. as the author of medical observation and experience, and the first who appreciated the value of studying accurately the phenomena, effects, and terminations of disease. It does not appear, however, notwithstanding the vague and general panegyrics of Riolan, Bartholin, Le Clerc, and Portal, that the anatomical knowledge of this illustrious person was either accurate or profound. Of the works ascribed to Hippocrates, five only are genuine. Most of them were written either by subsequent authors of the same name, or by one or other of the numerous impostors who took advantage of the zealous munificence of the Ptolemies, by fabricating works under that illustrious name. Of the few which are genuine, there is none expressly devoted to anatomy; and of his knowledge on this subject, the only proofs are to be found in the exposition of his physiological opinions, and his medical or surgical instructions. From these it appears that he had some accurate notions on osteology; but that of the structure of the human body in general, his ideas were at once superficial and erroneous. In his book on injuries of the head, and in that on fractures, he shows that he knew the sutures of the cranium, and the relative situation of the bones; and that he had some notion of the shape of the bones in general, and of their mutual connections. Of the muscles, of the soft parts in general, and of the internal organs, his ideas are confused, indistinct, and erroneous. The term φλεβς he seems, in imitation of the colloquial Greek, to have used generally to signify a blood-vessel, without being aware of the distinction of vein and artery; and the term αρτηρια, or air-holder, is restricted to the windpipe. He appears to have been unaware of the existence of the nervous chords; and the term is used by him, as by Grecian authors in general, to signify a *sinew* or *tendon*. On other points his knowledge is so much combined with peculiar physiological doctrines, that it is impossible to assign them the character of anatomical facts; and even the works in which these doctrines are contained are with little probability to be ascribed to the second Hippocrates. If, however, we overlook this difficulty, and admit what is contained in the genuine Hippocratic writings to represent at least the sum of knowledge possessed by Hippocrates and his immediate descendants, we find that he represents the brain as a gland, from which exudes a viscid fluid; that the heart is muscular and of pyramidal shape, and has two ventricles separated by a partition, the fountains of life—and two auricles, receptacles of air; that the lungs consist of five ash-coloured lobes, the substance of which is cellular and spongy, naturally dry, but refreshed by the air; and that the kidneys are glands, but possess an attractive faculty, by virtue of which the moisture of the drink is separated, and descends into the bladder. He distinguishes the bowels into colon and rectum (ὁ αρχος).

374. The knowledge possessed by the second Hippocrates was transmitted in various degrees of purity to the descendants and pupils, chiefly of the family of the Heracleidæ, who succeeded him. Several of these, with feelings of grateful affection, appear to have studied to preserve the written memory of his instructions, and in this manner to have contributed to form part of that collection of treatises which have long been known to the learned world under the general name of the *Hippocratic writings*. Though composed, like the genuine remains of the physician of Cos, in the Ionian dialect, all of them differ from these in being more diffuse in style, more elaborate in form, and in studying to invest their anatomical and medical matter with the fanciful ornaments of the Platonic philosophy. Hippocrates had the merit of early recognising the value of facts apart from opinions, and of those facts especially which lead to general results; and in the few genuine writings which are now extant, it is easy to perceive that he has recourse to the simplest language, expresses himself in terms which, though short and pithy, are always precise and perspicuous, and is averse to the introduction of philosophical dogmas. Of the greater part of the writings collected under his name, on the contrary, the general character is verboseness, prolixity, and a great tendency to speculative opinions. For these reasons, as well as for others derived from internal evidence, while the Aphorisms, the Epidemics, and the works above mentioned, bear distinct marks of being the genuine remains of Hippocrates, it is impossible to regard the book περι Φυσιος Ανθρωπου as entirely the composition of that physician; and it appears more reasonable to view it as the work of some one of the numerous disciples to whom the author had communicated the results of his observation, which they unwisely attempted to combine with the philosophy of the Platonic school and their own mysterious opinions.

Among those who aimed at this distinction, the most 374.
fortunate in the preservation of his name is Polybus, the son-in-law of the physician of Cos. This person, who must not be confounded with the monarch of Corinth immortalized by Sophocles in the tragic story of Œdipus, is represented as a recluse, severed from the world and its enjoyments, and devoting himself to the study of anatomy and physiology, and to the composition of works on these subjects. To him has been ascribed the whole of the book on *the Nature of the Child*, and most of that *on Man;* both physiological treatises, interspersed with anatomical sketches. His anatomical information, with which at present is our chief concern, appears to have been rude and inaccurate, like that of his preceptor. He represents the large vessels of the body to consist of four pairs: the first proceeding from the head by the back of the neck and spinal chord to the hips, lower extremities, and outer ankle; the second, consisting of the jugular vessels (αἰ σφαγιτιδες), proceeding to the loins, thighs, hams, and inner ankle; the third proceeding from the temples by the neck to the *scapula* and lungs, and thence by mutual intercrossings to the spleen and left kidney, and the liver and right kidney, and finally to the rectum; and the fourth from the fore-part of the neck to the upper extremities, the fore-part of the trunk, and the organs of generation.

This specimen of the anatomical knowledge of one of 363.
the most illustrious of the Hippocratic disciples differs not essentially from that of Syennesis, the physician of Cyprus, and Diogenes, the philosopher of Apollonia, two authors, for the preservation of whose opinions we are indebted to Aristotle.[1] They may be admitted as representing the state of anatomical knowledge among the most enlightened men at that time, and they only show how rude and erroneous were their ideas on the structure of the animal body. It may indeed, without injustice, be said, that the anatomy of the Hippocratic school is not only erroneous, but fanciful and imaginary, in often substituting mere supposition and assertion for what ought to be matter of fact. From this censure it is impossible to exempt even the name of Plato himself, for whom some notices in the Timæus on the structure of the animal body, as taught by Hippocrates and Polybus, have procured a place in the history of the science.

---

[1] Περι Ζωων Ἱστοριας, lib. iii. cap. ii.

History.

Amidst the general obscurity in which the early history of anatomy is involved, only two leading facts may be admitted with certainty. The first is, that previous to the time of Aristotle there was no accurate knowledge of anatomy; and the second, that all that was known was derived from the dissection of the lower animals only. By the appearance of Aristotle, this species of knowledge, which was hitherto acquired in a desultory and irregular manner, began to be cultivated systematically and with a definite object; and among the services which the philosopher of Stagira rendered to mankind, one of the greatest and most substantial is, that he was the founder of Comparative Anatomy, and was the first to apply its facts to the elucidation of zoology. The works of this ardent and original naturalist show that his zootomical knowledge was extensive, and often accurate; and from several of his descriptions it is impossible to doubt that they were derived from frequent personal dissection.

384. Aristotle, who was born 384 years before the Christian era, or in the first year of the 99th Olympiad, was, at the age of 39, requested by Philip to undertake the education of his son Alexander. During this period, it is said, he composed several works on anatomy, which however are now lost. The military expedition of his royal pupil into Asia, by laying open the animal stores of that vast and little known continent, furnished Aristotle with the means of extending his knowledge, not only of the animal tribes, but of their structure, and of communicating more accurate and distinct notions than were yet accessible to the world. A sum of 800 talents, and the concurrent aid of numerous
334–327. intelligent assistants in Greece and Asia, were intended to facilitate his researches in composing a system of zoological knowledge; but it has been observed, that the number of instances in which he was thus compelled to trust to the testimony of other observers, led him to commit errors in description, which personal observation might have enabled him to avoid.

The first three books of the *History of Animals*, a treatise consisting of ten books, and the four books on the *Parts of Animals*, constitute the great monument of the *Aristotelian Anatomy*. From these we find that Aristotle was the first who corrected the erroneous statements of Polybus, Syennesis, and Diogenes, regarding the blood-vessels, which they made, as we have seen, to arise from the head and brain. These he represents to be two in number, placed before the spinal column, the larger on the right, the smaller on the left, which, he also remarks, is by some called *aorta* (αορτη), the first time, we observe, which this epithet occurs in the history. Both he represents to arise from the heart, the larger from the largest upper cavity, the smaller or aorta from the middle cavity, but in a different manner, and forming a narrower canal. He also distinguishes the thick, firm, and more tendinous structure of the aorta from the thin and membranous structure of the vein. In describing the distribution of the latter, however, he confounds the *vena cava* and pulmonary artery, and, as might be expected, he confounds the ramifications of the former with those of the arterial tubes in general. While he represents the lung to be liberally supplied with blood, he describes the brain as an organ almost destitute of this fluid. His account of the distribution of the aorta is wonderfully correct. Though he does not notice the cœliac, and remarks that the aorta sends no direct branches to the liver and spleen, he had observed the mesenteric, the renal, and the common iliac arteries. It is nevertheless singular, that though he remarks particularly that the renal branches of the aorta go to the substance and not the *pelvis* (κοιλια) of the kidney, he appears to mistake the ureters for branches of the aorta.

History.

Of the nerves (νευρα) he appears to have the most confused notions. Making them arise from the heart, which he says has nerves (tendons) in its largest cavity, he represents the aorta to be a nervous or tendinous vein (νευρωδης φλεβς). By afterwards saying that all the articulated bones are connected by *nerves*, he makes them the same as ligaments; while the character of divisibility in the long direction identifies them rather with tendons; and the assertion that no part destitute of them has sensation, makes them approach to the nervous chords of the modern anatomists. He distinguishes suet, fat, and marrow, from each other; and though he admits the spinal chord to consist of the latter substance, he differs from those authors who regard the brain of the same nature, because while brain is cold, marrow is hot.

He distinguishes the windpipe or air-holder (αρτηρια) from the œsophagus, because it is placed before the latter, because food or drink passing into it causes distressing cough and suffocation, and because there is no passage from the lung to the stomach. He knew the situation and use of the epiglottis, seems to have had some indistinct notions of the larynx, represents the windpipe to be necessary to convey air to and from the lungs, and appears to have a tolerable understanding of the structure of the lungs. He repeatedly represents the heart, the shape and site of which he describes accurately, to be the origin of the blood-vessels, in opposition to those who made them descend from the head; yet, though he represents it as full of blood, and the source and fountain of that fluid, and even speaks of the blood flowing from the heart to the veins,[1] and thence to every part of the body,[2] he says nothing of the circular motion of the blood.

The diaphragm he distinguishes by the name διαζωμα, and ὑποζωμα. With the liver and spleen, and the whole alimentary canal, he seems well acquainted. The several parts of the quadruple stomach of the ruminating animals are distinguished and named; and he even traces the relations between the teeth and the several forms of stomach, and the length or brevity, the simplicity or complication, of the intestinal tube. Upon the same principle he distinguishes the *jejunum* (ἡ νηστις), or the empty portion of the small intestines in animals (το εντερον λεπτον), the *cœcum* (τυφλον τι και ογκωδες), the colon (το κωλον), and the sigmoid flexure (στενωτερον και ειλιγμενον). The modern epithet of *rectum* is the literal translation of his description of the straight progress (ευθυ) of the bowel to the anus (πρωκτος). He knew the nasal cavities and the passage from the tympanal cavity of the ear to the palate, afterwards described by Eustachius.

Next to Aristotle occur the names of Diocles of Carys- 354.
tus, and Praxagoras of Cos, the last of the family of the
Asclepiadæ. The latter is remarkable for being the first 341.
who distinguished the arteries from the veins, and the author of the opinion that the former were air-vessels.

Hitherto anatomical inquiry was confined to the examination of the bodies of brute animals. We have, indeed,

[1] Εκ της καρδιας γαρ εποχετευεται εις τας φλεβας. Αὑται γαρ ἐκ της καρδιας δεχονται το αἱμα. (Περι Ζωων Μοριων, lib. iii. cap. iv. v.)

[2] Συνισταμενων δε των μοριων εκ του αἱματος, καθαπερ ειπομεν, ευλογως ἡ των φλεβων ῥυσις δια παντος του σωματος πεφυκε. δει γαρ και το αἱμα δια παντος και περι παν ειναι, ειπερ των μοριων ἑκαστον εκ τουτου συνεστηκεν. εοικε δ᾽ ὡσπερ εν τε τοις κηποις αἱ ὑδραγωγιαι κατασκευαζονται απο μιας αρχης και πηγης, εις πολλους οχετους και αλλους αιει προς το παντη μεταδιδοναι. (*Ibid.* lib. iii. cap. v.)

History. no testimony of the human body being submitted to examination previous to the time of Erasistratus and Herophilus; and it is vain to look for authentic facts on this point before the foundation of the Ptolemaic dynasty of sovereigns in Egypt. This event, which, as is generally known, succeeded the death of Alexander, 320 years before the Christian era, collected into one spot the scattered embers of literature and science, which were beginning to languish in Greece under a weak and distracted government, and an unsettled state of society. The children of her divided states, whom domestic discord and the uncertainties of war rendered unhappy at home, wandered into Egypt, and found, under the fostering hand of the Alexandrian monarchs, the means of cultivating the sciences, and repaying with interest to the country of Thoth and Osiris, the benefits which had been conferred on the infancy of Greece by Thales and Pythagoras. Alexandria became in this manner the depository of all the learning and knowledge of the civilized world; and while other nations were sinking under the effects of internal animosities and mutual dissensions, or ravaging the earth with the evils of war, the Egyptian Greeks kept alive the sacred flame of science, and preserved mankind from relapsing into their original barbarism.

These happy effects are to be ascribed in an eminent degree to the enlightened government and liberal opinions
285. of Ptolemy Soter, and his immediate successors Philadelphus and Euergetes. The two latter princes, whose authority was equalled only by the zeal with which they patronised science and their professors, were the first who enabled physicians to dissect the human body, and prevented the prejudices of ignorance and superstition from compromising the welfare of the human race. To this happy circumstance Herophilus and Erasistratus are indebted for the distinction of being known to posterity as the first anatomists who dissected and described the parts of the human body. Both of these physicians flourished under Ptolemy Soter, and probably Ptolemy Philadelphus, and were indeed the principal supports of what has been named in medical history the Alexandrian School, to which their reputation seems to have attracted numerous pupils.

But though the concurrent testimony of antiquity assigns to these physicians the merit of dissecting the human body, time, which wages endless war with the vanity and ambition of man, has dealt hardly with the monuments of their labours. As the works of neither have been preserved, great uncertainty prevails as to the respective merits of these ancient anatomists; and all that is now known of their anatomical researches is obtained from the occasional notices of Galen, Oribasius, and some other wri-
304. ters. From these it appears that Erasistratus recognised the valves of the heart, and distinguished them by the names of *tricuspid* and *sigmoid;* that he studied particularly the shape and structure of the brain, and its divisions, and cavities, and membranes, and likened the convolutions to the folds of the jejunum; that he first formed a distinct idea of the nature of the nerves, which he made issue from the brain; and that he discovered lymphatic vessels in the mesentery, first in brute animals, and afterwards, it is said, in man. It is not uninteresting to observe, that he appears to have distinguished the nerves into those of sensation and those of motion.

Of Herophilus it is said that he had extensive anatomical knowledge, acquired by dissecting, not only brutes, but human bodies. Of these he probably dissected more than any of his predecessors or contemporaries. But it is History. almost superfluous to remind the classical reader, that the passage of Tertullian, in which he is said to have dissected 600 corpses, is not to be understood literally, and means only that he had dissected many; and that this language is employed by an author who speaks of him in terms of execration, and who evidently exaggerates in order to prejudice the reader against the anatomist. Devoted to the assiduous cultivation of anatomy, he appears to have studied with particular attention those parts which were least understood. He recognised the nature of the pulmonary artery, which he denominates *arterious vein;* he knew the vessels of the mesentery, and showed that they did not go to the *vena portæ*, but to certain glandular bodies; and he first applied the name of *twelve-inch* or *duodenum* (δωδεκαδακτυλος) to that part of the alimentary canal which is next to the stomach. Like Erasistratus, he appears to have studied carefully the configuration of the brain; and we learn from Galen that he first compared the linear furrow at the bottom of the fourth ventricle to the cavity of a writing pen; and though like him he distinguishes the nerves into those of sensation and those of voluntary motion, he adds to them the ligaments and tendons. A tolerable description of the liver by this anatomist is preserved in the writings of Galen.[1] He first applied the name of choroid or vascular membrane to that which is found in the cerebral ventricles; he knew the fourth or straight sinus, which still bears his name; he described the posterior end of the vault or fornix as the principal seat of the sensations; and to him the linear furrow at the bottom of the fourth ventricle is indebted for its name of *calamus scriptorius.*

The celebrity of these two great anatomists appears to have thrown into the shade, for a long period, the names of all other inquirers; for among their numerous and rather celebrated successors in the Alexandrian school, it is impossible to recognise a name which is entitled to distinction in the history of anatomy. In a chasm so wide it is not uninteresting to find, in one who combined the character of the greatest orator and philosopher of antiquity, the most distinct traces of attention to anatomical knowledge. Cicero, in his treatise *De Natura Deorum*, in a 44.
short sketch of physiology, such as it was taught by Aristotle and his disciples, introduces various anatomical notices, from which the classical reader may form some idea of the state of anatomy at that time. The Roman orator appears to have formed a pretty distinct idea of the shape and connections of the windpipe and lungs; and though he informs his readers that he knows the alimentary canal, he omits the details through motives of delicacy. In imitation of Aristotle, he talks of the blood being conveyed by the veins (*venæ*), that is, blood-vessels, through the body at large; and, like Praxagoras, of the air inhaled by the lungs being conveyed through the arteries.

Aretæus, though chiefly known as a medical author, makes some observations on the lung and the pleura, maintains the glandular structure of the kidney, and describes the anastomosis or communications of the capillary extremities of the *vena cava* with those of the portal vein.

The most valuable depository of the anatomical know- A. D. 3-5.
ledge of these times is the work of Celsus, one of the most judicious medical authors of antiquity. He left, indeed, no express anatomical treatise; but from the introductions to his 4th and 8th books, *De Medicina*, with incidental remarks in his 7th, the modern reader may

[1] Περι Ανατομικων Εγχειρησεων, lib. vi.

form very just ideas of the anatomical attainments of the Roman physician. From these it appears that Celsus was well acquainted with the windpipe and lungs, and the heart; with the difference between the windpipe and œsophagus (*stomachus*), which leads to the stomach (*ventriculus*); and with the shape, situation, and relations of the diaphragm. He enumerates also with accuracy the principal facts relating to the situation of the liver, the spleen, and the kidneys. His description of the situation and connections of the stomach is interesting. He appears, however, to have been unaware of the distinction of *duodenum* or twelve-inch bowel, already admitted by Herophilus, and represents the stomach as directly connected by means of the *pylorus* with the *jejunum* or upper part of the small intestine. His account of the rest of the alimentary canal, though brief and cursory, is accurate; and his subsequent descriptions of diseases seated in these parts show that he had formed ideas, upon the whole very just, of the relative positions of these parts.

The 7th and 8th books, which are devoted to the consideration of those diseases which are treated by manual operation, contain sundry anatomical notices necessary to explain the nature of the diseases, or mode of treatment. Of these, indeed, the merit is unequal; and it is not wonderful that the ignorance of the day prevented Celsus from understanding rightly the mechanism of the pathology of hernia. He appears, however, to have formed a tolerably just idea of the mode of cutting into the urinary bladder; and even his obstetrical instructions show that his knowledge of the uterus, vagina, and appendages was not contemptible. It is in osteology, however, that the information of Celsus is chiefly conspicuous. He enumerates the sutures and several of the holes of the cranium, and describes at great length the superior and inferior maxillary bones and the teeth. With a good deal of care he describes the vertebræ and the ribs, and gives very briefly the situation and shape of the *scapula, humerus, radius,* and *ulna,* and even the carpal and metacarpal bones, and then of the different bones of the pelvis and lower extremities. He had formed a just idea of the articular connections, and is desirous to impress the fact, that none is formed without cartilage. From his mention of many minute holes (*multa et tenuia foramina*), in the recess of the nasal cavities, it is evident that he was acquainted with the perforated plate of the ethmoid bone; and from saying that the straight part of the auditory canal becomes flexuous, and terminates in numerous minute cavities (*multa et tenuia foramina diducitur*), it is inferred by Portal that he knew the semicircular canals.

54–81. Though the writings of Celsus show that he cultivated anatomical knowledge, it does not appear that the science was much studied by the Romans; and there is reason to believe, that after the decay of the school of Alexandria it languished in neglect and obscurity. It is at least certain that the appearance of Marinus during the reign of Nero is mentioned by authors as an era remarkable for anatomical inquiry, and that this person is distinguished by Galen as the restorer of a branch of knowledge which had been before him suffered to fall into undeserved neglect. From Galen also we learn that he gave an accurate account of the muscles, that he studied particularly the glands, that he discovered those of the mesentery, and that he improved much the anatomical history of the nerves. The number of the latter he fixed at seven; he observed the palatine nerves, which he rated as the fourth pair; and described as the fifth the auditory and facial, which he regards as one pair; and the hypoglossal as the sixth.

Not long after Marinus, appeared Ruffus of Ephesus, a Greek physician, who in the reign of Trajan was much attached to physiology, and as a means of cultivating this science studied Comparative Anatomy, and made sundry experiments on living animals. Of the anatomical writings of this author, there remains only a list or catalogue of names of different regions and parts of the animal body. He appears, however, to have directed the attention particularly to the tortuous course of the uterine vessels, and to have recognised even at this early period the Fallopian tube. He distinguishes the nerves into those of sensation and those of motion. He knew the recurrent nerve. His name is further associated with the ancient experiment of compressing in the situation of the carotid arteries the pneumogastric nerve, and thereby inducing insensibility and loss of voice.

Of all the authors of antiquity, however, none possesses so just a claim to the title of anatomist as Claudius Galenus, the celebrated physician of Pergamus. This person, who was born about the 131st year of the Christian era, and lived under the reigns of Trajan, Antoninus, Commodus, and Ælius, was trained by his father Nicon, whose memory he embalms as an eminent mathematician, architect, and astronomer, to all the learning of the day, and initiated particularly into the mysteries of the Aristotelian philosophy. In an order somewhat whimsical he afterwards studied philosophy successively in the schools of the Stoics, the Academics, the Peripatetics, and the Epicureans. While at the age of 17, his father, he informs us, was admonished by a dream to devote his son to the study of medicine; but it was fully two years after, that Galen entered on this pursuit, under the auspices of an instructor, whose name he has thought proper to conceal. Shortly after, he betook himself to the study of anatomy under Satyrus, a pupil of Quintus, and of medicine under Stratonicus, a Hippocratic physician, and Æschrion, an empiric. He had scarcely attained the age of 20, when he had occasion to deplore the loss of the first and most affectionate guide of his studies; and soon after he proceeded to Smyrna to obtain the anatomical instructions of Pelops, who, though mystified by some of the errors of Hippocrates, is commemorated by his pupil as a skilful anatomist. After this he appears to have visited various cities, distinguished for philosophical or medical teachers; and, finally, to have gone to Alexandria with the view of cultivating more accurately and intimately the study of anatomy under Heraclianus. Here he remained till his 28th year, when he regarded himself as possessed of all the knowledge then attainable through the medium of teachers. He now returned to Pergamus, to exercise the art which he had so anxiously studied, and received, in his 29th year, an unequivocal testimony of the confidence which his fellow-citizens reposed in his skill, by being intrusted with the treatment of the wounded gladiators; and in this capacity he is said to have treated with success several wounds which used to be fatal. A seditious tumult appears to have caused him to form the resolution of quitting Pergamus and proceeding to Rome, at the age of 32. Here, however, he remained only five years; and returning once more to Pergamus, after travelling for some time, finally settled in Rome as physician to the emperor Commodus.

The anatomical writings ascribed to Galen, which are numerous, are to be viewed not merely as the result of personal research and information, but as the common depository of the anatomical knowledge of the day, and as combining all that he had learnt from the several teachers under whom he successively studied, with whatever personal investigation enabled him to acquire. It is on this account not always easy to distinguish what Galen had himself ascertained by personal research, from that which

History. was known by other anatomists. This, however, though of moment to the history of Galen as an anatomist, is of little consequence to the science itself; and, from the anatomical remains of this author, a pretty just idea may be formed, both of the progress and of the actual state of the science at that time.

The osteology of Galen is undoubtedly the most perfect of the departments of the anatomy of the ancients. He names and distinguishes the bones and sutures of the cranium nearly in the same manner as at present. Thus he notices the quadrilateral shape of the parietal bones; he distinguishes the squamous, the styloid, and the mastoid portions, and the lithoid or petrous portions of the temporal bones; and he remarks the peculiar situation and shape of the wedge-like or sphenoid bone. Of the ethmoid, which he omits at first, he afterwards speaks more at large in another treatise. The malar he notices under the name of zygomatic bone; and he describes at length the upper maxillary and nasal bones, and the connection of the former with the sphenoid. He gives the first clear account of the number and situation of the vertebræ, which he divides into *cervical*, *dorsal*, and *lumbar*, and distinguishes from the sacrum and coccyx. Under the head *Bones of the Thorax*, he enumerates the sternum, the ribs (αἱ πλευραι), and the dorsal vertebræ, the connection of which with the former he designates as a variety of *diarthrosis*. The description of the bones of the extremities and their articulations concludes the treatise.

Though in myology Galen appears to less advantage than in osteology, he nevertheless had carried this part of anatomical knowledge to greater perfection than any of his predecessors. He describes a frontal muscle, the six muscles of the eye, and a seventh proper to animals; a muscle to each *ala nasi*, four muscles of the lips, the thin cutaneous muscle of the neck, which he first termed *platysma myoides*, or muscular expansion, two muscles of the eyelids, and four pairs of muscles of the lower jaw, the temporal to raise, the masseter to draw to one side, and two depressors, corresponding to the digastric and internal pterygoid muscles. After speaking of the muscles which move the head and the scapula, he adverts to those by which the windpipe is opened and shut, and the intrinsic or proper muscles of the larynx and hyoid bone. Then follow those of the tongue, pharynx, and neck, those of the upper extremities, the trunk, and the lower extremities successively; and in the course of this description he swerves so little from the actual facts, that most of the names by which he distinguishes the principal muscles have been retained by the best modern anatomists. It is chiefly in the minute account of these organs, and especially in reference to the minuter muscles, that he appears inferior to the moderns.

The angiological knowledge of Galen, though vitiated by the erroneous physiology of the times, and ignorance of the separate uses of the arteries and veins, exhibits, nevertheless, some accurate facts which show the diligence of the author in dissection. Though, in opposition to the opinions of Praxagoras and Erasistratus, he proved that the arteries in the living animal contain not air, but blood, it does not appear to have occurred to him to determine in what direction the blood flows, or whether it was movable or stationary.[1] Representing the left ventricle of the heart as the common origin of all the arteries, though he is misled by the pulmonary artery, he nevertheless traces the distribution of the branches of the aorta with some accuracy. The *vena azygos* also, and the jugular veins, have contributed to add to the confusion of his description, and to render his angiology the most imperfect of his works. History.

In neurology we find him to be the author of the dogma, that the brain is the origin of the nerves of sensation, and the spinal chord of those of motion; and he distinguishes the former from the latter by their greater softness or less consistence. Though he admits only seven cerebral pairs, he has the merit of distinguishing and tracing the distribution of the greater part of both classes of nerves with great accuracy.

His description of the brain, though derived from dissection of the lower animals, is accurate; and his distinctions of the several parts of the organ have been retained by modern anatomists. His mode of demonstrating this organ, which indeed is clearly described, consists of five different steps. In the first the bisecting membrane, *i. e.* the falx (μηνιγξ διχοτομουσα), and the connecting blood-vessels are removed; and the dissector, commencing at the anterior extremity of the great fissure, separates the hemispheres gently as far as the *torcular*, and exposes a smooth surface (την χωραν τυλωδη πως ουσαν), the mesolobe of the moderns, or the middle band. In the second he exposes by successive sections the ventricles, the choroid plexus, and the middle partition. The third exhibits the conoid body (σωμα κωνοειδες) or conarium, concealed by a membrane with numerous veins, meaning that part of the plexus which is now known by the name of *velum interpositum*, and a complete view of the ventricles. The fourth unfolds the third ventricle (τις αλλη τριτη κοιλια), the communication between the two latter ones, the psalloid or arch-like body (σωμα ψαλιδοειδες) *fornix*, and the passage from the third to the fourth ventricle. In the fifth he gives an accurate description of the relations of the third and fourth ventricle, of the situation of the two pairs of eminences, *nates* (γλουτα) and *testes* (διδυμια vel ορχεις), the scolecoid or worm-like process, anterior and posterior, the tendons or processes, and lastly the linear furrow, called by Herophilus *calamus scriptorius*.[2] He appears not to have known the inferior recesses. Morgagni however concludes, from a passage of the 7th book περι Δογματων, that he did; but after accurately examining this and others of his anatomical writings, I cannot see any good reason for admitting the inference.

In the account of the thoracic organs equal accuracy may be recognised. He distinguishes the *pleura* by the name of inclosing membrane (ὑμην ὑπεζωκως, *membrana succingens*), and remarks its similitude in structure to that of the peritoneum, and the covering which it affords to all the organs.[3] The pericardium also he describes as a membranous sac with a circular basis corresponding to the base of the heart, and a conical apex; and after an account of the tunics of the arteries and veins, he speaks shortly of the lung, and more at length of the heart, which, however, he takes some pains to prove not to be muscular, because it is harder, its fibres are differently arranged, and its action is incessant, whereas that of muscle alternates with the state of rest. In the particular description of the parts of the organ he ascribes to the auricles a more cuticular structure than to the other parts; he gives a good account of the valves and of the vessels; and notices especially the bony ring formed in the heart of the horse, elephant, and other large animals.

The description of the abdominal organs, and of the

[3] Αλλ' ὁ ὑπεζωκως οὑτως ὑποτεινεται πασι τοις ενδον του θωρακος οργανοις, ὡς ὁ περιτοναιος ελεχθη, και εδειχθη τοις κατω των φρενων. *Ibid.*

kidneys and urinary apparatus, is still more minute, and in general very accurate. Our limits, however, do not permit us to give any abstract of them; and it is sufficient in general to say, that Galen gives correct views of the structure and distribution of the peritoneum and omentum, and distinguishes accurately the several divisions of the alimentary canal, and the internal structure of its component tissues. In the liver, which he allows to receive an envelope from the peritoneum, he admits, in imitation of Erasistratus, a proper substance or *parenchyma*, interposed between the vessels, and capable of removal by suitable dissection.

His description of the organs of generation is rather brief, and is, like most of his anatomical sketches, too much blended with physiological dogmas.

This short sketch may communicate some idea of the condition of anatomical knowledge in the days of Galen, who indeed is justly entitled to the character of rectifying and digesting, if not of creating, the science of anatomy among the ancients. Though evidently confined, perhaps entirely, by the circumstances of the times, to the dissection of brute animals, so indefatigable and judicious was he in the mode of acquiring knowledge, that many of his names and distinctions are still retained with advantage in the writings of the moderns. Galen was a practical anatomist, and not only describes the organs of the animal body from actual dissection, but gives ample instructions for the proper mode of exposition. His language is in general clear, his style as correct as in most of the authors of the same period, and his manner is animated. It is indeed impossible to imagine any thing so interesting as the description of the process for demonstrating the brain and other internal organs, which is given by this patient and enthusiastic observer of nature. To some it may appear absurd to speak of any thing like good anatomical description in an author who writes in the Greek language, or any thing like an interesting and correct manner in a writer who flourished at a period when taste was depraved or extinct, and literature corrupted,—when the philosophy of Antoninus, and the mild virtues of Aurelius, could do little to soften the iron sway of Lucius Verus and Commodus; but the habit of faithful observation in Galen seems to have been so powerful, that, in the description of material objects, his genius invariably rises above the circumstances of his age. Though not so directly connected with this subject, it is nevertheless proper to mention, that he appears to have been the first anatomist who can be said, on authentic grounds, to have attempted to discover the uses of organs by vivisection and experiments on living animals. In this manner he ascertained the position and demonstrated the action of the heart; and he mentions two instances in which, in consequence of disease or injury, he had an opportunity of observing the motions of this organ in the human body.[1] In short, without eulogizing an ancient author at the expense of critical justice, or commending his anatomical descriptions as superior to those of the moderns, it must be admitted that the anatomical writings of the physician of Pergamus form a remarkable era in the history of the science; and that by diligence in dissection, and accuracy in description, he gave the science a degree of importance and stability which it has retained through the lapse of many centuries.

The death of Galen, which took place at Pergamus in the 90th year of his age, and the 193d of the Christian era, may be regarded as the downfall of anatomy in ancient times. After this period we recognise only two names of any celebrity in the history of the science,—those of Soranus and Oribasius, with the more obscure ones of Meletius and Theophilus, the latter the chief of the imperial guard of Heraclius.

Soranus, who was an Ephesian, and flourished under the emperors Trajan and Hadrian, distinguished himself by his researches on the female organs of generation. He appears to have dissected the human subject; and this perhaps is one reason why his descriptions of these parts are more copious and more accurate than those of Galen, who derived his knowledge from the bodies of the lower animals. He denies the existence of the hymen, but describes accurately the clitoris. Soranus the anatomist must be distinguished from the physician of that name, who was also a native of Ephesus.

Oribasius, who was born at Pergamus, is said to have been at once the friend and physician of the emperor
Julian, and to have contributed to the elevation of that 361–363.
apostate to the imperial throne. For this he appears to have suffered the punishment of a temporary exile under Valens and Valentinian; but was soon recalled, and lived
in great honour till the period of his death. By Le Clerc, 387.
Oribasius is regarded as a compiler; and indeed his anatomical writings bear so close a correspondence with those of Galen, that the character is not altogether groundless. In various points, nevertheless, he has rendered the Galenian anatomy more accurate; and he has distinguished himself by a good account of the salivary glands, which were overlooked by Galen.

To the same period generally is referred the anatomical introduction of an anonymous author, first published in 1618 by Lauremberg, and more recently by Bernard. It is to be regarded as a compilation formed on the model of Galen and Oribasius. The same character is applicable to the treatises of Meletius and Theophilus.

The decline indicated by these languid efforts soon sunk into a state of total inactivity; and the unsettled state of society during the latter ages of the Roman empire became extremely unfavourable to the successful cultivation of science. The sanguinary conflicts in which the southern countries of Europe were repeatedly engaged with their northern neighbours, between the second and eighth centuries, tended gradually to estrange their minds from scientific pursuits; and the hordes of barbarians by which the Roman empire was latterly overrun, while they urged them to the necessity of making hostile resistance, and adopting means of self-defence, introduced such habits of ignorance and barbarism, that science was almost universally forgotten; and the art most essential to the success of military operations was either neglected or debased by the grossest ignorance. While the art of healing was professed only by some few ecclesiastics, or by itinerant practitioners, anatomy was utterly neglected; and no name of anatomical celebrity occurs to diversify the long and uninteresting period commonly distinguished as the middle ages.

Anatomical learning, thus neglected by European nations, is believed to have received a temporary cultivation from the Asiatics. Of these, several nomadic tribes, known to Europeans under the general denomination of Arabs and Saracens, had gradually coalesced under various leaders; and by their habits of endurance, as well as of enthusiastic valour, in successive expeditions against the eastern division of the Roman empire, had acquired such military reputation, as to render them formidable where-

[1] Περι Ανατομικων Εγχειρησεων, lib. vii.

ever they appeared. After a century and a half of foreign warfare or internal animosity, under the successive dynasties of the Ommiades and Abassides, in which the propagation of Islamism was the pretext for the extinction of learning and civilisation, and the most remorseless system of rapine and destruction, the Saracens began, under the latter dynasty of princes, to recognise the value of science, and especially of that which prolongs life, heals disease, and alleviates the pain of wounds and injuries. The caliph Almansor combined with his official knowledge of Moslem law, the successful cultivation of astronomy; but to his grandson Almamon, the seventh prince of the line of the Abassides, belongs the merit of undertaking to render his subjects philosophers and physicians. By the directions of this prince, the works of the Greek and Roman authors were translated into Arabic; and the favour and munificence with which literature and its professors were patronised, speedily raised a succession of learned Arabians. The residue of the rival family of the Ommiades, already settled in Spain, was prompted by motives of rivalry or honourable ambition to adopt the same course; and while the academy, hospitals, and library of Bagdad bore testimony to the zeal and liberality of the Abassides, the munificence of the Ommiades was not less conspicuous in the literary institutions of Cordova, Seville, and Toledo.

Notwithstanding the efforts of the Arabian princes, however, and the diligence of the Arabian physicians, little was done for anatomy, and the science made no substantial acquisition. The Koran denounces as unclean the person who touches a corpse; the rules of Islamism forbid dissection; and whatever their instructors taught was borrowed from the Greeks. Abu Bekr Al-Rasi, Abu-Ali Ibn-Sina, Abul-Casem, and Abu-Walid Ibn-Roschd, the Razes, Avicenna, Albucasis, and Averhoes of European authors, are their most celebrated names in medicine; yet to none of these can the historian with justice ascribe any anatomical merit. Al-Rasi has indeed left descriptions of the eye, of the ear and its *meatus*, and of the heart; and Ibn-Sina, Abul-Casem, and Ebn-Roschd, give anatomical descriptions of the parts of the human body. But of these the general character is, that they are copies from Galen, sometimes not very just, and in all instances mystified with a large proportion of the fanciful and absurd imagery and inflated style of the Arabian writers. The chief reason of their obtaining a place in anatomical history is, that, by the influence which their medical authority enabled them to exercise in the European schools, the nomenclature which they employed was adopted by European anatomists, and continued till the revival of ancient learning restored the original nomenclature of the Greek physicians. Thus, the *cervix*, or nape of the neck, is *nucha;* the œsophagus is *meri;* the umbilical region is *sumen*, or *sumac;* the abdomen is *myrach;* the peritoneum is *siphac;* and the omentum, *zirbus*.

From the general character now given, justice requires that we except Abdollatiph, the annalist of Egyptian affairs. This author, who maintains that it is impossible to learn anatomy from books, and that the authority of Galen must yield to personal inspection, informs us, that the Moslem doctors did not neglect opportunities of studying the bones of the human body in cemeteries; and that he himself, by once examining a collection of bones in this manner, ascertained that the lower jaw is formed of one piece; that the sacrum, though sometimes composed of several, is most generally of one; and that Galen is mistaken when he asserts that these bones are not single.

The era of Saracen learning extends to the 13th century; and after this we begin to approach happier times. The university of Bologna, which, as a school of literature and law, was already celebrated in the twelfth century, became, in the course of the following one, not
less distinguished for its medical teachers. Though the 1222-1224.
misgovernment of the municipal rulers of Bologna had disgusted both teachers and students, and given rise to the foundation of similar institutions in Padua and Naples, —and though the school of Salerno, in the territory of
the latter, was still in high repute,—it appears, from the 1241-1271.
testimony of Sarti, that medicine was in the highest esteem in Bologna, and that it was in such perfection as to require a division of its professors into physicians, surgeons, physicians for wounds, barber-surgeons, oculists, and even some others. Notwithstanding these indications of refinement, however, anatomy was manifestly cultivated rather as an appendage of surgery than a branch of medical science; and, according to the testimony of Guy de Chauliac, the cultivation of anatomical knowledge was confined to Roger, Roland, Jamerio, Bruno, and Lanfranc; and this they borrowed chiefly from Galen. For this and similar reasons, physicians were not in all instances respected by the best informed men of the age; and they fell, perhaps not altogether undeservedly, under the bitter lash of the satirical Petrarch.

In this state matters appear to have proceeded with the medical school of Bologna till the commencement of the fourteenth century, when the circumstance of possessing a teacher of originality enabled this university to be the agent of as great an improvement in medical science as she had already effected in jurisprudence. This era, indeed, is distinguished for the appearance of Mondino, under whose zealous cultivation the science first began to rise from the ashes in which it had been buried. This father of modern anatomy, who taught in Bologna about the year 1315, quickly drew the curiosity of the medical profession, by well-ordered demonstrations of the different parts of the human body. In 1315 he dissected and demonstrated the parts of the human body in two female subjects; and in the course of the following year he accomplished the same task on the person of a single female. But while he seems to have had sufficient original force of intellect to direct his own route, Riolan accuses him of copying Galen; and it is certain that his descriptions are corrupted by the barbarous leaven of the Arabian schools, and his Latin defaced by the exotic nomenclature of Ebn-Sina, and Abu-Bekr Al-Rasi. He died, according to Tiraboschi, in 1325.

Mondino divides the body into three cavities (*ventres*), the upper containing the animal members, as the head, the lower containing the natural members, and the middle containing the spiritual members. He first delivers the anatomy of the lower cavity or the abdomen, then proceeds to the middle or thoracic organs, and concludes with the upper, comprising the head, and its contents and appendages. His general manner is to notice shortly the situation and shape or distribution of textures or membranes, and then to mention the disorders to which they are subject. The peritoneum he describes under the name of *siphac*, in imitation of the Arabians, the omentum under that of *zirbus*, and the mesentery or *eucharus* as distinct from both. In speaking of the intestines, he treats first of the rectum, then the colon, the left or sigmoid flexure of which, as well as the transverse arch and its connection with the stomach, he particularly remarks; then the cæcum or *monoculus*, after this the small intestines in general under the heads of ileum and jejunum, and latterly the duodenum, making in all six bowels. The liver and its vessels are minutely, if not accurately examined; and the *cava*, under the name *chilis*, a corruption from the Greek κοιλη, is treated at length, with the emulgents and kidneys. His anatomy of the heart is wonderfully accurate; and it is a remarkable fact, which seems to be omitted by all subsequent authors, that his description contains the rudiments of the circulation of the blood. "Postea vero versus pulmonem est aliud orificium venæ arterialis, quæ *portat* sanguinem ad pulmonem a corde; quia cum pulmo deserviat cordi secundum modum dictum ut ei recompenset, cor ei *transmittit* sanguinem per hanc venam, quæ vocatur vena arterialis, et vena quæ portat sanguinem, et arterialis, quia habet duas tunicas; et habet duas tunicas, primo quia vadit ad membrum quod existit in continuo motu, et secundo quia portat sanguinem valde subtilem et cholericum." The merit of these distinctions, however, he afterwards destroys, by repeating the old assertion, that the left ventricle ought to contain spirit or air, which it generates from the blood.

His osteology of the scull is erroneous. In his account of the cerebral membranes, though short, he notices the principal characters of the *dura mater*. He describes shortly the lateral ventricles, with their anterior and posterior *cornua*, and the choroid plexus as a blood-red substance, like a long worm. He then speaks of the third or middle ventricle, and one posterior, which seems to correspond with the fourth; and describes the infundibulum under the names of *lacuna* and *emboton*. The inferior recesses he appears to have omitted. In the base of the organ he remarks, first, two mammillary caruncles, the origins of the olfactory nerves, which, however, he overlooks; the optic nerves, which he reckons the first pair; the oculo-muscular, which he accounts the second; the third, which appears to be the sixth of the moderns; the fourth; the fifth, evidently the seventh; a sixth, the *nervus vagus;* and a seventh, which is the ninth of the moderns.

Notwithstanding the misrepresentations into which this early anatomist was betrayed, his book is valuable, and has been illustrated by the successive commentaries of Achillini, Berenger, and Dryander.

1480. Matthew de Gradibus, a native of Gradi, a town in Friuli, near Milan, distinguished himself by composing a series of treatises on the anatomy of various parts of the human body. He is the first who represents the ovaries of the female in the correct light in which they were subsequently regarded by Steno.

Similar objections to those already urged in speaking of Mondino apply to another eminent anatomist of those times. Gabriel de Zerbis, who flourished at Verona to-
1495. wards the conclusion of the 15th century, is celebrated as
1505. the author of a system, in which he is obviously more anxious to astonish his readers by the wonders of a verbose and complicated style, than to instruct by precise and faithful description. In the vanity of his heart he assumed the title of *Medicus Theoricus;* but though like Mondino he derived his information from the dissection of the human subject, he is not entitled to the merit either of describing truly or of adding to the knowledge previously acquired. He is superior to Mondino, however, in knowing the olfacient nerves.

1463. Eminent in the history of the science, but more distin-
1512. guished than any of this age in the history of cerebral anatomy, Alexander Achillini of Bologna, the pupil and commentator of Mondino, appeared at the close of the 15th century. Though a follower of the Arabian school, the assiduity with which he cultivated anatomy has rescued his name from the inglorious obscurity in which the Arabesque doctors have in general slumbered. He is known in the history of anatomical discovery as the first who described the two tympanal bones, termed *malleus* and *incus*. In 1503 he showed that the tarsus consists of seven bones; he re-discovered the fornix and the infundibulum; and he was fortunate enough to observe the course of the cerebral cavities into the inferior *cornua*, and to remark peculiarities to which the anatomists of a future age did not advert. He mentions the orifices of the ducts afterwards described by Wharton. He knew the ileo-cæcal valve; and his description of the duodenum, ileum, and colon, shows that he was better acquainted with the site and disposition of these bowels than any of his predecessors or contemporaries.

Not long after, the science boasts of one of its most 1518.
distinguished founders. James Berenger of Carpi, in the Modenese territory, flourished at Bologna at the beginning of the 16th century. In the annals of medicine his name will be remembered not only as the most zealous and eminent in cultivating the anatomy of the human body, but as the first physician who was fortunate enough to calm the alarms of Europe, suffering under the ravages of syphilis, then raging with uncontrollable virulence. In the former character he surpassed both predecessors and contemporaries; and it was long before the anatomists of the following age could boast of equalling him. His assiduity was indefatigable; and he declares that he dissected above 100 human bodies. He is the author of a compendium, of several treatises which he names introductions (*Isagogæ*), and of commentaries on the treatise of Mondino. Like him, he is tinged with the mysticism of the Arabian doctrines; and though he employs the Grecian nomenclature in general, he never forgets to give the Arabian terms, and often uses them exclusively. In his commentaries on Mondino, which constitute the most perspicuous and complete of his works, he not only rectifies the mistakes of that anatomist, but delivers minute and in general accurate anatomical descriptions.

He is the first who undertakes a systematic view of the several textures of which the human body is composed; and in a preliminary commentary he treats successively of the anatomical characters and properties of fat, of membrane in general (*panniculus*), of flesh, of nerve, of *villus* or fibre (*filum*), of ligament, of sinew or tendon, and of muscle in general. He then proceeds to describe with considerable precision the muscles of the abdomen, and illustrates their site and connections by wooden cuts, which, though rude, are spirited, and show that anatomical drawing was in that early age beginning to be understood. In his account of the peritoneum, he admits only the intestinal division of that membrane, and is at some pains to prove the error of Gentilis, who justly admits the muscular division also. In his account of the intestines, he is the first who mentions the vermiform process of the cæcum; he remarks the yellow tint communicated to the jejunum by the gall-bladder; and he recognises the opening of the common biliary duct into the duodenum (*quidam porus portans choleram*). In the account of the stomach he describes the several tissues of which that organ is composed, and which, after Almansor, he represents to be three, and a fourth from the peritoneum; and afterwards notices the *rugæ* of its villous surface. He is at considerable pains to explain the organs of generation in both sexes, and gives a long account of the anatomy of the fœtus. He was the first who recognised the larger proportional size of the chest in the male than in the female, and conversely the greater capacity of the female than of the male pelvis. In the larynx he discovered the two arytenoid cartilages. He gives the first good description of the thymus; distinguishes the oblique situa-

History. tion of the heart; describes the pericardium, and maintains the uniform presence of pericardial liquor. He then describes the cavities of the heart; but perplexes himself, as all the anatomists of that age, about the spirit supposed to be contained. The aorta he properly makes to arise from the left ventricle; but confuses himself with the *arteria venalis* (pulmonary vein), and the *vena arterialis*, the pulmonary artery. His account of the brain is better. He gives a minute and clear account of the ventricles, remarks the *corpus striatum*, and has the sagacity to perceive that the choroid plexus consists of veins and arteries; he then describes the middle or third ventricle, the infundibulum or *lacuna* of Mondino, and the pituitary gland; and, lastly, the passage to the fourth ventricle, the *conarium* or pineal gland, and the fourth or posterior ventricle itself, the relations of which he had studied accurately. He rectifies the mistake of Mondino as to the olfactory or first pair of nerves, gives a good account of the optic and others, and is entitled to the praise of originality in being the first observer who contradicts the fiction of the wonderful net, and indicates the principal divisions of the carotid arteries. He enumerates the tunics and humours of the eye, and gives an account of the internal ear, in which he notices the *malleus* and *incus*.

It had been written in the book of the destinies, that the science of anatomy was to be cultivated first in Italy; and that the country, already so illustrious in literature, should be honoured in giving birth to the first eminent anatomists in Europe. This distinction she long retained; and the glory she acquired in the names of Mondino, Achillini, Carpi, and Massa, was destined to become more conspicuous in the labours of Columbus, Fallopius, and Eustachius. While Italy, however, was thus advancing the progress of science, the other nations of Europe were either in profound ignorance or in the most supine indifference to the brilliant career of their zealous neighbours. The sixteenth century had commenced before France began to acquire any anatomical distinction in the names of Dubois, Fernel, and Etienne; and even these celebrated teachers were less solicitous in the personal study of the animal body, than in the faithful explanation of the anatomical writings of Galen. The infancy of the French school had to contend with other difficulties. The small portion of knowledge which had been hitherto diffused in the country was so inadequate to eradicate the prejudices of ignorance, that it was either difficult or absolutely impossible to procure human bodies for the purposes of science; and we are assured, on the testimony of Vesalius and other competent authorities, that the practical part of anatomical instruction was obtained entirely from the bodies of the lower animals. The works of the Italian anatomists were unknown; and it is a proof of the tardy communication of knowledge, that while the structure of the human body had been taught in Italy for more than a century by Mondino and his followers, they are never mentioned by Etienne, who flourished long after.

Such was the aspect of the times at the appearance of Jacques Dubois, who, under the Romanized name of Jacobus Sylvius, according to the fashion of the day, has been fortunate in acquiring a reputation to which his researches do not entitle him. For the name of James Dubois, the history of anatomy, it is said, is indebted to his inordinate love of money. At the instance of his brother Francis, who was professor of eloquence in the College of Tournay at Paris, he repaired to this university, and devoted himself to the study of the learned languages and mathematics; but discovering that these elegant accomplishments do not invariably reward their cultivators with the goods of fortune, Dubois betook himself to medicine. After the acquisition of a medical degree in the university of Montpellier, at the ripe age of fifty-one Dubois returned to Paris to resume a course of anatomical instructions which had been interrupted by the canonical interference of the medical faculty. Here he taught anatomy to a numerous audience in the college of Trinquet; and, on the departure of Vidus Vidius for Italy, was appointed to succeed that physician as professor of surgery to the Royal College. His character is easily estimated. With a greater portion of coarseness in his manners and language than even the rude state of society can palliate, with much varied learning and considerable eloquence, he was a blind, indiscriminate, and irrational admirer of Galen, and interpreted the anatomical and physiological writings of that author, in preference to giving demonstrations from the subject. Without talent for original research or discovery himself, his envy and jealousy made him detest every one who gave proofs of either. We are assured by Vesalius, who was some time his pupil, that his manner of teaching was calculated neither to advance the science nor to rectify the mistakes of his predecessors. A human body was never seen in the theatre of Dubois; the carcasses of dogs and other animals were the materials from which he taught; and so difficult even was it to obtain human bones, that unless Vesalius and his fellow-students had collected assiduously from the Innocents and other cemeteries, they must have committed numerous errors in acquiring the first principles. This assertion, however, is contradicted by Riolan, and more recently by Sprengel and Lauth, the last of whom decidedly censures Vesalius for this ungrateful treatment of his instructor. It is certain that opportunities of inspecting the human body were by no means so frequent as to facilitate the study of the science. Though his mention of injections has made him be thought the discoverer of that art, he appears to have made no substantial addition to the information already acquired; and the first acknowledged professor of anatomy to the university of Paris appears in history as one who lived without true honour, and died without just celebrity. He must not be confounded with Franciscus Sylvius (De le Boe), who is mentioned by Ruysch and Malacarne as the author of a particular method of demonstrating the brain.

Almost coeval may be placed Charles Etienne, a younger 1503–64. brother of the celebrated printers, and son to Henry, who Hellenized the family name by the classical appellation of Stephen; (Στεφανος). It is uncertain whether he taught publicly. But his tranquillity was disturbed, and his pursuits interrupted, by the oppressive persecutions in which their religious opinions involved the family; and Charles Etienne drew the last breath of a miserable life in a dungeon in 1564. Etienne, though sprung of a family whose classical taste has been their principal glory, betrays not the same servile imitation of the Galenian anatomy with which Dubois is charged, and is the first anatomical author who deviates from the beaten path. He appears to have been the first to detect valves in the orifice of the hepatic veins. He was ignorant, however, of the researches of the Italian anatomists; and his description of the brain is inferior to that given 60 years before by Achillini. His comparison of the cerebral cavities to the human ear has persuaded Portal that he knew the inferior *cornua*, and *hippocampus*, and its prolongations; but this is no reason for giving him that honour, to the detriment of the reputation of Achillini, to whom, so far as historical testimony goes, the first knowledge of this fact is due. The researches of Etienne into the structure of the nervous system are, however, neither useless nor inglorious; and the circumstance of demonstrating a canal through the entire length of the spinal chord, which had neither been suspected by contemporaries nor noticed by successors, till M. Senac made it known, is sufficient to place him high among the class of anatomical discoverers.

The French anatomy of the sixteenth century was distinguished by two circumstances unfavourable to the advancement of the science,—extravagant admiration of antiquity, with excessive confidence in the writings of Galen, and the general practice of dissecting principally the bodies of the lower animals. Both of these errors were much amended, if not entirely removed, by the exertions of a young Fleming, whose appearance forms a conspicu-
1514. ous era in the history of cerebral anatomy. Andrew Vesalius, a native of Brussels, after acquiring at Louvain the ordinary classical attainments of the day, began, at the age of 14, to study anatomy under the auspices of Dubois. Though the originality of his mind soon led him to abandon the prejudices, by which he was environed, and take the most direct course for attaining a knowledge of the structure of the human frame; yet he neither underrated the Galenian anatomy, nor was he indolent in the dissection of brute animals. The difficulties, however, with which the practical pursuit of human anatomy was beset in France, and the dangers with which he had to contend, made him look to Italy as a suitable field for the cultivation of the science; and in 1536 we find him at Venice, at once pursuing the study of human anatomy with the utmost zeal, and requested, ere he had attained his 22d year, to demonstrate publicly in the university of Padua. After remaining here about seven years, he went by express invitation to Bologna, and shortly afterwards to Pisa; and Vesalius, thus professor in three universities, appears to have carried on his anatomical investigations and instructions alternately at Padua, Bologna, and Pisa, in the course of the same winter. It is on this account that Vesalius, though a Fleming by birth, and trained originally in the French school, belongs, as an anatomist, to the Italian, and may be viewed as the first of an illustrious line of teachers by whom the anatomical reputation of that country was in the course of the sixteenth century raised to the greatest eminence.

Vesalius is known as the first author of a comprehensive and systematic view of human anatomy. The knowledge with which his dissections had furnished him, proved how many errors were daily taught and learned under the broad mantle of Galenian authority; and he perceived the necessity of a new system of anatomical instruction, divested of the omissions of ignorance and the misrepresentations of prejudice and fancy. The early age at which he effected this object has been to his biographers the theme of boundless commendations; and we are told that he began at the age of 25 to arrange the materials he had collected, and accomplished his task ere he had completed his 28th year.

Soon after this period we find him invited as imperial physician to the court of Charles V., where he was occupied in the duties of practice, and answering the various charges which were unceasingly brought against him by the Galenian disciples. After the abdication of Charles, he continued at court in great favour with his son Philip II. To this he seems to have been led principally by the troublesome controversies in which his anatomical writings had involved him. It is painful to think, however, that even imperial patronage bestowed on eminent talents does not insure immunity from popular prejudice; and the fate of Vesalius will be a lasting example of the barbarism of the times, and of the precarious tenure of the safety even of a great physician. On the preliminary circumstances authors are not agreed; but the most general account states, that when Vesalius was inspecting, with the consent of his kinsmen, the body of a Spanish grandee, it was observed that the heart still gave some feeble palpitations when divided by the knife. The immediate effects of this outrage to human feeling were to denounce the anatomist to the inquisition; and Vesalius escaped the merciful dispensations of this tribunal only by the influence of the king, and by promising to perform a pilgrimage to the Holy Land. He forthwith proceeded to Venice, from which he sailed with the Venetian fleet, under James Malatesta, for Cyprus. When he reached Jerusalem, he received from the Venetian senate a message requesting him again to accept the Paduan professorship, which had become vacant by the death of his friend and
pupil Fallopius. His destiny, however, which pursued 1564.
him fast, suffered him not again to breathe the Italian air. After struggling for many days with adverse winds in the Ionian Sea, he was wrecked on the island of Zante, where he quickly breathed his last in such penury, that unless a liberal goldsmith had defrayed the funeral charges, his remains must have been devoured by beasts of prey. At the time of his death he was scarcely 50 years of age.

To form a correct estimate of the character and merits of Vesalius, we must not compare him, in the spirit of modern perfection, with the anatomical authors either of later times or of the present day. Whoever would frame a just idea of this anatomist, must imagine himself living in the days of Charles V., when learning did not uniformly liberalize,—when the rekindling light of ancient times shone on nothing but its own glories,—when education consisted in the knowledge of ancient opinions, and the authority of Grecian and Roman names usurped in the temple of science the legitimate worship of nature. He must imagine, not a bold innovator without academical learning,—not a genius coming from a foreign country, unused to the forms and habits of Catholic Europe,—nor a wild reformer, blaming indiscriminately every thing which accorded not with his opinions;—but a young student scarcely emancipated from the authority of instructors, and whose intellect was still influenced by the doctrines with which it had been originally imbued,—an individual strictly trained in the opinions of the time, living amidst men who venerated Galen as the oracle of anatomy and the divinity of medicine,—exercising his reason to estimate the soundness of the instructions then in use, and proceeding, in the way least likely to offend authority and wound prejudice, to rectify errors, and to establish on the solid basis of observation the true elements of anatomical science. Vesalius has been denominated the founder of human anatomy; and though we have seen that in this career he was preceded with honour by Mondino and Berenger, still the small proportion of correct observation which their reverence for Galen and Arabesque doctrines allowed them to communicate, will not in a material degree impair the original merits of Vesalius. The errors which he rectified, and the additions which he made, are so numerous, that it is impossible, in such a sketch as the present, to communicate a just idea of them.

Besides the first good description of the sphenoid bone, he showed that the sternum consists of three portions, and the sacrum of five or six; and described accurately the vestibule in the interior of the temporal bone. He not only verified the observation of Etienne on the valves of the hepatic veins, but he described well the *vena azygos*, and discovered the canal which passes in the fœtus between the umbilical vein and the *vena cava*, since named *ductus venosus*. He described the omentum, and its connections with the stomach, the spleen, and the colon; gave the first correct views of the structure of the pylorus; remarked the small size of the cæcal appendix in man; gave the first good account of the mediastinum and pleura, and the fullest description of the anatomy of the brain yet advanced. He appears, however, not to have understood well the inferior recesses; and his account of the nerves is confused by regarding the optic as the fifth pair, the third as the fifth, and the fifth as the seventh.

The labours of Vesalius were not limited to the immediate effect produced by his own writings. His instructions and example produced a multitude of anatomical inquirers of different characters and varied celebrity, but by whom the science was extended and rectified. Of these it belongs not to this place to speak in detail; but historical justice requires us to notice shortly those to whose exertions the science of anatomy has been most indebted.

1495 or 1500. The first that claims attention on this account is Bartholomeo Eustachi of San Severino, near Salerno, who though greatly less fortunate in reputation than Vesalius, divides with him the merit of creating the science of human anatomy. He extended the knowledge of the internal ear, by re-discovering and describing correctly the tube which bears his name; and if we admit that Ingrassias anticipated him in the knowledge of the third bone of the tympanal cavity, the *stapes*, he is still the first who described the internal and anterior muscles of the *malleus*, as also the *stapedius*, and the complicated figure of the *cochlea*. He is the first who studied accurately the anatomy of the teeth, and the phenomena of the first and second dentition. The work, however, which demonstrates at once the great merit and the unhappy fate of Eustachius, is his *Anatomical Engravings*, which, though completed in 1552, nine years after the impression of the work of Vesalius, the author was unable to publish. First communicated to the world in 1714 by Lancisi, afterwards in 1740 by Cajetan Petrioli, again in 1744 by Albinus, and more recently at Bonn, in 1790, they show that Eustachius had dissected with the greatest care and diligence, and taken the utmost pains to give just views of the shape, size, and relative position of the organs of the human body.

The first seven plates illustrate the history of the kidneys, and some of the facts relating to the structure of the ear. The eighth represents the heart, the ramifications of the *vena azygos*, and the valve of the *vena cava*, named from the author. In the seven subsequent plates is given a succession of different views of the viscera of the chest and abdomen. The seventeenth contains the brain and spinal chord; and the eighteenth more accurate views of the origin, course, and distribution of the nerves than were then given. Fourteen plates are devoted to the muscles.

Eustachius did not confine his researches to the study of relative anatomy. He investigated the intimate structure of organs with assiduity and success. What was too minute for unassisted vision he inspected by means of glasses. Structure, which could not be understood in the recent state, he unfolded by maceration in different fluids, or rendered more distinct by injection and exsiccation. The facts unfolded in these figures are so important, that it is justly remarked by Lauth, that if the author himself had been fortunate enough to publish them, anatomy would have attained the perfection of the 18th century two centuries earlier at least. Their seclusion for that period in the papal library has given celebrity to many names, which would have been known only in the verification of the discoveries of Eustachius.

Eustachius was the contemporary of Vesalius. Columbus and Fallopius were his pupils. The former, as his immediate successor in Padua, and afterwards as profes- 1523.
sor at Rome, distinguished himself by rectifying and improving the anatomy of the bones; by giving correct accounts of the shape and cavities of the heart, of the pulmonary artery and aorta, and their valves, and tracing the course of the blood from the right to the left side of the heart; by a good description of the brain and its vessels, and by correct understanding of the internal ear, and the first good account of the ventricles of the larynx.

The latter, who after being professor at Pisa in 1548, and at Padua in 1551, died at the age of 40, studied the general anatomy of the bones; described better than heretofore the internal ear, especially the tympanum and its osseous ring, the two *fenestræ*, and their communication with the vestibule and cochlea; and gave the first good account of the stylo-mastoid hole and canal, of the ethmoid bone and cells, and of the lacrymal passages. In myology he rectified several mistakes of Vesalius. He made some curious researches into the organs of generation in both sexes, and discovered the utero-peritoneal canal which still bears his name.

Osteology nearly at the same time found an assiduous 1510–46–
cultivator in John Philip Ingrassias, a learned Sicilian 80.
physician, who, in a skilful commentary on the osteology of Galen, corrected numerous mistakes. He gave the first distinct account of the true configuration of the sphenoid and ethmoid bones, and has the merit of first describing the third bone of the tympanum, called *stapes*, 1546.
though this is also claimed by Eustachius and Fallopius. He appears also to have known the *fenestræ*, the *chorda tympani*, the *cochlea*, the semi-circular canals, and the mastoid cells.

The anatomical descriptions of Vesalius underwent the 1530–89.
scrutiny of various inquirers, actuated, some by motives of hostility to the individual, others by the more honourable wish to ascertain if his representations accorded with nature. Of the latter, Fallopius was one; but the most distinguished by the importance and veracity of their researches, as well as the temperate tone of their observations, were Julius Cæsar Aranzi, anatomical professor for 32 years in the university of Bologna, and Constantio Varoli, physician to Pope Gregory XIII. To the former we are indebted for the first correct account of the anatomical peculiarities of the fœtus, and for being the first to show that the muscles of the eye do not, as was falsely imagined, arise from the *dura mater*, but from the margin of the optic hole. He also, after considering the anatomical relations of the cavities of the heart, the valves, and the great vessels, corroborates the views of Columbus regarding the course which the blood follows in passing from the right to the left side of the heart. I have already mentioned Alexander Achillini as the reputed and probable discoverer of the inferior recesses of the cerebral cavities; but whether he knew them or not, certain it is that neither his contemporaries nor successors gave any proof that they were acquainted with these regions of the brain. Aranzi is the first anatomist who describes them distinctly, who recognises the objects by which they are distinguished, and who gives them the name by which they are still known (*bombyx*, *hippocampus*); and his account is more minute and perspicuous than that of the authors of the subsequent century. He speaks at large of the choroid plexus, and gives a particular description of the fourth ventricle under the name of *cistern of the cerebellum*, as a discovery of his own.

Italy, though rich in anatomical talent, has produced 1545–75.
probably none greater than Constantio Varoli of Bologna.

History. Though limited in the measure of his existence to the short space of 32 years, he acquired reputation not inferior to that of the most eminent of his contemporaries. He is now known chiefly as the author of an Epistle, inscribed to Hieronymo Mercuriali, on the optic nerves, in which he describes a new method of dissecting the brain, and communicates many interesting particulars relating to the anatomy of the organ. Overlooking the fanciful comparison of the transverse eminence and the prolongations (*crura*) of the brain and cerebellum to a bridge over the water of an aqueduct, though he examines the lower surface of the organ with tedious minuteness, he gives evidence that he formed a more accurate and just idea of its configuration than any of the best modern anatomists. He observes the threefold division of the inferior surface or base, defines the limits of the anterior, middle, and posterior eminences, as marked by the compartments of the scull, and justly remarks that the cerebral cavities are capacious, communicate with each other, extending first backward and then forward, near the angle of the pyramidal portion of the temporal bone, and that they are folded on themselves, and finally lost above the middle and inferior eminence of the brain. He appears to have been aware that at this point they communicate with the exterior or convoluted surface. He recognised the impropriety of the term *corpus callosum*, seems to have known the communication, called afterwards *foramen Monroianum*, and describes the *hippocampus* more minutely than had been previously done.

1534. Among the anatomists of the Italian school, as a pupil of Fallopius, Eustachius, and Aldrovandus, is generally enumerated Volcher Coiter of Groningen. He distinguished himself by accurate researches on the cartilages, the bones, and the nerves, recognised the value of morbid anatomy, and made some experiments on living animals to ascertain the action of the heart and the influence of the brain.

The *Frutefull and Necessary Briefe Worke* of John Halle (1565), and *The Englisheman's Treasure*, by Master Thomas Vicary (1586), both English works published at this time, are tolerable compilations, partly from Berenger, partly from Vesalius, and much tinged by the Galenian and Arabian distinctions.

1537–66–1619. The celebrity of the anatomical school of Italy was worthily maintained by Hieronymo Fabricio of Aquapendente, who, in imitation of his master Fallopius, laboured to render anatomical knowledge more precise by repeated dissections, and to illustrate the obscure by researches on the structure of animals in general. In this manner he investigated the formation of the fœtus, the structure of the œsophagus, stomach, and bowels, and the peculiarities of the eye, the ear, and the larynx. The discovery, however, on which his surest claims to eminence rest, is that of the membranous folds, which he names *valves*, in the interior of veins. Several of these folds had been observed by Fernel, Sylvius, and Vesalius; and in 1547 Cannani observed those of the *vena azygos;* but no one appears to have offered any rational conjecture on their use, or to have traced them through the venous system at large, until Fabricius in 1574, upon this hypothesis, demonstrated the presence of these valvular folds in all the veins of the extremities.

Fabricius, though succeeded by his pupil Julius Casserius of Placenza, may be regarded as the last of that illustrious line of anatomical teachers by whom the science was so successfully studied and taught in the universities of Italy. The discoveries which each made, and the errors which their successive labours rectified, tended gradually to give anatomy the character of a useful as well as an accurate science, and to pave the way for a discovery which, though not anatomical, but physiological, is so intimately connected with correct knowledge of the shape and situation of parts, that it exercised the most powerful influence on the future progress of anatomical inquiry. This was the knowledge of the circular motion of the blood,—a fact which, though obscurely conjectured by Aristotle, Mondino, and Berenger, and partially taught by Servetus, Columbus, Cæsalpinus, and Fabricius, it was nevertheless reserved to William Harvey fully and satisfactorily to demonstrate.

I have already shown that Mondino believed that the blood proceeds from the heart to the lungs, through the *vena arterialis* or pulmonary artery, and that the aorta conveys the spirit into the blood, through all parts of the body. This doctrine was adopted with little modification by Berenger, who further demonstrated the existence and operation of the tricuspid valves in the right ventricle, and of the sigmoid valves at the beginning of the pulmonary artery and aorta, and that there were only two ventricles separated by a solid impervious septum. These were afterwards described in greater detail by Vesalius, who nevertheless appears not to have been aware of the important use which might be made of this knowledge. It was Michael Servet or Servetus,[1] a Spanish monk, who in his treatise *de Trinitatis Erroribus*, published at Basil in 1531, or, according to Sprengel, in 1552, first maintained the imperviousness of the septum, and the transition of the blood by what he terms an unknown route, namely, from the right ventricle by the *vena arteriosa* (pulmonary artery) to the lungs, and thence into the *arteria venosa* or pulmonary vein, and left auricle and ventricle, from which, he adds afterwards, it is conveyed by the aorta to all parts of the body.[2] Though the leading outlines, not only of the pulmonary

---

[2] The passage of Servetus is so interesting, that our readers may feel some curiosity in perusing it in the language of the author; and it is not unimportant to remark, that Servetus appears to have been led to think of the course of the blood, by the desire of explaining the manner in which the animal spirits were supposed to be generated. "Vitalis spiritus in sinistro cordis ventriculo suam originem habet, juvantibus maxime pulmonibus ad ipsius perfectionem. Est spiritus tenuis, caloris vi elaboratus, flavo colore, ignea potentia, ut sit quasi ex puriore sanguine lucens, vapor substantiam continens aquæ, aeris, et ignis. Generatur ex facta in pulmone commixtione inspirati aeris cum elaborato subtili sanguine, quem dexter ventriculus sinistro communicat. Fit autem communicatio hæc, non per parietem cordis medium, ut vulgo creditur, sed magno artificio a dextro cordis ventriculo, longo per pulmones ductu agitatur sanguis subtilis; a pulmonibus præparatur, flavus efficitur, et a vena arteriosa in arteriam venosam transfunditur. Deinde in ipsa arteria venosa, inspirato aeri miscetur, et exspiratione a fuligine expurgatur; atque ita tandem a sinistro cordis ventriculo totum mixtum per diastolen attrahitur, apta supellex, ut fiat spiritus vitalis. Quod ita per pulmones fiat communicatio et præparatio, docet conjunctio varia, et communicatio venæ arteriosæ cum arteria venosa in pulmonibus. Confirmat hoc magnitudo insignis venæ arteriosæ, quæ nec talis nec tanta esset facta, nec tantam a corde ipso vim purissimi sanguinis in pulmones emitteret, ob solum eorum nutrimentum; nec cor pulmonibus hac ratione serviret, cum præsertim antea in embryone solerent pulmones ipsi aliunde nutriri, ob membranulas illas seu valvulas cordis, usque ad horum nativitatem; ut docet Galenus, &c. Itaque ille spiritus a sinistro cordis ventriculo arterias totius corporis deinde transfunditur, ita ut qui tenuior est, superiora petit, ubi magis elaboratur, præcipue in plexu retiformi, sub basi cerebri sito, ubi ex vitali fieri incipit animalis, ad propriam rationalis animæ rationem accedens." (*De Trinitate*, lib. v.)

History. or small, but even of the great circulation, were sketched thus early by one who, though a philosopher, was attached to the church, it was only in his work *De Re Anatomica*, published at Venice in 1559, that Columbus formally and distinctly announced the circular course of the blood as a discovery of his own; and maintained, in addition to the imperviousness of the septum, the fact that the *arteria venalis* (pulmonary vein) contains not air, but blood mixed with air brought from the lungs to the left ventricle of the heart, to be distributed through the body at large.

1570–1593. Soon after, views still more complete of the small or pulmonary circulation were given by Andrew Cæsalpinus of Arezzo, who not only maintained the analogy between the structure of the arterious vein or pulmonary artery and the aorta, and that between the venous artery or pulmonary veins, and veins in general, but was the first to remark the swelling of veins below ligatures, and to infer from it a refluent motion of blood in these vessels. The discoveries of Aranzi and Eustachius in the vessels of the fœtus, tended at first to perplex, and afterwards to elucidate some of these notions. At length it happened, that between the years 1598 and 1600, a young Englishman, pursuing his anatomical studies at Padua under Fabricius of Aquapendente, learnt from that anatomist the existence of the valves in the veins of the extremities, and undertook to ascertain the use of these valves by experimental inquiry. It is uncertain whether he learnt from the writings of Cæsalpinus the fact observed by that author, of the tumescence of a vein below the ligature; but he could not fail to be aware, and indeed he shows that he was aware, of the small circulation as taught by Servetus and Columbus. Combining these facts already known, he, by a series of well-executed experiments, demonstrated clearly the existence, not only of the small, but of a general circulation from the left side of the heart by the aorta and its subdivisions, to the right side by the veins. This memorable truth was first announced in the year 1619.

It belongs not to this place, either to consider the arguments and facts by which Harvey defended his theory, or to notice the numerous assaults to which he was exposed, and the controversies in which his opponents wished to involve him. It is sufficient to say, that after the temporary ebullitions of spleen and envy had subsided, the doctrine of the circular motion of the blood was admitted by all enlightened and unprejudiced persons, and finally was universally adopted, as affording the most satisfactory explanation of many facts in anatomical structure which were either misunderstood or entirely overlooked. The inquiries to which the investigation of the doctrine gave rise produced numerous researches on the shape and structure of the heart and its divisions, of the lungs, and of the blood-vessels and their distribution. Of this description were the researches of Nicolas Steno on the structure of the heart, the classical work of Richard Lower, the dissertation of Pechlin, the treatise of Vieussens, the work of Malpighi on the structure of the lungs, several sketches in the writings of Mayow, and other treatises of less moment. Systematic treatises of anatomy began to assume a more instructive form, and to breathe a more philosophical spirit. The great work of Adrian Spigelius, which appeared in 1627, two years after the death of the author, contains indeed no proof that he was aware of the valuable generalization of Harvey; but in the institutions of Caspar Bartholin, as republished and improved by his son Thomas in 1651, the anatomical descriptions and explanations are given with reference to the new doctrine. A still more unequivocal proof of the progress of correct anatomical knowledge was given in the lectures delivered by Peter Dionis, at the Jardin Royal of Paris, in 1673 and the seven following years, in which that intelligent surgeon gave most accurate demonstrations of all the parts composing the human frame, and especially of the heart, its auricles, ventricles, and valves, and the large vessels connected with it and the lungs. These demonstrations, first published in 1690, were so much esteemed, that they underwent in the space of 30 years seven editions, were translated into English, and formed for a long time the best and only anatomical system in Europe. History.

The progress of anatomical discovery continued in the mean time to advance. In the course of the 16th century, Eustachius, in studying minutely the structure of the *vena azygos*, had recognised in the horse a white vessel full of watery fluid, connected with the internal jugular vein, on the left side of the vertebral column, corresponding accurately with the vessel since named *thoracic duct* Fallopius also described vessels belonging to the liver, distinct from arteries and veins; and similar vessels appear to have been noticed by Nicolaus Massa. The nature and properties of these vessels were, however, entirely unknown. On the 23d July 1622 Gaspar Asellius, professor of anatomy at Pavia, while engaged in demonstrating the recurrent nerves in a living dog, first observed numerous white delicate filaments crossing the mesentery in all directions; and though he took them at first for nerves, the opaque white fluid which they shed quickly convinced him that they were a new order of vessels. The repetition of the experiment the following day showed that these vessels were best seen in animals recently fed; and as he traced them from the villous membrane of the intestines, and observed the valves with which they were liberally supplied, he inferred that they were genuine chyliferous vessels. By confounding them with the lymphatics, he made them proceed to the pancreas and liver,—a mistake which appears to have been first rectified by Francis De le Boe. The discovery of Asellius was announced in 1627; and the following year, by means of the zealous efforts of Nicolas Peiresc, a liberal senator of Aix, the vessels were seen in the person of a felon who had eaten copiously before execution, and whose body was inspected an hour and a half after. In 1629 they were publicly demonstrated at Copenhagen by Simon Pauli, and the same year the thoracic duct was observed by Mentel for the first time since it was described by Eustachi. Five years after (1634), John Wesling, professor of anatomy and surgery at Venice, gave the first delineation of the lacteals from the human subject, and evinced more accurate knowledge than his predecessors, of the thoracic duct and the lymphatics. Highmore in 1637 demonstrated unequivocally the difference between the lacteals and the mesenteric veins; and though some perplexity was occasioned by the discovery of the pancreatic duct by Wirsung, yet this mistake was corrected by Thomas Bartholin; and the discovery by Pecquet in 1647, of the common trunk of the lacteals and lymphatics, and of the course which the chyle follows to reach the blood, may be regarded as the last of the series of isolated facts by the generalization of which the extent, distribution, and uses of the most important organs of the animal body were at length developed.

To complete the history of this part of anatomical science one step yet remained,—the distinction between the lacteals and lymphatics, and the discovery of the termination of the latter order of vessels. The honour of this discovery is divided between Jolyffe, an English anatomist, and Olaus Rudbeck, a young Swede. The former, according to the testimony of Glisson and Wharton, was aware of the distinct existence of the lymphatics in 1650, History. and demonstrated them as such in 1652. It is nevertheless doubtful whether he knew them much before the latter period; and it is certain that Rudbeck observed the lymphatics of the large intestines, and traced them to glands, on the 27th January 1651, after he had, in the course of 1650, made various erroneous conjectures regarding them, and, like others, attempted to trace them to the liver. The following year he demonstrated them in presence of Queen Christina, and traced them to the thoracic duct, and the latter to the subclavian vein. Their course and distribution were still more fully investigated by Thomas Bartholin, Wharton, Swammerdam, and Blaes, the two last of whom recognised the existence of valves; while Antony Nuck of Leyden, by rectifying various errors of his predecessors, and adding several new and valuable observations, rendered this part of anatomy much more precise than formerly.

After this period anatomists began to study more accurately organs and textures already known, and to obtain more precise knowledge of the intimate structure and organization of the human body. 1654. Francis Glisson distinguished himself by a minute description of the liver, and a clearer account of the stomach and intestines than had yet been given. 1656. Thomas Wharton investigated the structure of the glands with particular care; and though rather prone to indulge in fanciful generalization, he developed some interesting views of these organs; while Charleton, who appears to have been a person of great genius, though addicted to hypothesis, made some good remarks on the communication of the arteries with the veins, the fœtal circulation, and the course of the lymphatics. But the circumstance which chiefly distinguished the history of anatomy at the beginning of the seventeenth century, was the appearance of Thomas Willis, who rendered himself eminent not only by the first good researches on the brain and nerves, but by many judicious observations on the structure of the lungs, the intestines, the blood-vessels, and the glands. His anatomy of the brain and nerves is so minute and elaborate, and abounds so much in new information, that the reader is struck by the immense chasm between the vague and meagre notices of his predecessors, and the ample and correct descriptions of Willis. This excellent work, however, is not the result of his own personal and unaided exertions; and the character of Willis derives additional lustre from the candid avowal of his obligations to Wren and Millington, and, above all, to the diligent researches of his fellow-anatomist Richard Lower.

Willis was the first who correctly numbered the nerves, and described their origins in the order in which they have been generally named till the recent improvements of Soemmering. His observation of the connection of the eighth pair with the slender nerve which issues from the beginning of the spinal chord is known to all. He remarked the parallel lines of the mesolobe, afterwards minutely described by Vicq d'Azyr. He seems to have recognised the communication of the convoluted and figurate surfaces of the brain, and that between the lateral cavities beneath the *fornix*. He designates the objects of the central surface—the anterior as the lentiform eminences, with the striated appearance of their internal substance—the posterior as the optic chambers or *thalami;* the four orbicular eminences, with the bridge, which he first named *annular protuberance;* and the white pisiform bodies, since called mammillary eminences, behind the *infundibulum*. In the cerebellum he remarks the arborescent arrangement of the white and grey matter, and gives a good account of the internal carotids, and the communications which they make with the branches of the basilar artery. Wepfer had already demonstrated the peculiar curvature of the former vessels in the carotic canal, and refuted the fiction of the *rete mirabile*. History.

About the same time the researches of Malpighi tended greatly to improve the knowledge of minute structure. He gave the first distinct ideas on the organization of the lung, and the mode in which the bronchial tubes and vessels terminate in that organ. By the microscope he traced the transition of the arteries into the veins. He examined the omentum, and inquired into the manner in which fat and marrow are secreted. He endeavoured to unfold, by dissection and microscopic observation, the minute structure of the brain. He demonstrated the organization of the skin, and considered its constituents as the organ of touch. He studied the structure of bone, and rectified the errors of Gagliardi; he traced the formation and explained the structure of the teeth; and he finally carried his researches into the substance of the liver, the spleen, the kidneys, and the conglobate glands. In these difficult inquiries the observations of Malpighi are in general faithful, and his descriptions are accurate. He may be regarded as the founder of that part of anatomical science which treats of structure and organization; and, even in the present day, his writings are both interesting and instructive.

Nicolas Steno described with accuracy the lacrymal 1660.
gland and passages, and re-discovered the parotid duct. Bellini studied the structure of the kidneys, and described the tongue and tonsils with some care; and Drelincourt laboured to investigate the changes effected on the uterus by impregnation, and to elucidate the formation of the fœtus. The science might have derived still greater advantages from the genius of Regnier de Graaf, who investigated with accuracy the structure of the pancreas and of the organs of generation in both sexes, had he not been cut off at the early age of 32. Lastly, Wepfer, though more devoted to morbid anatomy, made, nevertheless, some just observations on the anatomical disposition of the cerebral vessels, the glandular structure of the liver, and the termination of the common duct in the duodenum.

The appearance of Frederic Ruysch, who was born in 1638, and became professor of anatomy at Amsterdam in 1665, gave a new impulse to anatomical research, and tended not only to give the science greater precision, but to extend its limits in every direction. The talents of Ruysch are said to have been developed by accident. To repel the audacious and calumnious aspersions with which De Bils attacked De le Boe and Van Horne, Ruysch published his tract on the valves of the lymphatics, which completely established his character as an anatomist of originality and research. This, however, is the smallest of his services to the science. The art of injecting, which had been originally attempted by Eustachi and Varoli, and was afterwards rudely practised by Glisson, Bellini, and Willis, was at length carried to greater perfection by De Graaf and Swammerdam, the former of whom injected the spermatic vessels with mercury and variously coloured liquors, while the latter, by employing melted wax with other ingredients, made the first approach to the refinements of modern anatomy. By improving this idea of using substances, which, though solid, may be rendered fluid at the period of injecting, Ruysch carried this art to the highest perfection.

By the application of this happy contrivance, he was enabled to obtain more correct views than his predecessors of the arrangement of minute vessels in the interior of organs, and to demonstrate peculiarities of organization which escaped the scrutiny of previous anatomists. Scarcely a part of the human body eluded the penetration of his syringe; and his discoveries were proportionally great. His account of the valves of the lymphatics, of the vessels of the lungs, and their minute structure; his researches on the vascular structure of the skin, of the bones, and their epiphyses, and their mode of growth and union; his observations on the spleen, the *glans penis*, the clitoris, and the womb impregnated and unimpregnated, were sufficient to give him the reputation of a skilful and accurate anatomist. These, however, were but a limited part of his anatomical labours. He studied the minute structure of the brain; he demonstrated the organization of the choroid plexus; he described the state of the hair when affected with Polish plait; he proved the vascular structure of the teeth; he injected the *dura mater*, the pleura, the pericardium, and peritoneum; he unfolded the minute structure of the conglomerate glands; he investigated that of the synovial apparatus placed in the interior of the joints; and he discovered several curious particulars relating to the lacteals, the lymphatics, and the lymphatic glands. So assiduously, indeed, did Ruysch study by injection the tissue of the organs of the animal body, that it is less easy to say what he did than what he neglected. To him we are indebted for many of the facts of which anatomy at the present day consists. The success of his injections, however, though it enabled him to trace the most delicate terminations of vessels in the substance of organs, perhaps exercised an unfavourable bias in making him look for vessels exclusively in the minute structure of all the tissues.

1670. Meanwhile, Meibomius re-discovered the palpebral
glands, which were known to Casserius; Swammerdam
studied the action of the lungs, described the structure
of the human *uterus*, and made numerous valuable obser-
vations on the *cæca* and pancreatoid organs of fishes; and
Kerckringius attempted to explain the process of ossifica-
tion, and determine its different stages. John Conrad Brun-
1687. ner, in the course of experiments on the pancreas, disco-
vered the muciparous glands of the duodenum,—a fact to
1677–81. which Conrad Peyer gave a more generalized character
by his description of the muciparous glands of the intes-
tinal canal at large. Leonard Tassin, distinguished for
original observation, rendered the anatomical history of
the brain more accurate than heretofore, and gave parti-
1678. cular accounts of the intestinal tube, the pancreatic duct,
and the hepatic ligaments. About the same time much light was thrown on the intimate constitution of several of the tissues, and on the minute communications of the arterial and venous tubes by the microscopical observations of Leeuwenhoeck.

That France might not be without participation in the glory of advancing the progress of anatomical knowledge, the names of Duverney and Vieussens are commemorated with distinction. The former, born in 1648, and first introduced into public life in 1676 in the Royal Academy of Sciences, decorated with the honorary title of professor of anatomy to the Dauphin, and appointed in 1679 professor at the Jardin Royal, distinguished himself by the first accurate account of the organ of hearing, and by his dissections of several animals at the academy, supplied valuable materials for the anatomical details of the natural history of animals published by that learned body. He appears to have been the first who demonstrated the fact, that the cerebral sinuses open into the jugular veins, and to have been aware that the former receive the veins of the brain, and are the venous receptacles of the organ. He understood the cerebral cavities, and their mode of communication; distinguishes the posterior pillars of the vault from the *pedes hippocampi*; recognises the two plates of the *septum lucidum*; and, what is still more remarkable, he first indicates distinctly the crossing or plaiting of the cerebral chords in the linear furrow between the right and left pyramidal bodies,—a fact afterwards verified by the researches of Mistichelli, Petit, and Santorini. He studied the ganglions attentively, and gives the first distinct account of the formation, connections, and distribution of the intercostal nerve. It is interesting to remark, that his statement that the veins or sinuses of the spinal chord terminate in the *vena azygos* has been verified by the recent researches of Dupuytren and Breschet, which show that the vertebral veins communicate by means of the intercostal and superior lumbar veins with the azygos and demi-azygos. His account of the structure of bones, and of the progress of ossification, is valuable. He recognised the vascular structure of the spleen; and he gives a correct account of the excretory ducts of the prostate gland, the *verumontanum*, and the anteprostates.

One of the circumstances which the history of this period of anatomical science shows tended considerably to its improvement, is the attention with which Comparative Anatomy was beginning to be cultivated. In ancient times, and at the revival of letters, the dissection of the lower animals was substituted for that of the human body; and the descriptions of the organs of the latter were too often derived from the former. The obloquy and contempt in which this abuse involved the study of animal anatomy made it be neglected, or pursued with indifference, for more than two centuries, during which anatomists confined their descriptions, at least very much, to the parts of the human body. At this period, however, the prejudice against Comparative Anatomy began to subside; and animal dissection, though not substituted for that of the human body, was employed, as it ought always to have been, to illustrate obscurities, to determine doubts, and to explain difficulties, and, in short, to enlarge and rectify the knowledge of the structure of animal bodies generally.

For this revolution in its favour, Comparative Anatomy was in a great measure indebted to the learned societies which were established about this time in the different countries of Europe. Among these the Royal Society of London, embodied by charter by Charles II. in 1660, and the Academy of Sciences of Paris, founded in 1665 by Colbert, are undoubtedly entitled to the first rank. Though later in establishment, the latter institution was distinguished by making the first great efforts in favour of Comparative Anatomy; and Perrault, Pecquet, Duverney, and Mery, by the dissections of rare animals obtained from the royal menagerie, speedily supplied valuable materials for the anatomical naturalist. In England, Nehemiah Grew, Edward Tyson, and Samuel Collins, cultivated the same department with diligence and success. The first has left an interesting account of the anatomical peculiarities of the intestinal canal in various animals; and the second, in the dissection of a porpoise, an opossum, and an ourang outang, adduces some valuable illustrations of the comparative differences between the structure of the human body and that of the lower animals. To the third belongs the merit of conceiving, and executing on an enlarged plan, a comprehensive system, embodying all the information then extant. With the aid of Tyson and his own researches, which were both extensive and accu-
rate, he composed a system of anatomical knowledge, in 1685.
which he not only delivers ample and accurate descriptions of the structure of the human body, and the various morbid changes to which the organs are liable, but illustrates the whole by accurate and interesting sketches of the peculiarities of the lower animals. The matter of this work

History. is so excellent, that it can only be ascribed to ignorance
that it has received so little attention. Though regarded
as a compilation, and though indeed much of the human
anatomy is derived from Vesalius, it has the advantage of
the works published on the Continent at that time, that it
embodies most of the valuable facts derived from Mal-
pighi, Willis, and Vieussens. The Comparative Anatomy
is almost all original, and acquired from personal research
and dissection; and the pathological observations, though
occasionally tinged with the spirit of the times, show the
author to have been endowed with the powers of observa-
tion and judicious reflection in no ordinary degree.

About this time also we recognise the first attempts to
study the minute atomic constitution of the tissues, by
the combination of the microscope and the effects of che-
mical agents. Bone furnished the first instance in which
this method was put in use; and though Gagliardi, who
undertook the inquiry, had fallen into some mistakes which
it required the observation of Malpighi to rectify, this
did not deter Clopton Havers and Nesbitt, in England,
and Courtial, Du Hamel, and Delasone, and afterwards
Herissant, in France, from resuming the same train of in-
vestigation. The mistakes into which these anatomists
fell belong to the imperfect method of inquiry. The facts
which they ascertained have been verified by recent ex-
periment, and constitute no unessential part of our know-
ledge of the structure of bone.

1695. Ten years after the publication of the work of Collins,
Henry Ridley, another English anatomist, distinguished
himself by a monograph on the brain, which, though not
free from errors, contains nevertheless some valuable ob-
servations. Ridley is the first who distinguishes by name
the restiform processes, or the posterior pyramidal emi-
nences. He recognised the figure of the four eminences in
the human subject; he remarked the mammillary bodies;
and he discovered the sinus which passes under his name.

Raymond Vieussens, by the publication of his great
work on neurography in 1684, threw new light on the
configuration and structure of the brain, the spinal chord,
and the nerves; and gave a description of the arrange-
ment and distribution of the latter more precise than
heretofore. Of the formation and connections of the
sympathetic nerve especially he gave views which have
been generally adopted by subsequent anatomists. His
new arrangement of the vessels, published in 1705, con-
tains several curious and some hypothetical opinions. His
observations on the structure of the heart, published in
1706, and enlarged in 1715, exhibit the first correct views
of the intimate structure of an organ, which afterwards
was most fully developed by the labours of Lancisi and
Senac. His treatise on the ear is not superior to that of
Duverney.

1685-97. To the same period belong the rival publications of
Godfrey Bidloo and William Cowper, the last of whom,
however, stained a reputation otherwise good, by publish-
ing as his own the engravings of the former. Cowper
further distinguished himself by a minute account of the
urethral glands, already known to Columbus and Mery; a
good description of the intestinal glands, discovered by
Brunner and Peyer; and by demonstrating the communi-
cation of the arteries and veins of the mesentery.

The anatomical genius of Italy, which had slumbered
since the death of Malpighi, was destined once more to
revive in Lancisi, Valsalva, and his illustrious pupils Santo-
rini and Morgagni. Valsalva especially distinguished him-
self by his description of the structure of the ear, which,
in possessing still greater precision and minuteness than
that of Duverney, is valuable in setting the example of
rendering anatomy altogether a science of description.
Santorini, who was professor at Venice, was no unworthy History.
friend of Valsalva and Morgagni. His anatomical observa-
tions, which relate to the muscles of the face, the brain, and 1724.
several of the nerves, the ducts of the lacrymal gland, the
nose and its cavities, the larynx, the viscera of the chest
and belly, and the organs of generation in the two sexes,
furnish beautiful models of essays distinguished for per-
spicuity, precision, and novelty, above any thing which
had then appeared. These observations, indeed, which
bear the impress of accurate observation and clear con-
ception, may be safely compared with any anatomical
writings which have appeared since. Those on the brain
are particularly interesting. Morgagni, though chiefly
known as a pathological anatomist, did not neglect the
healthy structure. His *Adversaria*, which appeared be- 1706.
tween 1706 and 1719, and his *Epistles*, published in 1728, 1717.
contain a series of observations to rectify the mistakes of 1719.
previous anatomists, and to determine the characters of 1728.
the healthy structure of many parts of the human body. 1740.
Many parts he describes anew, and indicates facts not
previously observed. All his remarks show how well he
knew what true anatomical description ought to be. In this
respect, indeed, the three anatomists now mentioned may
be said to have anticipated their contemporaries nearly a
century; for, while other authors were satisfied with giv-
ing loose and inaccurate or meagre notices of parts, with
much fanciful supposition, Valsalva, Santorini, and Mor-
gagni, laboured to determine with precision the anatomical
characters of the parts which they describe.

The same character is due to Winslow, a native of Den-
mark, but, as pupil and successor of Duverney, as well as
a convert to Catholicism, naturalized in France, and finally
professor of anatomy at the Royal Garden. His exposi- 1732.
tion of the structure of the human body is distinguished
for being not only the first treatise of descriptive anatomy,
divested of physiological details and hypothetical expla-
nations foreign to the subject, but for being a close de-
scription derived from actual objects, without reference
to the writings of previous anatomists. About the same
time Cheselden in London, the first Monro in Edinburgh, 1713-22.
and Albinus in Leyden, contributed by their several trea- 1726-32.
tises to render anatomy still more precise as a descriptive 1726-46.
science. The *Osteographia* of the former was of much 1733.
use in directing attention to the study of the skeleton,
and the morbid changes to which it is liable. This
work, however, magnificent as it was, was excelled by
that of Albinus, who, in 1747, published engravings de-
scriptive of the bones and muscles, which, perhaps, will
never be surpassed either in accuracy of outline or beauty
of execution. The several labours of this author, indeed,
constitute an important era in the history of the science.
He was the first who classified and exhibited the muscles
in a proper arrangement, and applied to them a nomencla-
ture which is still retained by the consent of the best
anatomists. He gives a luminous account of the arteries 1736.
and veins of the intestines, represents with singular fide- 1737.
lity and beauty the bones of the fœtus, inquires into the
structure of the skin, and the cause of its colour in differ-
ent races; represents the changes incident to the womb
in different periods of pregnancy, and describes the rela-
tions of the thoracic duct and the *vena azygos* with the 1757.
contiguous parts. Besides these large and magnificent
works, illustrated by the most beautiful engravings, six
books of Academical Annotations were the fruits of his 1754-64.
long and assiduous cultivation of anatomy. These con-
tain valuable remarks on the sound structure and morbid
deviations of numerous parts of the human body.

To render the knowledge of the skeleton more com- 1739-43.
plete, Duhamel and Delasone studied the minute structure

History. of bone, and the process of ossification; William Hunter
1751–52. and Herissant investigated the texture of the cartilages; and Weitbrecht gave a copious and minute account of the ligaments. M. Lieutaud also, who had already laboured to rectify many errors in anatomy, described with much accuracy the structure and relations of the heart
1753. and its cavities, and rendered the anatomy of the bladder very precise, by describing the triangular space and the mammillary eminence at its neck.

Albinus found a worthy successor in his pupil Albert Von Haller, who, with a mind imbued with every department of literature and science, directed his chief attention, nevertheless, to the cultivation of anatomical and physiological knowledge. Having undertaken at an early age (21) to illustrate, with commentaries, the physiological prelections of his preceptor Boerhaave, he devoted himself assiduously to the perusal of every work which could tend to facilitate his purpose; and as he found numerous erroneous or imperfect statements, and many deficiencies to supply, he undertook an extensive course of dissection of human and animal bodies, to obtain the requisite information. For 17 years, during which he was professor at Goettingen, he dissected 400 bodies,[1] and inspected their organs with the utmost care. The result of these assiduous labours appeared at intervals in the form of dissertations by himself, or under the name of some one of his pupils, finally published in a collected shape, between 1746 and 1751 (*Disputationes Anatomicæ Selectiores*); and in eight numbers of most accurate and beautiful engravings, representing the most important parts of the human body, *e. g.* the diaphragm, the uterus, ovaries and vagina, the arteries of the different regions and organs, with learned and critical explanatory observations. Some years after, when he had retired from his academical duties at Goettingen, he published, between 1757 and 1765, the large and elaborate work which, with singular modesty, he styled *Elements of Physiology*. This work, though professedly devoted to the latter science, rendered nevertheless the most essential services to the former. Haller, drawing an accurate line of distinction between the two, gave the most clear, precise, and complete descriptions of the situation, position, figure, component parts, and minute structure of the different organs and their appendages. The results of previous and coeval inquiry, obtained by extensive reading, he sedulously verified by personal observation; and though he never rejected facts stated on credible authorities, he in all cases laboured to ascertain their real value by experiment. The anatomical descriptions are on this account not only the most valuable part of his work, but the most valuable that had then or for a long time after appeared; and it is perhaps a sufficient proof of their intrinsic merit, that they are still resorted to by the anatomist as the most faithful guide to many of his researches. It is painful, nevertheless, to think, that the very form in which this work is composed, with copious and scrupulous reference to authorities, made it be regarded as a compilation only; and that the author was compelled to show, by a list of his personal researches, that the most learned work ever given to the physiologist, was also the most abundant in original information.[2]

With the researches of Haller, it is proper to notice those of his contemporary, John Frederick Meckel, and his pupil John Godfrey Zinn. The former, who was professor of anatomy at Berlin, described with unrivalled
1748–51. accuracy the Gasserian ganglion, the first pair of nerves and its distribution, and that of the facial nerves general- History.
ly, and discovered the spheno-palatine ganglion. He made some original and judicious observations on the
tissue of the skin and the mucous net; and above all, 1753–57.
he recognised the connection of the lymphatic vessels with the veins,—a doctrine which, though neglected, has been lately revived by Fohmann and Lippi. He also collected several valuable observations on the morbid states of the heart and brain. At the same time Zinn, who was professor of medicine at Goettingen, published on
the eye a classical treatise, which demonstrated at once 1755.
the defects of previous inquiries, and how much it was possible to elucidate, by accurate research and precise description, the structure of one of the most important organs of the human frame. As a general proof of the extraordinary merit of this work, it is sufficient to say, that in critical learning and descriptive accuracy it has not been equalled, and probably will never be surpassed. It
was re-published after his death by Wrisberg. 1780.

General anatomy, and the study of the atomic constitution of the tissues which had originally been commenced by Leeuwenhoeck, Malpighi, and Ruysch, began at this period to attract more general attention. De
Bergen had already demonstrated the general distribution 1732.
of cellular membrane, and shown that it not only incloses every part of the animal frame, but forms the basis of every organ,—a doctrine which was adopted, and still
more fully expanded, by his friend Haller, in opposition to 1757.
what was asserted by Albinus,[3] who maintains that each part has a proper tissue. William Hunter at the same time gave a clear and ingenious statement of the difference between cellular membrane and adipose tissue, in which he maintained the general distribution of the former, and represented it as forming the serous membranes, and
regulating their physiological and pathological properties,— 1757.
doctrines which were afterwards confirmed by his brother John Hunter. A few years after, the department of general anatomy first assumed a substantial form, in the systematic view of the membranes and their mutual connections traced by Andrew Bonn of Amsterdam. In his inaugural dissertation *De Continuationibus Membranarum*,
published at Leyden in 1763, this author, after some pre- 1763.
liminary observations on membranes in general and their structure, and an exposition of that of the skin, traces its transition into the mucous membranes and their several divisions. He then explains the distribution of the cellular membrane and the aponeurotic expansions, and the periosteum and perichondrium, by either of which, he shows, every bone of the skeleton is invested and connected. He finally gives a very distinct view of the arrangement of the internal membranes of cavities, those named serous and fibro-serous, and the manner of their distribution over the contained organs. This essay, which is a happy example of generalization, is remarkable for the interesting general views of the structure of the animal body which it exhibits; and to Bonn belongs the merit of sketching the first outlines of that system which it was reserved for the genius of Bichat to complete and
embellish. Lastly, Bordeu, in an elaborate essay on the 1767.
mucous tissue, or cellular organ, as he terms it, brought forward some interesting views of the constitution, nature, and extent of the cellular membrane.

Though anatomy was hitherto cultivated with much success as illustrating the natural history and morbid states of the human body, yet little had been done for the elucidation of local diseases, and the surgical means by

[1] "Pene quadringentis mea manu dissectis hominum cadaveribus." (Præfatio ad tom. vi. *Elementorum Physiologiæ*.)
[2] *Ibid.*

History. which they may be successfully treated. The idea of applying anatomical knowledge directly to this purpose appears to have originated with Bernardin Genga, a Roman surgeon, who published in 1672, at Rome, a work entitled *Surgical Anatomy, or the Anatomical History of the Bones and Muscles of the Human Body, with the description of the Blood-vessels.* This work, which reached a second edition in 1687, is highly creditable to the author, who appears to have studied intimately the mutual relations of different parts. It is not improbable that the example
1718-26. of Genga led Palfyn, a surgeon at Ghent, to undertake a similar task about 30 years after. For this, however, he was by no means well qualified; and the work of Palfyn, though bearing the name of Surgical Anatomy, is a miserable compilation, meagre in details, inaccurate in description, and altogether unworthy of the honour of being republished, as it afterwards was, by Antony Petit.

While these two authors, however, were usefully employed in showing what was wanted for the surgeon, others were occupied in the collection of new and more accurate facts. Albinus, indeed, ever assiduous, had, in his account of the operations of Rau, given some good sketches of the relative anatomy of the bladder and urethra; and Cheselden had already, in his mode of cutting into the urinary bladder, shown the necessity of exact knowledge of the relations of contiguous parts. The first decided application, however, of this species of anatomical research it was reserved for a Dutch anatomist of the 18th century to make. Peter Camper, professor of Anatomy at
1760. 1762. Amsterdam, published in 1760 and 1762 his anatomico-pathological demonstrations of the parts of the human arm and pelvis, of the diseases incident to them, and the mode of relieving them by operation. These observations are of the utmost value. The situation of the blood-vessels, nerves, and important muscles, is explained with the greatest clearness; and though the engravings are rather bold and accurate than elegant, they constitute a work indispensable to the anatomical reader. His remarks on the lateral operation of lithotomy, which contain all that was then known on the subject, are exceedingly interesting and valuable to the surgeon. It appears further that he was the first who examined anatomically the mechanism of ruptures, his delineations of which were published in 1801 by Soemmering.

It had been originally observed by Riolan, Severinus, Rudbeck, Harvey, and De Graaf, that in the fœtus the testicles are situate in the abdomen; but this observation, so pregnant with important results, appears to have been overlooked, nay doubted, till verified by Haller, who showed that their removal from this region is connected with the formation of congenital hernia. The situation of the testicles previous to birth, their gradual descent into the scrotum, and the mode in which a portion of intestine may slip down with them, was still more fully investigated by William Hunter, by Camper, and finally by John Hunter; and the peculiarities of the inguinal canal, and the manner in which its persistence after birth, or its re-opening, may occasion hernial protrusions, have been well explained by Sandifort, Scarpa, Sir Astley Cooper, Allan Burns, and Lawrence, and more recently by Hesselbach and Langenbeck.

The attention of anatomists was now directed to the elucidation of the most obscure and least explored parts of the human frame—the lymphatic vessels and the nerves. Although, since the first discovery of the former by Asellius, Rudbeck, and Pecquet, much had been done, especially by Ruysch, Nuck, Meckel, and Haller, many points, notwithstanding, relating to their origin, and distribution in particular organs, and in the several classes of animals, were imperfectly ascertained or entirely unknown. William Hunter investigated their arrangement, History.
and proposed the doctrine that they are absorbents; and 1746-48-51.
John Hunter, who undertook to demonstrate the truth of this hypothesis by experiment, discovered, in 1758, lymphatics in birds in the neck. As this doctrine required the existence of this order of vessels, not only in quadrupeds and birds, but in reptiles and fishes, the inquiry attracted attention among the pupils of Hunter; and William Hewson at length communicated, in December 1768, to the Royal Society of London, an account of the lacteals and lymphatics in birds, fishes, and reptiles, as he had discovered and demonstrated them. The subject appears about the same time to have been investigated by the second Monro, who indeed claimed the merit of discovering these vessels in the classes of animals now mentioned But whatever researches this anatomist may have instituted, Hewson, by communicating his observations to the Royal Society, must be allowed to possess the strongest as well as the clearest claim to discovery. The same author, in 1774, gave the first complete account of the anatomical peculiarities of the lymphatic system in man and other animals, and thereby supplied an important gap in this department. Hewson is the first who distinguishes the lymphatics into two orders, the superficial and the deep, both in the extremities and in the internal organs. He also studied the structure of the intestinal *villi*, in which he verified the observations of Lieberkuhn; and in inquiring into the minute structure of the glands, he adopted the views of Ruysch. He finally applied his anatomical discoveries to explain many of the physiological and pathological phenomena of the animal body. Ten years after, John Sheldon, another pupil of Hunter, gave a second history and description of the lymphatics, which, though divested of the charm of novelty, contains many interesting anatomical facts. He also examined the structure of the *villi*.

Lastly, Cruikshank, in 1786, published a valuable history of the anatomy of the lymphatic system, in which he 1786.
maintains the accuracy of the Hunterian doctrine, that the lymphatics are the only absorbents; gave a more minute account than heretofore of these vessels, of their coats and valves; and supplied the defect left by Hewson, by explaining the structure of the lymphatic glands. He also injected the *villi*, and examined them microscopically, verifying most of the observations of Lieberkuhn. The origin of the lymphatics he maintains rather by inference than direct demonstration. To these three works, though in other respects very excellent, it is a considerable objection that the anatomical descriptions are much mixed with hypothetical speculation and reasonings on properties, and that the facts are by no means always distinguished from mere matters of opinion. At the same time Haase published an account of the lymphatics of the skin and intestines, and the plexiform nets of the pelvis.

To complete this sketch of the history of the anatomy of the lymphatic system, it may be added that Mascagni, who had been engaged from the year 1777 to 1781 in the same train of investigation, first demonstrated to his pupils several curious facts relating to the anatomy of the lymphatic system. When at Florence in 1782, he made several preparations, at the request of Peter Leopold, grand duke of Tuscany; and when the Royal Academy of Sciences at Paris announced the anatomy of this system for their prize essay appointed for March 1784, Mascagni resolved on communicating to the public the results of his researches—the first part of his commentary, with four engravings. Anxiety, however, to complete his preparations detained him at Florence till the close of 1785; and from these causes his work did

History. not appear till 1787. These delays, however, unfavourable as they were to his claims of priority to Sheldon and Cruikshank, were on the whole advantageous to the perfection of his work, which is not only the most magnificent, but also the most complete, that ever was published on the lymphatics. In his account of the vessels and their valves, he confirms some of Hewson's observations, and rectifies others. Their origins he proves by inference much in the same manner as Cruikshank; but he anticipates this author in the account of the glands, and he gives the most minute description of the superficial and deep lymphatics, both in the members and in the internal organs.

General accounts of the nerves had been given with various degrees of accuracy by Willis, Vieussens, Winslow, and the first Monro; and the subject had been much rectified and improved by the indefatigable Haller. The first example of minute descriptive neurography was given in 1748 by J. F. Meckel, whose account of the fifth pair, and their connection with the intercostal, and of the nerves of the face, will long remain a lasting proof of accuracy and research. The same subject was investigated in 1765 by Hirsch, and in 1777 by Wrisberg. In 1766 Metzger examined the origin, distribution, and termination of the first pair,—a point which was afterwards very minutely treated by Scarpa in his anatomical disquisitions published in 1780; and the internal nerves of the nostrils were examined in 1791 by Haase. The optic nerve, which had been studied originally by Varoli, and afterwards by Mery, Duverney, Henkel, Mœller, Hein, and Kaldschmid, was examined with extreme accuracy, with the other nerves of the organ of vision, by Zinn, in his elaborate treatise. The phrenic nerves, and the œsophageal branches of the eighth pair, were studied by Haase; the phrenic, the abdominal, and the pharyngeal nerves, by Wrisberg; those of the heart most minutely by Andersch; and the origins, formation, and distribution of the intercostal nerve, by Iwanoff, Ludwig, and Girardi. The labours of these anatomists, however, were eclipsed by the splendid
1783. works of Walter on the nerves of the chest and belly; and
1794. those of Scarpa on the distribution of the 8th pair, and splanchnic nerves in general. In minuteness of description, and in beauty of engraving, these works have not yet been equalled, and will never perhaps be surpassed. About the same time Scarpa, so distinguished in every branch of anatomical research, investigated the minute structure of the ganglions and plexuses.

1780. The brain was also studied with great attention by Malacarne, Vicq d'Azyr, and Soemmering; more recently Reil examined the minute structure of the organ and its component parts with unrivalled research and accuracy; and Rolando studied the structure of the *cerebellum*.

Lastly, the anatomy of the gravid uterus, which had been originally studied by Albinus, Roederer, and Smellie, was again illustrated most completely by William
1774. Hunter, whose engravings will remain a lasting memorial of scientific zeal and sculptorial talent.

The perfection which anatomical science has attained has been evinced during the last ten years of the eighteenth century, and the first half of the nineteenth century, in the improved character of the systems published by anatomists. The first who gave a good modern system was Sabatier; but his work was speedily eclipsed by the superior merits of the treatises of Soemmering, Bichat, and Portal. To the first belongs the character of being at once the most learned and critical, and at the same time the most precise, yet published. The General Anatomy of Bichat is a monument of his philosophical genius, which will last as long as the structure and functions of the human body are objects of interest. His Descriptive Anatomy is distinguished by clear and natural arrangement, precise and accurate description, and the general ingenuity with which the subject is treated. The physiological observations are in general correct, often novel, and always highly interesting. It is unfortunate, however, that the ingenious author was cut off prematurely during the preparation of the third volume. It must nevertheless be acknowledged, that if the two last ones betray the want of the genius of Bichat, they are pervaded with the general spirit by which the others are impressed, and are highly creditable to the learning, the judgment, and the diligence of MM. Roux and Buisson. The system of Portal is a valuable and correct digest of anatomical and pathological knowledge, which, in exact literary information, is worthy of the author of the History of Anatomy and Surgery, and, in accuracy of descriptive details, shows that M. Portal trusts not to the labours of his predecessors only. Since the appearance of these standard works, Meckel published a Manual, which combines the philosophical generalizations of Bichat with the precise description and pathological knowledge of Portal. Of this work a French translation was published at Paris in 1825. Lastly, Cloquet formed, on the model of the Descriptive Anatomy of Bichat, a system in which he avails himself of the literature and precision of Soemmering, and the details of Portal. The system of Gordon is imperfect, its completion being interrupted by the death of the author; but, so far as it goes, it gives a correct summary of General Anatomy, and some accurate descriptive details of the heart and brain. The work of Dr Monro is entitled to mention in this place, as an elementary treatise, containing with anatomical description a good deal of physiological and pathological matter. These, however, must be considered foreign to the subject.

Of treatises on particular departments, those of Blumenbach on the bones, Innes and Sandifort on the muscles, the several anatomical writings and engravings of Charles Bell on the arteries, the nerves, and the brain, Barclay on the arteries, Tiedemann on the nerves of the uterus, and the same author's engraved delineations of the arteries, and Harrison's excellent work on the arteries, deserve notice. The most complete work, however, on the anatomy of the arteries was published at London between the years 1840 and 1844, by Richard Quain, Professor of Anatomy in London University College. In this work, Mr Quain has given with great accuracy, views of the normal origin, course, and distribution of all the important arteries of the human body; and has bestowed great attention in distinguishing and fixing all those which are normal from those which are abnormal. This work consists of eighty-seven most faithful lithographed engravings of large size, and is accompanied by 543 octavo pages of descriptive letterpress. From the attention with which it has been prepared, it ought long to continue a standard work on the anatomy of the arterial system.

The minute structure of bone which had been examined by Scarpa, was again studied by that indefatigable inquirer, and in this country by Howship. In 1834, Deutsch published at Breslau a dissertation containing some good observations on the minute structure of Bone; and in 1836, Miescher, with the aid of John Müller, published at Berlin a history of the general anatomy of bone, with some important observations on the *canaliculi* of Clopton Havers, and the manner in which the earthy matter is deposited in the bony texture. These observations, which were made by the aid of the microscope, form the basis of much of the modern knowledge on the structure of these organs.

On the minute structure of the teeth, the results of careful investigation were published by Retzius in 1837; by Alexander Nasmyth in 1839 and 1849; and by John Tomes in 1848; and the mode in which these organs are developed was elucidated with much skill in 1839 by Mr John Goodsir.

History.

The structure of the lungs, which was investigated in 1808 by Reisseissen, in 1821 by Magendie, and in 1827 by Sir E. Home, was anew subjected to scrutiny in 1836 by Bourgery, in 1842 by Mr William Addison; in 1845 by Mr George Rainey; and in 1846 by M. Rossignol.

On the anatomy of the nervous system numerous treatises have appeared during the last forty years. Joseph and
1812. Charles Wenzel investigated in 1812 the minute structure of the brain in man and the lower animals; Tiedemann traced the development of the organ in the fœtus, and rectified many errors on its formation and minute structure; Sir Everard Home and M. Bauer investigated its atomic constitution by the microscope. But this was done in a manner still more elaborate, and with improved means of observation, by Ehrenberg in 1833, by Valentin in 1834, by Remak in 1838, and by Purkinje about the same time. In 1836 Samuel Solly published an instructive treatise containing the anatomical history of the brain and its parts, elucidated chiefly after the method of demonstration proposed by Gall and Reil, and improved by Foville. A second edition of this work, enlarged and improved by much additional information, appeared in 1847; and though much of the volume is devoted to physiological and pathological matter, it may be regarded as the most complete treatise on the subject in the English language. More strictly anatomical, and not less valuable, is the Descriptive and Physiological Anatomy of the Brain, Spinal Chord, and Ganglions, by Robert Bentley Tod, published in 1845; a treatise remarkable for accuracy and precision in information.

Lobstein investigated in 1823 the structure and distribution of the Great Sympathetic Nerve; Bellingeri published the same year an accurate description of the Spinal Chord and its Nerves; Charles Bell, in his great work on the Nervous System, develops and establishes the truth of the ancient theory of the separate nature of the nerves of motion and those of sensation.

Between 1830 and 1834, Joseph Swan published a series of twenty-five excellent drawings, representing the connections, course, and distribution of all the demonstrable nerves of the human body, upon a scale as large as life; a work, the result of several years of personal dissection. Robert Lee gave in 1842 elaborate views of the position of the ganglia, and distribution of the Nerves of the Uterus in the virgin, and in the impregnated state; and the same parts were made the subject of investigation by Mr Snow Beck.

Comparative Anatomy, which, during the eighteenth century, was diligently cultivated by Daubenton, Pallas, Haller, John Hunter, and the second Monro, became during the first thirty years of the nineteenth century a subject of increased interest, from its intimate connection with the sciences of zoology, physiology, and geology, and has consequently been studied with great assiduity and skill by Cuvier, Dumeril, Home, Tiedemann, Meckel, Spix and Martius, Robert Grant, Rymer Jones, Richard Owen, and by numerous inquirers in the several countries of Germany.

The improvement which has been effected in the construction of the compound microscope during the thirty years subsequent to 1822, has contributed, in no small degree, to enable anatomists to obtain more correct information on the intimate structure of different organs and tissues of the animal body. For the first twenty years of the nineteenth century, opticians and instrument-makers had at intervals endeavoured to render the compound microscope at once an instrument of greater power, and more free from sources of error and optical illusion than it had hitherto been possible to obtain it. Two defects, however, still adhered to the compound microscope. The instrument was not achromatic; and a considerable degree of spherical aberration uncorrected rendered the image indistinct.

Between 1812 and 1815, Professor Amici of Modena had attempted to construct an achromatic object-glass of one single lens; but found that this was impracticable. M. Selligues of Paris, in 1823, after various trials, found that this could be done by making the object-glass consist of four achromatic compound lenses, each of which was composed of two single lenses. This method was carried into practice, and improved by the two MM. Chevalier of Paris. About the same time, Dr Goring in London, with the aid of Mr Tulley and Mr Pritchard, constructed compound microscopes upon a similar principle.

On the 5th of April 1824, M. Selligues presented to the Academy of Sciences a microscope, constructed by M. Chevalier, on the principle of combined lenses; and in the course of the same year, and without the knowledge of what had been done in France, the late Mr Tulley, at the suggestion of Dr Goring, constructed a compound microscope, an achromatic object-glass, of nine-tenths of one inch focal length, composed of three lenses, and transmitting a pencil of eighteen degrees. This was the first achromatic microscope that had been made in England.

By the labours of these practical opticians, and the suggestions of various scientific persons, as Sir John Herschel, Mr Airy, Mr Barlow, one great defect of the compound microscope was obviated. There was still another under which the instrument laboured; the effects of spherical aberration. This was overcome, in a very simple manner, by the experiments of Mr Jackson Lister, who had early observed that the combined achromatic object-glasses, devised by Selligues, were fixed in their cells with the convex side foremost, and that this is the most improper position, as it renders the spherical error very great. This gentleman found, after various trials, that, by placing three or more achromatic glasses with their plane surfaces directed foremost, it was possible to correct completely all spherical aberration.[1]

This fact was made known in the beginning of the year 1830; and by its application, the compound microscope was brought to a high degree of perfection as an achromatic instrument in 1831 and 1832, and became the means of affording valuable assistance in anatomical inquiries. After this period, accordingly, we find a succession of valuable monographical essays appearing, from time to time, from the anatomists of this country and the continent, on the minute microscopical anatomy of various important organs of the animal body. The whole of these writings it is impossible to mention in this place, further than to say that the use of the microscope in anatomy, which had in the times of Malpighi, Leeuwenhoeck, William Cowper, Baker, Fontana, Hewson, and the second Monro, been much cultivated, but had afterwards, from the imperfection of the instrument, and the illusions to which it not unfrequently gave rise, been unduly neglected, became so general and so necessary, that it may be said that, since the year 1832, minute structural anatomy has been, if not created anew, at least most thoroughly revised. The amount of knowledge has been increased; that which was already possessed was rendered greatly more accurate and precise.

By the aid furnished by these improved instruments, John Muller was enabled in 1830 to publish his elaborate Commentary on the Minute Structure of the Glands, the first work in which the anatomy of these organs was examined and elucidated in a comprehensive and systematic manner. By the aid of the same instrument Ehrenberg was enabled

[1] On some Properties in Achromatic Object-Glasses applicable to the Improvement of the Microscope. By Joseph Jackson Lister, Esq. *Philosophical Transactions,* 1830. Read 21st January 1830.

to publish, in 1833, his observations on the Minute Structure of the Brain; to explain in a manner hitherto impracticable the structure of numerous infusoria, and to disclose the peculiarities of many other structures, animal, vegetable, and mineral, which had previously eluded the most skilful researches. By the same means Francis Kiernan, in 1833, published the first correct account of the Minute Anatomy of the Liver. By means of the same assistance, Dr Martin Barry has communicated a large amount of new and correct information upon the structure of the Germinal Vesicle and the changes which it undergoes; the structure of cells; the minute structure of muscular fibres, and several other subjects intricate and little understood. By the same means, Mr William Addison and Mr George Rainey in this country, and M. Rossignol in Belgium, have been enabled to investigate carefully the minute structure of the lungs, and the disposition and figure of the air-vesicles. By the same means Gulliver, Queckett, and Wharton Jones, have studied to explain the minute structure of the corpuscules or globules of the blood in different classes of animals, and have thrown much light upon the forms of these globules. Lastly, by means of the same instrument, Mr Bowman has been enabled to give the first clear and intelligible views of the sacculo-vascular structure of the *corpora globosa* or Malpighian bodies of the kidncy, and has shown in what manner the cirriform or curling capillaries of these bodies contribute to the secretion of the urine; while in the same department Huschkc, Reichert, Gerlach, and Bidder, have laboured with grcat perseverance in elucidating various obscure points.

For several years past, in short, anatomists in Great Britain, France, Switzerland, Germany, Belgium, and Holland, have been industriously occupied in studying various departments of minute anatomy, by means of the improved compound microscope, and in throwing light upon all those points that are most obscure and uncertain. It cannot be said, nevertheless, that all has been discovery and all acquisition. These investigations have given rise to a large proportion of discordance in the representations given by different observers; and though all must have beheld the same objects, yet all have not put upon them the same interpretation. The result is, that it is a work of no ordinary difficulty to reconcile these discordant points, and out of the whole stock of facts, to form a consistent and correct description. Perhaps a considerable time must elapse before all these difficulties can be fully explained, and all thc points of discordance can be satisfactorily reconciled.

Meanwhile, it is proper to mention that systematic treatises have shared in the general improvements and rectifications thus introduced into anatomical science. In the year 1833 Carl Frederick Theodore Krause published at Hanover the first division or section of the first volume, in the year 1836 the second part, and in 1838 the third division, completing the first volume of a Handbook or Manual on Anatomy, General and Special. The general anatomy is given in the first part of the first division; the rest of the first division is occupied with the anatomy of the skeleton, thc muscles, the ligaments, and the fasciae. The second division is employed in explaining the anatomy of the compound organs and apparatus, including the organs of the senses, those of respiration, digestion, the organs of secretion, and those of reproduction. In the third division the author treats of the heart, the bloodvessels and lymphatics, and the nervous system.

This treatise is one of great merit. It is remarkable for clearness and method, brevity, accuracy, and precision; and the author must be allowed to have presented a most instructive system of anatomical knowledge. Krause has given in it accurate average estimates of the weights and dimensions of the different organs. This work appeared in a second edition in 1841 and 1842.[1]

In the year 1837, Joseph Berres, professor of anatomy at Vienna, published in that city the *Microscopical Anatomy of the Human Body;* and in which he gave views of the anatomy of all the simple textures and the various organs, as disclosed by the microscope. The instrument which Professor Berres employed was one made by Ploesslich. This work is undoubtedly one of great labour and no ordinary value; but probably it is in its plan too comprehensive, and embraces too large a field to be in all points accurate. The descriptions are given in the German and Latin languages.[2]

Cruveilhier published in 1834 and 1835, a good general treatise on Descriptive Anatomy, which was translated into English, and published in 1841 as part of the Library of Medicine.[3] A new and improved edition of this treatise the author himself published at Paris in 1842 and 1844.

The excellent work by Samuel Thomas Soemmering,[4] originally published in the German language, between the years 1791 and 1796; then in the Latin language between the years 1794 and 1800; and in a second edition in the German language in 1800 and 1801, maintaining the high character which it first possessed for clear arrangement, accurate description, and general precision; was between the years 1841 and 1844 republished in eight volumes at Leipsic, by Bischoff, Henle, Huschke, Theile, Valentin, Vogel, and Wagner, with suitable additions, and a large amount of new and accurate information. In this edition Rudolph Wagner gives in the first division of the first volume, the Life, Correspondence, and Literary writings of Soemmering; and, in the second volume, the anatomy of the Bones and Ligaments. The third volume contains the anatomy of the Muscles and the Vascular system by Theile. Valentin devotes one volume, the fourth, to the minute anatomy of the Nervous system and its parts, as disclosed by careful examination by the microscope; and it must be allowed that the author has been at great pains to present just views of the true anatomy of the Brain, the Spinal Cord, the Nervous Branches, and the Ganglia. In the fifth volume, Huschke of Jena, gives the anatomical history of the Viscera, and the organs of the senses; a department which had been left in some degree incomplete in the original; but for one division of which the author had left useful materials in his large figures already mentioned. In the sixth volume, an entire and complete system of General Anatomy, deduced from personal observation, and that of other careful observers, the materials being in general new,

History. and in all instances confirmed and rectified, is given by Henle, at that time at Zurich, but subsequently professor at Heidelberg. The seventh volume contains the history of the process of Development in Mammalia and Man, by Th. L. W. Bischoff. The eighth volume contains the Pathological Anatomy of the Human Body, by Julius Vogel, but only the first division thereof, relating to the generalities of the subject.

This, which is probably the most accurate, as it is the most elaborate system of anatomical knowledge up to the date of its publication in 1844, was translated into the French language by Jourdan, and published in 1846, under the name of *Encyclopedie Anatomique.* The eighth volume was translated into the English language in the year 1847.

In 1840, Francis Gerber published at Berne a Manual of General Anatomy in the Human Subject and the Domestic Mammalia. Of this work, which contains a large amount of new and accurate information, an English translation was published by Mr Gulliver in 1842.[1]

In 1846, Joseph Hyrtl published at Prague a system of Anatomy of the Human Body in reference to Physiology, which contains short but interesting views of the Physiological Anatomy of the different organs. In the course of the same year, and in 1847, the same writer published a Manual of Topographical and Surgical Anatomy; the latter chiefly for surgeons and accoucheurs, as the former work was intended for the benefit of physicians. The second volume contains the surgical anatomy of the Male and Female Pelvis, the Spine, and the extremities.[2]

Bourgery began in 1834 to publish a work on Elementary Anatomy; and in 1837 a large and complete system of anatomical knowledge, illustrated with large figures of all the divisions and organs of the human body. This work consist of two divisions, one on Medical and Physiological Anatomy; the other on Surgical Anatomy. It is only now completed.

In England the treatise by Jones Quain, which was highly esteemed, was republished in a fifth edition between the years 1843 and 1848, by Mr Richard Quain and Dr Sharpey, in two volumes. The work was in this form enlarged to about double its previous size; and it contains a large amount of accurate information in General Anatomy, and in several of the divisions of Descriptive Anatomy. The General Anatomy is written entirely anew by Dr Sharpey, who has taken great pains to present a just and accurate view of the state of knowledge in that department. This work is the most complete English system hitherto published. Of various English manuals, those by Ellis, by Wilson, and Harrison, are most entitled to recommendation.[3]

In the three years between 1846 and 1849, Dr Arthur Hill Hassall published the *Microscopic Anatomy of the Human Body in Health and Disease.*[4] Though in this work the author treats of the morbid state of the fluids and solids, as well as their normal or healthy condition; yet as he takes great pains to give correct views of the minute anatomy of the textures in the state of health, it would be unjust here to omit mentioning his services. The work is illustrated by sixty-nine coloured drawings, and may be recommended as one giving very just views of the minute anatomy of the tissues and organs, both from personal observations, and that of contemporary inquirers.

In the year 1850, Dr A. Kolliker, Professor of Anatomy at Wurzberg, published at Leipsic the first half of the second volume of a work devoted to the elucidation of the microscopical anatomy of the human body: and in 1852 the second half of the same volume. For manifold reasons the author states that he publishes the second volume, which is devoted to the history of the Special or Particular Tissues, before the first. In the first half of this volume, Kolliker treats of the microscopical anatomy of the Skin, the Muscles, the Bones, and the Nerves, and in the first division of the second half of the microscopical anatomy of the Organs of Respiration and Digestion.[5] From the specimens already published, this work gives the promise of being the most complete and accurate hitherto published on the subject of minute structural anatomy. The author has been at great pains in examining every texture with the greatest care, and comparing his own observations with those given by previous and contemporary anatomists; and while the information is ample on every disputed point, every reader must feel that he finds in this work more accurate knowledge on the intimate structure of organs than he had previously possessed. This work, when completed, will, in short, probably prove to be the standard treatise on general and microscopical anatomy. The descriptions are illustrated by numerous beautiful wood engravings (295), and four lithographed tables.

The account now given embraces the principal works upon anatomy, not by any means the whole, that have been published since the use of the improved compound microscope has become general. Many writings of very considerable merit upon individual subjects and questions in anatomy have during the same time appeared in different countries of Europe. Upon the brain and the nervous system they have been most numerous; some inquirers devoting their attention to the nerves, as Remak, Purkinje, Pappenheim, Bidder, and Volkmann, Budge, Schiff, Bowman; others, as Valentin, Longet, Solly, Todd, Lockhart, to the Brain and its Vertebral Prolongation. These, however, the limits assigned to the present outline prevent us from recording. It shall be our study, nevertheless, in the proper place to notice whatever facts may seem most important, as ascertained by each, as far as the nature and objects of this article will admit. Minute details it will not be possible to introduce. But it shall be our endeavour to present upon the structure of the tissues and the different organs, such accounts as may convey a just idea of the facts hitherto ascertained, and may enable readers to form correct notions on the state of anatomical knowledge in the middle of the nineteenth century.

[5] Mikroscopische Anatomie; oder Gewebelehre des Menschen von Dr A. Kolliker, Professor der Anatomie und Physiologie in Wurzburg. Zweiter Band Specielle Gewebelehre; Erste Hälfte mit 168 Holzschnitten. Leipzig 1850, grösse 8vo, seite 554, Zweite Hälfte I. Abtheilung Mit. 127 Holzschnitten. Leipzig 1852, seite 346.

In the foregoing account we have been anxious to trace merely a general sketch of the progressive advancement of anatomical discovery, from the first cultivation of the art to the present time. To mention every circumstance is impracticable, and would have extended this outline much beyond its legitimate limits. Though no name of genuine importance, however, has been omitted, every one not directly connected with strict anatomy has been excluded. For more minute and detailed information, we refer in general to the elaborate History of Anatomy and Surgery by Portal, the BIBLIOTHECA ANATOMICA of Haller, and the critical and learned history of Lauth. The latter work is not completed. But by combining its perusal with that of the works already mentioned, and several of the chapters of Sprengel's History of Medicine, the anatomical inquirer will form very just ideas of the literary history of his science.[1]

Human Anatomy.

## HUMAN ANATOMY.

ALL animal bodies agree in the possession of certain general characters, by which they are distinguished equally from inorganic bodies and from vegetables.

Besides the round shape by which organic bodies are distinguished, most animals are, externally at least, symmetrical, or present on each side of the mesial plane, lateral halves mutually alike. The substances of which they consist are not entirely solid, but are soft, compressible, distensible, and elastic, and contain a proportion of liquid matter, which is generally in the ratio of majority to that of the solid. These substances are enveloped in a thready or filamentous matter, named areolar or cellular, from the interstitial spaces which result from the intersection of its filaments; and the whole is inclosed in a general covering, which in several classes is soft, membranous, and elastic, but in others is hard, crustaceous, and even horny. The body is perforated by an internal cavity for the reception of food; and this cavity is lined by a membranous covering, which is continuous with that by which the exterior is involved. In several classes of animals there are tubular canals, distributed in an arborescent form, for conveying, in definite directions, the nutritious matter to all parts of the frame. These are named blood-vessels, or organs of circulation. One modification of these, arranged in such manner that this matter is subjected to the influence of the atmospheric air, forms lungs, gills, or organs of *respiration;* and another, in which part of it is separated from the whole, constitutes secreting organs or glands. The genital or reproductive organs consist of a cavity, from which the germs or *ova* are detached. For the purpose of motion, animals further possess organs generally of a fibrous structure, and which have the remarkable property of undergoing contraction on the application of a stimulus or irritating agent. These organs are denominated muscles (*lacerti, tori*); and their contractile property is termed *irritability* or *contractility.* For receiving the impression of external objects, they are provided with one or more organs of sensation, of structure more or less complex. And in almost all animal bodies, except the very lowest, there are found soft, gray, or whitish cords, inelastic, but marked in their course by fusiform, spheroidal, or irregular-shaped swellings, and connected at their further extremity with the muscles, with the organs of sensation, or with the exterior or interior coverings. It is remarkable that the purpose of these cords, which are named nerves, is not exactly known. They neither communicate mobility to the muscles, nor sensibility to the organs of sensation; but they render the actions of the former steady, regular, and voluntary; and the impressions received by the latter they certainly serve to convey to the centre of the nervous system. The faculty ascribed to the nerves is named *nervous action, nervous energy, nervous power, nervous influence,* or simply *innervation.*

In chemical composition, animal bodies consist of gelatine, albumen, fibrin, fat or oleaginous matter, a modification of mucus, and various saline substances. Subjected to combustion, or spontaneous decomposition, while vegetable substances furnish water, carbonic acid, and carburetted hydrogen, animal matters furnish also ammonia,—a circumstance which shows that they contain azote. They furnish also sulphuretted hydrogen, apparently from the decomposition of albuminous matters.

The fluids of animal bodies (*liquores, latices, humores*) are contained in tubular canals or vessels. If these fluids move through the vessels, they are denominated generally blood, whatever be their colour. All the fluids consist either of this, or of some modification separated from it by means of glandular action; and of the fluids so separated, some are destined for purposes within the economy, and are therefore secretions proper; others are intended to be eliminated immediately, and may therefore be regarded as excretions. Though it is impossible to estimate accurately the proportion of the fluids, some idea of it may be formed by the fact, that an animal body may be reduced by desiccation to $\frac{1}{9}$ or $\frac{1}{10}$ even of its previous weight. The proportion may be stated, in general terms, to vary from 9 or 6 of fluid, to 1 of solid matter.

The various forms of animal bodies may be referred to general divisions or classes, according to certain peculiarities in configuration and structure. These divisions are, the VERTEBRATA, MOLLUSCA, ARTICULATA, and RADIATA.

In the first class the central portion of the nervous system, consisting of the brain and spinal chord, is inclosed in a case of hard matter, containing much calcareous earth, and denominated bone. While one portion of this forms, by the union of its pieces, a cavity named the scull or *cranium,* the other is composed of separate pieces, which by their union constitute at once a continuous canal and a sort of internal pillar or column for attaching and supporting the soft parts. These pieces are named *vertebræ* (σπονδυλοι); and their presence is so uniform, that they constitute the character of the class, which are therefore named VERTEBRATED ANIMALS; (ANIMALIA VERTEBRIS PRÆDITA, *sive* VERTEBRATA).

The presence of vertebræ is accompanied with other peculiarities of structure. Thus the vertebrated animals have red blood and a muscular heart; a system of tubes for conveying blood from this to the different organs,—the distributory, or arteries; another system for returning it,—the regredient, or veins; and a particular system of

[1] *Histoire de l'Anatomie et de la Chirurgie, &c.* par M. Portal, Lecteur au Roi, &c. Paris, 1770–1773, 6 vols. *Bibliotheca Anatomica, qua Scripta ad Anatomen et Physiologiam facientia a rerum initiis recensentur.* Auctore Alberto von Haller Domino a Goumoens, &c. Halle, 1792–1803. 3e Auflage, 1821–28.

vessels for exposing the latter blood to the influence of the atmosphere. They have further a mouth with two horizontal jaws; distinct organs of vision, hearing, smell, and taste, lodged in the cavities of the face; never more than four members; separate sexual organs; and considerable similarity in the arrangement of the central masses and the ramified chords of the nervous system. In all the vertebrated animals the blood which serves for the secretion of bile is the venous, which has circulated in the intestines, and which is afterwards made to undergo a ramifying distribution in the portal vein. In all the vertebrated animals also a peculiar secretion is formed from the arterial blood by two large glands, denominated kidneys.

In the second general division, which are destitute of those firm pieces named bones, the central portion of the nervous system, instead of being inclosed in portions of the skeleton, is placed on the œsophagus, and, with the other internal organs, is inclosed in a general soft envelope, contractile, corresponding to the skin, to which the muscles are attached, and in which stony patches named shells are occasionally formed. Of the four proper organs of sensation, those only of taste and sight are observed; and the last are often wanting. One family only are provided with organs of hearing. There is always a complete system of circulation, and organs for respiration. Those of digestion and secretion are almost as complicated as in the vertebrated animals. The division of the animal world thus distinguished have been named Molluscous Animals; (Animalia Mollusca).

In the third general division, the nervous system consists of two chords extending longitudinally along the belly, and swelling at intervals into knots or ganglions. The first of these, placed on the œsophagus, and distinguished as the brain, is scarcely larger than the others. The covering of the trunk is divided by transverse folds into a number of rings, the integuments of which may be hard or soft, but to the interior of which muscles are in all cases attached. The sides of the trunk, though often provided with, are nevertheless often without, articulated members. The annular appearance of the trunk has given these animals the character of Articulated; (Animalia Articulata). They have been occasionally named Annulosa.

This class of animal bodies is remarkable for presenting the first transition from circulation in close tubes or vessels, to nutrition by imbibition, and the corresponding transition from respiration in circumscribed organs to that which takes place in air-tubes distributed through the whole body. The only distinct organs of sensation are those of taste and sight; and a single family have organs of hearing. The jaws, when present, are lateral.

In these three divisions of animals the organs of motion and sensation are arranged symmetrically on both sides of an axis or imaginary line. In a fourth class they are distributed circularly round a centre. In these, which in homogeneous structure approach the nature of plants, neither distinct nervous system nor proper organs of sensation are observed. Scarcely do we recognise traces of circulation. The organs for respiration are almost always at the surface of the body. Most of them have for intestine a sac without vent; and some present only a homogeneous pulp, movable and sensible. To this class, which comprehends those beings denominated since the time of Aristotle *zoophytes* (ζωοφυτα), or *animal plants*, the name of Radiated Animals has been recently applied; (Animalia Radiata).

The vertebrated animals, however similar in general characters, present certain peculiarities by which they are naturally distinguished into classes. The first, and perhaps the most striking difference, is in the mode of birth, one large division being separated from the body of the female parent in a state of complete life, and therefore denominated viviparous; the other being detached in the form of an *ovum* or egg, which, though possessed of the elements of life, is not yet endowed with it, and requires for the full developement of that principle the assiduous care of the parent. This difference, however obvious, is more apparent than real. In viviparous birth the fœtus or new animal remains attached to the inner surface of the womb by means of nutrient blood-vessels, and is enveloped in membranes, which correspond very accurately to the coverings of the *ova* of oviparous animals. The rupture of these membranes at the moment of birth or detachment from the body of the parent is the only circumstance which constitutes a material difference between viviparous and oviparous generation. The viviparous animals, nevertheless, are further distinguished by nursing their offspring by means of teats or *mammæ*, glands destined for separating from the mass of blood the oleo-albuminous fluid denominated *milk*.

A still more important source of distinction among the vertebrated animals is found in the disposition of the vascular organs destined for respiration. The blood, which proceeds from the heart by the distributing tubes or arteries to the different organs, thereby undergoes a certain change, in consequence of which it is no longer capable of answering the several purposes of nutrition, secretion, &c. which are necessary to the maintenance of the animal body in the healthy state. To fit it once more for these purposes, the blood, in whole or in part, is, by means of the veins, brought back to the heart, and thence conveyed by means of a system of arborescent tubes to the surface of an organ, where it is, through the interposition of a thin membrane, exposed more or less freely to the atmospheric air. When it is exposed directly to this fluid introduced into the body by means of a single tube divided into ramifying branches, the respiratory organ is denominated *lungs*. When the blood, on the other hand, is exposed to atmospheric air by means of water, which passes over a pectiniform organ, the latter is denominated *gills*. Respiration varies, therefore, according as the structure of the organ allows the whole or part of the blood to be exposed to air, and according as this exposure is direct or indirect.

Taken together, these circumstances may be viewed as the integrant or constituent elements of the quantity, extent, or degree of respiration, which conversely, indeed, depends on two circumstances,—the quantity of blood present in the respiratory organ at any given moment, and the relative quantity of oxygen in the respired fluid.

The organs of circulation may be double, so that the whole mass of blood which is brought by the veins from the remote parts must circulate in the respiratory organ before it is again distributed by the arteries;—or they may be single, so that one portion only of the regredient blood is made to pass through the respiratory organ, while the residue is distributed by the arteries without undergoing this circulation. Of this mode of respiration an example is given by the class of animals denominated *Reptiles;* (Reptilia; Animalia Repentia); in which the heart is so constructed that only part of the blood is conveyed to the lungs, and in which, consequently, the amount or degree of respiration, and the concomitant qualities, vary according to the proportion of this fluid which goes to the lungs at each pulsation.

In Fishes, on the other hand, though the circulation is two-fold, that is, distributory by means of arteries, and regredient by means of veins, the respiratory organ is formed for respiration through the medium of water, and the blood thus exposed to air receives the influence of that only which is mingled or held in solution by the water. Their extent of respiration is therefore supposed to be less than that of reptiles, by reason of the imperfect exposure to the operation of the air. Their respiration may be termed *hydro-aerial.*

In mammiferous animals, again, though the circulation is two-fold, or distributory and regredient, the respiration is single, or confined to the lungs only. Their extent of respiration is therefore superior to that of the reptiles, by reason of the shape of their circulatory organs, and to that of fishes by reason of the nature of the element in which they live. Their respiration is *aerial.*

In another class of vertebrated animals, however, respiration assumes a form still more perfect and extensive, since not only is the circulation two-fold, and the respiration aerial, as in the *mammalia*, but their structure is such that the air of the trachea communicates with other cavities, especially those of the bones, and surrounds the branches of the aorta as completely as it does those of the pulmonary artery. The effect of this arrangement with regard to the ambient atmosphere is at once to render these animals specifically lighter, and enable them to support themselves in the air, and to restore and change the regredient or venous blood so completely, that when again distributed it may impart to the various organs the highest degree of energy of which they are susceptible.

From these characters a division of vertebrated animals may be formed in the following manner. 1*st*, Quadrupeds, in which the extent of respiration is moderate, and which are distinguished for walking or running, or other muscular exertion with strength; 2*d*, Birds, in which the extent of respiration is the greatest possible, and is connected with the levity of substance and energy of muscle requisite for flight; 3*d*, Reptiles, in which the small extent of respiration is connected with languor of motion and occasional seasons of torpor; and, 4*th*, Fishes, in which the still more limited form of the respiratory organ requires a fluid of nearly equal specific weight to their own bodies to enable them to move with facility. These characters are necessarily general; but they are so essential, that between them and the other circumstances of organization proper to each class, and especially those relating to motion and sensation, a necessary relation exists.

To the quadrupeds, mammiferous animals, or viviparous vertebrated animals, which form the first of these great classes, this place belongs, not only by the mode of generation and respiration, but by the more perfect form of the animal functions, and the higher degree of intelligence which their habits and actions indicate. They are less under the influence of that blind animal propensity denominated instinct, which, like the properties of inorganic matter, seems to operate regularly and uniformly, independent either of sensation or volition.

This class of animals is distinguished by great uniformity and regularity of structure and organization. In all of them the upper jaw forms part of the cranium; and upon this the lower jaw, consisting of two pieces only, articulated by a prominent condyle to the temporal bone, is made to move. The neck consists of seven, and, in one species only, of nine vertebræ; to the sternum are attached certain of the ribs, therefore named *sterno-vertebral;* the thoracic extremity is supported by a flat bone named shoulderblade (*scapula*, *ωμοπλατη*), not articulated, but simply suspended in the muscles, and in some species supported on the sternum by an intermediate bone, named collar-bone or clavicle (*clavicula*, *κληις*); in all excepting the *cetacea* or whale-like animals, the first part of the pelvic extremity is fixed to the vertebral column, and forms a cincture or basin (*pelvis*), which in early life is divided into three pairs of bones, the *os ilium*, which is attached to the spine, the *os pubis*, which constitutes the anterior or abdominal part of the pelvis, and the *os ischium*, which constitutes the most remote lateral portions of the pelvis. At the point of junction of these three bones on each side is a spherical cavity, in which the articular head of the thigh-bone is lodged.

The scull, articulated by two prominent convex surfaces with the first vertebra, denominated *atlas*, may be represented as consisting of three annular portions, an anterior formed by the frontal and ethmoid bones, a middle by the parietal and sphenoid bones, and a posterior by the occipital bone; the temporal bones, which are common to the face and scull, being interposed between the sphenoid, the occipital, and the parietal bones.

The face is formed essentially by the superior and inferior maxillary bones. Between the former is the cavity of the nostrils above, separated by the azygos bone named *vomer;* before are the intermaxillary bones, and behind are the two palate bones. The entrance of the nasal cavity is bounded above by the proper nasal bones; and to a groove in this cavity are attached the inferior turbinated bones, so as to cover partially the entrance into the maxillary sinus.

The brain consists of two similar hemispherical halves, united by a white mass, fibrous, especially in the transverse direction, named mesolobe, middle-band, or smooth body (*σωμα τιλλοειδες*, *corpus callosum*). Each hemisphere contains an interior cavity, formed into definite-shaped masses, uniform and symmetrical. These cavities communicate with each other, and with a third situate on the mesial plane, and extending by a narrow canal to a fourth situate between the *cerebellum* and *medulla oblongata.* The proper matter of the cerebral and cerebellic hemispheres is united on the mesial plane in a mass named *annular protuberance* or *pons Varolii*, the lower surface of which is marked by transverse fibres, while the upper is moulded into four roundish eminences named *nates* and *testes*, or *corpora quadrigemina.*

In the eye, lodged in a cavity of the cranium named orbit, and provided with two eye-lids and the vestige of a third, the crystalline lens is fixed by the ciliary processes; and the sclerotic, though firm, is cellular. The ear consists of a cavity named *tympanum*, closed externally by a membrane, and containing four minute but articulated and movable bones; an oval cavity or vestibule, in the orifice of which, one of these bones, the *stapes*, is fixed, and which communicates with three semi-circular canals; and, lastly, a spiral and tapering cavity, termed *cochlea*, parted by a thin plate into two spiral canals, one of which communicates with the tympanum, the other with the vestibule. The tongue is fleshy, and is supported by a *parabola*-shaped bone, attached to the cranium by ligaments, and to the larynx by membranes.

The lungs, in number two, consisting of numerous tubular canals, proceeding from the windpipe, and terminating in an infinity of minute intersecting canals, named cells or vesicles, are inclosed without attachment, in a cavity formed by the ribs on each side, the diaphragm abdominally, and on the mesial plane by a membranous partition named mediastinum, and lined all over by a thin transparent membrane; (*pleura*). At the guttural extremity of the windpipe is placed a particular apparatus, formed of cartilages put in motion by muscles, and which serves at once to regulate the quantity of air admitted into the tube, and to form the voice. This is named the larynx. A membranous fleshy production, suspended from the palate bones like a veil or valve, also moved at the will of the animal, establishes a direct communication between the larynx and the posterior nostrils.

The intestinal canal is suspended to a duplicature of the peritoneum, named mesentery, between the folds of which the blood-vessels, nerves, lymphatics, and lymphatic glands pertaining to the canal, are lodged. The peritoneum, after passing over the intestines, forms a similar duplicature, which in the manner of a prolongation hangs freely before them.

The urine, after secretion by the kidneys, is retained for a time shorter or longer in a distensible musculo-membranous bladder, and is expelled at various periods by a canal which opens, with few exceptions, in common with that of the organs of generation.

The latter function is, in all the mammiferous animals, essentially viviparous. The ovum, consisting of the fœtus and the enveloping membranes, immediately after conception is conveyed by appropriate tubes into the womb, to the inner surface of which it is attached by one or more plexiform clusters of vessels named *placentæ*, and which furnish the blood requisite to the nourishment of the new body. In the earliest periods of uterine life, however, the mammiferous animals present a bladder or *vesicula* (vitellar membrane), analogous to that which contains the yolk of the oviparous animals, and receiving also mesenteric vessels.

The peculiar mode in which viviparous animals nurse their offspring has been already noticed as that which distinguishes them particularly from the other three divisions of vertebrated animals.

Another character peculiar to this class, are the hairs with which their integuments are provided, and which, though analogous to the feathers or quills of birds, are nevertheless so characteristic, that they cannot be properly omitted in this enumeration. They are found in all mammiferous animals except the cetacea, in which marine residence is supposed to render them less necessary. Lastly, the blood of the mammalia is said to differ from that of oviparous animals in the shape of the coloured particles. In the former they are represented as lenticular, or of the shape of flat or oblate spheroids; in the latter they are ovoidal, or like oblong spheroids.

The mammiferous animals may be subdivided into subordinate groups or orders, according to certain natural characters in organization, which imply again peculiarities of habit and mode of life. These characters are derived from the organs of touch or prehension, on which depends their degree of ability or address; and from the organs of mastication, which always bear a certain relation to the nature of the food on which the individual animal subsists.

The delicacy of the organ of touch depends on the number and mobility of the toes, and on the extent to which their tips are enveloped in nail or hoof. The latter, enveloping entirely the part of the foot which touches the ground, impairs sensation, and renders the foot or paw incapable of prehension. When, on the contrary, a single plate of nail covers one of the surfaces of the tip of the toe, it not only leaves the other all its natural nicety of touch, but gives each toe that free and unembarrassed motion which enables the animal to seize and hold by the claws.

The nature of the aliment used by animals bears a relation to the teeth, with the form of which, again, the articulation of the jaws corresponds. To divide flesh, incisive teeth, like a saw, and jaws mutually opposed, like the blades of scissors, which simply open and shut, are requisite. In order to break grains or roots, teeth with a flat crown, and jaws admitting of horizontal motion, are required. The crowns of these teeth must further be unequal or tuberculated, like the surface of a mill-stone, and their substance must be unequally firm, since certain parts are more exposed to attrition than others.

All hoofed animals are necessarily herbivorous, or have flat-crowned teeth, since their feet do not allow them to seize living prey. Unguiculated animals, again, are susceptible of greater variety in the shape of the teeth, and their aliment depends on the mobility and delicacy of their toes One character of this description, which exercises great influence on their address, and multiplies their means of industry, is the faculty of opposing the great toe to the others, or the thumb to the fingers,—a circumstance which essentially constitutes what is termed the hand, and which is carried to its highest perfection in the case of man, in whom the pectoral extremity is entirely free and susceptible of every mode of prehension.

The several combinations now mentioned furnish characters for distinguishing the mammalia into the following orders.

| | | |
|---|---|---|
| UNGUICULATA; animals with separate toes or claws. | BIMANA; hands on the thoracic extremity; supported vertically by the pelvic extremities. | |
| | QUADRUMANA; hands on the thoracic and pelvic extremities. | |
| | CARNIVORA; toes without free and opposable thumb. | *MARSUPIALIA.* |
| | RODENTIA; no canine teeth; gnawing incisors. | |
| | EDENTATA; no incisors; occasionally no canine; sometimes teeth wanting. | |
| UNGULATA; hoofed animals. | PACHYDERMATA; dense, compact, callous hide. | |
| | SOLIDIPEDA; six incisors and six molars in each jaw; single stomach and large cæcum; one undivided hoof. | |
| | FISSIPEDA *s.* RUMINANTIA; no incisors in the upper jaw; quadruple stomach; cloven foot. | |
| CETACEA; animals with very short pelvic extremities, living in the water. | C. HERBIVORA. | |
| | C. CAPITULATA. | |
| | C. CAPITONES. | |

Of these subdivisions, the first three orders are known by the common character of possessing all the three varieties of teeth, molar, canine, and incisive. They differ from each other in the possession of complete hands on the thoracic extremities, of imperfect hands on the four extremities, and in the want of thumb or opposable toe on the four extremities. The fourth order is peculiar in wanting canine teeth, and having incisors constructed for gnawing. In the fifth the toes are much constrained in motion, being sunk in large claws; and the incisors are wanting. Some genera want the canine teeth, and some are void of teeth entirely.

This distribution of unguiculated animals would be complete, and would form a regular series, were it not interrupted by a small lateral series from New Holland, the native soil of the Marsupial animals. Of these, it is the peculiar distinction, that while some of their genera correspond to the CARNIVORA, others to the RODENTIA, and a third set to the EDENTATA, in the form of teeth and nature of food, all of them agree in the common character of having a large sac or purse (*marsupium*) for retaining some time after birth their offspring, which are detached from the body of the parent in a state of imperfection, corresponding nearly to the fœtus of other mammiferous animals shortly after conception.

In the series of hoofed animals, which are less numerous, less irregularity is also observed. The order of RUMINANT animals is well distinguished by cloven feet, the absence of incisors in the upper jaw, and the quadruple stomach, or that with four compartments. The other hoofed quadrupeds may be united in one order, distinguished by the absence of the ruminating stomach, and a peculiar density of integuments, from which they are named PACHYDERMATA. The elephant alone constitutes a distinct family, and is allied, by the form and mechanism of the teeth, with the family of RODENTIA. A third family of hoofed quadrupeds is distinguished by one apparent toe and one hoof in each foot; though beneath the skin, on each side of the *metacarpus* and *metatarsus*, are prominences corresponding to lateral toes. This small family (SOLIDIPEDA) includes the horse, ass, zebra, and quagga.

Lastly, the CETACEOUS or whale-like animals form a family by themselves, so peculiar, that though viviparous and mammiferous, they might readily be regarded as belonging to the class of fishes. Their organization, however, immediately shows their proper place in the classification; and even the fact observed by the ancients, that, though pisciform, they have warm blood, demonstrates their title to the character of Mammalia.

Man, who, as the most perfect specimen of mammiferous animal with which we are acquainted, is placed at the head of this class, partakes of the general characters of structure and function belonging to the class, and possesses also certain peculiarities by which he is distinguished. The study of the facts of the former description belongs properly to Comparative or Animal Anatomy. That of the latter constitutes Human Anatomy proper. It is, however, expedient to waive this distinction, and trace the anatomical history of the human body, without supposing the reader already minutely acquainted with the structure of mammiferous animals in general. In the course of this description, however, it is requisite to recur frequently to the lower animals, and to derive from them information more or less direct, tending to illustrate the structure of the human subject.

The external appearance of the human frame it is superfluous to describe minutely. Naturalists distinguish man as a bimanous and biped animal, or as one possessing two complete hands, and supporting himself in the vertical position by the two pelvic extremities. These characters are neither arbitrary nor unessential. Both depend on invariable peculiarities of structure; and whatever attempts have been made by men, more distinguished for ingenious paradox than accurate observation, to show that man was naturally quadruped, are readily refuted by appealing to the anatomical configuration and disposition of the four members, and their relation to the trunk.

Another character of the human subject is the globular or rather spheroidal shape of the skull, and its large size in proportion to the rest of the frame, with the general tendency of the plane of the face to the vertical direction. In no other mammiferous animal does the head make so near an approach to the spheroidal shape; and in no other is the plane of the face so nearly vertical. In the other Mammalia, the skull is angular-oblong, and the face acquires a peculiar character, which is readily ascribed to the lower animals by the extreme projection of the mouth, or, in other words, by the length to which the two jaws are prolonged. Even in the monkey tribe, the similitude of which to the human face was remarked by the poet Ennius, this remarkable character is by no means lost; and the upper and lower jaws make a much more conspicuous projection than in the human skull.

The great characteristic of the human race, however, is articulate or oral speech, which, combined with the perfect developement of which the mental faculties are susceptible, constitutes a very wide distinction between man and the lower animals. The latter possess what may be termed laryngeal voice, or that which is formed in the larynx. To man is superadded the faculty of articulate speech by means of the lips, tongue, and teeth.

All the known individuals of the human species, though agreeing in the possession of the general characters now enumerated, and therefore to be regarded as unigenous, or of one general family, differ nevertheless by certain peculiarities in external characters, which have been supposed sufficient to justify the separation into individual races or breeds. Of these, three appear to be very distinct, the WHITE or CAUCASIAN, the TAWNY or MONGOLIAN, and the NEGRO or ETHIOPIAN; and to one or other of these all the various forms which the human body assumes in different climates and countries may be referred.

The CAUCASIAN race is distinguished by the oval shape of the head, the softened aspect, and symmetrical harmony of the general person, and the high degree of cultivation of which the intellectual faculties admit. The colour of the skin and of the hair varies. In warm climates the former is dark or olive-coloured, and the latter is black and glossy. In colder regions the skin is fair and light-coloured, or ruddy, and the hair becomes chesnut, fair, or even red.

The MONGOLIAN or ALTAIC race is distinguished by prominent cheek-bones, flat countenance, oblique eyes, parted by a small interval, straight black hair, slender beard, and olive, tawny, or copper-coloured complexion. This race has formed great empires in China and Japan, and has sometimes extended its conquests beyond the Great Desert; but its civilisation has remained stationary.

The NEGRO or ETHIOPIAN race is confined to the south of the Atlas. Black complexion, crisp woolly hair, compressed skull, and flat nose, prominent mouth, and large thick or everted lips, form its distinguishing external characters. The tribes of which it consists have ever remained barbarous.

The first of these races, from which Europe, Asia, and the north and east of Africa have been peopled, is denominated CAUCASIAN, because tradition and the natural affinity of nations seem to justify the opinion that this race had originally inhabited the mountainous range between the Caspian and Black Seas, from which it has spread by radiation. In confirmation of this, it may be observed that the tribes of the Caucasus, the Circassians, the Georgians, and the Armenians, afford at the present hour the most perfect and beautiful specimens of the human form. This race may be distinguished, by the analogy of languages spoken by them, into three principal branches.

1. The Aramæan or Syrian branch, proceeding to the south, gave birth to the Assyrians, the Chaldeans, the Arabs ever unsubdued, and who, after Mahomet, aspired at the sovereignty of the world; the Phœnicians, the Jews, the Abessins, colonies of the Arabs, and probably the Egyptian or Koptic race. From this first branch, ever prone to mysticism, the most extended forms of religious belief have issued. Science and literature, occasionally flourishing among them, have, nevertheless, been always disguised or corrupted by fanciful ceremonials and a style highly figurative.

2. The Indian, German, and Pelasgic branch was much earlier divided into tribes, and much more extensively diffused. The most numerous affinities may nevertheless be traced between its four principal languages,—the Sanscrit, at present the sacred language of the Hindoos, and the parent of all the dialects of Hindostan; the ancient language of the Pelasgi, the common parent of the Greek, the Latin, of many extinct languages, and of all the present dialects of southern Europe; the Gothic or Tudesc, from which are derived the languages of the north and north-west, for instance the German, Dutch, Anglo-Saxon, and English, the Danish, Swedish, and their dialects; lastly, the Sclavonian, from which are sprung the languages of the north-east, the Russ, the Polish, the Bohemian, and the Vend.

By this branch of the Caucasian race, philosophy, the sciences, and the arts, have been carried to the highest degree of perfection; and of these they may be regarded as the chief depositaries. In Europe this race is believed to have been preceded by the *Celtæ* or *Titano-Celtæ*, whose tribes, proceeding by the north, and formerly very extensive, were nevertheless confined to the most western points; and by the Cantabrians, who passed from Africa to Spain, and who are now almost lost among the numerous nations, the posterity of which is mingled in the European peninsula. The ancient Persians are derived from the same source as the Indians; and their descendants still bear the most conspicuous marks of connection with the European nations.

3. The Scythian and Tartar branch, bending first to the north and north-east, always erratic in the immense plains of these countries, have returned only to ravage the happier establishments of their brethren. From this branch issued the Scythians, who anciently distinguished themselves by inroads into Upper Asia; the Parthians, who destroyed the Greek and Roman dominions; the Turks, who subverted that of the Arabs, and subdued in Europe the last remnant of the Hellenic nation. The Fins and Hungarians are tribes of the same family disseminated among the Sclavonian and Judaic nations. The north and east of the Caspian, their native soil, still maintains tribes which have the same origin and speak similar languages; but they are intermingled with numerous other small septs of different origin and speech. The Tartar tribes remained more unchanged in that tract from which they long threatened Russia, which has at length subdued them, from the mouths of the Danube to beyond the Irtish. Their blood, nevertheless, has been mixed with that of the Mongols, many traces of which may be seen in the younger Tartars.

On the east of this Tartar branch of the Caucasian race begins the MONGOLIAN, which thence extends to the shores of the Eastern Ocean. Its branches, still nomadic, the Calmucks and the Kalkas, roam the Great Desert. Three times have their ancestors, under Attila, Gengis, and Timour, spread the terror of their name among the settled inhabitants of Europe and Asia. The Chinese constitute the branch most early civilized, not only of this race, but of known nations. The Mantchoux, a third branch, who recently conquered, still retain, China. To the same race in great part belong the Japanese and the Coreans, and almost all the hordes which stretch to the north of Siberia, under the sway of the Russians. Excepting some learned Chinese, the whole Mongolian race are attached to the sects addicted to the worship of Fo.

The origin of this great race appears to be in the mountains of the Altaic range, as that of the Asio-European is in the elevation of Caucasus. It is impossible, however, to trace the filiation of its branches with the same accuracy. The history of these nomadic nations is as transitory as their establishments; and that of the Chinese, confined to the bosom of their empire, furnishes only short and unconnected views of the contiguous nations. The affinities of their modes of speech are further too little known to guide us in this labyrinth.

The languages spoken in the north of the Ultra-Gangetic peninsula, as well as that of Thibet, present some relations, at least in monosyllabic character, with the Chinese; and the nations by whom they are spoken are not void of features of physical resemblance to the other Mongolian tribes. The south of this peninsula, however, is inhabited by the Malays, a much handsomer race, whose breed and language have spread to the coasts of all the islands of the Indian Archipelago, and have occupied the greater number of those of the South Sea. In the largest of the former, especially in the wildest places, dwell other tribes, with crisp hair, black complexion, and negro features, all extremely barbarous. The best known are denominated Papous, which may be applied to the whole.

Neither the Malays nor the Papous can be readily referred to any one of the three great races. The former it is difficult to distinguish from the neighbouring races on each side the Caucasian Indians and the Mongolian Chinese. The Papous may be negroes anciently cast away in the Indian Seas; but to determine this point we require both accurate figures and descriptions.

The inhabitants of the north of the two continents, the Samoieds, the Laplanders, and the Esquimaux, spring, according to some, from the Mongolian breed; according to others, they are degenerate slips of the Scythian and Tartar branch of the Caucasian breed.

The Americans have not yet been clearly traced either to one or other of the races of the ancient continent; yet they are void of character sufficiently precise and constant to constitute a peculiar race: their copper-coloured skin is inadequate: by the dark hair and slender beard they approach to the Mongols; but from these again they are distinguished by the well-marked features and the prominent nose. The modes of speech are as numerous as their tribes; and neither between themselves nor with those of the ancient world has any satisfactory analogy been traced.

Of the various breeds now enumerated, the Caucasian or Asio-European is supposed to furnish the most perfect model of the human frame; and from this, therefore, anatomists derive their descriptions both of the body at large and of individual parts and organs.

The structure of the human body may be studied in two modes, either as an assemblage of organic substances endowed with characteristic physical and vital properties, or as an assemblage of organs destined to effect particular and definite purposes.

The human body, like that of every other mammiferous animal, consists of several kinds of animal organic substances endowed with appropriate characters and properties. The substances thus distinguished have been named *elementary textures*, since into them, as into so many elements or integrant principles, the human body is supposed capable of being resolved. To enumerate these elementary textures, to ascertain their minute structure or organization, to investigate their distinctive properties, and to determine the extent to which they enter into the composition of particular organs, is the province of GENERAL ANATOMY. In this department the anatomist, abstracting from the shape, position, and mechanical configuration of parts, studies only their intimate and distinctive characters as organic substances.

General Anatomy.

The human body may further be regarded as an assemblage of organs, and sets of organs, destined to effect certain purposes. These purposes may be referred to two general heads; those which are common to plants and animals, and those which are proper to the latter. The first comprehends nutrition and generation, and have been named vital, organic, or automatic functions; the second embraces muscular action, sensation, and nervous influence or innervation, and are distinguished as animal functions. Since these purposes are effected by certain processes going on successively and simultaneously by the action of one or more organs, they are distinguished by the general name of FUNCTIONS, or orders of functions. Each function consists of several integrant and individual processes; every process consists of one or more actions; each action depends on certain properties; and properties in living bodies, though mechanical, chemical, or vital, are always connected either with the intimate structure of parts or with the configuration of organs. Thus nutrition is at once termed a function, and is said to consist of the several functions of digestion, absorption, circulation, respiration, and secretion. Generation, on the other hand, is said to be a function consisting of several processes—the formation of germs or *ova*, the secretion of semen, impregnation, gestation, and exclusion. Of the functions proper to animals, muscular action, modified in various modes, produces locomotion, gesture, voice, and several motions necessary to the performance of nutrition and generation. Sensation may be said in all cases to depend on nervous action and the mechanism peculiar to each species of sensation. Nervous energy, again, may be said to consist of three properties, those of receiving, transmitting, and recognising impressions. Lastly, a form of faculties connected with the immaterial or thinking part of the system peculiar to man constitutes what are named the intellectual functions.

This division of the phenomena of living bodies into certain assemblages or functions, has given rise to a similar division of these bodies into organs. An organ may be defined to be a part of a living body, of a definite shape, consisting of certain parts, composed of various elementary textures, the seat of one or more actions, and placed in a certain position and region. It rarely happens that one organ only is sufficient for the performance of a function. Several are commonly required to concur to the same general purpose; and hence the organs are arranged in classes, sets, or assemblages, according to the functions to which they are subservient. Thus the organs subservient to the function of digestion consist of the teeth, tongue, and mouth, as organs of mastication; the pharynx and œsophagus as the tube of deglutition; the stomach as the organ of chymification; the duodenum and small intestines as that of chylification; and the large intestines as the temporary receptacle of the excrementitial residue of food and drink. Such assemblages of organs have received, for want of better, the denomination of apparatuses; and the anatomist, when he designates a class of organs devoted to the performance of a specific function, is compelled to distinguish them as the apparatus of digestion, the apparatus of absorption, of circulation, of respiration, of secretion, and so forth. To this method of distinction it may indeed be objected, that scarcely in one instance are all the organs of any apparatus exclusively directed to the performance of the function of that apparatus; and an organ concerned in the function of digestion may also contribute to that of circulation or respiration. Thus the larynx, though more particularly the organ of voice, is also an organ of respiration; the tongue and teeth, though belonging in one sense to the organs of digestion, are not less important as those of speech; the diaphragm and abdominal muscles, though organs of respiration, are also accessary agents of digestion. These, however, are only to be regarded as examples of the ingenuity with which one organ in the animal body is made to answer several purposes; and since all arrangements are artificial, or bear relation, not to the purpose of construction, but to the mind of the observer, the best course is to choose that which is least so, and which makes the nearest approach to the apparent objects of nature.

To acquire a just knowledge of the organs of the human body, with the views now stated, it is requisite to study their external shape and configuration, their position and contiguous relations, their ordinary size and dimensions, the mechanical divisions of which they consist, their external characters and physical properties, their intimate structure and the elementary textures of which they are composed, their chemical constitution, their vital properties and consequent actions, and the uses to which they are obviously applied. The history of the organs, arranged upon these principles, constitutes the business of DESCRIPTIVE, PARTICULAR, or SPECIAL ANATOMY. The term *Topographical Anatomy*, which has also been proposed, is inadequate, since it indicates one class only of facts,—those belonging to local relations. That of *Morphology* is equally objectionable. The term *Organology*, though preferable by reason of greater generality, is not sufficiently appropriate to justify its adoption, to the exclusion of the one already in general use.

## GENERAL ANATOMY.

THE human body consists of solid and fluid substances, the former of which are organized, and determine the shape of the body and its parts. These organized solids are not in a strict physical sense solid and impenetrable. Most of them are soft, compressible, and elastic, by reason of the fluid matter contained in their interstices; and when deprived of this by desiccation, they shrink in various degrees, and lose both bulk and weight. The general ratio of the fluid to the solid parts has been already stated to vary from 7 to 1, to 9 to 1. An adult carcass weighing perhaps from 9 to 10 stones, has been reduced by desiccation to $7\frac{1}{2}$ lbs. In short, a human body may be reduced to nearly the weight of its skeleton, which varies from 150 ounces $= 9\frac{3}{8}$ lbs. to 200 ounces $= 12\frac{1}{2}$ lbs.

These organized solids agree in the possession of certain general characters. Their internal structure appears to consist of a union of solid and liquid matter, which is observed to exude in drops more or less abundant from the surface of sections. The solid parts are generally arranged in the form of collateral lines, sometimes oblique, sometimes perfectly parallel, sometimes mutually intersecting. Such lines are denominated *fibres*, and occasionally *filaments*. In other instances the solids are observed to consist of minute globular or spheroidal particles, connected generally by delicate filaments. Most of these solids anatomists and microscopical observers have attempted to resolve into what they conceive to be an ultimate fibre or last element; but this inquiry leads beyond the bounds of strict observation.

Most of the solids may be demonstrated to be pene-

General Anatomy.

trated by minute ramifying tubes or bloodvessels, which traverse their substance in every direction, and in which is contained the greater part, perhaps the whole, of the fluid matter found in the solids. In a few in which ramifying vessels cannot be positively demonstrated, their existence is inferred by analogy from those in which they can. The filamentous, fibrous, or globular arrangement, with the distribution of arborescent vessels, constitutes organisation. The substances so constructed are named *organised tissues* (*telæ*, *textus*), or *textures*, or simply *tissues*.

The organised solids also resemble each other in chemical constitution. They may be resolved into proximate principles, either the same or very closely allied. The proximate principles most generally found are albumen, fibrin, and gelatine, one or other of which, sometimes more, form the basis of every tissue of the human body. Next to these are mucus, and oily or adipose matter. Osmazome or extractive matter is found in certain tissues. And lastly, several saline substances, as phosphate of lime, carbonate of lime, soda, hydrochlorate of soda, are found in variable proportions in most of them. Of these principles albumen and fibrin, which are closely allied and pass into each other, are the most common and abundant. Osmazome, which is probably a modification of fibrin, is less frequent. These also are contained in the blood, and probably derived from that fluid. Gelatine, though not found in the blood, is nevertheless a principle of extensive distribution, being found in skin, filamentous tissue, tendon, cartilage, and bone. These proximate principles are resolved, in ultimate analysis, into carbon, oxygen, hydrogen, azote, phosphorus, chlorine, and sulphur. From the saline substances, calcium, potassium, sodium, chlorine, iron, manganese, and, according to some, titanium and arsenic may be obtained.

The organised solids, which enter into the composition of the human body, though agreeing in the characters now mentioned, differ, nevertheless, in other respects. The most remarkable differences of this kind consist in peculiarities in the arrangement of their constituent fibres, peculiarities in the nature of these fibres, and different proportions or modifications of their proximate chemical principles. From one or other of these circumstances the organised solids may be referred to the following 17 elementary tissues:—Filamentous or cellular tissue, including ordinary cellular membrane, and adipose membrane; artery, vein, with their minute communications, termed capillary vessels, and the erectile vessels; lymphatic vessel, and gland; nerve, plexus, and ganglion; brain, or cerebral matter; muscle; white fibrous system, including ligament, periosteum, and fascia; yellow fibrous system, including the yellow ligaments, &c.; bone and tooth; gristle or cartilage; fibro-cartilage; skin; mucous membrane; serous membrane; synovial membrane; and lastly, glandular structure, or the peculiar matter which forms the liver, the pancreas, the kidneys, the female breast, the testicle, and other organs termed glands.

These tissues may be distinguished into orders, according to the mode of their distribution in the animal frame. Several,—for instance filamentous tissue, artery and vein, lymphatic vessel, and nerve,—are most extensively distributed, and enter into the composition of all the other simple tissues. To these, therefore, which are named by Bichat general or generating systems, the character of *textures of distribution* may be applied. A second order, consisting of substances confined to particular regions and organs, and placed in determinate situations, viz., brain, muscle, white fibrous system, yellow fibrous system, bone, cartilage, fibrocartilage, and gland, may be denominated *particular tissues*. To a third order, consisting of substances which assume the form of a thin membrane, expanded over many different tissues and organs, may be referred skin, mucous membrane, serous membrane, and synovial membrane, under the denomination of *enveloping tissues*. It may indeed be objected that the circumstance of mechanical disposition is insufficient to communicate a distinctive or appropriate character, and several of the tissues referred to the second head, *e.g. fascia*, must, on this principle, be referred to the third. The objection is not unreasonable. But it may be answered that it is almost vain to expect an arrangement entirely faultless; and the present is convenient in being, on the whole, more natural, and therefore more easily remembered, than any other. A distinct idea of it may be formed from the following tabular view.

| | | |
|---|---|---|
| General or Common Tissues. | Filamentous tissue. | |
| | Artery. | Capillary vessel. |
| | Vein. | |
| | Lymphatic vessel. | |
| | Nerve. | |
| Particular Tissues. | Brain. | |
| | Muscle. | |
| | White fibre. | Ligament. Periosteum. Fascia. |
| | Yellow fibre. | Yellow ligaments. Ligamentum nuchæ. |

| | Fibro-cartilage. | |
| | Gland. | |
| Enveloping Tissues. | Skin. | |
| | Mucous membrane. | |
| | Serous membrane. | |
| | Synovial membrane. | |

### The Fluids or Liquids.

The fluids of the animal body are various, but may be distinguished into three sorts; the circulating nutritious fluid named the blood; the fluids which are incessantly mixed with the blood for its renewal; and those which are separated from it by secretion.

I. The blood is well known to be a viscid liquid, of red colour, peculiar odour, and saline, something nauseous taste. Its temperature in the living body is about 97°; its specific gravity is about 105 to water as 100. Its quantity is in the adult considerable, varying from seventeen and nineteen pounds (Lehmann) to thirty pounds.

The colour of the blood varies in different parts of the system. In the left auricle, ventricle, and arterial trunks generally, its colour is bright scarlet, a tint which it loses in the capillary vessels. In the veins, venous trunks, right auricle, right ventricle, and pulmonary artery, its colour is a dark or purple-red, or Modena. As it moves from the trunk and branches through the minute divisions of the pulmonary artery, it gradually parts with this tint; and in the branches of the pulmonary veins it is found to have acquired the bright scarlet colour which it has in the left auricle, ventricle, and aorta. Hence the Modena or dark-coloured blood is distinguished as venous, or proper to the veins; and the bright red or scarlet-coloured as proper to the arteries.

Globules or blood corpuscula.

According to the results of microscopic observation, blood consists of red particles suspended in a serous fluid. On the shape of these red particles various opinions have been entertained. Generally represented as globular, Hewson describes them as flattened spheroids, or lenticular bodies, a view which is partly confirmed by the observations of Prevost and Dumas, of Beclard, of Hodgkin and Lister, of Gulliver and Wharton Jones. The opinion of Home and Young, that the flattening of these globules is a process posterior to the discharge of the fluid, is not improbable. These particles have, indeed, since the time of Hewson, been almost universally represented as consisting of a cen-

General Anatomy.

Globules or blood corpuscula.

tral transparent whitish globule, inclosed in a red translucent vesicle, which gives them the shape of an oblate spheroid. The diameter of these particles is estimated, by the subdivided scale of Kater, the micrometer of Wollaston, and the eriometer of Young, at $\frac{1}{5000}$th, and by the common micrometer, at $\frac{1}{1700}$th of an inch. (*Phil. Trans.*) Mr Gulliver estimates the average diameter of the human blood-corpuscle at $\frac{1}{3200}$th part of an English inch, and the average thickness at $\frac{1}{12400}$th part. This description applies to the blood circulating in the vessels.

In man, and the MAMMALIA in general, the blood-globules have, like a biconcave disk, a depression on each side of the broad surface. In the camel tribe they have an oval or elliptical outline, but agreeing in size and structure with the corpuscles in the Mammalia in general. In Birds, Reptiles, and most Fishes, they are oval disks, with an apparent central elevation. But the oval shape is liable to vary, and is in some osseous fishes shortened to nearly a circle. The blood-disks of the lamprey, and other cyclostomatous fishes are circular and biconcave. In the Aspondylous classes, or those void of vertebræ, the blood-corpuscles are colourless and flattened disks; but as to figure, in some they are orbicular, in others oblong oval.

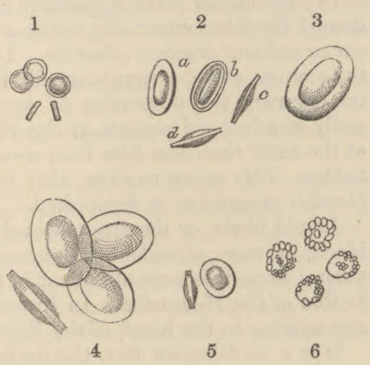

Fig. 1. Red particles of human blood (Wagner).
... 2. Red particles of the blood of the common fowl. *a*, Ordinary appearance when the flat surface is turned towards the eye. *b*, Appearance sometimes presented by the particle in the same portion. *c*, *d*, Different appearances of the particle viewed edgeways.
... 3. Red particles of the frog.
... 4. Red particles of the *Squalus squatina* (Wagner).
... 5. Red particles of the *Lophius piscatorius*, or angler fish.
... 6. *Corpuscula* from the blood of the scorpion.

As to size of the globules in relation to the different kinds of animals, the general rule is, that in the Mammalia they are smaller than in Birds, Fishes, and Reptiles; and in the small Mammalia they are as large as in the large Mammalia. In the harvest mouse the corpuscles are as large as those of the horse; and in the common mouse they are larger than in the ox and horse. The blood-corpuscles of the elephant are larger, [$\frac{1}{2745}$th of an inch,] than those of any other mammiferous animal; they are next in size in the sloth; next in the whale, in which they are larger than in man; next in the capybara and the porpoise. They appear to be smallest in the goat and deer family. In the Napu musk-deer the corpuscles are the smallest yet observed, $\frac{1}{12325}$th of an inch; those of the Stanley musk-deer are about the same size ($\frac{1}{10825}$th); in the ibex (*Capra Caucasia*) they are larger; and in the goat a little larger, being about double the size of those of the Napu musk-deer.

In Birds in which the corpuscles are oval, there is considerable variation in size. But, in general, the long diameter is greater than the diameter of the corpuscles in the Mammalia; while the short diameter varies from the $\frac{1}{4000}$th part of one inch to the $\frac{1}{10000}$th part of one inch. In the majority, the short diameter is about the same as the diameter of the circular corpuscles in man.

In Reptiles in general, in which the corpuscles are oval, they are much larger than in the Mammalia; the average long diameter being about $\frac{1}{1260}$th of one inch, and the average short diameter about $\frac{1}{2286}$th.

The corpuscles are largest in size in what are called the AMPHIBIA, including the frog, toad, triton, and siren. In the frog, the long diameter is $\frac{1}{1108}$th part of one inch, the short diameter $\frac{1}{1821}$th. In the siren, the long diameter is $\frac{1}{420}$th part of one inch, and the short diameter $\frac{1}{760}$th part of one inch.

In the large Ruminants and Rodents the corpuscula are larger than in the small species. The FERÆ, if arranged according to the size of the corpuscula, would assume the following order: the seal, dog, bear, weasel, cat, viverra. Among genera of doubtful affinity, if regard be given to the size of the blood-corpuscula, the hyæna would be arranged with the CANIDÆ, *Basaris* with the Ursine family, and *Cercoleptes* with the VIVERRIDÆ. In the fox the corpuscles are smaller than in the dog.

In the Frog, salamander, and other lower vertebrated animals, the large Corpuscula consist of a thin, transparent vesicular covering, enclosing another body in general oval, which appears to be solid, and surrounded by a quantity of soft red coloured matter. This inclosed body has been named a *nucleus.* When weak acetic acid is dropped upon these corpuscula, the colouring matter is removed, the nucleus becomes distinct, and the envelope is rendered faint. Strong acetic acid dissolves the envelope, and the nucleus escapes.

Some observers have attempted to demonstrate an analogy between the *nucleus* of the lower VERTEBRATA and the central spot of the human corpuscula. But according to the testimony of the most careful observers, it is not possible to recognise in the corpuscula of the Mammalia any body similar to the *nucleus* of the lower vertebrated animals.

When blood is drawn from the vessels and immediately afterwards examined by the microscope, the red corpuscula are observed dispersed in a confused manner in the *liquor sanguinis*, as is represented in Fig. 2. In the course of half a minute or a little longer, the red corpuscula are seen to overlap each other, and assuming the appearance of standing on their edges, to be applied to each other by their broad surfaces, like a pile or rouleau of coins. In a small quantity of blood several piles or rolls of blood-disks are in this manner formed; the direction of these is not exactly straight, but often slightly curved; and the rolls intersect each other so as to form interstitial spaces. In the case of healthy blood, these intervening spaces are small. In the case of blood that is drawn during the state of inflammation, they are larger.

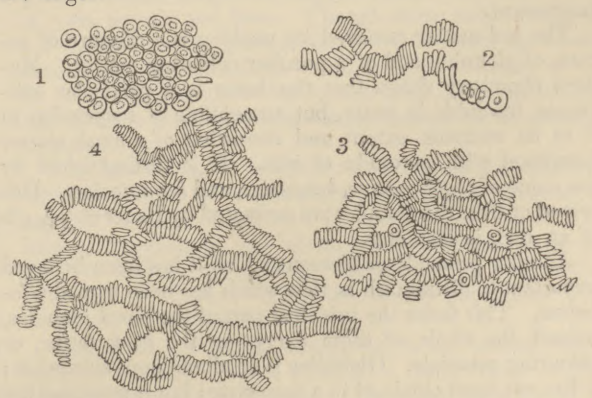

Fig. 1. Red *corpuscula* of healthy blood dispersed confusedly in *liquor sanguinis* (W. Jones).
... 2. Arrangement of the red *corpuscula* like coins in rolls, when beginning and when fully formed.
... 3. The irregular net-like arrangement of the rolls of red *corpuscula* in healthy blood. Meshes small.
... 4. The net-like arrangement of the same rolls presented by buffy blood. The meshes are large.

**Globules or blood-corpuscula.**

Henle admits two sorts of blood *corpuscula;* the one coloured, those namely belonging to the vertebrated animals, and especially to Mammalia, Birds, and Fishes; another sort, colourless, found mostly in the lower vertebrated animals, as the frog and triton, and in the Aspondylous animals. These are the same as those called lymph-globules. They are smaller in size than the coloured globules; those in the frog being 0·005 in diameter, according to Wagner. The proportion of these colourless globules to the coloured particles, varies according to rate of feeding and other circumstances. After the blood of a healthy frog has stood two hours, there are, in one drop of the upper stratum, among 55 coloured globules, 76 colourless particles.

**Mechanical separation; its results.**

Discharged from the vessels, the blood exhales, during the process of cooling, a thin watery vapour, consisting of water suspending animal matter capable of impressing the sense of smell, and undergoing decomposition. During the same space it is observed to be converted into a firm mass, which, though still soft and elastic, is entirely void of fluidity. As this process advances, a thin watery fluid, straw-coloured, not perfectly transparent, is observed to exude from every part of the solid mass, which also diminishes in size, till at length it is found floating like a tolerably thick cake in the thin watery fluid. The thick solid mass is named the clot or *coagulum;* the watery fluid is denominated *serum;* and the process of the separation, which is spontaneous, is termed *coagulation.* The blood at the same time is said to discharge carbonic acid.

The clot, if divided and washed in water often changed, or in alcohol or *aqua potassæ,* may be deprived of its red colour, and made to assume a gray or bluish-white tint. This gray mass, which is tough, coherent, opaque, and more or less dense, homogeneous, but void of traces of organic structure, consists chiefly of albumen or fibrin, or a substance partaking of several of the characters of both. To this substance the blood owes its viscidity and its property of spontaneous coagulation; and from the circumstance of its resemblance to the lymph or albuminous fluid which is effused from wounds and inflamed surfaces, and to the fibrin of muscle, and the albumen of many of the tissues, it may be regarded as the most vital and nutritious part of that fluid. It is a mistake nevertheless to assert, as is done by Beclard and others, that this substance presents to the microscope the aspect and structure of muscular fibre. Its aspect is by no means so regular as this, nor can its particles be said to present traces of organic structure or arrangement.

The red matter removed by washing is a mixture of serum, of globules, and of a peculiar colouring matter. Modern chemistry shows that the latter is a particular substance, insoluble in water, but susceptible of suspension in it to an extreme extent, and consisting of animal matter combined with peroxide of iron. It is distinguished by the name of *zoohæmatine, hæmatine,* and *hæmatosine.* Deprived of this, the globules are estimated by Bauer at $\frac{1}{2000}$th of an inch in diameter.

Another principle or element which it has been believed important to distinguish is, that which has been named *Globuline.* This forms the principal part of the blood globules, indeed, the whole of them excepting the *hæmatosine,* or colouring principle. Globuline is an albuminous substance; it has not been obtained in a pure state; but it possesses the composition and characters of albumen. By stirring blood so as to separate the fibrin, and mixing it with six volumes of a saturated solution of sulphate of soda, and then boiling the mass with alcohol acidulated with sulphuric acid, sulphate of hæmatosine is dissolved, and sulphate of globuline remains. This is gray or white, and is said to contain four atoms of sulphuric acid and one of proteine.

General Anatomy.

**Mechanical separation; its results.**

The serum, with the taste and odour of the blood, rather alkaline, coagulates at 162° F. or on the addition of acids, nitrate of silver, or corrosive sublimate, and then resembles boiled white of egg. The coagulated matter is albumen; and a little water containing soda and salts of soda may be separated. It is a remarkable difference between this albumen, which is suspended in the serum, and that which constitutes the clot, that while the former requires heat as a re-agent, the latter assumes the solid form spontaneously.

The specific gravity of arterial serum is 1022; of venous serum 1026.

The proportion of serum to clot varies in different animals, in different individuals, and in different states of the system.

In the human body a quantity of five ounces of blood usually furnishes about one ounce and two drachms, or one ounce and four drachms of serum. In inflammatory diseases the amount of the serum is usually increased. In fever, on the contrary, the proportion of serum is diminished, especially at advanced periods of the disease. But the clot is at the same time less firm than usual, and is soft, loose, and flabby. This seems to show, that the force with which the blood is coagulated is diminished.

Liquid fibrin, or the spontaneously coagulable part of the blood, is most abundant in warm-blooded animals; and among these it is more abundant in the blood of Birds than in that of the Mammalia. In Fishes it is scanty; and it is also sparing in the blood of the Reptiles and Amphibia.

It is a well-known fact, that in frogs the blood does not coagulate on exposure of the vessels to air, as it does in the Mammalia. This must be owing, either to the blood of these animals containing a much smaller proportion of fibrin than that of the Mammalia, or the fibrin having much less coagulating power.

This property of spontaneous coagulating power has been supposed by Saissy and others to bear some relation to the state of respiration, or what may be denominated the intensity and energy of that function in the different classes of animals; and the idea seems accordant with the facts. In Birds the function of respiration is most fully developed. In Reptiles and Fishes it is very imperfectly developed.

***Liquor Sanguinis* or Plasma.**

When blood, drawn from the veins of a person labouring under acute rheumatism and other inflammatory diseases, is undergoing coagulation in a glass vessel, a colourless fluid may be perceived round the edge of the surface; and, after an interval of four or five minutes, a bluish appearance is observed from the formation of an upper layer of the blood, in consequence of the subsidence of the red particles to a certain distance below the surface, and the clear liquor being left between the place of the red particles and the edge of the vessel. This liquid may be collected by a spoon and placed in another vessel, where it is first clear, though opalescent, viscid, homogeneous. After some time, however, it undergoes separation into two parts, one coagulated, the other fluid. The coagulated part is the fibrin of the blood, or that which is spontaneously coagulable; the fluid part the serum. The opalescent liquor has been named *Liquor Sanguinis* (Babington).[1]

To this the name of *Plasma* has been given by Müller, Henle, and other German writers. The former by filtering the blood of the frog, which coagulates very slowly, causing the larger corpuscula to be retained by the filter, and the *liquor sanguinis* to come though clear and colourless, obtained it in a separate form.

---

[1] Some Considerations with respect to the Blood, &c. *Medico-Chirurgical Transactions,* vol. xvi., p. 293.

General Anatomy.

Chemical constitution.

Oil or fat.

From the facts now stated, it seems reasonable to infer, that the element of the blood which is called *Liquor sanguinis* and *Plasma*, is the coagulable part, or the albuminous or fibrinous, freed from the colouring matter and the serum.

In 1830, Dr Babington found a yellow concrete oil in blood in the state of health;[1] Boudet, in 1833, found in the serum a peculiar oily or fat matter, to which he gives the name of seroline, and which melts at 97° F.;[2] and Gmelin, Chevreul, and Lecanu, obtained from the blood stearine and elaine. In certain morbid states these adipose principles are liable to become greatly increased in amount, and their presence then renders the serum opaque and milky-like. The globules are often at the same time deficient (Lecanu).

The chemical constitution of the blood and its elements has been examined by many chemists with different degrees of accuracy and completeness. It may be sufficient here to advert to the results of those given by Denis and Lecanu, the former of which was given in 1830, and the last was published in 1837.

In the first place, it is to be observed, that one thousand parts of blood consist of 869 parts of serum, and about 131 parts of what has been named coagulum, that is, globules and colouring matter.

In the second place, it is admitted, that the serum contains all the immediate principles of the blood, excepting fibrine and colouring matter; that the fibrine and colouring matter make part of the globules; and that the serum represents exactly the fluid, in the midst of which, during life, the globules float; while the clot or coagulated portion represents the globules themselves, though in a state more or less deformed and altered.

For these reasons, chemists in ascertaining the chemical constitution of the blood have subjected the serum only to accurate analysis.

The two following tables exhibit the quantitative analyses of the serum, as given by Denis and Lecanu.

According to Denis.

| | |
|---|---|
| Water .................. | 900·0 |
| Albumen ............... | 80·0 |
| Soda ..................... | 0·5 |
| Lime.................. } Magnesia traces ... } | 0·2 |
| Sulphate of potash ... | 0·8 |
| Sulphate of soda ...... | 0·8 |
| Phosphate of soda .... | 0·4 |
| Chloride of sodium ... | 4·0 |

| Hydrochlorates of soda and potash......... | 6· | 5·52 |
| Alkaline. Subcarbonate... } Phosphate ...... } Sulphate......... } | 2·10 | 2· |
| Subcarbonate of lime and magnesia, phosphate of lime and magnesia | 0·91 | 0·87 |
| Loss.................... | 1· | 1·41 |
| | 1000·00 | 1000·00[4] |

These tables show the substances contained in the blood taken as a whole, and the proportions, as nearly as may be, in which each substance is contained. But it is of consequence to ascertain, as nearly as may be practicable, the proportion in which these articles are present in the serum and the globules respectively. This Lecanu attempts to exhibit in the following table, which he gives as representing in man the medium composition of the venous blood in the normal state.

| | | | |
|---|---|---|---|
| Free oxygen, | | | |
| ... azote, | | | |
| ... carbonic acid, | | | |
| Extractive matters, | | | |
| Fat phosphorated matter, | | | |
| Cholesterine, | | | |
| Seroline, | | | |
| Free oleic acid, | | | |
| Free margaric acid, | | | |
| Hydrochlorate of soda, | | | |
| ... of potash, | | | |
| ... of ammonia, | 10·9800 | | |
| Sulphate of potash, | | Serum | 869·1547 |
| Carbonate of soda, | | | |
| ... lime, | | | |
| ... magnesia, | | | |
| Phosphate of soda, | | | |
| ... lime, | | | |
| ... magnesia, | | | |
| Lactate of soda, | | | |
| Salt with fat fixed acids, | | | |
| ... volatile and yellow colouring matter, | | | |
| Albumen, | 67·8040 | | |
| Water, | 790·3707 | | |
| Fibrin, | 2·9480 | | |
| Hematosine, | 2·2700 | Globules, | 130·8453 |
| Albumen, | 125·6273 | | |
| | 1000·0000 | | 1000·0000 |

Further, if we suppose that one thousand parts of blood give

869·1547 of serum,
130·8453 of globules,

these numbers may then be represented in distribution in the following manner.

| | | | |
|---|---|---|---|
| 869·1547 | | Serum. | |
| 130·8453 | 2·9480 | Fibrin. | Globules. |
| | 2·2700 | Globules. | |
| | 125·6273 | Albumen of globules | |
| 1000·0000 | | | |

The main point which it is important to know, is that blood consists of albumen and fibrin to the extent of between 78 and 81 parts in the thousand, suspended in about 902 parts of water, with some adipose matter, and salts, chiefly of soda, potash, and lime. Though these saline substances are neutral, yet in general the blood presents an alkaline reaction, which is ascribed to a slight predominance of soda. In persons and animals that subsist much on vegetable food, this alkaline reaction ought also to depend on the presence of potash.

The blood may be believed to contain all the substances which are found to be present in the different textures and organs. It either does so, or it contains their material elements, excepting in one instance. It contains, so far as is hitherto known, no gelatine. According to Marchand, it contains a little urea. But in the healthy state, this is in exceedingly small quantity.

The blood, that is, the serum, has in the normal state an alkaline reaction, which is ascribed to the presence of phosphate of soda, not carbonate. The saline matter is of use in maintaining the fluidity of the blood; in contributing to

General Anatomy.

its red colour (Stevens); and probably it may be useful in contributing to certain galvanic or electro-magnetic actions in different organs.

Chemical constitution.

From the blood and its elements the animal tissues derive the materials of their nutrition, and the different secreted fluids are formed.

Arterial blood differs from venous according to Lecanu, besides the difference in colour already mentioned, chiefly in the following circumstances.

It contains a larger amount of globules, a greater proportion of fibrin, an amount of albumen, extractive matters, saline and fatty matters, to all appearance equal, more oxygen in proportion to its carbonic acid, less combined carbon and oxygen. In consequence chiefly of the larger proportion of globules, it shows a greater tendency to coagulation, and the clot is more bulky, more firm, and gives a small proportion of serum. Its density is to that of venous blood as 1050 to 1053 (J. Davy).

The proportion of serum is smaller, and the proportion of globules greater in man than in the female; in the blood of sanguine persons than in the blood of lymphatic individuals of the same sex; in the blood of adults than in the blood of children and of the aged; and in the blood of persons well fed than in those imperfectly nourished.

The blood of the portal vein contains a smaller proportion of globules and a larger proportion of water, serum, and fat, than the blood of the venous system in general.

The blood of the placenta is greatly more rich in globules, and contains less water than the blood of the veins.

In the fœtus, the blood contains little coagulable matter; and this principle is entirely wanting in the blood of the menstrual discharge.

Chyle and Lymph.

II. The fluids received by the blood are chyle and lymph. Chyle is derived from chyme, a gray pulpy substance, formed from the alimentary mass in the stomach and duodenum. Detached from this substance, and received by the chyliferous tubes, it is whitish and scarcely coagulable. In the mesenteric glands, it becomes more coagulable, and assumes a rose colour. Lastly, in the thoracic duct, and before joining the mass of blood, it is distinctly rose-coloured, coagulable and globular in its particles. In the branches of the pulmonary artery it appears to become perfect blood. Lymph is a colourless, viscid, albuminous fluid, imperfectly known.

The globules or *corpuscula* of the chyle, of the thymus fluid, and of the lymph, appear delicately granulated on the surface. They are generally globular or lenticular, never following the differences in shape and size of the blood-disks in different classes of animals, nor in birds affecting the long oval figure of the nucleus of the red corpuscle.

The globules of chyle, thymus fluid, and of lymph, are smaller than the colourless globules of the blood. They also differ in structure. In the last, two, three, or four nuclei are seen when the envelope is made more or less transparent by acetic, sulphuric, citric, or tartaric acid. But the globules of chyle, of lymph, and of the thymus fluid, like the nuclei of the red corpuscula of the blood, are only rendered more distinct and smaller by any of these acids, so that the central part presents no regular nuclei, or divided nucleus, such as are contained in the colourless globules of the blood. In short, according to Mr Gulliver, who has examined these bodies with great care, the colourless globules of the blood have the character of elementary cells, while the globules of chyle resemble, and probably are, nuclei or immature cells.

The microscopical and chemical characters of the globules of the chyme, of the thymus, and of the lymphatic glands, are nearly the same. When quite recent, they swell on being mingled with pure water, as does the nucleus of the blood corpuscle. When well mixed with a strong solution of alkali, or of a neutral salt, the globules undergo partial solution, become misshapen or faint, forming a ropy tenacious compound with the fluid (Gulliver).

Secreted fluids.

III. Of the fluids separated from the blood, all cannot be said to belong to the animal body. Several,—for instance, the perspired fluid of the skin and lungs, the fluid of the cutaneous and mucous follicles, and the urine,—become, after secretion, foreign to the body, and require to be removed. Those belonging to the body are such as are prepared for some purpose within it, and after this are either re-absorbed, or, being decomposed, are expelled. Of the former kind, fat, serum of serous membranes, and synovia, afford examples. To the latter description belong tears, saliva, gastric juice, pancreatic fluid, bile, the seminal fluid of the male, and the milk of the female, all of which are the result of a distinct glandular secretion for a specific purpose, after which they are expelled from the economy.

Of the fluids secreted upon the surface, or on different points of the alimentary canal, some are alkaline, some acid; but all agree in possessing some albuminous or albuminoid principle, which is believed to act by what is called catalysis, or being placed in contact with foreign bodies introduced, to act on them, either by inducing chemical changes, or by causing actions of assimilation.

1. Thus saliva contains salivine, a species of diastase, besides sulphocyanic acid, chlorides, lactates, and phosphates. It is alkaline when food is taken, and during mastication.

2. Gastric juice contains pepsine and chlorine or hydrochloric acid, and, according to some, lactic acid.

3. Bile contains choleic acid or biline, taurine, free soda, and the salts of the blood; while taurine, which is an albuminoid principle, contains sulphur. Thenard and Gmelin found in it picromel. Bernard states that the liver forms sugar.

4. Pancreatic juice contains, besides an albuminous principle, which may be named Pancreatinine, according to the observations of Bernard, free soda, which gives it an alkaline reaction.

5. The intestinal fluid (*Succus intestinalis*) has a reaction, sometimes acid, sometimes alkaline.

Urine may be regarded as urea suspended or dissolved in water. Urea is the peculiar and characteristic element of the secretion. It contains also a little uric acid, which is probably produced from the urea, as this acid can scarcely be said to be a constituent of healthy urine. The other ingredients are saline matters common to the blood and the urine or complementary between them.

The density of healthy urine varies from 1015 to 1033, water being as 1000; and the average, as determined from the examination of the urine in fifty instances of persons in good health, is at the highest 1026 and at the lowest 1017. The general average, therefore, amounts to 1022. This is understood while the quantity discharged daily is from 45 to 53 ounces, which is about the general average in healthy individuals who consume liquids at the ordinary rate.

This density above that of water, urine owes to the presence of urea and saline matters. If the urea and saline matters be increased, the density of the urine is increased; if they be diminished, the density of the urine is also diminished.

It may here be observed, that urea is the form which the elements of the fibro-albuminous parts of the blood assume, after these fibro-albuminous principles have been employed in repairing the waste of the tissues. If the proximate chemical principles of albumen be compared with those of urea, it is seen that the latter are the complement of the former. Thus,—

General Anatomy.

Secreted fluids.

| | Hydrogen. | Carbon. | Oxygen. | Nitrogen. |
|---|---|---|---|---|
| Albumen consists of...... | 7·77 | 50·00 | 26·66 | 15·55 |
| Urea consists of.......... | 6·66 | 20.00 | 26·66 | 46·66 |

Thus while albumen and urea contain the same proportion of oxygen, the former contains one-seventh more hydrogen, three-fifths more carbon, and two-thirds less nitrogen. It is known that the former proportions of these principles are employed in repairing the waste of the albuminous tissues, especially the muscular system; and while carbon and oxygen are discharged by the lungs, and carbon, oxygen, and hydrogen by the liver, the large superfluous portion of nitrogen not required, namely 31 per cent., uniting with hydrogen, oxygen, and carbon in the form of urea, is left to pass through the blood, and by means of the kidneys to be expelled from the system.

In the healthy state urine is always slightly acid when discharged. This acidity is liable to become excessive on the one hand; and on the other to diminish so far as to render the urine alkaline. This change is much favoured, if not wholly occasioned by the presence of mucus, purulent matter, or other azotised substances.

## BOOK. I.

### CHAP. I.—FORMATION, DEVELOPMENT, AND ULTIMATE ANALYSIS OF THE TISSUES.

Cell-formation.

It has, at different times, in the history of Anatomy and Physiology, been an object with various ingenious observers to trace to some one simple element all the different forms which the animal textures assume. In general, however, these attempts have not been successful, and have led to generalisations too great to be just, and more fanciful than to be founded in careful observation.

In the year 1773 William Hewson communicated to the Royal Society his account of the Red Particles of the Blood, making known among other points the fact of the existence in them of an opaque central spot, and of an opaque body in the globules of the oviparous vertebrated animals. The application of this fact it was not easy at that time, perhaps not possible, to discover. After the lapse of sixty years, in 1833, Robert Brown, well known as a skilful botanist, in Observations on the family of the *Orchideæ*, in the *Transactions of the Linnæan Society*, made known the existence of a vesicular or celluliform body containing a solid, to which he gave the name of *Areola* or *Nucleus* of the cell. The signification, however, of this structure was little or not understood. At length in 1838, J. M. Schleiden, professor of Botany in the university of Jena, made known the fact, that when a slice from the succulent part of certain plants is examined under the microscope, part of it appears to consist of an infinite number of minute vesicles, rounded or polygonal, generally flattened, cohering by the margins, and containing in their interior matters coloured or colourless. This appearance is most perceptible in various monocotyledonous orders, as *Orchideæ*, *Commelineæ*, and *Asphodeleæ*, and many dicotyledonous orders, as the *Cacteæ*, *Balanophoreæ*, &c. But it is also found in different degrees of distinctness in the greater part of the vegetable world. This close vesicle generally contains a fluid, sometimes jelly-like; but it also contains a body more or less rounded, to which Schleiden applied the name of Cell-Kernel and *Cytoblastus*. It is attached on one side to the inner surface of the vesicle, but on the other is free. When perfectly formed it is a flat, lenticular, sharply defined, transparent, pale-yellow body, in which it is possible to distinguish one or two, seldom three, hollow corpuscula. These are called *nucleoli*.[1]

General Anatomy.

Cell-formation.

The Cytoblast is represented by Schleiden to be a nitrogenous body or proteine compound, perhaps in its simplest state pure proteine. Its minuteness is almost inconceivable, being from 0·00009 to 0·0022 of one inch in circumference.[1]

The Cytoblast has been more generally known under the name of *Nucleus;* and the vesicle containing it has been called Nucleated Cell; (*Cellulæ Nucleatæ*); *Elementary Cells; Primary Cells.*

In 1839, the year following that in which Schleiden published his doctrines on Phytogenesis, or the formation of plants, Schwann made known the fact, that in the animal tissues the same structure exists which Schleiden had shown is found in those of the vegetable world.[2] The fact has been stated in general terms by Henle in the following manner. In most vegetable and animal tissues, there exist during the whole period of life, or a certain time of the development of these tissues, microscopical *corpuscula* of peculiar and very characteristic shape. These are minute bladders or *vesiculæ*, consisting of a fine enclosing membrane and a fluid, occasionally something granular, content. In the wall of these *vesiculæ* lies a smaller darker body, namely, the Kernel or *Nucleus* of the cell,—Cytoblast of Schleiden; and this is generally distinguished by one or two, rarely more, darker and almost regularly round specks (*Nucleoli*).

It is here to be observed, that nucleated cells as thus described are not perceptible in the tissues at all times of their existence. It is chiefly in the early period, or that of formation and development that they are observed. The process of cell-formation is in truth progressive; and this circumstance has led Schwann, Henle, and others, to speak of the life of the cell and of its youth or early period of existence, though Henle himself makes an apology for the use of the term youth in this manner.

The cells lie in a shapeless or amorphous matter, the *Cytoblastema*, in which they float when this is fluid, and are imbedded when it is semi-solid or solid. The solid Cytoblastema, in which the cells are more or less compressed, appears like inter-cellular substance, and is also the connecting medium of the cells.[3]

What is now stated embraces almost all the points in which observers are agreed. Upon all others minute but real differences of opinion exist;—upon the nature and composition of the cell, upon the mode in which cells are developed and multiplied, and upon the transformations which they undergo.

The covering or wall of the cell is allowed by most to be an albuminoid or proteine substance. It is rendered transparent and indistinct, but not dissolved by acetic acid. The contents of cells are semifluid, often granular, that is, consisting of small grains or bodies differently coloured, of fat particles, and of a fine molecular substance, that is minute atoms, the nature of which is unknown.

On the nature and general characters of the body called

General Anatomy.

Cell-formation.

the *Nucleus*, opinions are discordant. In some instances the nucleus has the appearance of a granular body, more or less solid, while in other instances it has that of a pale vesicle, with a distinct cell-wall and fluid content. The pale vesicular form is the most general, and, according to Kölliker, it is the constant form of the early stages of the life of the cell. That the composition of the nucleus is different from that of the cell, is shown by the fact, that many agents which act upon the one, have no effect upon the other. Kölliker is of opinion, that the membrane of the *nucleus* is composed of pyin, the clear content of albumen, and the *nucleolus* of fat.

In the animal tissue cell, as in the vegetable cell, the nucleus is commonly situate on the wall of the cell, apparently imbedded in its substance, but according to Schwann most frequently attached to its inner surface. Occasionally the nucleus is situate towards the centre of the cell, as is the case in the cells of cylinder epithelium.

The phenomena now mentioned are most easily seen in cartilage in its early or growing stage.

On the mode in which Elementary or Primary Cells are themselves formed, different representations have been given by different observers. In general a nucleus is first formed; and even upon this process different views are given. According to Schleiden and Schwann, in the Blastema or plastic fluid *nucleoli* first appear; and as new matter continues to collect, round one or more of these, the *nucleus* is formed. Afterwards, matter deposited on the nucleus forms the cell-wall or vesicular membrane. Henle, on the other hand, thinks, from various facts, that a *Nucleus* may be formed independent of any *Nucleolus*. He supposes in the *blastema* the existence of elementary particles or granules, which, he says, are found wherever new formations are taking place; for instance, in the yolk of the egg, in milk, in chyle, and in lymph, in the delicate commencements of glands, and the epithelium, when rapid regeneration takes place, and in pathological fluids.[1]

These elementary granules are for the most part, as far as can be ascertained, composed of fat, and a membrane inclosing the fat-drops; and he adduces, in proof of the correctness of this view, the fact made known by Ascherson, that when oil and albumen are allowed to unite in small drops, there are formed minute *corpuscula*, consisting of fat, inclosed in an albuminoid membrane.

It appears, in the *second* place, that, in certain circumstances, cells are formed without the previous existence of a nucleus. Thus, in addition to the fact, that in cryptogamic, and many higher plants, a minute spherule first appears, soon becomes a vesicle, and is eventually formed into a cell; in the *chorda dorsalis* of fishes and reptiles, cells are formed without the previous formation of any *nucleus*. It is to be remarked, however, that even in this instance, nuclei appear after the cells have been formed.

In the *third* place, it is observed that cells and nuclei are in certain circumstances formed simultaneously. Thus, in the embryonic cartilage of the toad, the formation of both bodies is so simultaneous, that Vogt never could detect nuclei without a cell-wall, or cells which did not enclose a nucleus.

On the mode in which cells are reproduced and multiplied, several conjectures have been formed, but nothing can be said to be ascertained. It is the opinion of Schwann, for the subject cannot be said hitherto to admit of proof, that the continued increase of cells is in most cases effected, though he does not show how, in the plastic fluid or blastema. In other instances new cells are formed within cells which had previously existed; and by these they are surrounded, until they have attained, by growth, a certain size, when they escape, apparently by rupturing the original or parent cell. This is supposed to be illustrated by the process of what is called cleavage in the ovum, and by what takes place in the cells of cartilage. But, excepting in these instances, this process of cell-multiplication, which has been termed *endogenous*, though common in vegetable productions, is rare in the textures of the animal world.

Influence of cells and nuclei in formation of tissues.

It was believed, with considerable confidence, when the discovery of the existence of elementary cells was made known that an easy and intelligible method was found of explaining the formation of all the textures which enter into the composition of the animal body. It is quite possible that this belief is well-founded; and in a few instances probably it may be said to be in a slight degree realised. But it must not be concealed, that the whole theory is in a state of imperfection and transition; and that it is far from presenting those clear, certain, and consistent phenomena, which might be applied with any confidence in explaining the growth and visible structure of the several tissues of which the animal body is composed. It is manifest, that in order that the cell and its nucleus should be the means of forming these tissues, they should undergo certain transformations. Now, upon these transformations, and upon the mode in which they are effected, observers are by no means agreed. In some instances it appears that the cell is the agent of transformation and creation, and in others it is the nucleus that is believed to be the agent. Schwann supposed, that to form certain tissues, as the Cellular, that is the Filamentous, the Tendinous, and the fibrous or Ligamentous, the cells become elongated and were thus converted into fibres. But though such elongation seems to take place in certain circumstances, the doctrine has not been generally admitted.

The tissues in which the agency of cells and their nuclei are believed with least certainty to be seen, are cartilage in its early state, bone in a certain degree, tooth, nerve-substance, arterial tissue, muscle, adipose membrane, and the secreting glands, as the liver, the kidney, the pancreas, the salivary glands, the female mamma.

The appearances observed during the growth of Nerve-Fibres in the embryo, particularly by Schaffner and Kölliker, are thought to afford good examples of the influence, if such it may be called, of the nucleated cell. In the earliest period of its formation, nerve substance consists almost entirely of round, mostly nucleated, cells, filled with a fine granular material, and, with the exception of being somewhat smaller, exactly similar to the nerve *corpuscula*, found in the nervous centres of the adult animal. As development advances, many of these cells send forth fine tubular processes of a structure apparently homogeneous, which unite with similar processes from other cells, and thus eventually gave rise to continuous Nerve Tubules. Kölliker finds that in young batrachoid reptiles, a complete net-work of nerve tubules is formed by this junction and coalescence of the processes from branching cells. A similar observation was made by Schwann. In this particular instance, therefore, it appears, that Nucleated Cells, by sending out some shoots, and uniting with similar offsets from other cells, eventually form tubulated structures. According to Schaffner, as the nerve tubules coalesce and increase in size, the walls of the cells from which they proceed are gradually drawn out, and merge into the walls of the tubules, while the granular content becomes continued and identified with the content of the tubules.

Henle gives schemes or plans of the mode in which the

[1] Allgemeine Anatomie, Seite 162, 163, Erste theil.

General Anatomy.

Influence of cells and nuclei in formation of tissues.

nuclei are transformed into the higher tissues;[1] and Kölliker subsequently gave his representations of the process. It was supposed by Schwann, that the nucleus disappears shortly after the cell is completely formed. But according to Retzius, Henle, and Kölliker, the nucleus is a main agent of development in many tissues. The only parts in which, according to Henle, the nucleus disappears, are the blood-globules, the cells of the epidermis and the nails, most of the fat-cells, the tubules of the crystalline lens and of tooth-enamel, and many of the cartilage *corpuscula*. But in all fibres or fibriform tissues, supposed to be formed from coalescing cells, excepting those of the lens and of enamel, the *nuclei* not only remain persistent, but they undergo, or are the agents of, certain transformations.

First, they assume an oval shape, then gradually elongating and becoming narrow, they are converted into fine dark streaks, which lie straight, angular, or curvilinear, or for some space serpentine upon their proper cells. The Nucleus corpuscula then disappear. By reason of their sharp outlines, these streaks look like fibrous tissues, and are frequently taken for elongated cells, in which case the intermediate substance is overlooked or considered as cellular substance. At this stage, sometimes the absorption of the *Nucleus* commences by being divided into a row of minute dots, which constantly become paler and smaller. Similar rows of minute dots are found in all fibrous tissues, and most numerously in the cornea and in the organic muscles.

In opposite cases the elongated *Nuclei* gradually form a mutual connection by means of threads which each send out, and which, at first delicate and pale, gradually acquire the strength and firmness of the dark *corpuscula* from whence they proceed.

In consequence of the representations now given, Henle distinguishes two kinds of fibres;—namely, Cell-fibres and *Nuclei*-fibres; the former being those in which cells are split or divided into fibres, and the latter into fibrils; the latter those in which the nuclei are elongated, and by mutual union form fibres. The latter, again, he distinguishes into two different types, according to the original position of the nucleus on the surface, or on the edge of the flat nucleus-fibre; and the position of the nucleus is regulated by the form of the Cell-Fibre. Perfectly flat nuclei-fibres have the nucleus on the surface; cell-fibres, which approach the cylindrical form have the nucleus on the edges. To the latter order, he states, belong the fibres or filaments of the cellular tissue (*tela conjunctiva*), the fibres of the cornea, and those of tooth-bone.

The *nuclei* and *nuclei*-fibres are represented by the same anatomist to be of much use in forming the texture of the bloodvessels. In the development of these tissues, layers of cytoblastema are deposited in the form of stuctureless membrane; in these nuclei are formed, and undergo various changes. In the innermost layer, cells grow round the nuclei, and form the epithelial coat of the vessel. In the next layer, which forms what has been usually called the inner coat of the vessel, the nuclei remain unchanged. In the formation of the fibrous or elastic contractile coat, the nuclei are elongated, and arrange themselves in rows or lines, in the manner already mentioned.

The second type of Nucleus-Fibres, which are arranged on the surface of the flat Cell-Fibres, are distinguished by the tendency which they manifest to shoot lateral branches, and in this manner to form junctions with other lateral branches and make a network which covers the layer of cell-fibres; so that in the normal development they are situate between two layers of cell-fibres. This mode of development may be seen in the tissues of the bloodvessels, both arteries and veins, and in the muscular coat of the viscera.

The whole of this doctrine, however, is yet in a state of uncertainty and contradiction; and it would be unprofitable in this place to spend more time upon it. Whenever under particular heads it is possible to state any well-authenticated facts, this shall be done, so far as the limits and nature of this article admit.

Relation between nucleated cells and corpuscula.

The only subject which it is required further at present to notice, is the relation between the nucleated cells and the *corpuscula* of the blood. This subject is still, notwithstanding the observations of several skilful inquirers, Martin Barry, Henle, Vogt, Kölliker, Wharton Jones, Gulliver, beset with contradictions and involved in a considerable degree of uncertainty. Nor have these difficulties been diminished by connecting with the relation between the nucleated cells and the *corpuscula*, the question regarding the formation of the latter.

One of the great sources of difficulty in the inquiry is this, that the *corpuscula* of Man and the Mammalia, though similar in several circumstances to those of the lower vertebrated and the Aspondylous animals, do not present complete resemblance to them.

According to the observations of Mr Wharton Jones, the blood of Fishes, that is, of the lower vertebrated animals, presents three kinds of cells, 1*st*, the granule blood-cell, containing a nucleus not at first visible, but discovered to be so by addition of acetic acid, which dissolves the granules and renders the nucleus evident; and, 2*d*, The nucleated blood-cell, which is the red oval *corpusculum*, but with the nucleus cellæ-form; and 3*d*, The pale or colourless granule cell. It appears further, that between the granule blood-cell and the nucleated blood-cell there subsists this relation, that they form two different phases of development of the same body; the granule cell being the early stage, and the nucleated cell the second or more advanced. It seems also probable, from the observations of the same inquirer, that the pale or colourless granule cells mentioned as the third kind, form advanced stages of the dark looking granule cell.

In the blood of the frog, which is taken as the representative of the reptile family, there are recognised two forms of *corpuscula:* 1. Granule cells in coarse and fine granular stages; and, 2. Nucleated cells in colourless and coloured stages. The nucleated blood cell in its coloured stage is the red oval corpuscle of the blood of the frog, that is, the blood globule of the frog in its most complete form.

Regarding the blood *corpusculum* of the Mammalia and Man, it appears to be certain that the central spot does not correspond to the nucleus, though this has been imagined by some observers.

In all the vertebrated animals hitherto examined, Oviparous and Mammiferous, there are, first, blood *corpuscula* in the first stage of development, or presenting the phase of Granule Cell, either coarsely grained or finely granular. Secondly, in all the animals examined there are blood *corpuscula*, in the second stage of development, that is in the phase of Nucleated Cell, which may be *a* in the colourless stage, or *b* in the coloured stage.

Regarding the nucleated blood-cell in the coloured stage, this occurs in its highest degree of development, and in great numbers, only in the Oviparous Vertebrata, in which it constitutes the red *corpusculum*, and in the early mammiferous embryon. In the fully formed blood of the Mammalia it occurs in a comparatively low degree of development, and in very small number.

[1] Allgemeine Anatomie, Seite 193, 194, 198.

In the Mammalia alone is the blood *corpusculum* found in what Mr W. Jones calls the third stage of development, or the phase of free cellæ-form nucleus. This is found in both uncoloured and coloured stages. In the former stage it is rare; in the latter it is the red corpuscle of the fully formed blood of man and the mammalia. In short, it is the opinion of Mr Jones, that the red *corpusculum* or globule of the fully formed blood of man and the mammalia is the cellæ-form Nucleus of the nucleated cell set free by the bursting of this cell itself, and become filled and red by the secretion of globuline and colouring matter into its interior.

For the facts and arguments establishing this inference, we refer to the memoirs of Mr Wharton Jones.[1]

## CHAP. II.—THE COMMON TISSUES.

*Filamentous or Cellular Tissue.* (*Tela Cellulosa,—Tissu Cellulaire,—Tissu Muqueux* of Bordeu,—*Corpus Cribrosum* Hippocratis,—*Corps Cribleux* of Fouquet,—Reticular Membrane of William Hunter.) Das Bindegewebe of Müller and Henle.

Under the name of Connecting Tissue, Henle describes a tissue consisting in its final elements of long, very fine, soft, transparent filaments, or cylinders or fibrils of uniform strength, and of a diameter varying from 0·0003–0·0008 of one line. This tissue he distinguishes into two general forms; one the shapeless or unformed Connecting Web; the other the formed Connecting Web. The first of these corresponds to what has been described by various authors under the names of Cellular Tissue, Mucous Tissue, and Filamentous Tissue. Under the second, which he divides into two orders, the Non-contractile and the Contractile Joining Web, he arranges a great number of textures in the following manner:—I. Non-contractile formed Web, including, 1. Tendon; 2. Ligament; 3. Fibrous Sheaths; 4. Fibrous Membranes, as the fibrous covering of the *Corpora Cavernosa* the *Dura Mater*, the *Membrana Tympani*, the Valves of the veins, the Neurilema, the Fasciæ, the Periosteum, and the Perichondrium; 5. The *Tunica Nervea* of the intestinal canal; 6. The External Coat of the Bloodvessels; 7. The Serous Membranes; 8. The *Pia Mater* and the Choroid Membrane;—II. Formed Contractile Joining Web, including the Skin; the *Dartos;* the Investing membrane of the *Corpora Cavernosa;* and the Contractile Web of the longitudinal and annular coat of the veins and lymphatic vessels.

Without pretending to offer any opinion upon the propriety of arranging all these different tissues under the head of Connecting Web, it may be remarked, that it is not very easy in this manner to communicate correct ideas of the true anatomical and physical characters of these tissues; and as the method already adopted in this article possesses the advantage of being at once simple, free from hypothesis, and serviceable to readers, it seems more prudent to adhere to it, after the explanations now given.

The general distribution of the filamentous or cellular tissue was first maintained by Haller and Charles Augustus de Bergen, and afterwards made the subject of elaborate discussion by William Hunter and Bordeu. It may be described as a substance consisting of very minute thready lines, which follow no uniform or invariable direction, but which, when gently raised by the forceps, present the appearance of a confused and irregular network. As these minute lines cross each other, they form between them spaces of a figure not easily determined, and perhaps not uniform. By some authors these spaces or intervals have been named cells; but, accurately speaking, the term is not fortunately applied. The component lines, which do not exceed the size of the silkworm threads, are so slender, that they do not form those distinct partitions which the term *cell* implies; and though by forcible distension, such as takes place in insufflation, or separation by forceps, cavities appear to be formed, these, it will be found, are artificial, and result from the separation of an infinity of the slender filaments of which the part is composed. These interlinear spaces necessarily communicate on every side with each other; and indeed the most distinct way of forming a true idea of the structure of the cellular tissue, is to suppose a certain space of the animal body which is divided and intersected into an infinite multitude of minute spaces (*areolæ*) by slender thready lines crossing each other. This description, derived from personal observation, renders the name of *filamentous* more appropriate to this tissue than that of *cellular* by which it is generally known.

The interstitial spaces resulting from the interlacement of these filaments do not exist as distinct cavities in the healthy state, so that they cannot be said to contain any substance solid or fluid. But when an incision is made into this tissue in the living body, it is found, that if we except those fluids which issue from divided vessels, nothing is observed to escape but a thin exhalation or vapour, which is evidently of an aqueous nature. This is what some authors have termed, from its resemblance to the serous part of the blood, the *cellular* serosity (Bichat), and the quantity of which has been greatly exaggerated. In the living body it appears not to exist as a distinct fluid, but merely as a thin vapour, which communicates to the tissue the moist appearance which it possesses.

This fluid is understood to be derived from the minute colourless capillaries named *exhalants;* and it is supposed to be no sooner poured forth in an insensible manner, than it is removed by the absorbing power of lymphatics, minute veins, or both. It is further believed, that whatever serous fluid is secreted into the interstitial spaces or cells of the filamentous tissue, is in the healthy state speedily removed; so that exhalation implies absorption; and the filamentous tissue is therefore represented as the seat of incessant exhalation and absorption.

The serous fluid of the filamentous tissue varies in quantity in different regions. In the cellular tissue of those parts which are free from fat, as in the eyelids, the prepuce, the *nymphæ* and *labia*, and the scrotum, it is said to be more abundant than in others. The peculiar structure of those parts, which is cellular, may render any excess of serous fluid more conspicuous; for it is matter of observation, that in many persons otherwise healthy these parts are not unfrequently distended with serous fluid. On the other hand, it must be remarked that the submucous cellular tissue, and that which surrounds arteries, veins, and excreting ducts, which is delicate in substance and compact in structure, contains but a small proportion of serous fluid, and does not readily admit its presence.

This fluid has been generally said to be of an albuminous nature; and if it be identical with the serum of the blood, from which it is believed to be secreted, this character is not unjustly given it. Bichat, who maintained this opinion, injected alcohol into the filamentous tissue of an animal previously rendered emphysematous, and found in various parts whitish *flocculi*, which he regarded as coagulated albumen. He also obtained the same result by immersing a portion of the scrotum in weak nitric acid; and when a considerable quantity of this tissue was boiled, it furnished much whitish foam, which Bichat regarded as albuminous.[2] These ex-

[1] *Philosophical Transactions of the Royal Society of London* for the year 1846, Part II., and *Edinburgh Medical and Surgical Journal*, vol. sixty-third, 1847, p. 529, and vol. seventy-third, 1850, p. 395.

[2] *Anatomie Générale*, tom. i. p. 50.

periments, however, are liable to this objection, that the effects in question may have arisen from coagulation of part of the filamentous tissue itself, which contains a considerable proportion of albuminous matter. The best mode of determining the point is to obtain the fluid apart, and to try the effects of the usual tests on it when isolated from the tissue in which it is lodged.

The description here given applies to the proper filamentous tissue. This substance was shown by Ruysch, and afterwards by William Hunter and Mascagni, to be penetrated by arteries and veins. Exhalants, absorbents, and nerves, it is also said to receive. The arteries certainly belong in the healthy state to the order of colourless capillaries, which are nearly the same with exhalants. It does not appear that the nervous twigs observed to pass through this tissue are lost in it; for in general they have been traced to some contiguous part.

Such are the general properties of this tissue, considered as an elementary organic substance extensively diffused through the body. In particular regions it undergoes some modifications, which may be referred to the following heads:—1. Beneath the skin, or rather under the adipose membrane,—the subcutaneous and intermuscular cellular tissue; 2. Beneath the villous or mucous membranes,—the submucous cellular tissue; 3. Beneath the serous membranes,—the subserous cellular tissue; 4. Round bloodvessels, excreting ducts, and other organs,—the inclosing tissue, vascular sheaths, &c.; 5. In the substance of organs,—the penetrating cellular tissue.

The situation of the subcutaneous filamentous tissue deserves particular notice. Though generally represented as below the skin, it is not immediately under this membranous covering. The skin rests on the adipose membrane, beneath which again is placed the filamentous tissue, extending like a web over the muscles and bloodvessels, penetrating between the fibres and bundles of the former, surrounding the tendons and ligaments, and connected by these productions with a deep-seated layer, on which the muscles move, where they do not adhere to the periosteum and to bones.

The extensive distribution of the subcutaneous filamentous tissue, the mutual connection of its parts, and its ready communication with the filamentous tissue of the mucous and serous membranes, were demonstrated by Haller, William Hunter, and Bordeu, and have been clearly explained by Portal and Bichat. The principal points worthy of attention may be stated in the following manner.

The filamentous tissues of the head and face communicate freely with each other, and with that of the brain by the cranial openings, and with the submucous tissue of the eyelids, nostrils, lips, and the inner surface of the mouth and cheeks. It communicates also with the subcutaneous tissue of the neck all round; and at the angle of the jaw, in the vicinity of the parotid gland, is the common point of reunion. To this anatomical fact is referred the frequency of swellings and purulent collections in the region of the parotid in the course of the various diseases of the head, face, and neck.

The filamentous tissue of the neck may be viewed as the connecting medium between that of the head and trunk. From the former region it may be traced downwards along the back, loins, breast, sides, flanks, and belly. At the cervical region, and between the shoulders, it is dense and abundant; and, surrounding the dorsal part of the vertebral column, it is connected with the mediastinal tissue, the submucous tissue of the lungs, and the subserous tissue of the costal pleura. At the fore part of the neck it is in like manner connected with the abundant tissue of the pectoral region, and by means of that surrounding the larynx and trachea, 1*st*, with the submucous tissue of the bronchi; and, 2*d*, with the anterior mediastinum. Passing downwards, the same communication may be traced with the intermuscular tissue of the loins and belly, the tissue surrounding the lumbar and sacral portion of the vertebral column, that connecting the mesentery and large vessels to the vertebræ, and extending all round under the muscular peritoneum, and into the pelvis, where, by means of the tissue at the posterior surface of the abdominal muscles, at the anterior surface of the *iliacus internus*, and through the obturator hole and ischiadic notch, it communicates with the filamentous tissue of the lower extremities. From the rectum and branches of the ischium it is continued along the perineum by the urethra, and into the scrotum.

In the whole of this course, it is abundant in the space before the vertebræ, round the *psoæ* and *iliacus internus* muscules, and round the bladder, rectum, prostate gland, and womb. The tissue surrounding the vertebral column communicates with that in the interior of the column by the intervertebral holes.

The armpit may be considered as the point of union between the filamentous tissue of the trunk and that of the upper extremities, while the groin is the corresponding spot for the lower extremities. These facts should be kept in mind in observing the phenomena of diseases of this tissue.

Notwithstanding this general connection, however, certain parts of the tissue are so dense and close as to diminish greatly the facility of communication. Thus, along the median line it is so firm, that air injected invariably stops, unless impelled by a force adequate to tear open its filaments; and water is rarely found effused in this situation. In the neighbourhood of some parts of the skeleton also, as at the crest of the ilium, over the great trochanter, and on the shin, the filamentous tissue is very dense and coherent.

In chemical composition it consists principally of gelatine, but contains some albuminous matter.

*Adipose Tissue.* (*Tela Adiposa,—Tissu Adipeux.—Tissu Graisseux.*) *Fett-Gewebe* (Henle).

The separate existence of an adipose membrane was suspected by Malpighi, maintained by De Bergen and Morgagni, and demonstrated by William Hunter. It was however, confounded with the filamentous tissue, under the general name of cellular membrane, adipose membrane, and cellular fat, by Winslow, Portal, Bichat, and most of the continental anatomists, till distinguished and described by M. Beclard.

According to the dissections of De Bergen and Morgagni, the demonstrations of Hunter, and the observations of Beclard, its structure consists of rounded packets or parcels separated from each other by furrows of various depth, of a figure irregularly oval, or rather spheroidal, varying in diameter from a line to half an inch, according to the degree of corpulence and the part submitted to examination. Each packet is composed of small spheroidal particles, which may be easily separated by dissection, and which are said to consist of a cluster of vesicles still more minute, and agglomerated together by delicate cellular tissue. The appearance of these ultimate vesicles is minutely described by Wolff in the subcutaneous fat, and by Clopton Havers and Monro, in the marrow of bones, in which the last two authors compared them to strings of minute pearls. If the fat with which these vesicles are distended should disappear, as happens in dropsy, the vesicles collapse, their cavity is obliterated, and they are confounded with the contiguous cellular tissue, without leaving any trace of their existence.

Hunter, however, asserts, that in such circumstances the cellular tissue differs from the tissue of adipose vesicles, in containing no similar cavities; and justly remarks that the latter is much more fleshy and ligamentous than the filamentous tissue, and contends, that though the adipose receptacles are empty and collapsed, they still exist. When the skin is dissected from the adipose membrane it is always possible to distinguish the latter from the filamentous tissue, even if it contain no fat by the toughness of its fibres, and the coarseness of the web which they make.

The distinguishing characters between the cellular or filamentous and the adipose tissue may be stated in the following manner.—1*st*, The vesicles of the adipose membrane are closed all round, and, unlike cellular tissue, they cannot be generally penetrated by fluids which are made to enter them. If the temperature of a portion of adipose membrane be raised by means of warm water to the liquefying point of the contents, they will remain unmoved so long as the structure of the visicles is not injured by the heat. If, again, an adipose packet be exposed to a heat of + 40 centigr. = 104 F. though the fat be completely liquefied, not a drop escapes until the vesicles are divided or otherwise opened, when it appears in abundance. The adipose matter, therefore, though fluid or semifluid in the living body, does not, like dropsical infiltration, obey the impulse of gravity. 2*d*, The adipose visicles do not form, like cellular tissue, a continuous whole, but are simply in mutual contiguity. This arrangement is demonstrated by actual inspection, but becomes more conspicuous in the case of dropsical effusions, when the filamentous tissue interposed between the adipose molecules is completely infiltrated, while the latter are entirely unaffected. 3*d*, The anatomical situation of the adipose tissue is different from that of the filamentous tissue. The former is found, 1*st*, in a considerable layer immediately beneath the skin; 2*d*, between the peritoneal folds which form the omentum and mesentery; 3*d*, between the serous and muscular tissues of the heart; and, 4*th*, round each kidney.

In each of these situations it varies in quantity and in physical properties. In the least corpulent persons a portion of fat is deposited in the adipose membrane of the cheeks, orbits, palms of the hand, soles of the feet, pulp of the fingers and toes, flexures of the joints, round the kidney, beneath the cardiac serous membrane, and between the layers of the mesentery and omentum. In the more corpulent, and chiefly in females, it is found not merely in these situations, but extended in a layer of some thickness almost uniformly over the whole person; and is very abundant in the neck, breasts, belly, *mons veneris*, and flexures of the joints.

Besides the delicate cellular tissue by which the packets and vesicles are united, the adipose tissue receives arterial and venous branches, the arrangement of which has been described by various authors, from Malpighi, who gave the first accurate account, to Mascagni, to whom we are indebted for the most recent. According to the latter, who delineates these vessels, the furrow or space between each packet contains an artery and vein, which, being sub-divided, penetrate between the minute grains or particles of which the packet is composed, and furnish each with a small artery and vein. The effect of this arrangement is, that each individual grain or adipose particle is supported by its artery and vein as by a foot-stalk or peduncle, and that those of the same packet are kept together, not only by contact, but by the community of ramifications from the same vessel. These grains are so closely attached, that Mascagni, who examined them with a good lens, compares them to a cluster of fish-spawn. Grutzmacher found much the same arrangement in the grains and vesicles of the marrow of bones.

It has been supposed that the adipose tissue receives nervous filaments; and Mascagni conceives he has demonstrated its lymphatics. Both points, however, are so problematical, that of neither of these tissues is the distribution known.

The substance contained in these vesicles is entirely inorganic. Always solid in the dead body, it has been represented as fluid during life by Winslow, Haller, Portal, Bichat, and most authors on anatomy. The last writer indeed states, that under the skin it is more consistent, and that in various living animals he never found it so fluid as is represented. The truth is, that in the human body, and in most mammiferous animals during life, the fat is neither fluid nor semifluid. It is simply soft, yielding, and compressible, with a slight degree of transparency or rather translucence. This is easily established by observing it during incisions through the adipose membrane, either in the human body or in the lower animals.

The properties and composition of fat form a subject for chemical rather than anatomical inquiry; and in this respect its nature has been particularly investigated by M. Chevreul. According to the researches of this chemist, fat consists essentially of two proximate principles, *stearine* (*στεαρ*, *sebum*, *sapo*), and *elaine* (*ελαιον*, *oleum*). The former is a solid substance, colourless, tasteless, and almost inodorous, soluble in alcohol and ether, and preserving its solidity at a temperature of 138° F., but fusible between 140° and 145° F. Elaine, on the contrary, though colourless, or at most of a yellow tint, and lighter than water, is fluid at a temperature of from 17° to 18° centigrade, = 63° to 64° F., and is greatly more soluble in alcohol.

Of this substance marrow appears to be merely a modification; and the membranous cavities or medullary membrane in which it is contained may be viewed as an intraosseous adipose tissue.

Little doubt can be entertained that animal fat is the result of a process of secretion; but it is no easy matter to determine the mode in which this is effected. Malpighi, departing, however, from strict observation, imagined a set of ducts issuing from glands, in which he conceived the fat to be elaborated and prepared. To this he appears to have been led by his study of the lymphatic glands, and inability to comprehend how the process of secretion could be performed by arteries only. This doctrine, however, was overthrown by the strong arguments which Ruysch derived from his injections; and Malpighi himself afterwards acknowledged its weakness and renounced it. In short, neither the glands nor the ducts of the adipose membrane have ever been seen.

Winslow, though willing to adopt the notion of Malpighi, admits, however, that the particular organ by which the fat is separated from the blood is unknown. Haller, on the contrary, aware of the permeability of the arteries, and their direct communication with the cells of the adipose tissue, and trusting to the testimony of Malpighi, Ruysch, Glisson, and Morgagni, that it existed in the arterial blood, saw no difficulty in the notion of secretion, or rather of a process of separation; and upon much the same grounds the opinion is adopted by Portal and others. Bichat, again, contends that no fat can be recognised in the arterial blood, and adduces the fact, that none can be distinguished in blood drawn from the temporal artery.

All this, however, is more or less erroneous. It has been ascertained by Babington, Gmelin, Denis, Boudet, and Lecanu, that fat or oil exists in blood in the normal state; and there is no difficulty in understanding that from this fluid it must be secreted and deposited in the adipose tissue. The truth is, that fatty matter is found in the chyle, and is conveyed into the blood by the chyliferous vessels; and that it is found in the blood after meals of certain kinds of food, has been shown by the researches of Dr R. D. Thomson and others. From these facts, it may be inferred, that adipose matter or its elements are conveyed in minute quantities into the blood, and that the fat itself is deposited from the vessels in various parts of the adipose tissue, and in the medullary membrane of the bones, in which it is afterwards found. From the phenomena of various diseases, and from those manifested by hybernating animals, which retire in the beginning of winter fat and heavy, and come out in spring meagre and extenuated, there is reason to believe that fat is absorbed by the veins and lymphatics.

There is little difficulty in understanding the sources from which fat is derived in animal bodies. All amylaceous and saccharine articles of food furnish the elements of fat; and it is impossible to doubt that from these chiefly, together with the oils found in the seeds and other parts of vegetables, fat may be formed. In animals which live almost entirely on grass and the seeds of grassy vegetables, as the ox, sheep, horse, deer, and camel, the amylaceous and saccharine matters of their food are manifestly converted into fat and marrow.

Insects abound in fat; and in the bee this substance is prepared from sugar.

*Artery, Arterial Tissue.* (*Arteria,—Tissu Arteriel.*)

Most anatomical writers, previous to the time of Henle, distinguished in the arterial tissue three tunics; 1*st*, an internal; 2*d*, a middle or fibrous coat, consisting of annular fibres; and 3*d*, an external or common covering of condensed filamentous tissue.

Henle enumerates six different tunics; 1*st*, the first or inner coat, consisting of pavement epithelium; 2*d*, the striped or trellised coat; 3*d*, the longitudinal fibrous coat; 4*th*, the annular fibrous coat; 5*th*, an elastic tissue found only in arteries of large calibre; and 6*th*, the external, filamentous, or adventitious coat.

Of these six tissues, the first three correspond to the inner coat; the fourth is the ordinary fibrous or elastic coat of arteries; the fifth is not present in all vessels; and the sixth is the ordinary external coat of filamentous tissue.

The Epithelial coat is seen in the smallest vessels as a simple granular membrane in which the cell-nuclei only are deposited in a certain order. Frequently it has quite the same structure as the Epithelium of the Serous Membranes; in other instances the nuclei are oval, the cells extremely pale, and so flat, that those standing on the edge appear as thin filaments, something swollen in the centre, the region of the nucleus. Henle allows that this arterial epidermis may be wanting or transformed into the next tissue.

The second layer, the Striped or Trellised coat, is a very fine, transparent, moderately stiff, brittle membrane, the filaments of which divaricate and decussate each other.

The third layer, the best specimens of which are seen in the valves of the veins, belongs only doubtfully to the arterial tissue.

The two first-mentioned tissues correspond to the inner coat described below.

Every arterial tube greater than one line in diameter is visibly composed of one adventitious and two essential substances: the first, the sheath, reputed to consist of condensed filamentous tissue; the last two, the proper arterial and internal tissues. (*Tunica propria et membrana intima.*)

1. The inner surface of the arterial tube is formed by a very thin semitransparent polished membrane, which is said to extend not only in the one direction over the inner surface of the left ventricle, auricle, and pulmonary veins, but in the other to form the minute vascular terminations which are distributed through the substance of the different organs. This membrane is particularly described by Bichat under the name of *common membrane of the system of red blood*, because he believed it to exist wherever red blood was moving,—in the pulmonary veins, in the left side of the heart, and over the entire arterial system.

The inner membrane may be demonstrated by cutting open or inverting any artery of moderate size, when it may be peeled off in the form of thin slips by the forceps. Or, if the tube be fitted on a glass rod, by removing the layers of the proper membrane in successive portions, the inner one at length comes into view in the form of a thin translucent pellicle, of uniform, homogeneous aspect, without fibres or other obvious traces of organization. Under the microscope, however, if we can trust the descriptions of Henle, this coat appears to be composed of the filaments above mentioned. These filaments cannot be said, strictly speaking, either to be transverse or longitudinal in relation to the axis of the artery. Most of them are rather oblique; and they ramify at acute angles, and form anastomotic unions with each other. The stripes formed by these filaments are extremely pale and difficult to be seen. Henle further mentions as scattered between the fibres, holes variable in size, mostly round in shape, but here and there regularly broad, as if the effect of laceration.

This membrane is supposed to be prolonged to form those minute vessels in which the proper coat connot be traced. It is very brittle, and is distinguished during life by a remarkable activity in forming the morbid states to which arteries are liable. In other respects it is deemed by Bichat peculiar, and, though similar to the proper membrane, is to be considered as unlike any other tissue. Its chemical composition is not known.

2. Exterior to this *common* or *inner* membrane is placed a dense strong tissue of considerable thickness, of a dun yellowish colour, which is found to consist of fibres disposed in concentric circles placed contiguous to each other round the axis of the artery. If this substance be examined either from without or in the opposite direction, it will be found that, by proper use of forceps, its fibres can be separated to an indefinite degree of minuteness, even to that of a hair, and that they uniformly separate in the same direction. Longitudinal fibres are visible neither in this nor any other tissue of the arterial tube. This is the proper arterial tissue; (*tunica propria.*) Its uniform dun yellow colour is perceived through the semitransparent inner membrane, and is most conspicuous either when this is removed, or when the outer cellular envelope is detached and the component threads separated from each other; and if it be less distinct in the smaller branches, it is because the tissue on which the colour depends is here considerably thinner. In this respect it varies in different regions. Though in general less dense and abundant as the arteries recede from the heart, it is thicker, *cæteris paribus*, in those of the lower than in those of the upper extremities. In the vertebral and internal carotid arteries, and in those distributed in the substance of the liver, spleen, &c., it is thinner than in vessels of the same size in the muscular interstices.

This is the tunic which Henle calls the Annular Coat. His description includes both this proper or middle coat of the Arteries and the proper coat of the Veins, and has thereby been made less appropriate than it might otherwise have been. He describes the arterial annular coat as presenting fine dark streaks, or rows of dark-coloured *punctula*, running across the axis of the artery; and he thinks it certain that these streaks proceed from the original transverse oval Nuclei, and that therefore they give distinct evidence of the mode in which the annular coat is developed.

In acetic acid the annular arterial coat is resolved into fine vessels, so that the transversely oval nuclei float about free in the mass. The peculiar fibres of the middle arterial coat become by acetic acid pale, transparent, yet not dissolved. The dark stripes and *punctula* remain unchanged.

In rare instances the proper fibres of the middle arterial coat are curled as fasciculi of fibro-filamentous tissue.

Henle maintains that no proper filamentous tissue is found in the annular coat, not even to connect the separate layers of the coat, though this is frequently asserted. He has occasionally met with shreds of the trellised coat itself in the external layer of the annular coat. Răuschel saw on all fine sections of the aorta, the layers of the proper fibres separated by means of transparent fine partitions, which consequently must perforate the proper fibres in all directions. If the middle coat be stripped from an artery, after it has been treated with wood vinegar, and again softened in water, it is easily divided into layers which are not separated by fibres, but by a white, fibreless transparent substance. Portions of this are sometimes attached to the transverse fibres. Henle thinks, in short, that the trellised coat forms not only the internal layer of the annular coat, but also separates the component layers of that coat. Răuschel counted in the aorta forty-four layers, in the carotid artery twenty-eight, in the axillary artery fifteen layers, separated by similar partitions. In the other arteries, these must be wanting.

The nature of this tissue has been the subject of much controversy. It was long believed to be muscular, and to possess the properties of muscular fibre. Bichat showed that the arguments by which this opinion was supported are inconclusive, and that the arterial tissue has very few qualities in common with the muscular. The circumstances from which he derived his proofs were its physical and physiological properties.

The arguments derived from the physical properties of this tissue are chiefly the following:—The arterial tissue is close, elastic, fragile, and easily divided by ligature; muscular fibre is more loose in structure, by no means elastic; and, instead of being divided or cut by ligature as artery is, undergoes a sort of strangulation. The action of alcohol, diluted acids, and caloric, by means of hot fluids which are not corrosive, affords a proof of the chemical difference of these animal substances. All of them produce in the arterial tunic a species of shrivelling or crispation, which seems to depend on more complete coagulation of one of the chemical principles; but no similar effect takes place in muscular fibres. According to Berzelius, the proper arterial tunic contains no fibrin.[1] Beclard, however, asserts that he has ascertained that it contains a portion of this principle; but nevertheless hesitates to consider it as a muscular or fibrinous tissue, and expresses his opinion that it would be with greater propriety referred to that order of substances which he has named yellow or tawny fibrous system.

The consideration of the physiological or organic properties leads to similar results. Neither mechanical nor chemical agents applied as stimulants produce any change or motion in the living arterial membrane. 1. The arteries of an amputated limb, exposed the moment after amputation, while the muscles are in active motion, do not contract or move when punctured by the scalpel. 2. The experiments of Bikker and Van-den-Bos with the electric spark, and those of Vassalli-Eandi, Giulio, and Rossi with the galvanic pile, may be considered as disproved by the experiments of Nysten,[2] who found no contraction in the human aorta after violent death, while the heart and other muscles could still be excited. In performing the same experiment with the artery of the living dog, this physiologist was equally disappointed. 3. The circular contraction of the calibre of an artery either partially or wholly divided, depends not on irritability, but either on its elasticity, or on that property which it possesses of contracting strongly the instant the distending agent is removed. This power is different from muscular contraction or irritability, and must not be confounded with them; but it depends on the living state of the body and the individual arterial tube. 4. The contraction said to take place in living arteries after the application of alcohol, acids, or alkalies, is to be ascribed to the chemical *crispation*, and not to stimulant power. It does not relax. 5. These inferences are not inconsistent with the experiments of Thomson, Philips, Hastings, Wedemeyer, and Kaltenbrunner, on minute arterial tubes, which may be admitted to possess something like irritability, or rather susceptibility of contraction, without the necessity of supposing the same property in the large branches and trunks. 6. This is so much more probable, as in these minute arteries the proper arterial tunic is either wanting, or is so much thinner and so modified, that it is impossible to conceive its presence capable of affecting the result of experiments made to determine the degree or kind of arterial contraction.

On the other hand, Henle maintains that the outer layers of the annular coat are muscular, and belong to the same category to which are referred the muscular fibres of the intestinal canal and those of excretory ducts.[3]

3. The outer surface of the proper arterial tissue is enveloped, as above noticed, in a layer of dense filamentous or cellular membrane, which is very firmly attached to it, and which was formerly considered as part of the arterial tissue. It is adventitious; a modification of filamentous or cellular texture, which establishes a communication between the artery and the contiguous parts, and is necessary to the nutrition and healthy state of the vessel. It incloses and transmits the minute vessels anciently denominated *vasa vasorum* (*arteriolæ arteriarum*, Haller); and if detached even through a trifling extent, the arterial portion thus divided is sure to become dead, to be affected with inflammatory and sloughing action, and ultimately to give way and discharge the contents of the vessel. M. Beclard considers it a fibro-cellular membrane, which may in the larger arteries be divided into two layers; one exterior, similar to the general filamentous tissue; the other inside, between the outer layer and the proper tissue, yellowish and firm, but still sufficiently distinct from the proper tunic. In the cerebral arteries it is wanting, and in most parts of the chest and belly its absence is supplied by a portion of pericardium, pleura, or peritoneum. Yet even there a thin layer of fine cellular tissue appears to connect these membranes to the proper tunic. In the extremities the cellular sheath is removed in dissecting arterial preparations.

The internal filamentous tissue above-mentioned is what Henle calls the fifth arterial coat. It occurs only in arteries of large size. It is a coat of true elastic tissue; a white membrane, which can be rent into fibres neither transversely nor longitudinally, but always follows the tug of the forceps in small shreds. This membrane possesses the firmness of the elastic tissue, while the annular coat is slender and brittle. When treated with acetic acid, this membrane retains completely its white colour, while the annular coat becomes transparent; though thinner, it has a much greater degree of elasticity than the annular coat; and it possesses the microscopical character of the elastic tissue in a remarkable degree.

At different periods several anatomists, as Willis, Douglas and Delasone, have maintained the existence of longitudinal fibres in arterial tissue; and even at the present day this no-

tion is not entirely abandoned. Morgagni was the first who, trusting to mere observation, doubted the existence of these fibres, and stated that he was unable to perceive them.[1] Upon the same ground Haller would not admit of their existence;[2] and Bichat and Meckel positively denied them. The longitudinal filaments mentioned by Henle are found principally in the veins.

Though arterial tissue does not appear to be very vascular, it is furnished with arteries and veins (*vasa vasorum, arteriolæ arteriarum*), which do not come from the artery or vein itself, but from the neighbouring vessels.[3] Thus the aorta at its origin is supplied with minute arteries from the right and left coronary, and in some instances with a proper vessel adjoining to the orifice of the right coronary artery, which Haller regards as a third coronary. The rest of the thoracic aorta derives its vessels from the upper bronchials, from twigs of the internal mammary arteries, from the bronchials, from the œsophageals, and from the phrenics. The abdominal portion is supplied from the spermatics, the lumbar, and in some instances the mesocolic artery. The same arrangement nearly is observed with regard to the veins.

Few textures are more liberally supplied with nerves than arteries are. Almost every considerable trunk or vessel is surrounded by numerous plexiform filaments of nerves, many of which may be traced into the tissue of the artery. The anterior part of the arch of the aorta is abundantly supplied with branches from the superficial cardiac nerves, which Haller was unable to trace beyond the artery. The cœliac, the mesenteric, and the mesocolic arteries are invested with numerous plexiform nervous filaments derived from the large semilunar ganglion of the splanchnic nerve. The renal arteries in like manner are surrounded by numerous twigs of the renal plexus; and each of the intercostal arteries at its origin receives nervous threads from the intercostal nerves. This arrangement, which is observed chiefly in the blood-vessels going to the internal organs, led Bichat to announce it as a general fact, that the arteries derive their nerves almost exclusively from the ganglions and the gangliar nerves.[4] The inference does not rest upon strict observation, and evidently owes its birth to the hypothetical opinions of this ingenious physiologist. All the arteries going to the extremities, the axillary, and iliac, and their branches, receive nerves from the neighbouring nervous trunks, which are formed chiefly from cerebral or spinal nerves, and have no immediate connection with the system of the ganglions. In the internal carotid and the vertebral arteries, and their branches, nerves cannot be distinctly traced.[5]

Organized in the manner now described, it is requisite to take a short view of the anatomical connections of the arterial system, or to consider it in its origin, its course, and its termination.

The arterial system of the animal body may be viewed as one large trunk divided into several branches, which again are subdivided and ramified to a degree of minuteness which exceeds all calculation. It is requisite, therefore, to consider the origin, 1*st*, of the aorta, the large trunk; 2*dly*, of the branches which arise from it; and, 3*dly*, of the small vessels into which these are divided.

Every one knows that the aorta is connected at its origin with the upper and anterior part of the left ventricle. The manner of this connection has been well examined by Lancisi, by Ludwig, and particularly by Bichat. It may be demonstrated by dissection, but is much more distinctly shown by boiling the heart with the blood-vessels attached. In a heart so treated, the thin internal membrane may be traced passing from the interior of the ventricle along the margin of its orifice to the inside of the arterial tube. Exactly at the point of union it is doubled into three semicircular folds, forming semilunar valves, and thence is continued along the whole course of the artery. This membrane is entirely distinct from the proper or fibrous coat. Of the latter, the cardiac extremity or beginning is notched into three semicircular sections, each of which corresponds to the base or attached margin of a semilunar valve. These sections are attached to the aortic orifice of the ventricle by delicate filamentous tissue, but are not connected with the fleshy fibres of the heart; and at the angle or point of attachment the thin inner membrane is folded in so as to fill up a space or interval which is left between the margin of the orifice and the circumference of the proper arterial tissue, where it is notched or trisected.

The aorta is soon divided into branches, which again are subdivided into small vessels. With the mathematical physiologists it was a favourite problem to ascertain the number of branches into which any vessel might be subdivided. Keill made them from forty to fifty. Haller states that, counting the minutest ramifications, he has found scarcely twenty. The inquiry is vain, and cannot be subjected to accurate calculation. In no two subjects is the same artery found to be subdivided the same number of times; and in no two subjects are the same branches found to arise from the same trunk.

A branch issuing from a trunk generally forms with it a particular angle. Most generally, perhaps, these angles are acute; but in particular situations they approach nearly to a right angle. Thus the *innominata*, left carotid, and left subclavian, issue from the arch of the aorta nearly at a right angle, at least to the tangent of the arch. The intercostals form a right angle with the thoracic aorta; the renal and lumbar arteries form a large acute angle, approaching to right, with the abdominal; and the cœliac comes off nearly in the same manner from the anterior part of the vessel. The internal and external carotids, again, the external and internal iliacs, the branches of the humeral, and those of the femoral, form angles more or less acute with each other. The angle which the spermatics make is, generally speaking, the most acute in the arterial system.

I have already alluded to the structure of the arterial tissue at the divarications. These changes relate both to the inner and to the proper membrane. In the inside of the vessel the inner membrane is folded somewhat so as to form a prominent or elevated point, the disposition of which varies according to the angle of divarication. 1*st*, When this is rectangular, the prominence of the inner membrane is circular, and is equally distinct all round. 2*d*, When the angle is obtuse, as in the mesenteric artery, the prominence is distinct, and resembles a semicircular ridge between the continuation of the trunk and the branch given off, but indistinct on the opposite side where the angle is obtuse. 3*d*, If the angle is acute, and that

formed by the branch with the continuation of the trunk is obtuse, the beginning of the artery presents an oblique circle, the elevated half of which is near the heart, the other more remote.

The arrangement of the fibres of the proper tissue is described by Ludwig from the divarication of the iliac arteries, and may be seen in any part of the arterial system where the vessels are large. The circular fibres separating form on each side a half-ring, from which is produced a complete ring, which incloses the smaller rings formed by the circular fibres of the vessel given off. These circular fibres proceed to the prominence of the internal membrane already described, and are arranged round it much in the same manner in which those of the large vessel surround its inner membrane. In this, however, no continuity between the rings of the large vessel and those of the small one can be recognised. The latter are inserted as it were into the former, and they are connected by the continuity of the inner membrane only.

In observing the course or transit of arterial tubes, the principal point deserving notice is the sheltered situation which they generally occupy, their tortuous course, and their mutual communications. In the extremities they are always found towards the interior or least exposed part of the limb, generally deep between muscles, and sometimes lying along bones. When they are minutely subdivided, they enter into the interior of organs, without, however, sinking at once into their intimate substance. In the muscles they are lodged between the fibres; in the brain, in the convolutions; in glands, between their component lobes. In such situations they are generally observed to be more or less tortuous in the course which they follow. On the reasons of this much difference of opinion still prevails. (Bichat and Magendie.)

In the course of the arteries, no circumstance is of greater moment than their mutual communications or inosculations (*anastomoses*). Of this there may be two forms, the first when two equal trunks unite, the second when a large vessel unites with a smaller one. Of the first, three varieties have been mentioned. 1*st*, Two equal trunks may unite at an acute angle to form one vessel. Thus, in the fœtus, the *ductus arteriosus* and the aorta are conjoined; and the two vertebral arteries unite to form the basilar trunk. 2*d*, Two trunks may communicate by a transverse branch, as the two anterior cerebral arteries do in forming the anterior segment of the circle of Willis. 3*d*, Two trunks may, by mutual union, form an arch, from the convexity of which the minute vessels arise, as is seen in the branches of the mesenteric arteries. (Plate XXIX. fig. 4.)

The second mode of inosculation is frequent in the extremities, especially round the joints. The multiplied communications of the arterial system in these regions, though well known to anatomists, and enumerated by Haller, were first clearly and systematically explained by Scarpa, and afterwards by Cooper and Hodgson. The importance of this arrangement, in facilitating the motions of the circulation,—in obviating the effects of local impediment in any vessel or set of vessels,—and in enabling the surgeon to tie an arterial trunk when wounded, affected with aneurism or any other disease,—has been clearly established by these authors. Their researches have shown, that there is not a single vessel which may not be tied with full confidence in the powers of the collateral circulation. Even the aorta has in seventeen instances been found narrowed or obstructed in the human subject, and a ligature has been put on its abdominal portion. (Cooper.)

To ascertain the several modes in which arteries terminate has been a problem of much interest to the physiologist, and of no small difficulty to the anatomist. The alleged terminations, as believed to be established, are minutely and elaborately enumerated by Haller, who, however, multiplied them too much according to the modern acceptation of the term.

1. The first undoubted termination of arteries is immediately in veins. It is unnecessary to adduce in support of this fact the long list of observers enumerated by Haller. It is sufficient to say that it was clearly established by the microscopical observations of Leeuwenhoeck, Cowper, and Baker, by Haller himself, and by Spallanzani in his beautiful experiments on the circulation of the blood.

2. The second termination which may be mentioned here is that into the colourless artery, (*arteria non rubra*). This is sufficiently well established by the phenomena of injections.

3. A third termination which is supposed to exist, but of which no sensible proofs can be given, is that into colourless vessels supposed to open by minute orifices on various membranous surfaces, and therefore termed exhalants. The nature of these vessels shall be considered afterwards.

Haller admits a termination in, or communication with, lymphatic vessels, but allows that it is highly problematical. Partial communications have been traced between arteries and lymphatics by several anatomists; but the point requires to be again submitted to accurate researches.

Another mode of termination, that namely into excreting ducts, admitted by Haller, scarcely requires particular mention. So far as an artery can be said to terminate in such a manner, it would come under the head of that into exhalant vessels. Many of the proofs mentioned by Haller, however, may be shown to be examples of a morbid state of the mucous membranes of these ducts, in which their capillary vessels are disorganized.

In considering the several terminations of arteries, it is not unimportant to advert to the distribution of these vessels. Injections show that they penetrate into every texture and organ of the animal body, excepting one or two substances in which they have never yet been traced. But in different textures they are found in different degrees; and they may vary in extent even in the same texture in two different conditions. The parts which receive the largest and most numerous vascular ramifications are the brain and spinal chord, the glandular organs, the muscles voluntary and involuntary, the mucous membranes, and the skin. In bones, on the contrary, in the fibrous membranes, and their modifications, tendons, and ligaments, and in the serous membranes, few arteries are seen to penetrate; and these are generally minute, sometimes only colourless capillaries. In some textures arteries cannot be traced, though their properties indicate that they must receive vessels of some kind. Such are cartilage and the arachnoid membrane. (Ruysch and Haller.) Lastly, arteries are not found in the scarf-skin, in nails, the enamel of the teeth, the hair, nor in the membranes of the umbilical chord. In early life bones are much more vascular than in adult age; and in the bones of young subjects arteries may be traced going out through the epiphyses into the cartilages, in which they cannot at a later period of life be demonstrated. (*Phil. Trans.* No. 470.)

*Vein, Venous Tissue.* (Φλεψ,—*Vena*,—*Tissu Veneux.*)

Veins.

The structure of the tubular canals, termed veins, has been much less examined by anatomists than that of the arteries. Some incidental observations in the writings of Willis, Glass, and Clifton Wintringham, comprise all that was published regarding them previous to the short ac-

General Anatomy.

count of Haller. Since that time they have been described with various degrees of minuteness and accuracy by John Hunter, Bichat, Magendie, Gordon, Marx,[1] and Meckel. In the following account, the facts collected by these observers have been compared with the appearance and visible organization presented by veins in different parts of the human body.

Veins.

The veins are membranous tubes extending between the right side or pulmonary division of the heart and the different organs in which their minute branches are ramified.

Every venous tube greater than one line in diameter consists of three kinds of distinct substance. The outermost is a modification of the filamentous tissue (*membrana cellulosa*), and though less compact and less thick than the arterial filamentous envelope, is in every other respect quite similar, and is in general intimately connected with it. The innermost (*membrana intima*) is a smooth very thin membrane. Between these is found a tunic somewhat thicker, which is termed the *proper venous tissue* (*tunica propria venæ*). The structure and aspect of this proper membrane shall be first considered.

1*st*, When the loose filamentous tissue in which the blood-vessels are inclosed, and the more delicate and firm layer immediately contiguous to the veins, are removed, the observer recognises a red or brown-coloured membrane, not thick or strong, but somewhat tough, which is the outer surface of the proper venous tunic. If dissected clean it is tolerably smooth; but however much so it can be made, a glass of moderate powers, or even a good eye, will perceive numerous filaments adhering to it, which appear to be the residue of the cellular envelope.

According to Bichat, parallel longitudinal fibres, forming a very thin layer, may be distinguished in the larger veins; but he admits, although they are quite real, that they are always difficult to be seen at the first glance. In the trunk of the inferior great vein (*vena cava inferior*), they are always seen, he observes, more distinctly than in that of the superior; and they are always more obvious in the divisions of the former than in those of the latter vessel, and also in the superficial than in the deep-seated veins. These longitudinal fibres, he asserts, are more distinct in the saphena than in the crural vein, which accompanies the artery. Lastly, he remarks, these fibres are proportionally more conspicuous in branches than in trunks. (*Anatomie Générale*, tom. i. p. 399.)

Notwithstanding the apparent correctness of this description, Magendie informs us he has sought in vain for the fibres of the proper venous membrane; and he remarks that, though he has observed very numerous filaments interlacing in all directions, yet these assume the longitudinal and parallel appearance only when the tube is folded longitudinally,—a disposition often seen in the larger veins.

By Meckel, on the contrary, the accuracy of the observation of Bichat is maintained. This anatomist states that he has, by the most minute dissections, assured himself that these fibres are longitudinal; but he admits that they are not uniformly present in all parts of the venous system, and that in degree and abundance they are liable to great variation. He follows Bichat also in representing these fibres as thicker and more distinct in the system of the inferior than in that of the superior *cava*, and in the superficial than in the deep veins.

In the inferior cava of the human subject, certainly, filaments or fibres may be recognised. But instead of being longitudinal, they may be made to assume any direction, according to the manner in which the filamentous tissue is removed. For this reason probably these fibres are to be viewed as part of the filamentous sheath In the saphena vein of the leg oblique fibres may be seen decussating each other; but it is doubtful whether these belong to the proper venous tissue or to the filamentous covering.

The nature of this proper membrane, or venous fibre, as it is sometimes named (Bichat), is not at all known. Its great extensibility, its softness, its want of elasticity in the circular direction, or fragility, its colour and general aspect, distinguish it from the arterial tunic. It possesses some elasticity in the longitudinal direction, and is retracted vigorously when stretched. It possesses considerable resistance, or in common language is tough. The experiments of Clifton Wintringham show that it sustains a considerable weight without breaking, and that this toughness is greater in early life, or in the veins of the young subject, than at a later period.[2] In short, it may be stated as a general fact, that venous tissue, though thinner, possesses greater elasticity and tenacity than arterial tissue. According to the experiments of the same inquirer, this property depends on that of the superior density of the venous tissue; the specific gravity of the matter of the *vena cava* being invariably greater than that of the aorta in the same subject, both in man and in brute animals.

From some experiments Magendie is disposed to consider it of a *fibrinous* character. But it exhibits in the living body no proof of muscular structure or irritable power. When punctured by a sharp instrument, or exposed to the electric or galvanic action, it undergoes no change or sensible motion.

This tunic is wanting in those divisions of the venous system termed *sinuses*, in which its place is supplied by portions of the hard membrane (*dura meninx*).

2*dly*, The inner surface of any vein which has been laid open and well washed is found to be smooth, highly polished, and of a bluish or blue-white colour. This is the inner or free surface of the inner venous membrane (*membrana intima*). It is exceedingly thin, much more so than the corresponding arterial membrane, much more distensible and less fragile. It bears a very tight ligature without giving way as the arterial does; but it also sustains considerable weight, which shows that it is tough and resisting. This is the membrane termed by Bichat *common membrane of dark or modena blood.* According to the views of this anatomist, it forms the inner or free surface, not only of all the venous twigs, branches, and trunks composing this system of vessels, but it is extended from the superior and inferior great veins over the inner surface of the right auricle and ventricle, and thence over that of the pulmonary artery and its divisions; and through this whole tract it is the same in structure and properties.

This doctrine has not yet been controverted. But perhaps it may be doubted, both with regard to the inner arterial membrane, that the inner tunic of the aorta and of the pulmonary veins is quite the same; and in regard to this inner venous membrane, whether that of the veins in general is quite the same with that of the pulmonary artery. The subject demands further research. Meanwhile strong confirmation is found in the interesting remark of Bichat, that the osseous or calcareous depositions which are common in various spots of the inner arterial

[1] *Diatribe Anatomico-physiologica de Structura atque Vita Venarum.* Caroliruhæ, 1819.
[2] *Experimental Inquiry on some parts of the Animal Structure.* London, 1740.

membrane, and especially at the mitral and aortic valves, are never found in the inner venous membrane, or at the tricuspid valve, or in the semilunar valves of the pulmonary artery. Have these depositions been found inside the pulmonary veins, and not inside the pulmonary artery? Ossific deposit in the valves of the pulmonary artery was seen by Bransby Cooper.

The inner or common venous membrane is, however, the most extensive and the most uniform of all the venous tissues. It is the only one which is found in the substance of organs, and is present where the cellular and proper membranes are wanting. This is the case not only with venous branches and minute canals as they issue from the substance of muscles, bones, and such organs as the liver, kidneys, spleen, &c., but is also very remarkably observed with regard to the venous canals of the brain. I have already noticed the absence of the cellular and proper tissues in these tubes; and I have now to remark, that the cerebral veins consist solely of the inner membrane while in the brain or membranes, and when in the sinuses, of this inner membrane, placed between two folds of the *dura mater*. When the jugular vein reaches the temporo-occipital sinuosity, it loses its proper membrane, while its common or inner membrane passes into the hollow of the *dura mater*, called *sinus*, and thus forms the venous canal. This fact is readily demonstrated by slitting open either the lateral or the superior longitudinal sinus, when a thin delicate membrane, quite distinct from the fibrous appearance of the *dura mater*, will be found to line the interior of these canals.

Valves. The inner surface of many veins presents membranous folds projecting obliquely into the cavity of the vessel. These folds, which, from their mechanical office, have been named *valves* (*valvulæ*), are parabolic in shape, have two margins, an attached and free,—and two surfaces, a concave turned to the cardiac end of the vein, and a convex turned in the opposite direction. The attached margin is not straight, as may be imagined, but circular, and adheres to the inner surface of the vessel. The free margin resembles in shape an oblong parabola; and the direction of the valve is such, that a force applied to its convex surface would urge it more closely to the vein, whereas a force applied to the concave surface would either obliterate the circular area of the vessel, tear the valve from the vein, or otherwise meet with resistance.

The size of the valves is variable. In some instances they are sufficiently large to fill the canal of the vessel, and in others they are too small to produce this effect. The obliteration of the circular area of the vessel is most perfect when there are two or three at the same point. Bichat ascribed the variable state of this quality to the dilated or contracted condition of the veins at the moment of death. This, however, is denied by Magendie.

In structure these valvular or parabolic folds are said to consist of a doubling, or two-fold layer of the inner membrane; and with this statement no fact of which we are aware is at variance. A hard prominent line, which generally marks the attachment of their fixed margin to the vein, is asserted by Bichat to consist of the proper venous tissue, the fibres of which, he says, alter their direction for this purpose; and when the common or inner membrane reaches this line, it doubles or folds itself to form the valve, which thus consists of two layers of the inner or common membrane. This, however, is denied by Hunter,[1] who considers them of a tendinous nature, and by Gordon, who made several unsuccessful attempts to split these two layers.[2]

Valves are not uniformly present in all veins. They are found, 1*st*, in the following branches of the superior great vein—the internal jugular, the azygos, the facial veins, those of the arms, &c.; 2*d*, in the following branches of the inferior great vein—the divisions of the posterior iliac, of the femoral, tibial, internal and external saphena, and in the spermatic veins of the male.

They are wanting in the trunk of the inferior great vein (*cava inferior*), in the renal, mesenteric, and other abdominal veins, in the portal vein, in the cerebral sinuses, in the veins of the brain and spinal chord, in the veins of the heart, of the womb generally, and of the ovaries, and perhaps in all other veins less than a line in diameter.[3] In the cerebral sinuses the transverse chords are supposed to supply their place.

In the lungs they were supposed to be wanting, till their presence was established by Mayer of Bonn.

In situation the valves vary considerably. In general they are found in those parts of venous canals at which a small vein opens into a larger. But even from this arrangement there are deviations. The only valve which is definite and invariable in its situation is the Eustachian (*valvula Eustachiana, valvula nobilis*), which is always placed at the cardiac end or beginning of the inferior *cava*, where that vessel is attached to the sinus of the right auricle. Shaped in general like a crescent, the attached margin of which is the arch of a large circle, and the free that of a small one, it proceeds from the left extremity of the sinus downwards, forwards, and towards the left side, where it is insensibly lost on the membrane of the auricular *septum*. At its lower end it generally covers the orifice of the large coronary vein. This membranous production is always larger, more perfect, and more distinct in the fœtus and in the infant, than in the adult. In the latter it is almost always reticulated; and sometimes the only vestige of its existence is a thin chord or two representing its anterior margin. I have seen it reticulated even at the age of sixteen or seventeen, and almost destroyed beyond thirty. Haller was much perplexed to account for the use of this membranous fold.[4] The conjecture of Bichat, that it is connected with some purpose in the fœtal circulation, is entitled to regard.

Dr Gordon mentions a third partial substance, which is occasionally found in local patches at various parts of veins. This I believe to be the deposit found at the union of two veins to form one trunk.

Besides the cellular or filamentous envelope, veins receive capillary arteries, to which there are corresponding veins. The arteries rise from the nearest small ramifying arteries; and the corresponding veins do not terminate in the cavity of the vein to which they belong, but pass off from its body, and join some others from different parts; and at last terminate in the common trunk somewhere higher.[5] Nervous branches, or rather filaments, are observed in the pulmonary artery and great veins only. Are they derived from the great sympathetic, as is generally said?

In the veins, as in the arteries, the anatomist recognises two extremities, the cardiac or collected, and the organic or the ramified. Examined physiologically, however, the terms *origin* and *termination* are not of the same import as when applied to the arteries. In reference to the veins, they become convertible terms; and it is the

usage even of writers on anatomy to represent the veins as arising where the arteries terminate, and terminating at the organ from which the latter arise. This distinction must be kept in view in the following observations.

The cardiac extremity or termination of the veins is so well known as to render any minute explanation unnecessary.

The organic extremity or origin of the venous system is more obscure and difficult to be understood. It is indeed impossible to trace the origin of the small venous vessels, unless in the manner in which Leeuwenhoeck,[1] William Cowper,[2] Henry Baker,[3] Haller, and Spallanzani,[4] did in their observations on the transparent parts of animals in general cold-blooded. From the experiments of these observers, we know that a very small vessel, evidently tending and conveying blood *towards* a larger, connected with a venous branch, may be seen passing directly from a similar small vessel, as evidently conveying blood *from* a larger, which is connected with the arterial system. All that we know from this, however, is, that a vein containing red blood may rise from an artery conveying red blood. This is matter of observation; all beyond is little more than conjectural.

Haller, indeed, admits origins of veins as manifold as the terminations of the arterial system, a view in which he has been followed by almost all subsequent authors; and Bichat states it as a leading proposition, that the veins arise from the general capillary system. Neither conclusion is founded on strict observation; and while that of the former physiologist is derived chiefly from uncertain facts and loose analogies, the statement of the latter is too hypothetical and general to be either entirely true or wholly false.

Of one fact only are we certain. The blood which is conveyed into the small vessels and the substance of the tissues and organs is brought back by the veins. We have seen that the only origin which is strictly susceptible of demonstration is that of the red vein from the red artery. The point then to be ascertained is, whether colourless veins and absorbent veins arise from the several textures, as colourless and exhalant arteries terminate in them. The proper place for the further examination of this question is the subsequent section.

I must not omit to mention, nevertheless, that the veins have been shown to be connected at their ramified extremities with the lymphatics.

When the veins become distinct vessels, branches, and trunks, they become once more objects of sensible examination. In their course from their organic to their cardiac extremities they present various circumstances which merit attention.

1. In general every artery is accompanied by a venous tube, which is divided in the same manner, and furnishes or receives an equal number of branches. Thus the descending aorta is accompanied by the *vena cava inferior;* the common iliac arteries by common iliac veins; the anterior iliac, femoral, and popliteal, by anterior iliac, femoral and popliteal veins. These veins are deep-seated, and are generally named the concomitant veins (*venæ comites vel venæ satellites*). In some situations an artery may be accompanied either in its trunk or in its branches by two veins of equal size. Thus in general the brachial artery, and its branches the radial and ulnar, are each accompanied by two veins. The only situations in which the number of veins can be said to be exactly equal to that of the arteries, are in the stomach, in the intestinal canal, in the spleen, in the kidneys, in the testicles, and in the ovaries.

2. In the extremities and in the external regions of the trunk we find, in addition to the concomitant veins, an external layer of venous tubes immediately beneath the skin, (*venæ subter cutem dispersæ*, Pliny). These subcutaneous or superficial veins do not correspond to any artery; but as they are chiefly destined to convey the blood from the skin and other superficial parts, they open into the deep-seated veins. Thus in the case of the basilic and cephalic, two superficial veins of the arm, the former, after passing the bicipital fascia, forms in the sheath the brachial vein; and becoming the axillary in the axilla, receives the latter vessel. In the same manner the saphena (φλεψ σαφηνης, *vena manifesta*), or superficial vein of the leg, passes through the falciform process of the *fascia lata* to join the femoral vein.

From this it results that the venous canals are on the whole more numerous than the arterial. In a few situations only a single vein corresponds to two arteries, as in the penis, the clitoris, the gall-bladder, and the umbilical chord. Often also in the renal capsules and the kidneys two or more arteries have only one corresponding vein. In such circumstances the vein is always large and capacious.

It has been generally stated that the calibre and area of the venous tubes are much larger than those of the corresponding arteries, and consequently that the capacity of the venous system is much greater than that of the arterial. I acknowledge that I know not on what exact evidence the former of these propositions, the only one with which the anatomist is concerned, is made to rest. If it be mere inspection in the dead subject, or the effects of injection, little doubt can be entertained that the alleged greater calibre depends chiefly on the laxity and distensible nature of the venous fibre. The arterial tubes appear small in consequence of annular contraction, or the tendency which they have to collapse, when the distending force has ceased to operate. The venous canals appear large by reason of their distension and distensibility during life, from the tendency to accumulation in their branches in most kinds of death, except that by hemorrhage, and from a smaller degree of the physical property of shrinking and annular contraction when empty.

When a vascular sheath is exposed in the human subject, as in the operation for aneurism, or in the lower animals in the way of experiment, the vein generally appears larger than the corresponding artery. This, however, is never so considerable as it is represented by most authors, and certainly cannot afford grounds for the estimates which Keill, Jurin, and other mathematical physiologists have assigned to the relative capacity of the arteries and veins. It is also to be observed that something of this greater size depends on the increase of dilatation resulting from removing the pressure of incumbent parts. In young animals also the difference between the size of the veins and their corresponding arteries is so trifling as to be scarcely discernible. This shows that

---

General Anatomy. Vein.

something is to be ascribed to the incessant operation of a dilating force increasing uniformly with the duration of life.

Upon the whole, it is chiefly on the ground of their larger numerical arrangement that the veins collectively can be said to be more capacious than the arteries. On this subject some observations of Bichat are entitled to attention.[1]

3. The veins in general accompany the arteries. The venous trunk placed contiguous to the arterial in the same sheath, is divided into branches at the same points, and is distributed into the substance of organs much in the same manner. From this arrangement, however, certain deviations are observed in particular regions. Thus, in the brain, neither the internal carotid, nor the basilar artery, nor their large branches, are accompanied with veins. The small branches only have corresponding veins, which, as they unite to form large ones, pour their blood into the venous canals termed sinuses, the arrangement of which is unlike any other part of the venous system. In the chest also a different disposition of the venous from the arterial tubes is observed. The *venæ cavæ*, though conveying the blood to the pulmonic division of the heart, as the aorta conveys it from it, do not, however, correspond with the latter either in situation or in dependent branches. The *azygos* and the *demiazygos* veins, in like manner, which receive the intercostal veins, have no concomitant artery, but open into the superior *cava*, to which they may be viewed as appendages. *Lastly*, The portal vein, which is formed of the united trunks of the splenic, superior mesenteric and inferior mesenteric veins, corresponds to no individual arterial trunk, and forms of itself a peculiar arrangement in the venous system.

Some anatomists have dwelt much on the more superficial and less sheltered situation of the veins than of the arteries. On this point no positive inferences can be established. In the extremities the former are in general most superficial; but in the interior of the body, especially in the chest, the venous trunks are quite as deep-seated as the arterial.

The course of the venous canals is in general more rectilineal and less tortuous than that of the arteries. In no part of the venous system is such an inflection presented as that which the internal carotid makes in the carotic canal. The general result of this is, that a set of venous tubes is shorter than a corresponding set of arterial ones. The trunks also are less inflected than the branches.

4. The mutual communications of the venous system (*anastomoses, inosculationes,*) are more numerous and frequent than those of the arterial. 1. The minute veins communicate so freely as to form a perfect net-work. 2. In the twigs, though more rare, these communications are still frequent. 3. In the branches, though less numerous, they are nevertheless observed; and in this respect alone the venous must be greatly more numerous than the arterial inosculations, which are confined chiefly to the smaller and more remote parts of the system. These inosculations, indeed, between the venous branches constitute one of the most peculiar and important characters of their arrangement, in so far as by their means the communication is maintained between the superficial and deep-seated vessels of the system. Thus the emissary veins are the channel of communication between the cerebral sinuses and the temporal, occipital, and other external veins. The external and internal jugulars communicate by one or two considerable vessels; and the free communication between the basilic and cephalic by the median veins, that between them and the deep brachial vessel, and that between the saphena and its branches and the femoral vein, are sufficiently well known. The application of these anatomical facts to the ready motion of the venous blood is obvious.

General Anatomy. Capillaries.

But of all the communications between the branches or large vessels of the venous system, the most important, both anatomically and physiologically, is that maintained by means of the *vena azygos* between the superior and inferior *cavæ*. The azygos itself is connected at its upper or bronchial extremity with the superior *cava*, and at its lower extremity it is in some subjects connected directly with the inferior *cava*, in others by means of the right renal vein, and in most by the first lumbar veins. By means of the *demiazygos*, again, it is connected with the left renal vein, or the lumbars of the same side, and in some instances directly with the inferior *cava*. To the azygos and demiazygos, therefore, belongs the remarkable property of connecting not only the venous canals of the upper and lower divisions, but those of the right and left halves of the body.

### *System of Capillary Vessels,—Terminations of Arteries,—Origins of Veins.*

Though we can scarcely, with propriety, speak of the *capillary tissue*, or the tissue of capillary vessels, we find it requisite to introduce in this place the general facts of the anatomical peculiarities of this important part of the human body.

The term *capillary system*, though much spoken of in physiological and pathological writings, is perhaps not always precisely defined or distinctly understood. According to Bichat, it is not only the common intermediate system between the arteries and veins, but the origin of all the exhalant and excreting vessels.[2] If we consider the modes in which arteries have been said to terminate, and veins to take their origin, we find, that in this view of the capillary system there are some things which are doubtful, and some which are inconsistent with the rest.

Haller, and most of the physiological authorities since his time, concluded, chiefly from the phenomena of injections, sometimes from microscopical observation, and, where these failed, from the obscure and uncertain evidence of analogy, that an artery traced to its last or minute divisions will be found to terminate in one or other of the following modes. 1*st*, Either directly in a red vein or veins; 2*d*, in excreting ducts, as in the lacrymal and salivary glands, the kidney, liver, and pancreas, the female breast, and the testicle of the male; 3*d*, in exhalants, as in the skin, in the membranes of cavities (serous membranes), the cavities of the brain, the chambers of the eye, the filamentous tissue, the adipose cells, the pulmonary vesicles, and mucous surfaces and their follicular glands; 4*th*, in smaller vessels, for instance lymphatics; and, 5*th*, in the colourless artery (*arteria non rubra*).[3]

A similar application of the same facts has assigned to the veins a mode of origin not unlike. If, therefore, we admit the definition given by Bichat, it follows that the capillary system consists, 1*st*, of minute arteries communicating with veins; 2*d*, of excreting ducts; 3*d*, of exhalants; and, 4*th*, of minute arteries or veins containing a colourless portion of the blood. It is obvious, however, that it is absurd to say that the system of capillary vessels at once comprehends and gives origin to the excretories and exhalants. In other respects the whole of

General Anatomy.

Capillaries.

this theory, for little of it is matter of strict observation, rests on very hypothetical grounds.

Of the different kinds of terminations assigned to arteries, and of origins assigned to veins, one only admits of sensible demonstration. Arteries, when they have so much diminished as to become *capillary*, are seen by the microscope, in some instances by the naked eye, to pass directly into corresponding capillary veins, or to end abruptly in some organ or membrane unconnected with any other vessel.[1] It is likewise certain that the microscope shows every capillary vein to arise from a capillary artery; and if there be any other mode of origin, it has not yet been demonstrated.[2] Only one other circumstance requires to be taken into account in this inquiry. This is, that the capillary artery and vein may contain either red or colourless blood; for, according to the size of the vessels, and the nature of the organs or tissues in which they are distributed, the blood which flows through them will be coloured or colourless. This view of the communication of minute arteries and veins, which is perfectly consistent with the known facts, affords the only explanation which it is possible to give of the singular division of the capillary system which Bichat has chosen.

This author considers the capillary system under three general heads: 1*st*, In organs in which it contains blood only, for instance, in the muscles, the spleen, some parts of the mucous membranes; 2*d*, In organs in which it contains blood and other fluids, for example, in bone, cellular tissue, serous membrane, part of the fibrous system, the skin, the vascular *parietes*, glands, &c.; and 3*d*, In organs in which it contains no blood, the instances of which are, tendon, cartilage, ligament, hair, &c.

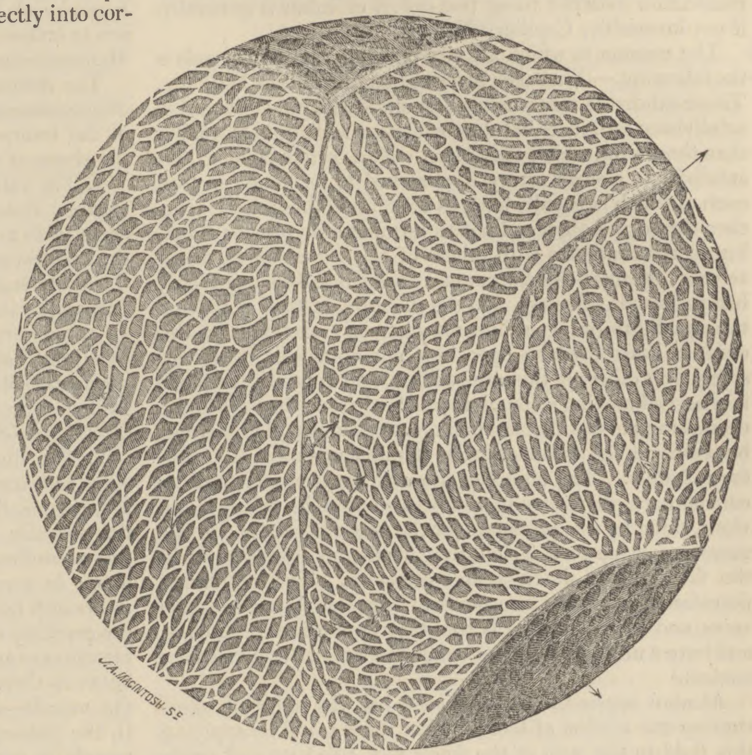
Now, it is of little consequence to say that the tissues of the last two divisions contain other fluids than blood, when we are also told that the phenomena of injections, which prove that their capillaries communicate directly with arteries conveying red blood, the effect of irritating applications, mechanical or chemical, and the phenomena of acute or chronic inflammation, show that they may receive and convey red blood. The conclusion of this in common language is, that the capillary arteries and veins of the second order of tissues do not all contain red blood, but that many of them contain a colourless part of that fluid; and that all the capillary arteries and veins of the third order of tissues convey in the natural state colourless blood only. What, then, is the precise idea which ought to be formed of the intermediate system which Bichat conceived to exist between the minute arteries and veins, or what have been termed the venous *radiculæ?*

From the present state of facts it results that nothing more can be admitted to constitute the capillary system than those minute vessels, whether conveying coloured or colourless blood, in which inspection, microscopic observation, and injections show that arterial branches at once terminate, and minute veins (*radiculæ venosæ*) have their origin. It is clear that, physiologically speaking, these vessels can neither be regarded as arteries nor as veins strictly; for the characters on which this distinction is founded are necessarily obliterated in this system of vessels. There is no precise point at which the arterial tissue can be said to terminate, and none at which the venous structure can be said to commence.

General Anatomy.

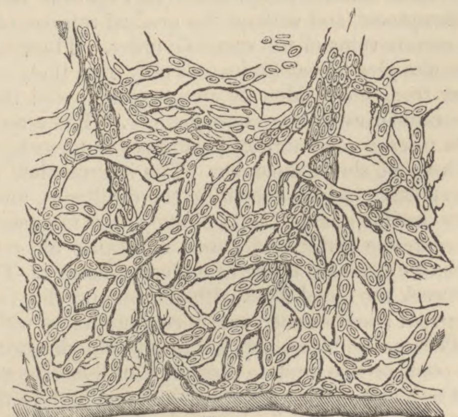
Physical and Anatomical characters of the capillary vessels.

One of the first distinct and intelligible descriptions of the physical characters and arrangement of the capillary vessels was given in 1831 by Dr Marshall Hall, from microscopical observations made on the vessels of the fin and tail of the stickle-back, the web of the frog's foot, the mesentery of the toad, and the lungs of the salamander, frog, and toad.



THE ARTERIES, VEINS, AND INTERVENING CAPILLARY VESSELS AS SEEN IN THE LUNG OF THE TOAD, HIGHLY MAGNIFIED.

In the web of the foot of the frog, the minute arteries are characterized by their straight course and small size, by the light colour and rapid motion of their contents, and by a distinct pulsatory movement, which extends not to the capillaries. The arteries are nearly equal in number to the veins.



CAPILLARIES IN THE WEB OF THE FOOT OF THE FROG (A. THOMSON).

The latter, which first strike the eye, are tortuous, red, and present the most distinct view of the blood moving within their canals in single globules or successive rows. Though Dr Hall could in no instance detect any anastomosis or in-

[1] Gordon, p. 56.

General Anatomy.

Physical and Anatomical characters of the capillary vessels.

osculation between the minute arteries, except in the mesentery of the toad, this arrangement was frequent among the veins, and in the anastomosing branches of two apparent veins a double and contrary current of blood is sometimes observed. In no instance could Dr Hall observe a distinct termination of an artery or a vein, and the medium of communication between these two orders of tubes is generally, if not invariably, Capillary Vessels.

The manner in which arteries pass into capillary vessels is the following.—The large arteries first divide into branches. These subdivide into smaller branches, which by successive subdivision terminate in tubes, which are successively smaller than those from which they issue. At a certain point of this subdivision, a small artery is observed to terminate in two, each of which is equally large as itself; and these vessels further traced are observed not to terminate in smaller tubes, but to communicate with others of the same size as themselves. At this point the course of the blood becomes of only half its former velocity; and the globules, instead of moving too rapidly to be seen, become distinctly visible. To this order of vessels, which open into, and communicate exclusively with others of the same calibre, and in which the blood is observed moving so much more slowly than they did in the decreasing vessels, that the motion of individual globules may be observed, the author restricts the denomination of *Capillary System.* The object of the uniform diameter, and its concomitant phenomenon, retarded motion, he thinks is obvious, since by this arrangement the blood is retained in the vessels of organs, a sufficient time for the accomplishment of the functions of nutrition and secretion. The capillaries, therefore, are situate intermediate between the arteries and veins, and their character is that they form minute cylinders, and have a uniform diameter, while the arteries and veins are conical.[1]

Alcohol applied to these vessels has the effect of interrupting the motion of blood within them; and by applying this fluid to the web of the frog's foot, two layers of capillaries are brought into view; one superficial, in which the motion of the blood is suspended, the other deep-seated, in which it is still moving.

Of the pulmonary capillaries, the arrangement is slightly modified. The division of the minute arteries into capillaries is more immediate, and without those successive subdivisions observed in the arteries of the systemic circulation. On the other hand, the capillaries open into the veins with equal abruptness, and without the gradual reunion observed in the minute veins of the systemic order. These ultimate arteries also give off capillaries, not only from their extremities but from their sides, by minute pores; and the veins receive capillaries in the same manner. The arteries and veins in no case communicate by direct anastomosis, at least in the lung of the salamander. The intermediate vessels, on the contrary, which constitute the capillaries, inosculate in every possible manner, and infinitely more frequently than in the systemic order, and hence constitute an extensive network of cylindrical tubes, of uniform diameter. Through this network the blood flows with extreme rapidity in a uniform current; and as each artery communicates with several capillaries, the blood appears to run like diverging rays from a point or line, and to converge in the same manner, when it proceeds from the capillaries opening into the pulmonary veins. It may be inferred, that one effect of this arrangement is to distribute the moving globules over a surface as extensive as possible, and thus to expose the greatest possible number of them, in a given time, to the inspired air.

This is the distribution of the Capillary Vessels in the lung of the salamander. In the frog and toad, the lungs of which combine the vesicular and cellular arrangement, it is much the same, with this exception, however, that the arteries, previous to their termination in capillaries, follow the external margins of the vertical meshes of which the vesicles consist, while the veins run along their internal margins.

This account applies of course to the capillaries of the Saurial and Batrachoid Reptiles. But there is every reason to believe, that the same arrangement takes place in the Mammiferous class of animals.

The difference of the capillary network depends on three circumstances: 1. The calibre of the tubes; 2. the diameter of the interposed spaces between these tubes; and 3. on the shape of these spaces.

1. The calibre of the tubes varies in different tissues and organs. The smallest are still large enough to allow the blood *corpuscula* to pass one after the other; consequently, in man, the smallest capillaries are not much below 0·003 of one line. This rate is also given by the measurements of Weber from preparations injected and dried in the method of Lieberkuhn. In some parts they vary between 0·004 and 0·003 of one line; and Valentin estimates the smallest vessels of the stomach at 0·0057 in diameter, and in the ileum at 0·0048. Müller represents those of the kidney to range between 0·0037 and 0·0069 of one line.

2. The dimensions of the intervening spaces depend in some measure on the fulness of the tubes. The fuller these are, the smaller are the interstitial spaces. The spaces in the vascular network of the white substance of the brain are, according to C. H. Weber, 0·0142 broad, and 0·025 long; in length, consequently, from eight to ten times, and in breadth from four to six times larger than the diameter of the capillary vessels. In the capillary network of the mucous membranes and the external skin, the meshes are often only between three and four times larger than the diameter of the vessels—often of the same width, or even narrower. In the kidneys, Müller found the diameter of the capillary vessels, in relation to the intervascular spaces, as 1 to between 3 and 4.

3. As to figure, Henle distinguishes two principal shapes; the roundish and the oblong. But besides these, some assume the square figure, others the polygonal, and some are irregular.

Bichat describes two great capillary systems in the human body: 1*st*, The general one, or that which consists of the minute terminations of the aortic divisions, and the origins of the superior and inferior great veins; and, 2*d*, the pulmonary capillary system, or that which consists of the minute terminations of the pulmonary artery, and the origins of the pulmonary veins. The general capillary system further consists of an individual capillary system, not only for every organ, but in some instances for every tissue. The brain possesses an individual capillary system; and that of the membranes is evidently distinct from that belonging to the organ itself. The heart and the kidneys possess each an individual capillary system; and the liver may be said to have two, one formed by the communication of the hepatic artery and veins, and another consisting of the divisions of the portal vein, with the branches of the hepatic hollow vein; (*Vena cava hepatica*).

The organic properties of the capillary vessels are as little known as their structure. Many physiological and pathological writers, especially experimentalists, have ascribed to them a power which has at different times been called muscular, tonic, irritable, contractile; and have asserted that, because the larger arteries are provided with a fibrous membrane, which they have called muscular, and to which they have ascribed irritability, or the power of contraction when stimulated, their minute or

[1] A Critical and Experimental Essay on the Circulation of the Blood, p. 29.

General Anatomy.

Capillaries.

capillary terminations must have the same property. This conclusion is completely unfounded for two reasons. 1*st*, I have already shown that the proper arterial tunic is not muscular in structure, and, according to the best experiments, possesses no property of contraction when stimulated. 2*d*, Although it be admitted that the proper arterial tissue is muscular and irritable, it is quite certain that observation has not hitherto shown that this tunic can be recognised in arteries smaller than a line in diameter; and in the capillaries properly so called, that is, in vessels which partake of the nature of artery and vein, no such structure has yet been observed.

It is not improbable, however, that the capillaries possess certain organic or vital properties; but all that has been taught on this subject is either hypothetical or derived from an insufficient and imperfect collection of facts. It is certain that the blood which moves through them is beyond the direct influence of the action of the heart, and can be affected by this only so far as it keeps the larger vessels constantly distended with a column of blood which cannot retrograde, and must therefore move forward in the only direction left to it. It has been therefore argued that the capillaries must have an inherent power of contraction, by which this motion is favoured. Is it not sufficient to say that they act merely as resisting canals, to prevent their contents from escaping, and to minister to the various tissues and organs those supplies of blood which the several processes of nutrition, secretion, &c. require?

The effects which the application of mechanical irritants, or chemical substances, as alcohol, acids, and alkalies, produced in the experiments of Hunter, Wilson Philip, Thomson, and Hastings, have been supposed to demonstrate the irritable nature of the capillary vessels. The conclusion is illegitimate, in so far as the results of these experiments are open to several sources of fallacy. In some instances these effects are to be ascribed to incipient inflammation, in others to shrivelling of the capillary structure, or crispation by chemical action, in others to actual coagulation of the blood of the capillaries; but none of them prove satisfactorily any peculiar properties in the vessels of which the capillary system is composed.

While the views of Reuss, and the experiments of Dutrochet, Wedemeyer, and Kaltenbrunner, render it probable that the capillaries possess some contractile power, they by no means prove that this is adequate to impel the blood through them, independently of the impulse of the heart. According to the hypothesis of Reuss, the arterial system is in a state of positive, and the venous in that of negative, electricity; and by the operation of this agent the blood is made to move from the former class of vessels through the capillaries into the latter. From the experiments of Dutrochet, again, on the transmission of fluids through organic membranes, that author infers that, by means of the inward and outward impulse, or that property which he denominates *Endosmose* and *Exosmose*, the blood flows through the capillaries into the veins. Lastly, Wedemeyer, who further maintains that the impulsive force of the heart is propagated to the capillary system, concludes, from the effects of injecting fluids, both mild and irritative, and from microscopic observation, combined with the effects of mechanical and chemical irritants, that the capillaries possess considerable contractile power, the operation of which is under the influence of galvanism, or nervous energy, or both; but that this, instead of promoting, ought to resist the motion of the blood through them.

*Erectile Tissue.* (*Vasa Erigentia,—Vascula Erectilia,—Tissu Erectile.*)

Erectile vessels.

The system of capillary arteries and veins does not present the same arrangement in all situations and in all the tissues of the human body. A peculiar arrangement of these vessels was early recognised by our countryman William Cowper, who states that he demonstrated the direct communication of arterial and venous canals, not only in the lungs, but in the spleen and penis, "in which," says he, "I have found these communications more open than in other parts."[1] This fact, however, was long overlooked by subsequent anatomists.

Among the terminations of arteries enumerated by Haller, one which he referred to the head of exhalants was that of a red artery or arteries pouring their blood into the spongy or cellular structure of the cavernous bodies of the nipple, the clitoris, and the penis, that of the wattles of the turkey, and the comb of the cock.[2] His detailed examination of those parts shows, that, with a correct knowledge of their anatomical structure, he had not a very distinct conception of the manner in which their vessels are disposed. It was afterwards observed, however, by John Hunter, that the spongy structure of the urethra and glans consists of a plexus of veins.

Bichat remarked that the spleen, and the cavernous body of the penis, instead of presenting, as the serous surfaces, a vascular or capillary net-work, in which the blood oscillates in different directions according to the impulse which it receives, exhibit only spongy or lamellar tissues, still little known in their structure, in which the blood appears often to stagnate instead of moving. As this peculiar structure was known in the cavernous body to be the seat of a motion long known by the name of *erection*, MM. Dupuytren and Richerand distinguished this arrangement of arteries and veins as a peculiar tissue, under the name of *erectile*,—a distinction which, though partly understood before, has only now been admitted as well founded in the writings of anatomical authors. According to the recent arrangements of M. Beclard this tissue comprehends not only the structure of the cavernous body, but that of the spongy substance (*corpus spongiosum*), which incloses the urethra, and forms its two extremities, the bulb and gland, the *clitoris*, the *nymphæ*, and the nipple of the female, the structure of the spleen in both sexes, and even that of the lips.[3]

It is unfortunate that the researches of anatomists on this erectile tissue have been restricted chiefly to the spongy body of the urethra and the cavernous body of the penis; and it is rather by analogy than direct proof that similarity of structure between them and the other parts referred to the same head is maintained. I shall here state what is ascertained.

The cavernous body of the urethra, or what is now termed its *spongy body*,[4] is represented by Haller to consist of fibres and plates issuing from the inner surface of the containing membrane, and mutually interlacing, so as to form a series of communicating cells,[5] into which the

General Anatomy.

Erectile vessels.

proper urethral arteries pour their blood directly during the state of erection.[1]

The cavernous body of the penis is in like manner represented to be a part of a spongy nature, or to consist of innumerable sacs or cells separated by plates and fibres, which at the moment of erection are distended with blood poured from the arteries, and which is afterwards removed by some absorbing power of the veins.

This opinion, which was that of many subsequent anatomists, even Bichat himself,[2] was derived apparently from the facility with which the blood so deposited escapes, not, as it was believed, from divided vessels, but from *areolæ*, or interlaminar spaces. It appears, however, to have been at variance with what had been anciently taught by Vesalius, Ingrassias, and Malpighi, and positively stated regarding these vessels by Hunter; and modern researches have shown it to be completely erroneous. Cuvier and Ribes in France, Mascagni, Paul Farnese, Moreschi in Italy, and Tiedemann in Germany, have shown that there are no cells or spongiform structure in the erectile tissue of the cavernous body.

The first correct view of the structure of parts of this description in the human subject was given by Mascagni in his account of the arterial and venous communications in the spongy body of the urethra. In 1787 he announced in his work on the Lymphatics, that the parts called cavernous bodies, both in the *penis* and in the *clitoris*, are simply *fasciculi*, or accumulations of arterial and venous vessels without interruption of canal; but that between the arteries and veins of the spongy bodies a dilated cavity or minute cell is interposed. In 1795 repeated minute injections led him to doubt the existence of this sort of cell; and about the close of 1805 he publicly demonstrated the fact, that many veins of considerable calibre, collected in the manner of a plexus, with corresponding arteries, but small and less numerous, really form the outer and inner membranes of the urethra, the whole of the *glans penis*, and the whole substance of the spongy body. In each of these parts, and also in the spongy structure inclosing the orifice of the vagina, he ascertained by repeated injections that there are no cells, as was imagined, and that the arteries, reflected as it were, give origin to numerous veins,[3] which, forming an intimate plexiform net-work, constitute the whole glans, and the entire vascular body which surrounds the urethra and the entrance of the vagina.

In the cavernous bodies of the penis and clitoris he had not sufficient facts to ascertain the existence of the same structure, as he had never succeeded in injecting these parts so completely as the *glans* and the spongy part of the urethra. Eventually, however, he succeeded, especially in children, in injecting fully these cavernous bodies of the penis and clitoris. He found in their interior nothing but *fasciculi* of veins, with corresponding arteries, but rather smaller. He inferred, therefore, that these vessels, collected and ramified in various directions, constitute a vascular texture capable of expanding and shrinking, according to the quantity of blood conveyed to it.[4]

The general accuracy of this description has been since confirmed by the researches of Paul Farnese and Moreschi. The latter, especially, has shown, 1*st*, that the glans consists of arteries and a very great number of minute veins, which pour their blood into the cutaneous dorsal vein; 2*d*, that the urethra, and especially its posterior part, may in like manner be shown to consist of numerous minute veins, which terminate in a posterior branch of the dorsal vein, and communicate with the veins of the bulbous portion of the urethra; and, 3*d*, that in the cavernous bodies, though also receiving blood-vessels, these are much less numerous, and are chiefly derived from the urethral vessels.[5]

The same arrangement was recognised by Cuvier in the penis of the elephant, by Tiedemann in that of the horse, by Shaw in the human subject and in the horse,[6] and by Mr Houston in the tongue of the chameleon.[7]

Upon the whole, the facts collected by different anatomists on this subject furnish the following results.

If the arteries, on the one hand, be injected, they are found to terminate in very fine ramifications, the disposition of which is exactly the same as in other parts. If, on the other, the veins be injected, it is easy to perceive the two following circumstances: 1*st*, That they are much dilated at their origin, that is, that the venous *radiculæ* are really more dilated than might be anticipated from the other characters of these vessels; 2*d*, That the tubular dilatations to which they are accessory form very numerous inosculations or anastomoses, precisely as the capillary system of which they constitute a part. The effect of this arrangement is to give these vessels the appearance of being penetrated with sieve-like openings, resembling *areolæ*, or interlaminar spaces mutually communicating. As the whole difference, therefore, between the capillary vessels of this and other parts of the human frame consists in the minute veins (*radiculæ venosæ*) being dilated or distended in a peculiar manner, Beclard concludes that the erectile tissue of the cavernous body consists simply of minute arteries and dilatable veins interwoven in the manner of capillary nets. These distended venous cavities are indeed so remote from being cells, that they are truly continuous with veins, the inner membrane of which may be easily recognised among them.[8]

During erection the blood accumulates in this tissue; but the cause and mechanism of this accumulation are completely unknown.

Since these observations were made, Johann Müller of Berlin has, by injecting the arteries of the penis, been enabled to give an account of the characters of Erectile vessels, something more detailed and specific.

By injecting the principal artery of the penis before its subdivision, and dividing longitudinally one of the *corpora cavernosa*, the ramifications of the nutrient arteries are seen upon the inner side of the venous spaces, the arteries becoming gradually smaller, until they pass into the capillary net-work, where their divisions cannot be seen by the naked eye. Besides these nutrient ramified arteries there is seen, on careful inspection, another set of arterial branches, of

[1] "Sed et in pene, et in clitoride, et in papilla mammæ, et in collo galli indici, nimis manifestum est, verum sanguinem effundi, neque unquam ejus color totus de iis partibus evanescit, quæ ab effuso sanguine turgere solent." (*Elementa*, lib. xxvii. sect. 3, § 10.)

General Anatomy.

Erectile vessels.

different size, shape, and disposition, which are given off nearly at right angles, from both the large and small trunks. These arterial processes are about one-hundredth part of one inch in diameter, and one-twelfth long, and are clearly seen by the naked eye. They project into the cavities of the spongy substance, and terminate either in blunt extremities or in dilated extremities, without undergoing any division or ramification. These short arterial processes are turned round at their extremities into a semicircle or more, and present a spiral appearance like the end of a cork-screw. This disposition suggested to M. Müller the name of Helicine, or Spiral or Screw-like Arteries (*Arteriæ Helicinæ*).[1]

The helicine arteries of the penis are more easily seen in man than in any other animal examined by Professor Müller. He found them in all the animals in which he sought for them; they are to be seen at the posterior part only of the penis in the stallion, but in the dog exist throughout the whole organ.

In man the helicine twigs of the penal arteries sometimes come off singly; at other times they form tufts or clusters, consisting of from three to ten branches, and having in general one very short common stem. The swelling at the extremity, when present, is gradual, and is greatest a little way from the end. The helicine branchlets given off from large arteries are not of greater size than those coming from small ones; and even the smallest capillary arteries of the *Profunda Penis*, which can be seen with the aid of a glass alone, give off helicine twigs of a much greater size than themselves.

Each helicine branchlet projecting into a venous cavity is covered by a thin membrane, which Professor Müller regards as the inner coat of the dilated vein; and when there is a tuft of helicine twigs, the whole tuft is covered with one envelope of a gauze-like membrane. This covering is considerably thicker on the helicine arteries in the posterior part of the *Corpus Spongiosum Urethræ*, than in the *Corpus Cavernosum;* but it is possible that this is in some measure connected with the state of repletion of the arteries; for when the injection has gone well, it becomes difficult to distinguish the external covering.

Professor Müller could not discover any apertures either on the sides or on the ends of the helicine arteries. But he seems to regard it as probable that there are minute apertures, which may be of that nature that they allow the passage of the blood in certain states and not in others.

The helicine arteries are not, as some may suppose, loops of vessels which have been incompletely filled, and which, after forming a coil, pass into venous spaces, as E. H. Weber found to be the case with the arteries of the maternal portion of the placenta. Müller, it is seen, distinguishes in the branches from the *Arteria Profunda*, p. 800, two orders of vessels; one *Rami Nutritii*, corresponding to the arteries of other organs which serve the purpose of nutrition, and pass continuously into the veins; the others, *Rami Helicini*, with shut ends, forming processes or shoots from the *Arteria Profunda*, bent in the manner of tendrils which project into the cells or spaces of the *Corpora Cavernosa*, and, according to the conjecture of Müller, pour the blood during erection through openings in their ends immediately into the spaces of the *Corpora Cavernosa.* Their diameter is between 0·07 and 0·08 of one line.

The helicine arteries are more numerous towards the root than near the point of the penis. They are observed in the *Corpus Spongiosum Urethræ*, especially towards its bulb; but they are not there so easily seen as in the *Corpora Cavernosa.* They have not hitherto been observed in the *Glans.*

Their structure is nearly the same in all the animals in which they have been examined. The helicine arteries of the ape bear the nearest resemblance to those of man; and in most animals they are less obvious than in the human subject. In the horse and dog, they give off from their sides small nutrient twigs, which render them more difficult to be seen in these animals than in man.

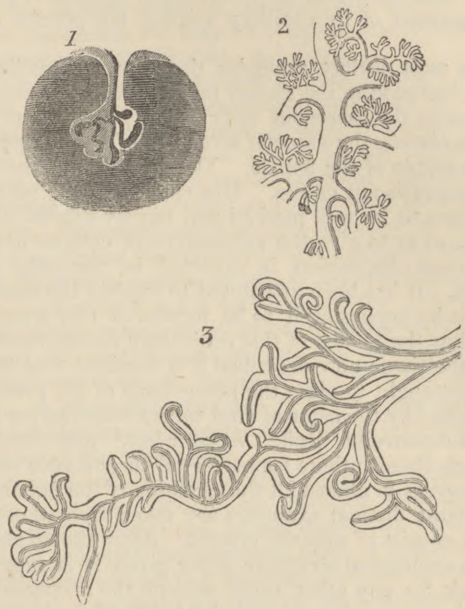

Fig. 1. One single Helicine Artery (Müller).
... 2. A portion of the *Arteria Profunda Penis* in Man, with the Helicine Arteries magnified.
... 3. Individual Helicine Arteries from the posterior part of the *Corpus Cavernosum Urethræ* in man; greatly magnified.

These helicine arteries, on the other hand, Valentin regards as artificial, that is, resulting from the mode of injection.[2] It is impossible here to enter into the details of his arguments. It is sufficient to say that Müller, after repeated researches, adheres to his original views; that Krause confirms his inference;[3] and that Hyrtl saw helicine arteries not only in the penis of man and the horse, but also an analogous formation in the wattles of the throat and head of the turkey-cock.[4] Henle thinks it undoubted that the greatest part of the tendril-shaped appendages of arteries, which at first sight appear entirely like the helicine arteries delineated by Müller, are artificial products. He makes, however, an admission that there may be some genuine or true helicine arteries.[5]

The spleen, M. Beclard thinks, may be said to resemble the cavernous body both in structure and phenomena; and he considers it as at once consisting of erectile tissue, and to be the seat of a species of erection more or less similar to that of the cavernous body. This organ, he argues, becomes the occasional seat of a motion of expansion and contraction; and he adduces the three following conditions in which it takes place. 1*st*, In experiments; when in a living animal the course of the blood in the splenic vein is arrested, the spleen swells, but returns to its former dimensions as soon as the circulation is restored. 2*d*, In diseases; the paroxysms of intermittent fever are

General Anatomy.

accompanied with obvious enlargement of this organ, which subsides at the conclusion of the paroxysm. 3*d*, It appears that the same phenomenon takes place during digestion.

Sir Everard Home, with the assistance of the microscopic inspection of M. Bauer, has made many observations on the structure of this organ. But his purpose appears to have been more particularly directed to ascertain the phenomena of its function and uses; and I cannot discover that his ideas on its intimate structure, and the arrangement of its capillary system, are precise or distinct.

The most distinct examples, therefore, of erectile tissue are to be found in the spongy texture which surrounds the *urethra*, in the cavernous body of the *penis*, in the vessels of the *clitoris*, the vascular structure of the *nymphæ*, and in the nipple of the female. The structure of the lips in both sexes is not unlike. The veins of these parts may be shown to be well marked and largely dilated at their origin, so as to give the appearance of cellular net-work. The same disposition is observed in the pulp of the fingers. It has been attempted to explain the motions of the iris by supposing it to be formed of this erectile tissue; but the justice of this conjecture seems doubtful.

In the tissue now described it is manifest that the physiologist ought to place the phenomena of the process distinguished by the name of vital turgescence (*turgor vitalis*) by Hebenstreit,[1] Reil,[2] Ackermann,[3] and Schlosser.[4] Though these authors suppose vital turgescence in different degrees in almost all the textures of the animal body, their most distinct examples are taken from those parts which consist of erectile vessels. After the explanation of the anatomical structure above given, it is superfluous to seek for any other cause except the arrangement of the minute vessels, and especially that of the veins.

*System of Exhalants, Exhalant System. (Vasa Exhalantia,—Système Exhalant.)*

Exhalants.

Are there such vessels as the exhalants described by physiological authors? Is their existence proved by observation or inspection? If not, what are the proofs from which their existence has been inferred?

The existence of minute arteries, the open extremities of which are believed to pour out various fluids in different tissues of the human body, has long been a favourite speculation with physiological anatomists. The decreasing vessels (*vasculorum continuo decrescentium multi sibique succedentes ordines*[5]), and exhalant orifices of Boerhaave, must be known to almost all. Haller ascribes to the skin, membranes of cavities (*serous membranes*), ventricles of the brain, the chambers of the eye, the cells of the adipose membrane, the vesicles of the lung, the cavity of the stomach and intestines, an abundant supply of these exhalant arteries or canals, which, according to him, pour out a thin, aqueous, jelly-like fluid, which in disease, or after death, is converted into a watery fluid susceptible of coagulation. The existence of these vessels, he conceives, is established by the watery exudation which appears in these several parts after a good injection of the arteries.[6]

As these minute canals, however, through which this injected fluid is believed to percolate, have never been seen, or rendered capable of actual inspection, their existence was denied by Mascagni, who ascribed the phenomena of exhalation to the presence of inorganic pores in the arterial parietes, through which, he imagined, the fluids transuded to the membranes or organs in which they were found. This mechanism, which was equally invisible with the Hallerian, was, for obvious reasons, denied by Bichat, who resolved to reject every opinion not founded on anatomical observation, and to determine the existence of the exhalants by this evidence alone. Obliged, however, to avow the difficulty of forming a distinct idea of a system of vessels, the extreme tenuity of which prevents them from being seen, he undertook to attain his object by what he terms a rigorous train of reasoning.

General Anatomy

Exhalants.

This consists in the effects observed to result from successful injections of watery fluids, or of spirit of turpentine containing some finely levigated colouring matter; from the phenomena of active hemorrhage, which Bichat considers merely as exhalation of blood instead of serous fluid; and from numerous considerations unfolded in the further prosecution of the subject. In this manner he concludes, that the only points ascertained are, 1*st*, the existence of exhalants; 2*d*, their origin in the capillary system of the part in which they are distributed; and, 3*d*, their termination on the surfaces of serous and mucous membranes, and the outer surface of the corion or true skin.

The exhalant vessels, the existence, origin, and termination of which he thus proved, he distinguished into three classes. The first contains those exhalants which are concerned in the production of the fluids which are immediately removed from the body,—the cutaneous and the mucous exhalants; the second contains those exhalants which are employed in the formation of fluids which, continuing a given time on various membranous surfaces, are believed to be finally taken again into the circulation by means of absorption; and the third class consists of the exhalants concerned in the process of depositing nutritious matter in the different tissues and organs of the human frame. This arrangement is more distinctly seen in the following table.

| | | |
|---|---|---|
| Exhalants may be, | 1. Exterior, opening on natural surfaces or canals........................................ | Cutaneous.<br>Mucous. |
| | 2. Interior, opening on membranes, or within cellular textures............................ | Serous.<br>Synovial.<br>Cellular.<br>Medullary. |
| | 3. Nutritious. | |

Each organic tissue is in this system supposed to have its appropriate exhalant arteries, from which it derives the material requisite for its nutrition.

The clearness and regularity of this arrangement would render it desirable that the existence of these vessels were demonstrated with certainty. It is evident, however, that the regularity of arrangement is the only advantage which it possesses over the views of those authors whose method and opinions Bichat professed not to follow. The existence of exhalants is as little proved

(*Elementa*, lib. vii. sect. 2, § 1.)

General Anatomy. Exhalants. in the rigorous reasoning of Bichat as in the fanciful theories of Boerhaave, the generalizing conclusions of Haller, or the bold supposition of lateral porosities by Mascagni. This defect in his system has therefore been recognised both by Magendie and Beclard, the first of whom, though he admits the existence of exhalation as a process of the living body, allows that no explanation of its mechanism or material cause has been given, and asserts that Bichat has created the system of vessels termed exhalants; while the second thinks that anatomical observation furnishes no evidence of their existence.

The colourless capillaries, he observes, which are admitted by all, and the existence of which is satisfactorily established by the well-known experiment of Bleuland, proves nothing whatever concerning the existence of exhalant vessels; for these colourless arteries are observed to terminate in colourless veins, and there is no proof hitherto adduced of their proceeding further, or terminating by open mouths. He admits that the fact of exhalations in the living body, of nutrition, of transudation by arterial extremities, shows that these extremities possess openings through which the fluids of exhalation, the materials of nutrition, and the matter of injection, escape. But whether these openings are found at the point at which the capillary arteries are continuous with veins, or belong to a distinct order of vessels continued beyond these arteries, is a question which observation has not yet determined, and which it perhaps is unable to determine. Such is the present state of knowledge in relation to the existence of exhalant arteries. While the process of exhalation is admitted, we must avow, as Cruikshank did long ago, that we are unable to prove satisfactorily the existence of any set of vessels, or any mechanism by which it might be accomplished.

*Lymphatic System.* (*Vasa Lymphatica, Vasa Lymphifera, Lymphæ-Ductus* of Glisson and Jolyffe,—*Systême Absorbant,—Die Saugadern.*)

Lymphatics. In most situations of the human body, and especially in the vicinity of arterial and venous trunks, there are found long, slender, hollow tubes, pellucid or reddish, which present numerous knots, joints, or swellings in their course, and to which the name of lymphatics or absorbents has been given. It is most expedient to employ the former appellation only, as the latter implies the performance of a function, the reality of which has been much questioned of late years.

Though Eustachius had seen the thoracic duct in the horse, and some slight traces of a knowledge of vascular tubes, different either from arteries or veins, are found in the writings of Nicolaus Massa, Fallopius, and Veslingius, the merit of establishing their existence is generally ascribed to Caspar Asellius, a physician of Pavia. This anatomist, who had in 1622 seen the white-coloured tubes, then first named *lacteals*, issuing from the intestines of the dog, observed also a cluster of vessels less opaque near the portal eminences of the liver,—an observation which he afterwards repeated in the horse and other quadrupeds. The same vessels were also described and delineated by Highmore.

Passing over the uncertain and obscure hints given by Walæus and Van Horne, the first exact information after Asellius is that which relates to Olaus Rudbeck, who, in 1650, is said to have seen them in a calf, and to have demonstrated the thoracic duct, and the dilated sac, afterwards termed *receptaculum chyli*.

Glisson informs us that Jolyffe had in 1652 imparted to him the knowledge of a set of vessels different from arteries and veins; and it appears, from the testimony of Wharton, that Jolyffe had demonstrated these vessels in 1650.[1] In short, the discovery of lymphatics, and the correction of some errors of Asellius, are ascribed to the English anatomist, not only by Wharton and Glisson, but by Charleton, Plott, Wotton, and Boyle.

The existence of these vessels, thus partially demonstrated, was afterwards more fully established by the researches of Bartholin, Pecquet, Bilsius, Nuck, the second Monro, and Haller. It is chiefly to the exertions of William Hunter, and his pupils Hewson,[2] Sheldon,[3] and Cruikshank,[4] in this country, and to those of Mascagni[5] in Italy, that the anatomical world are indebted for the complete examination and history of this system of vessels.

The lymphatic vessels consist, in the members, of two layers, a superficial and a deep-seated one. The first is situate in the subcutaneous cellular tissue, between the skin and the aponeurotic sheaths, and accompanies the subcutaneous veins, or creeps in the intervals between them. A successful injection of these superficial lymphatics will show an extensive net-work of mercurial tubes surrounding the whole limb.

The deep-seated layer of lymphatics is found chiefly in the intervals between the muscles, and along the course of the arterial and venous trunks. In tracing both layers of lymphatics to the upper, fixed, or attached end of the members, we find they increase in volume and diminish in number. At the connection of the members with the trunk, they are observed to pass through certain spheroidal or spherical bodies, termed lymphatic glands or ganglions. The lymphatics of the upper extremity, after passing through the glands of the armpit, terminate in trunks, which open into the subclavio-jugular veins, one on each side of the neck. Those of the lower extremity, after passing through the glands of the groin, proceed with the common iliac vein into the abdomen, where they unite with other lymphatics.

The lymphatics of the trunk consist in like manner of two layers, a subcutaneous and deeper seated one, distributed in the chest between the muscles and pleura, and in the abdomen between the muscles and peritoneum. In the chest and belly, each organ possesses a superficial layer of lymphatics distributed over its surface, and pertaining to its membranous envelope; the other ramifying through its surface, and pertaining to the peculiar tissue of the organ. This twofold arrangement is most easily seen in the lungs, the heart, the liver, spleen, and kidneys.

In a similar manner are arranged the lymphatics in the external parts of the scull; on the face, where they are very numerous; in the spaces between the muscles; and on the neck, in which they pass through numerous glands. No lymphatics, however, have been found in the brain, the spinal chord, their membranous envelopes, the eye, or the ear.

General Anatomy.

Lymphatics.

All the lymphatics hitherto known terminate in two principal trunks. One of these, termed from its site *thoracic duct* (*ductus thoracicus*, die Milchbruströhre, *le canal thoracique*), is situate on the left side of the dorsal vertebræ. It receives the lymphatics of the lower extremities, of the belly, and the parts contained in it; those of great part of the chest, and those of the left side of the head, neck, and trunk, and left upper extremity. The other lymphatic trunk, which is situate on the right side of the upper dorsal vertebræ, is formed by the union of the lymphatics of the right side of the head, neck, right upper extremity, and some of those of the chest. Both of these trunks open into the subclavio-jugular vein of each side.

That lymphatics terminate in branches of the venous system, has been asserted on the authority of various observers. Steno, for instance, states that he traced the lymphatics from the right side of the head, the chest, and pectoral extremity, in animals, into the right axillary vein; and he gives delineations of anastomotic connections of several lymphatics with the axillary and jugular veins. Similar facts have been reported by Nuck, Richard Hale, Bartholin, and Hartmann. Ruysch traced the lymphatics of the lung into the subclavian and axillary veins; Drelincourt those of the thymus gland in animals into the subclavians; and Hebenstreit saw those of the loins pass into the *vena azygos*.

Haller, though unwilling to deny the testimony of these observers, considers it liable to various sources of fallacy, and doubts the direct communication of the lymphatic and venous systems. By John F. Meckel the grandfather, nevertheless, this communication was maintained, from the circumstance that he found mercury injected into the lymphatics pass into the veins without any traces of extravasation. From injecting the lymphatics also he found the *inferior* cava full of mercury, not a particle of which had passed by the thoracic duct into the *superior* cava. Injecting afterwards an indurated lumbar gland from a pelvic lymphatic, when he found its lower half only was filled, he increased the pressure, with the view of filling the minute vessels of the gland. When this was continued a little, he observed the fluid metal pass into the *inferior* cava, and thus traced the minute lymphatics into the venous system.[1]

These facts have received too little attention, from the circumstance that Hewson, though not doubting them as stated by the author, regarded them as liable to considerable fallacy, and, along with William Hunter, imputed the effect in question entirely to extravasation. Both Hunter and Hewson, indeed, appear to have injected veins from lymphatics in the same manner in which Meckel did; but both saw reason to infer that extravasation had taken place. Cruikshank, again, states that he never saw a lymphatic vessel inserted into any other red veins than the subclavians and jugulars. The termination remarked by Steno and his successors constitutes in truth the common trunk or lymphatic vein admitted by Cruikshank,—a *thoracic duct* of the right side.

Recently this mode of termination has been revived by Tiedemann and Fohmann,[2] who state that, in the seal, the lactiferous vessels communicate with veins arising from the mesenteric glands, and pass thence into the venous trunks without proceeding through the thoracic duct. M. Lauth junior, of Strasburg, again, conceives that he has demonstrated that lymphatics communicate with veins within the substance of organs, and in the interior of the lymphatic glands;[3] an inference which at present requires further verification. The statements of Lippi of Florence,[4] that every lymphatic almost communicates freely with venous tubes, is still more improbable, and has been rendered exceedingly doubtful by the recent researches of Rossi.[5]

The connections of the ends of lymphatics with the organs and tissues from which they arise, termed their *origins*, are completely unknown. In some favourable instances the lymphatics of the intestinal canal are so filled with a reddish or whitish fluid after the process of digestion has continued for some time, that not only are their larger branches easily seen, but by the aid of the microscope some of the smaller may be traced to their commencement. This, which was ascertained by Cruikshank (p. 55 and 58), and confirmed by Hewson, Bleuland, and Hedwig, has been contradicted by the observations of Rudolphi and Albert Meckel. In all other parts, however, though a successful injection may show the course and distribution of many of the smallest lymphatics, yet no orifices are perceptible at the point at which they seem to stop, and we are uncertain whether these points are their origins. (Cruikshank.) Mere observation is here as unavailing as in regard to the termination of exhalants. The continuation of lymphatics with arteries, unless in the case of those which arise from the interior of arterial tubes (Lauth), is not satisfactorily established. It has been conjectured, however, that their ends or imperceptible origins are connected to the tissues to which they are traced, and that the lymphatics arise in this manner from these tissues.

The lymphatics are distinguished by being in general cylindrical in figure, and by varying in calibre at short spaces. In this respect they differ from the arteries and veins. It has been further justly remarked by Gordon, that the middle-sized lymphatics are remarkably distinguished from the corresponding parts of the arterial and venous system by three peculiarities: 1*st*, When two lymphatics unite to form a third, the trunk thus formed is seldom or never larger than either of them separately; 2*dly*, their anastomoses with each other are continual; and, 3*dly*, they seldom go a great space without first dividing into branches, and then reuniting into trunks.

The outer surface of a lymphatic is filamentous and rough, the inner smooth and polished, like that of small veins. It is impossible to observe the structure of these tubes in the middle-sized, or even in the large lymphatics; and anatomists have generally been satisfied with supposing that the structure of all of them is similar to that of the thoracic duct, or some other large vessels equally susceptible of examination. According to the observations of Cruikshank (chap. xii.), which have been verified by Bichat, the thoracic duct presents, 1*st*, a layer of dense, firm, filamentous or cellular tissue, exactly similar to that found inclosing arterial and venous tubes, which the latter regards as foreign to the vessel, but giving it a great degree of support and protection; 2*dly*, a proper membrane, delicate, transparent, and moistened inside by an unctuous fluid, which he seems inclined to

ascribe to transudation. Muscular fibres, of which Sheldon speaks positively, Cruikshank represents, though seen in some instances (chap. xii.), yet to be more generally not demonstrable. Their existence, though admitted by Schreger and Soemmering, is denied by Mascagni, Rudolphi, and J. F. Meckel, and, I may add, by Bichat and Beclard. This account differs not much from that of Dr Gordon, who could not recognise distinctly more than one coat, similar to the inner coat of veins. The filamentous layer noticed by Bichat, and considered by Mascagni as an external coat, is of course excluded.

The knotted or jointed appearance of lymphatics is occasioned chiefly by short membranous folds in their cavity, called *valves*. These folds are thinner than the venous valves; but they are equally strong, and have the same shape and mode of attachment to the inside of the vessel. They are generally found in pairs, but never three at the same point. A single valve is sometimes found at the junction of a large branch with a trunk, or of a trunk with a vein. According to Cruikshank, there is considerable variety in the distribution of valves; but in general a pair of valves will be found at every one-twentieth of an inch in lymphatics of middling size. In the larger lymphatics they are less numerous than in the small. The structure of these valvular folds is as little known as that of the inner membrane, of which they appear to be prolongations. According to Mascagni, they sometimes contain a small portion of fine adipose substance.

The tissue which forms the lymphatic tubes is strong, dense, and resisting; and from the weight of mercury which they bear without rupture, it has been generally concluded that they are stronger in proportion to their size than veins. This tissue also possesses considerable elasticity.

The opposite states of lymphatics during digestion and after long fasting, and the phenomena of mercurial injections, prove that the tissue of which they consist is distensible and contractile. Though it does not exhibit appearances of muscular structure, it has been long supposed to be endowed with a property analogous to irritability. Such is the inference which Hunter, Hewson, Cruikshank, and others, have derived from various phenomena in the living and recently dead tissue.

Though Bichat doubts what he terms organic sensible contractility, yet he admits insensible contractility as necessary to the functions ascribed to lymphatics. Previous to his time Schreger, in different experiments, observed the first of these qualities, in consequence of the application not only of acids, butter of antimony, and alcohol, but even of hot water and cold air. Similar contractions and relaxations have been induced by mechanical irritation. Such phenomena are observed not only during life, but even after death; and if to this we add, that the thoracic duct is often after death large and flaccid, though empty, but in the living body is almost always contracted and scarcely visible, and that a portion of it included between two ligatures, and punctured, quickly expels its contents, it may be inferred that the lymphatic tissue possesses a considerable degree of this organic property.

*Lymphatic Gland or Ganglion, Kernel. (Glandulæ Lymphaticæ,—Glandulæ Conglobatæ,—Die Saugader-Drüsen.)*

Lymphatic glands.

This is the proper place to consider the structure of those bodies which are in common language termed *kernels*, to which anatomists have applied the name of *lymphatic glands*, and the French anatomists have more recently given that of *lymphatic ganglions*. The usual appearance, figure, and situation of these bodies are well known. In general they are spheroidal, seldom quite globular, and most commonly their shape is that of a flattened spheroid. In different subjects, and in subjects at different ages, they vary from two or three lines to an inch in diameter. The medium rate is about half an inch. Their surface is smooth; their colour grayish-pink, sometimes pale red, bluish, or of a peach-blossom tinge,—varieties which seem to depend on degrees of bloody transudation; for, when washed and slightly macerated, they assume the gray or whitish-blue colour. In a few instances they are jet black,—a peculiarity which seems to depend on a degree of black infiltration, or on the incipient stage of that change which has been termed *melanosis*, or melanotic deposition. The idea that it may be derived from the carbonaceous matter suspended in the atmosphere of great cities, has been shown by Cruikshank to be absurd. Its anatomical possibility may be justly questioned.

They are always situate in the celluloso-adipose tissue found in the flexures of the joints. They are found in small number at the bend of the ham, and that of the elbow; in the armpit and groin they are more numerous; in considerable number in the cellular tissue of the lumbar region, before the *psoas* and *iliacus* muscles; and they are most abundant round the neck. The posterior mediastinum, and the cellular tissue between the mesentery and vertebral column, abound with lymphatic glands mutually connected in clusters.

Each gland may be said to consist of a peculiar substance, inclosed in a thin membrane like a capsule. The capsule is a thin, pellucid, colourless substance, which is resolved by maceration into fine whitish fibres. It is very vascular; and Mascagni appears to have detected absorbents in it. It is connected to the proper substance by fine filamentous or cellular tissue. The capsule is considered by Beclard as a fibro-cellular membrane. The proper substance of lymphatic glands consists of a homogeneous pulp, in which injections have shown numerous ramifications of minute vessels. As these vessels are injected from the lymphatics which are seen to enter the body of the gland, they are believed to be continuous with them, and to be lymphatics arranged in a peculiar manner. These vessels are of two kinds, one entering the gland, called *vasa afferentia* or *inferentia*, entrant lymphatics; the other quitting, are called *vasa efferentia*, egredient lymphatics. This distinction is founded on the direction of the valves. In the *vasa inferentia* the free margins of the valves are turned towards the gland; in the *vasa efferentia* they are turned from it.

The number of entrant lymphatics varies from one to thirty, and, what is more remarkable, very rarely corresponds with that of the egredient lymphatics, which are in general much fewer. Cruikshank states that he has injected fourteen entrant lymphatics to one gland, to which only one egredient vessel corresponded. When the entrant lymphatic reaches the gland, it splits into many radiated branches, which immediately sink into its substance. The egredient lymphatics are generally larger than the entrants.

The arrangement of these vessels in the interior of the glands is best described by Mascagni, whose observations are confirmed by Gordon. To see this well, it is requisite to inject the entrant lymphatics of two glands in two different modes; one with mercury, the other with wax, glue, or gypsum. After a successful mercurial injection, the entrants are seen, before sinking in the gland, to divide into two orders of branches. One of them, which belongs chiefly to the surface or circumference of the gland, consists of large vessels, bent, convoluted, and in-

General Anatomy.

Lymphatic glands.

terwoven in every direction, communicating with each other, and swelling out into dilated cells at certain parts; and of smaller vessels, which form a minute net-work on the surface, and which seem to terminate in the cells or distended parts of the larger vessels.

From these distended parts or cells, again, arise many minute vessels, which, after winding about on the surface of the gland, unite gradually, and form the egredient vessels of the gland.

The wax, glue, or gypsum injection is employed to show the deep-seated or central vessels of the gland. The distribution of these is found to be quite the same as that of the superficial vessels.

The cells delineated by Cruikshank I am disposed to regard as mere dilated parts of the lymphatic vessels which constitute the intimate structure of the gland.

These minute tubes are connected by delicate filamentous tissue, which is more abundant in early life than afterwards.

Injections show the existence of blood-vessels which accompany the convolutions of the lymphatics in the glands; but no nerves have been found either in the glands or their capsules.

The white matter described by Haller and Bichat is not contained in the cellular substance, but in the cells of the lymphatic vessels themselves.

The three orders of tubes or canals, the anatomical characters of which have now been completed, constitute what has been termed the VASCULAR SYSTEM; (*Vasa; Systema Vasorum;* Das Gefass System; *Le Système Vasculaire.*) The great extent of its distribution, and the part which it performs in all the processes of the living body, both in health and during disease, must be easily understood. In every texture and organ arteries and veins are found; and in all, except a few, the art of the anatomist has demonstrated those colourless valvular tubes denominated lymphatics. The arrangement of the former, especially in the substance of the several textures, essentially constitutes what is termed the *organization* of these textures. Many anatomists have imagined that each texture has a proper matter, or *parenchyma*, by which it was supposed to be particularly distinguished, and which was conceived to consist of minute, inorganic, solid atoms. Whether this opinion be well founded or not, it is perhaps of little moment to inquire. At present it is certain that it is not susceptible of demonstration.

The phenomena of injections, in which he was eminently successful, led Ruysch to entertain the opinion, that every substance of the animal frame consists of nothing but vessels. This idea, though opposed by Albinus,[1] on the same grounds on which it was advanced, was nevertheless revived by William Hunter, who believed that the inorganic parts of animal bodies are too minute for sensible, or even microscopical examination. In every part, however minute, always excepting nails, hair, tooth enamel, &c. vessels may be traced; and even a cicatrix, he demonstrated, is vascular to its centre.[2]

By the aid of the microscope the researches of Lieberkuhn tended still more powerfully to favour this opinion.[3] But repeated observation of the effects of injection in every part and texture almost of the body, by Barth and Prochaska, has led the latter to conclude that this opinion, understood in the ordinary mode, is not tenable. Prochaska, who has investigated this subject with much attention, thinks he is justified in dividing all the substances of the animal frame into two,—those which may be injected, and those which cannot. In this manner he regards skin, especially its outer surface, muscle, various parts of the mucous membranes, the *pia mater*, the lungs, the muscular part of the heart, the spleen, the liver, kidneys, and other glands, as very injectible; but tendon, ligament, cartilage, &c. as not injectible.[4] Without entering minutely into the merits of this distinction, or the inferences which Prochaska deduces from it, it is sufficient, so far as all useful knowledge is concerned, to infer that blood-vessels are an essential constituent of every organic texture, however different; and if there be any other matter inherent in such textures, it must be derived from these as a secretion. Nerve, brain, muscle, osseous matter, and cartilage, are depositions or the product of nutritious secretion from the respective arteries of these organized substances.

*Nerve, Nervous Tissue.* (Νευρον,—*Nervus,*—*Tissu Nerveux,*—*Système Nerveux.*)

Nerves.

The nervous system of the animal body includes two general divisions. The first of these, named Brain and spinal Chord, is collected in a single and indivisible mass, and contained in a peculiar cavity, formed by part of the osseous system of the animal,—the vertebral column, and cranium, in the Vertebrated animals generally. The second division of the nervous system, with which alone we are at present concerned, is found in the form of long chords or threads mutually connected, and running in various directions through the body in the mode of ramification. To these the name of nervous trunks or chords, or simply nerves, has been long applied.

The structure of the nerves has been examined with different degrees of accuracy and minuteness by a great number of anatomists. The more ancient authors, who wrote at a period when observation was much corrupted by fancy, and most of those who gave descriptions in general systems, may be without much injustice passed over in silence. It is sufficient to say that some good facts are given in the works of Willis, Vieussens, Morgagni, and Mayer; that Prochaska, Pfeffinger, the second Monro, and Fontana, are the first who professedly wrote on the structure of the nerves; that the works of Reil,[5] Bichat, and Gordon, contain the most accurate information on the nervous chords in general; and that the treatises of Scarpa[6] and Wutzer[7] contain the best descriptions of the arrangement of those parts named ganglions and plexuses.

Lastly, by the microscopic researches of Ehrenberg, Treviranus, Berres, Müller, Purkinje, Valentin, Weber, Burdach, Remak, and Pappenheim, some facts, though rather discordant, have been communicated on the minute structure of the microscopic filaments.

All the nervous chords of the animal body may be distinguished in physical characters into two different orders, which, though frequently mingled with each other, neverthe-

less possess sufficiently different properties to enable the observer to distinguish them, independent of knowledge of their intimate structure.

The first order of nerves are firm, glistening white, marked by cross-stripes, and are distributed principally to the muscles of the trunk and the skin. The second order are soft, reddish-gray in colour, flat, much interwoven with each other, and belong more to the viscera, and accompany the bloodvessels. The former have knotty swellings only at their origins, and at spots where they form connections with nerves of the second sort; the latter are in all parts occupied by small knots. The white nerves of the first order are named animal, or Cerebro-spinal nerves; the gray nerves of the second are known as soft, entrophic, sympathetic, vegetative, or organic, also as vascular or Gangliar nerves.

The following description applies to the nerves of the first order, unless where the contrary is expressly stated.

Each nerve forms connections in three different ways. 1*st*, A nerve must be connected to some part of the central mass by one of its extremities,—the cerebral or spinal end; 2*d*, it must be connected to some texture or organ, or part of an organ, by the other extremity,—the organic end; and, 3*d*, it may be connected to other nerves by a species of junction called anastomosis (*ansa*), anastomosing or uniting point. By means of the first two connections, it is supposed to maintain a communication between the central mass and the several organs; and by the latter it is understood to be subservient to a more general and extensive intercourse, which is believed to be necessary in various functions and actions of the animal system.

Every nerve consists essentially of two parts; one exterior, protecting, and containing; the other interior, contained, and dynamic,[1] forming the indispensable part of the nervous structure.

The first of these, which has been known since the time at least of Reil by the name *neurilema* (νευρο εἰλεω εἰλημα, *nervi involucrum*), or nerve-coat (*Nervenhaut*, Reil; *Nervenhülle*, Meckel), has the form and nature of a dense membrane, not quite transparent, which is found on the outside of the nervous chord or filament, and invests the proper nervous substance. It must not, however, be imagined that the *neurilema* forms a cylindrical tube, in the interior of which the nervous matter is contained. The latter disposition, if it actually exists, applies to the smaller nerves only, and to some of those which go to the organs of sensation,—a peculiarity which we shall notice subsequently.

Any large nervous trunk, for example the spiral or median of the arm, or the sciatic nerve of the thigh, is found to be composed of several small nervous chords placed in juxtaposition, and each of which, consisting of appropriate *neurilema* and nervous substance, is connected to the other by delicate filamentous tissue. These, however, do not through their entire course maintain the parallel disposition in respect to each other, but are observed to cross and penetrate each other, so as to form an intimate interlacement of nervous chords and filaments, each of which, however minute, is accompanied with its investing neurilema. The neurilema, in short, may be represented as a cylindrical membranous tube, giving from its inner surface many productions forming smaller tubes (*canaliculi;* die Nervenröhre; primitive cylinders of Fontana[2]), in which the proper nervous matter is contained.

Of this arrangement the consequence is, that each nerve or nervous trunk, enveloped in its general neurilema, is composed nevertheless, of a number, more or less considerable, of smaller chord-like nervous threads (*funiculi nervei*, Prochaska; *chordæ, funes, Nervenstränge*, Reil), into which the nerve, by maceration and suitable preparation, may be resolved. Each chord, again, or *nerve-string*, as Reil terms it, though invested with a proper neurilem, may be further resolved into an infinite number of minute filiform or capillary filaments (*fila, fibrillæ, Nervenfasern*, Reil), which, invested in a delicate covering, are understood to constitute the ultimate texture of the nerve.

This threefold division may be easily observed in the brachial and spiral nerves of the arm, and still more distinctly in the sciatic in the thigh. The utility of understanding the internal arrangement from which it results will appear forthwith, when the structure of those parts termed ganglions and plexuses comes under examination.

Of this arrangement in different nerves, and in different regions, this membrane undergoes great modification; and all opinions on its nature derived from thickness or transparency are liable to considerably fallacy. Scarpa seems to view it as connected, in anatomical origin and character, with the hard membrane (*meninx dura, dura mater*). Reil, who devoted more care and time to the examination of its nature and structure than any other inquirer, represents it as consisting of cellular substance, many bloodvessels, and some lymphatics.[3] Bichat thinks it resembles the soft membrane of the brain (*pia meninx, pia mater*), and is derived from it.[4] The neurilema of the cerebral nerves may be regarded as consisting of soft membrane (*pia mater*) at their origin, but in all other situations as a species of filamento-fibrous membrane.

The connection supposed by Mayer to exist between the neurilema and the *pia mater* was disproved by Reil; and though its analogy with the denticulated ligament were established, it would prove nothing regarding the neurilema. Upon the whole, the idea of Reil is the most probable. According to the observations of this anatomist, who examined the neurilema after fine and successful injection, it is liberally supplied with bloodvessels. These proceeding from the neighbouring arteries penetrate the filamentous sheath of the nerve; and, immediately on reaching the neurilema, divaricating at right angles, generally run along the nervous threads (*funes*), parallel to them, forming numerous anastomotic communications, and divide into innumerable minute vessels, which penetrate between them into the minute neurilematic canals. So manifold is the ramification, and so minute the distribution, that in these canals not a particle of nervous substance is found which is not supplied with a vessel.[5] The arrangement of the veins is analogous.

It appears, therefore, that the neurilema is a tissue of membranous form, with a multiplied mechanical surface, liberally supplied with bloodvessels, from which the nervous matter is secreted and nourished. It is impossible, indeed, to doubt that, of the two parts which compose the nervous chord, it is the most perfectly organized; and that, though it may not be similar in structure to the *pia mater*, it is quite analogous in the use to which it is subservient. Like that membrane, it sustains the vessels of the nerve; it presents a multiplied surface, over which the vessels are distributed; and, by penetrating deep into the body of the nerve, it conveys the nutritious vessels in the most capillary form to the inmost recesses of the nervous substance.[6]

The arrangement which has been above described is the

---

[1] The term *dynamic* is used to denote in a general sense the properties of animal substances.

General Anatomy.

Nerves.

only one which can be regarded as general. It varies in particular regions; and these varieties in the neurilematic disposition occur principally in the nerves which are distributed to the proper organs of sensation.[1] *1st*, The olfactory nerve is soft, pulpy, and destitute of neurilema, from its origin in the Sylvian fissure, to the gray bulbous enlargement which terminates its passage in the cranium; but as soon as it reaches the *canaliculi* or grooves of the ethmoid bone, and begins to be distributed through the nasal anfractuosities, it is distinctly neurilematic. *2d*, The optic nerve is still more peculiar in this respect. The instant it quits the optic commissure (*commissura tractuum*), it begins to be invested by a firm general neurilema, which sends into the interior substance of the nerve various membranous *septa* or partitions, forming separate canals, in which the nervous matter is contained. These partitions, however, are so thin, that at first sight the optic nerve seems to consist merely of one exterior membranous cylinder inclosing the proper membranous substance. *3d*, Lastly, we may remark, that the auditory nerve, or the soft portion of the seventh pair of most anatomical writers, is the only nerve in which this covering cannot be traced.

The neurilema is much thinner and more delicate in the nerves which are distributed to the internal organs, as the lungs, heart, stomach, &c., (nerves of the organic life, great sympathetic and pneumogastric nerves *par vagum*), than in those belonging to the muscular system.

The second component part of the nervous chord or filament is the proper nervous matter which occupies the cavity of the neurilematic canals. Little is known concerning the nature or organization of this substance. It is whitish, somewhat soft, and pulpy; but whether it consists of aggregated globules, as was attempted to be established by Della Torre and Sir Everard Home, or of linear tracts disposed in a situation parallel to each other, as appears to be the result of the inquiries of Monro, Reil, and others, or of capillary cylinders containing a transparent gelatinous fluid, as Fontana represents, seems quite uncertain. It has been presumed, rather than demonstrated, that it resembles cerebral substance. But this analogy, though admitted, would throw little light on the subject; for at present it is almost impossible to find two anatomical observers who have the same views of the intimate nature of cerebral substance itself. Whatever be its intimate arrangement, it appears to be a secretion from the neurilematic vessels. (Reil.)

The structure of the nervous chord may be demonstrated in the following manner. When a portion of nerve is placed in an alkaline solution, the whole, or nearly the whole, of the nervous matter is softened and dissolved, or may be washed out of the neurilematic canals, which are not affected by this agent, and the disposition of which may be then examined and demonstrated.[2] Aqueous maceration may likewise be advantageously employed to unfold this structure; for it separates and decomposes the cellular tissue by which the neurilematic canals are united, and subsequently occasions decomposition of the nervous substance, while it leaves, at least for some time, the neurilema not much affected. When, however, the maceration is too long continued, it is separated and detached like other macerated textures.

*Lastly*, If a large nerve be placed in diluted acid for the space of one or two weeks, the neurilema is gradually dissolved, and the nervous matter becomes so much indurated and consolidated, that it may be separated from the contiguous chords in filaments with great facility.[3] In undergoing this change, the portion of nerve becomes much shorter and considerably contracted,—is subjected, in short, to the process of crispation; so that unless a large nerve like the sciatic be employed for the experiment, it may be impossible to obtain the result in the most satisfactory form. These experiments, with many others of the same nature, were first performed by Professor Reil, and afterwards repeated and varied by Bichat and Gordon.

The minute structure of the nerves has been examined by Fontana, Prochaska, Bauer, Ehrenberg, Valentin, Muller, Wagner, Remak, and Purkinje. But the results at which they have arrived are far from agreeing with each other; and either from the difficulty of the subject, and the minuteness of the objects, or from imperfections in the observations, it is next to impossible to present an account consistent and intelligible.

M. Bauer found the optic nerve to consist of many bundles of very delicate fibres, connected together by means of a jelly-like, transparent, semi-fluid, viscid substance, easily soluble in water. These fibres consist of rows of globules, which are from $\frac{1}{2800}$th to $\frac{1}{4000}$th part of one inch in diameter, with a few at $\frac{1}{2000}$th part of one inch in diameter; the latter being the size of the red globules of the blood, when deprived of colouring matter. The Retina appeared like a continuation of the bundles composing the optic Nerve, consisting of the same sized globules connected into fibrous lines, and forming bundles radiating from the end of the nerve to the circumference of the Retina, where they disappear, terminating in smooth membrane.[4]

Before noticing the observations of Ehrenberg, it may be proper to state that he distinguishes the following forms of organic structure, as visible by the microscope in the Brain or its parts, the Spinal Chord, and Nerves.

1. A series of tubes which present, at definite intervals, globular or spheroidal expansions, so as to resemble a string of beads which do not touch each other, but have a short communicating space interposed between each bead. To these tubes Ehrenberg gives the name of Varicose, from their resemblance to the Varices of a vein, and Jointed or Articulated tubes, because of the slight resemblance to a set of joints. The best name for them is Moniliform, or bead-like, when they really resemble a string of beads. These tubes, which present to the microscope the appearance of parallel fibres, he shows by various proofs to have an internal cavity, and to contain a peculiar matter, to which he assigns the name and qualities of nervous fluid. They are confined chiefly to the white matter of the brain; but occur also in several of the sensiferous nerves.

2. A set of tubes, straight and uniform, without the alternate spheroidal enlargements, also hollow, and to which he applies the name of Simple Cylindrical Tubes. These are found chiefly in the nervous trunks and chords. These are generally larger and coarser than the Articulated Tubes; but in certain points the latter are found to pass into the former by gradually losing their bead-like enlargements. These tubes he further represents to be distinguished from the Cerebral Jointed Tubes, by containing in their interior a viscid, white, but less transparent matter, to which he applies the name of Medullary.

3. Besides the two now mentioned, Ehrenberg mentions

[1] By the term "proper organs of sensation" are understood those of sight, hearing, smell, and taste, which are confined to a fixed spot in the system.

[2] Reil, *de Structura Nervorum*, cap. i. p. 3 and 5.

[3] According to the experiments of Reil, nitrous acid diluted with water answers best. Muriatic acid, though equal or even superior in effecting solution of the neurilema, softens the nervous matter too much, and separates the component filaments too completely. (*De Structura Nervorum*, cap. iii. p. 16.)

[4] Philosophical Transactions, 1821 and 1824.

a substance consisting partly of very minute fine grains, with some coarser-grained matter disseminated, as is said in the language of mineralogy, through the fine-grained matter. The latter is confined entirely to the gray matter of the convoluted surface of the Brain, and the laminated surface of the Cerebellum.

The olfactory, optic, and auditory nerves, Ehrenberg found to consist of varicose or moniliform medullary tubules, directly continued from the moniliform tubes of the white cerebral matter. The moniliform tubules of the olfactory nerves are the thickest known, and vary from $\frac{1}{160}$th to $\frac{1}{400}$th part of one line in diameter. Those of the optic nerve are smaller, being from $\frac{1}{300}$th to $\frac{1}{500}$th part of one line in diameter; and tubules of the same dimensions are observed in the *Chiasma* or Decussation, in which the tubules are represented as crossing each other; while the Retina consists of articulated tubules $\frac{1}{2000}$th part of one inch in diameter, traversing medullary grains about $\frac{1}{500}$th part of one line in diameter. It contains also mace-like or club-shaped bodies, that is, bodies terminating in thick round ends.

The structure of the Auditory Nerve is peculiar. The simple tubules of this nerve Ehrenberg found considerably thicker than those of the others, and the spheroidal enlargements or *ampullulæ* flatter, and less permanent, yet everywhere distinctly seen. In other respects it was similar to the olfactory and optic nerves.

The great Sympathetic Nerve, in like manner, consists of articulated cerebral tubules; but there is at each extremity a mixture of simple cylindrical tubules.

The nerves now specified, the Olfactory, Optic, Auditory, and Great Sympathetic, are Articulated or Moniliform Nerves.

All the other nerves consist not of Articulated or Moniliform tubules, but of simple cylindrical tubules somewhat larger, being from $\frac{1}{120}$th to $\frac{1}{110}$th part of one line in diameter. These tubules are surrounded and enclosed by vascular networks, and contained within ligamentous or neurilematic partitions; and they contain a medullary substance, semifluid, but capable of expression from them, and of coagulation within their interior. These are *Tubulated Nerves.*

The ganglia vary in structure. All consist of articulated or bead-like cerebral tubules, which, either alone, as in the *Chiasma*, form the knot, or, as in all the ganglia of the sympathetic examined, are mingled with large cylindrical nervous tubules, enclosed within a close slender vascular network, between the meshes of which are deposited granules similar to those observed in the Retina.

The tubules and cylinders now specified, which correspond with the primitive cylinders of Fontana, are merely in juxtaposition, and do not intermingle in substance with each other.

Neither Ehrenberg nor Müller were able to recognise in the roots of the sensiferous and motiferous nerves any essential difference in microscopic structure.

In the hypoglossal and glossopharyngeal Nerves are seen only cylindrical tubes.

It is a remarkable proof of the difficulty of microscopical observation, that much, if not the whole, of this varicose or moniliform appearance in the nervous matter is called in question by other observers. Valentin, for instance, regards it as the effect of pressure or some similar force; and Henle is disposed to regard the appearances as probably chiefly dependent on chemical changes.

The nervous content or *medulla*, he remarks, is a tough, soft substance, which may be squeezed out by pressure, and must therefore be regarded as in some degree fluid. In the recent nerve, it appears to be quite homogeneous, and takes its peculiar form under particular circumstances.

As no good analysis of nervous matter has been given, Henle takes as equivalent the analyses of cerebral matter made by John, Vauquelin, Denis, and Couerbe. The essential result of all these researches is, that a saponaceous and a free fatty substance is found in connection with albumen and water in the nervous *medulla.* During life, and at the temperature of the body, this is an actual solution, not an emulsion; because in an emulsion the fat is only in a state of minute division, and contained in microscopical globules. But the nervous matter is only separated into globules after death; and even then not pure fat globules are formed, but only fat-like globules; and this probably is caused by the separation of the fat and albuminoid constituents.

Under the microscope this nervous matter forms globules which run together in irregular figures. The dark edge is thus rendered broader, and advances on all sides towards the axis of the nervous chord, and at length fills the whole tube. This is covered by granules and irregular lines, which gradually increase, and thereby give the nervous medulla a fine granulated aspect. Similar changes take place, though more quickly, in the nervous matter, when it springs from a wound or lacerated opening in the sheath; there are then formed irregular granular masses, or it retains the cylindrical shape which it had in the sheath. The same process is observed in the fine nerves, though less distinctly.

When the nervous tubules are subjected to pressure or stretching, previous to the action of chemical coagulating agents, there are formed oval swellings, and between these shrivelled puckerings, often with great regularity. By continuing the force, the oval swellings are converted into globules which are connected by thinner cylindrical portions. In this manner, says Henle, are formed the varicose swellings, that is the bead-like figures of the nerve fibres, which have been much mentioned since the descriptions given by Ehrenberg. He adds, that from any tough viscid matter, from mucilage, saliva, or albumen, it is possible to manufacture similar varicose fibres, by drawing the substances to a thread between the tips of two fingers. There is even an instant at which the thread is changed into a row or string of globules, and so remains until it is torn asunder.

It thus appears that the moniliform aspect and arrangement is the conjoined result of the physical and chemical properties of the nervous tubular content, and of certain mechanical treatment.

Müller, on the other hand, allows that the nervous matter and the cerebral matter has a great tendency to assume the varicose and moniliform arrangement.

From the statements now made only one conclusion can be deduced. This is, either that the minute atomical arrangement of nervous matter is such that it eludes microscopical research, and is placed beyond the boundary at which correct representations can be obtained; or that hitherto microscopical research has presented results so variable, and so discordant, that they convey little useful information. The greater part of microscopic anatomy is still in a state of great imperfection.

Soon after death, and particularly soon after treatment with cold water, there is formed in large nerves, along each edge, a second parallel-running dark line, which first arises quite close to the outer margin, and gradually turns inward from the same. Each fibre is therefore bounded by two dark outlines on each side; at the same time transverse streaks and wrinkles appear on the fibre, by which it has the aspect of a ligament. The two dark lines on each side are not quite continuous; they are often in one single point, below which, within or without, arises a new point, which is quickly split into two parallel lines, or meet with each other, forming, by inclosure, round or oval figures. This twofold outline is seen only in nerves of a certain size. In fine nervous fibres which swell only at certain points, this is seen only at the swellings.

General Anatomy.

Nerves.

Very frequently, it may be said according to Henle, normally, coagulation, beginning from the margins, does not reach the axis of the nerve tube; and there is left in the middle a clear stripe which looks like a cylinder drawn along the length of the nerve-tube. This is sometimes straight, sometimes tortuous, and follows not exactly the outline of the outer margin. Often it lies closer to the one margin, or it draws near to it at one part of its course. This is seen equally in thick and in delicate tubules; in the former more distinctly; it is particularly remarkable when the external nervous *medulla* is coagulated uniformly, and in fine grains. This streak is the *Cylinder Axis* of Purkinje, who considered it to be the same with a structure previously described by Remak under the name of Primitive Band. Its diameter is variable; but often it is seen very much the same in nervous fibres of like diameter, that is, about one-fourth to one-half the size of the diameter of the whole tube. When the cut section of a nerve is turned to the eye, this clear streak appears in general round or oval, often irregular, triangular, or quadrangular. This streak is seen also to be bent like a hook or a shepherd's crook, and upon pressure it may be made straight. In some instances the coagulated parts are dissolved, and the clear substance remains with its dark outline as a pale soft isolated thread.

From all these circumstances, Henle concludes that the Nervous fibre consists of a cortical or outer and a medullary substance, which are chemically different.

It appears, however, doubtful whether the central streak (*Cylinder Axis* of Purkinje) is always present, and is always to be considered as a substantive and real formation; at least, Henle allows, that similar illusive formations arise from quite a different source.

The Cylinder Axis is not in all instances so regular as it is represented in the examples selected. Sometimes it is seen swelled in certain points, sometimes very much attenuated, often altogether interrupted, consisting only of a row of oblong drops, which after being discharged assume a globular shape. Often the coagulated substance extends far beyond the middle of the tubule; the central stripe is then quite irregular, jagged, corresponding to the outline of the coagulated substance. In short, Henle is inclined to the opinion, that this alleged cylinder axis of Purkinje, is a fluid which has become coagulated either after death or by reason of chemical changes. He remarks, that in nerves which have been stretched but not subjected to coagulating agents, the medullary matter is frequently formed into individual oval necklace-like globules connected with each other in rows, and which are thus connected throughout the whole streak. This, he thinks, would not be possible, were the *medulla* a solid cylinder. If a part of the medulla, he adds, escape through a lateral rent, often, also, there takes place in the matter protruded a discoloration of the central stripe, which is gradually lengthened, and often at its apex is parted into individual globules; a sure proof, he thinks, that the cylinder axis is in this instance fluid. Other similar proofs he adds. It seems to us doubtful whether the point is of sufficient importance to enter into further detail. It is enough for readers to know that this Cylinder Axis, or central portion of the nerve tube, is a sort of hypothetical part inferred to exist from certain microscopical phenomena, but the existence of which, as a fluid or as a solid, the result of certain changes, is at present problematical. Henle allows that amidst so many sources of illusion, it is difficult to arrive at any certain results regarding the cylinder axis.[1]

Kölliker is of opinion that the Cylinder Axis is not an artificial formation, but a substantive part of the nervous chord; and adduces various reasons in proof of his opinion. These, however, it is unnecessary here to consider.

General Anatomy.

Nerves.

The Gray, Soft, or Organic Nerves, evince their peculiar characters most distinctly in the roots of the Sympathetic Nerve, especially in those branches which, accompanying the internal carotid artery, proceed from the superior cervical ganglion to the fifth and sixth pairs of cervical nerves; and on the branches which proceed downwards from the same ganglion upon the carotid artery.

These nerves are reddish gray in colour, gelatinous, transparent, but tolerably firm. The transverse stripes are not wanting in them; but they are not easily distinguished, are close, and proceed only from the inflections of the *Neurilema.*

According to Henle, this *Neurilema* has an external layer of longitudinal filamentous tissue, like that of the White Nerves. But upon the external layer follows a very dense layer of annular fibres, which resemble the filamentous fibres of the embryo, taken during the period of development. These are very clear, apparently homogeneous, flat fibres, from 0·002 to 0·003 of one line in breadth, with numerous round and oval cell-nuclei placed mostly on the flat surface, and arranged at intervals, many of which show the regular nucleus-*corpuscula,* and not a few are drawn out at both poles into apices. The oval nuclei are in the longest diameter 0·003 of one line. When the nuclei are oval or are elongated into fusiform *corpuscula,* their long diameter lies parallel to the long axis of the Nervous Fibre, and consequently at right angles to the long axis of the Nervous Bundle. The more the nuclei are elongated and attenuated, the weaker is the connection with the bundles, the more easily is it dissolved, especially after employing acetic acid, from the bundles; and then they roll together or are twined in a serpentine manner. This is best seen in the smallest branches of the *Nervi Molles,* which can be placed without injury upon the object-holder and observed by a powerful lens.

In the Gray Nerves are observed two sorts of longitudinal fibres. The one set differ in no respect from the primitive tubules of the White Nerves; they belong, however, for the most part, to the finest nerves, and are accordingly slightly varicose or moniliform. The other set resemble the fibres of the annular layer of the Neurilema; and in them a division of the fibres into fine fibrils occasionally takes place.

On the relative proportion of the two sorts of fibres depends, according to Henle, the external appearance of the gray nerves. The greater the number of the peculiar nerve-tubules, the closer is their likeness to the animal nerves. In the roots of the Sympathetic Nerve, the nerve tubules are present in proportionally small number. They lie detached and at distances of from 0·013 to 0·018 of one line, so that at between every four and six of the nucleus-covered fibres a nerve-tube follows. In this manner every nerve-fibre appears to be surrounded by fibres of the second sort, because the nerve presents upon every longitudinal section nearly the same figure. But in what relation the nucleus-covered fibres with their surfaces stand to the nerve-tubes is, to Henle, not clear.

More numerous than in the roots of the great Sympathetic are the Nerve Tubes in the greater part of the Nerves of the Viscera, in the branches which proceed from the Cœliac Ganglion, from the hypogastric plexus, and similar foci. In these we easily find within the gray branches, the primitive, several beside each other, forming secondary bundles. Nevertheless, their number is more considerable in the chord of the Sympathetic and in the Splanchnic

[1] Henle, Allgemeine Anatomie, seite 629.

**Nerves.**

Nerves. The Nerves of the heart have scarcely any but Nerve-tubes. These, as all those proceeding from the Sympathetic Nerve, are distinguished from those of the voluntary muscles by their tenuity only.

Nervous tissue, like all others, receives a proportion of what may be denominated the systems of distribution,—cellular tissue and bloodvessels. In the substance of the former, the disposition of which we have already remarked, we find the more conspicuous branches of the latter distributed. In a more minute and divided form they penetrate the neurilema and nervous substance. Reil, who derived his conclusions from the result of delicate and successful injections, perhaps overrated the quantity of blood which in the sound state they convey; for it is quite certain that, in the healthy state, hardly any red blood enters the nervous tissue, as may be easily shown by exposing the sciatic nerve of a dog or rabbit.

No good chemical analysis of nervous matter has yet been published. Every chemical examination of it has been conducted on the assumption that it is analogous to cerebral matter. Of this, however, there is no direct proof. In the analysis by Vauquelin, the neurilematic covering appears not to have been detached,—a proceeding always necessary to obtain correct results in this inquiry. The effects of acids and alcohol show that it contains albuminous matter; but beyond this it is impossible at present to make any precise statements.

This description may communicate an idea of the structure of the nervous chord in general. In particular situations this structure is considerably modified. The modifications to which we allude occur under two forms—ganglions (die Knoten), and plexuses (die Nervengeflechte).

**Nervous ganglions.**

Every ganglion consists essentially of three parts,—1*st*, an exterior covering; 2*d*, a collection of minute nervous filament; and, 3*d*, a quantity of peculiar cellular or filamentous texture, by which these filaments are connected, and which constitutes the great mass of the ganglion.

The ganglions are of two kinds, the spinal or simple, and the non-spinal or compound. These two kinds of bodies differ from each other,—1*st*, in the situation which they respectively occupy; 2*d*, in the kind of envelope with which they are invested; 3*d*, in the mode in which the nervous filaments pass through them and from them. By Wutzer, who considers the ganglion of Gasserius, the ciliary and the maxillary of Meckel, as cerebral ganglions, they are divided into three sets, those of the *cerebral* system, the *spinal* system, and the *vegetative*, or those connected with the organs of involuntary motion.[1]

Void of the dense strong coat with which the others are invested, the cerebral ganglions consist of soft secondary matter, connected to the filaments of one, or at most two branches, and are arranged with less complexity (Wutzer).

The spinal ganglions are said to possess two coverings, one of which resembles the hard cerebral membrane (*meninx dura*), the other the soft cerebral membrane (*meninx tenuis, pia mater*). The non-spinal or compound ganglions have also two coverings, which are merely different modifications of filamentous tissue, less dense and compact than in the former. Both these sets of ganglions being by maceration stripped of their tunics, and deprived of the soft, pulpy, cellular matter, are resolved into an innumerable series of nervous threads, most of which are minute and scarcely perceptible: all are continuous with the nerve or nerves above and below the ganglion. It appears that the nervous chord, when it enters the one apex of the ganglion, begins to be separated into its component threads, which diverge and form intervals, between which the delicate cellular tissue is interposed; and that these filaments are subsequently collected at the opposite extremity of the ganglion, where they are connected with the other nerve or nerves. Scarpa, to whom we are indebted for most of the knowledge we possess on this subject,[2] compares the arrangement to a rope, the component cords of which are untwisted and teased out at a certain part. *Lastly*, In the simple ganglions, the filaments of which they consist invariably follow the axis of the ganglion; but in the compound ones they are found to rise towards the sides and emerge from them; and upon this variety in the direction and course of these filaments depends the variety of figure for which these two orders of ganglions are remarkable. These nervous threads (*stamina s. fila nervea*), described by Scarpa, correspond to the medullary filaments (*fila medullaria*) of Wutzer. According to this anatomist, these filaments, when about to enter the ganglion, lay aside their neurilem: yet they are sufficiently tough to resist a certain degree of tension.

Wutzer mentions a cluster of vesicles or cells (*cancelli*) in the filamentous tissue of the ganglion; but he was not enabled by any means, mechanical or chemical, to ascertain their exact nature.

Probably the explanation of the nature of these vesicles or cells is to be found in the structure described by Henle. According to this anatomist, if, by means of two needles, a portion of a ganglion be torn and pulled to pieces, we find in the water in which the preparation is washed, a quantity of very peculiarly shaped *corpuscula*, which have received the name of gangliar globules, though only rarely are they globular. More frequently they are ovoidal, triangular, quadrangular, prismatic, kidney-shaped, wedge-shaped, often even quite irregular. In size these bodies are equally variable. The largest are seen in the ganglions of the cerebral nerves. In the Gasserian ganglion of the calf, Henle found some 0·033 of one line in diameter; the greatest part between 0·022 and 0·027 of one line. In the superior cervical ganglion of the same animal, the majority were from 0·009 of a line and less.

**Gangliar globules.**

These bodies are distinguished by their reddish-yellow colour and soft consistence.

In all, or almost all, there is seen an exactly round *corpusculum*, which shines like a drop of fat, and in large and small gangliar globules, has pretty uniformly a diameter from 0·001 to 0·0015 of one line. Concentric with this is observed a very fine-drawn and exactly circular line.

In all the rolling movements of the gangliar globules, the small glistening *somation* remains in the centre of the clear circle, and both continue perfectly round,—a circumstance which shows that both are *vesiculæ*, or globules inclosed within each other. The external one is transparent as water, and its diameter is from 0·006 to 0·008 of one line. Their size bears a proportion to the size of the globules.

If we compare the Gangliar Globules with other cells, the outer substance of the same might appear to correspond to the Cell, the clear vesicular part to the Cytoblast, and the glistening somation to the nucleus-corpuscle. One circumstance, however, which contradicts this interpretation, is, that the whole globule, consequently not only the cell, but also the Nucleus and the nucleus-corpusculum, is instantaneously completely dissolved by acetic acid.

On the deposited gangliar globules depends the yellowish colour and the swelling or enlargement of the nerves in the ganglion. These globules lie together in dense heaps; the most regular and rounded at the surface, the polyhedral in the substance of the ganglion.

---

[2] *Anatomicarum Annotationum liber primus de Nervorum Gangliis et Plexibus.* Auct. Ant. Scarpa.

General Anatomy.

Gangliar globules.

Between these globules pass the nervous threads or filaments to their destination, part of them unchanged and uninterrupted; while part of them are resolved into their primitive constituent filaments, and wind in multiplied bendings and turnings round the individual globules and heaps of globules.

Further, the extended nerve-fasciculi approach each other and form plexuses, in the meshes of which globules are received. Normally, the nerve-fibres keep mostly together in the axis of the ganglion, and are dissociated and follow the winding course more at the surface; because one central nerve-bundle is on all sides surrounded by gangliar globules. In other instances, the globules are in a greater degree accumulated on one side, form an eminence on the nerve in which they are seated, or the nerve-fibres are principally disposed at the surface, while the nucleus of the ganglion consists chiefly of gangliar globules. Henle thinks it probable that in the axis of the ganglion lie those nerve-fibres, which only break through the ganglion in order to run still farther away in the nervous chord; that, on the other hand, the external enclosing filaments of each separate ganglion for separation are fixed.

In the ganglion of the sympathetic nerve with the proper nerve-fibres of the gray nerves the gelatinous fibres are united, and these stand to the gangliar globules in a particular relation. This is, that the fibres of one bundle are expanded in a funnel-shaped fashion, in order to receive a gangliar globule or a row of these globules; then they are united in order to be again implaited. Thus it is often possible to extract a whole string of gelatinous fibres from one ganglion, which are enlarged like the pearls of a necklace, and contain globules in these enlargements.

For further details on this point, readers are referred to the General Anatomy of Henle, and the fourth book of the second volume of Kölliker, who, in figure 161, page 524, gives a delineation of the gangliar globules and the nerve-fibres in the first thoracic ganglion of the great sympathetic.[1]

The ganglions are well supplied with bloodvessels, derived in general from the neighbouring arteries. The intimate distribution is represented by Wutzer to be the following. The artery proceeding to a ganglion gives vessels to the filamentous tissue, and, perforating the proper coat, is immediately ramified into innumerable minute canals, the first order of which forms vascular nets on the inner surface of the tunic, while the residual twigs penetrate the flocculent texture, and the individual vesicles of the secondary or filamentous matter of the ganglion.[2]

This short exposition of the structure of the ganglions shows the mistaken notions of Johnstone, Unzer, Bichat, and others, on the structure and uses of these bodies. 1*st*, The idea, first advanced by Johnstone and Unzer, adopted by Metzger, Hufeland, Prochaska, Sue, and Harless, and afterwards applied with so much ingenuity by Bichat, that the ganglions are so many nervous centres or minute brains, is disproved by strict anatomical observation. 2*d*, That they are connected with the order of involuntary actions, and influence these actions, is not improbable; and has acquired a certain amount of verisimilitude from the facts and arguments adduced by Bellingeri, Charles Bell, Herbert Mayo, Longet, and other inquirers. Ganglions are not observed in any of the nerves proceeding to organs of voluntary motion. Sensation, circulation, nutrition, and secretion, are the functions over which they preside, or at least with which they are associated; and they seem to have considerable relation with, if not influence over, the involuntary motions. By some physiologists again this doctrine is limited and modified; and the sympathetic especially has been several times represented as a nerve pertaining solely and exclusively to the nutritious nerves. This, however, leads to the question of the exact functions of the gray or soft nerves, and cannot be considered in this place. 3*d*, Lastly, we remark, as a circumstance of some importance, that the only difference between a ganglion and any other part of a nervous chord is, that in the former the minute nervous filaments appear to be uncovered with neurilema, and lodged in a mass of cellular tissue, which is inclosed in the neurilematic capsule; while in the latter each nervous filament has its appropriate neurilema, and the cellular tissue, instead of being within, is on its exterior, and connects it to the contiguous filaments.

Nervous plexuses.

In various situations two, three, or more nervous trunks or chords mutually unite by means of some of their component threads, and after proceeding in this manner for a short space, again separate, but not in the same number of original trunks, or preserving the same appearance. In general, the number of chords into which they finally separate is greater than that of which they consisted before union. Three or four nervous trunks, for example, after uniting in this manner, will form on their final separation five or six nerves or nervous chords; and it is quite impossible to determine which of the latter order was derived from any one or two of the former, or what number of individual chords it has received from each. Between the two points, also, the first point of union and the last of separation, many of the more component threads are detached from two or more of their trunks, and, after first uniting with each other in an indistinct network, are again united to two or more of the nervous chords near the point at which they finally separate from the further end of union. This arrangement has been termed a *plexus*, *plait*, or *weaving*, in consequence of the manner in which the nervous chords are interlaced or plaited together. The arrangement which we have noticed as consisting of the more minute nervous threads has been called a *smaller plexus* (*plexus minor*). It is a subordinate plexus within a larger one.

The best and most distinct example of a plexus is that commonly named the brachial or axillary. This, as is well known, is situate in the space contained between the broad dorsal muscle (*latissimus dorsi*) behind, and the great pectoral muscle before, and is formed in the following manner. The fifth, sixth, seventh, and eighth cervical nerves, and the first dorsal, after following the usual connections (*ansæ*), pass downwards from the vicinity of the vertebræ between the middle and anterior *scaleni* muscles, and, nearly opposite the lower margin of the seventh cervical *vertebra*, or about the level of the first rib, begin to be united by the component threads of each nerve. Threads of the fifth and sixth cervical unite, sometimes to form a single chord, in other instances to be connected a short space onward with threads of the seventh cervical in a similar manner. The seventh and eighth form two kinds of union. When the seventh is large, it divides almost equally into two chords or branches, one of which is connected first with the fifth and sixth, afterwards with the eighth, and with the first dorsal by interlacement of minute nervous threads. The other either passes downward to form one of the separate brachial nerves, or is also connected with the eighth cervical and first dorsal in a plexiform manner.

From this arrangement immediately arise the individual

General Anatomy.

Nervous plexuses.

nervous branches which form the nerves of the arm, and which are named brachial nerves. The interlacement of minute nervous threads between the seventh and eighth cervical and the first dorsal, is what Scarpa has termed the *plexus minor*. He says it is peculiar, in being quite uniform, and in connecting those nervous branches which, from their subsequent destination, are called *median* and *ulnar*.

This description, though not generally applicable, will communicate some faint idea of the nervous unions and interlacements termed *plexus* or webs. For more minute information on the distribution, arrangement, and configuration of this part of the nervous system, we refer to the work of Scarpa already quoted.[1]

Henle thinks that we may distinguish the Plexuses into two orders; the first, those in which the nervous trunks send mutually branches to each other; the second, those in which, simply placed beside each other, they lie for a long tract inclosed in one common sheath, and then divide again into different branches. The first kind Kronenberg names *Plexus per anastomosin;* the second, *Plexus per decussationem.* The last author adds a third; that, namely, in which both modes of arrangement are united, *Plexus Compositi.*

Plexiform arrangements are not confined to the exterior regions of the body. They are more numerous internally; and almost all the organs of the chest and belly have each a plexus, sometimes two, from which they derive their nervous chords.

Plexiform arrangements are generally situate in the neighbourhood of bloodvessels, and in some instances inclosing considerable arterial trunks more or less accurately. Thus the axillary plexus surrounds the axillary artery. The cœliac artery is surrounded with the solar plexus; and the coronary, hepatic, splenic, superior mesenteric, and renal, are also surrounded with plexiform nervous filaments. In some instances these nervous filaments are so intimately connected with the arterial tubes as to lead some anatomists to consider them as forming a peculiar network surrounding the vessel, and to exercise great influence on the circulation (Wrisberg, Ludwig, and Haase).

It is remarkable that the structure of the nervous chords which form a plexus has either appeared so simple as not to demand particular attention, or is so obscure as to be never noticed. Have the nervous chords and threads in such situations their usual envelope? Is the nervous matter in the chords quite the same as in other situations? Are there any other means of union, save the nervous substance itself? We believe there is no doubt that every chord in a plexus is provided with its neurilema, as in other places; but this neurilema is generally thinner and more delicate, and the general neurilema seems to be wanting. Its mechanical properties of cohesion and resistance have not been examined.

The view now given of the structure and arrangement of the nervous plexus leads Scarpa to consider them as nearly allied to ganglions. The same separation of the component threads or filaments of the nerve or nerves, the same interlacement, and the same or similar formation of new chords, appear to take place in both orders of structure. A ganglion, indeed, he conceives, is a condensed or contracted plexus; and a plexus is an expanded or unfolded ganglion. The anatomical purpose of both appears to be simply a new arrangement or disposition of nervous branches, previous to their ultimate distribution in the tissues or organs to which they are destined. This is nothing but the expression of a fact,—the interpretation in intelligible terms of an arrangement of organized parts, without reference to any supposed uses.

General Anatomy.

Nerves.

I have already shown what is meant by the organic end or termination of a nerve. Although the nervous trunks are distributed in every direction through the animal body, they do not terminate in all the tissues or organs indiscriminately, and have been observed to be lost in the following only: 1*st*, The proper organs of sensation, the eye, ear, nose, palate, and tongue; 2*dly*, the muscles, whether subservient to voluntary or to involuntary motion, as the heart, stomach, intestines, &c.; 3*dly*, the mucous surfaces; 4*thly*, the skin; 5*thly*, glands, salivary, liver, kidneys, &c.; 6*thly*, bones.

Nerves, therefore, are not organs of general distribution. According to Bichat, they have never been traced to the following tissues:—the cartilages, both articular and of the cavities; fibrous textures, viz. *periosteum*, *dura meninx*, capsular ligaments, aponeurotic sheaths, aponeurosis in general, tendon, and ligament; fibro-cartilaginous textures—those of the external ear, nose, trachea, and eyelids (cartilages of other authors); the semilunar cartilages of the knee-joint; those of the temporo-maxillary articulation; those of the intervertebral spaces; marrow; the lymphatic glands.

To this we may add the testimony of Walter of Berlin, who, after several laborious researches, came to the conclusion that the pleura, the pericardium, the thoracic duct, and the peritoneum, receive no nerves, and that, contrary to the opinions of the most eminent recent anatomists, no nerves terminate in the lymphatic or conglobate glands. Sometimes, indeed, these organs are perforated by one or two twigs, as he often had occasion to observe; but they instantly proceed to the next place assigned to them, and in which they are finally lost.[2] If, after this conclusion of Walter, personal testimony can be of any use, I may add, that I have examined the dura mater, the periosteum, and most of the synovial membranes repeatedly, to discover nervous filaments in them, and always without success; and I may say the same regarding the absence or non-appearance of nerves in the peritoneum and pleura.

The nerves have different uses in the different organs and tissues to which they are distributed. 1. In the organs of sensation they receive the material impressions made on the mechanical part of the organ. In the mucous membrane of the nasal passages, the filaments of the olfactory nerve are affected by aromatic particles, dissolved or suspended in the air. In the eye the retina receives the last image formed by the transmitting powers of the transparent parts. In the ear the terminations of the auditory nerve are affected by the oscillations or minute changes in the fluid of the labyrinth, occasioned by the motions of the tympanal bones. In the palate, tongue, and throat, the gustatory nerves are affected by sapid bodies dissolved in the mouth, or applied in a fluid state to the mucous membrane of that cavity. 2. In the system of voluntary muscles, the nerves retain the action of the muscular fibres in a state of uniformity and equality, and keep them obedient to the will. In the involuntary muscles they appear merely to keep their action equable, regular, and uniform; and in both they maintain a communication, consent, or harmony of action between different parts of the same system of organs, or even between organs concurring to the same function. 3. In the glandular organs the nerves certainly exercise some influence over the process of secretion; but what is the exact nature of this influence, or in what degree it takes place, is quite uncertain.

When we observe the nerves distributed to organs of sensation and organs of motion, it is a natural thought to inquire whether the nerves minister to both functions, and whether different nerves or different sorts of nerves minister to each function. It seems to have been an idea of considerable an-

tiquity, that one set of nerves are sensiferous, and another set motiferous. Erasistratus derives the nerves of motion from the brain and cerebellum, and those of sensation from the membranes; and Galen distinguishes the nerves into Νευρα Αἰσθετικα and Νευρα Κινητικα, the former soft, from the brain, the latter hard, from the spinal marrow. This distinction was not altogether lost sight of among the anatomists and physiologists of the eighteenth century; but it was rather maintained as a probable speculation, than elucidated and enforced as an established doctrine, pregnant with important results. It was recognised by Glisson, and taught by Boerhaave,[1] and received and promulgated by his pupils, Tissot and Van Eems;[2] but opposed by Haller[3] and Cullen. The distinction was, nevertheless, maintained by Lecat, Morin, and Pouteau, the last of whom was led from various examples of persons, who, after injuries, had lost sensation, but retained the power of movement, to espouse it with considerable energy.[4]

In 1784 George Prochaska, Professor of Anatomy at Vienna, published on the functions of the nerves a commentary, in which he gave, after Haller, Caldani, Whytt, and Unzer, a more precise and correct view of the uses, properties, and powers of these organs, than had hitherto been formed. In this commentary he fully recognises the distinction between sensorial nerves, or those devoted to sensation, and motific nerves, or those ministering to motion; he shows that sensorial impressions, or impressions made on the sensitive nerves, are reflected or transmitted in a reflex direction to the motific nerves; that the latter nerves are thereby excited to action; that the purpose of this reflex operation is the preservation of the individual; and that the whole are under the influence of the *Sensorium Commune*. He distinctly states, that this reflected action is not regulated by physical laws, where the angle of reflexion is equal to the angle of incidence, but obeys peculiar laws impressed by nature, as it were, on the sensorium, and which laws we can understand from their effects alone. This reflex action further takes place either without or with the consciousness of the soul. The motion of the heart, stomach, and intestines, is independent of the cognizance of the soul; and in many other instances of sensorial impressions being transmitted to motific nerves, though the soul is conscious, it can neither prevent them nor promote them.[5]

The commentary of Prochaska is the first precise view of functions of the nervous system in modern times; and the first in which the automatic and instinctive phenomena enumerated by Whytt are referred to a reflex operation.

In 1811, Sir Charles Bell, in a tract containing *the Idea of a New Anatomy of the Brain*, stated that he had proved experimentally that "the posterior *fasciculus* of spinal nerves, which are gangliophorous, might be detached from its origin without convulsing the muscles of the back; whereas, on touching the anterior *fasciculus* with the point of the knife, these muscles were immediately convulsed." From this it seemed a probable inference that gangliophorous nerves had no concern in motion, and that nerves void of ganglion ministered in some way to that function.

In 1818, Charles Francis Bellingeri published at Turin,[6] a Dissertation treating, among other subjects, of the anatomy and physiology of the fifth and seventh pairs of nerves. In this he showed that the great portion of the fifth pair or trifacial nerve, which forms the large semilunar plexus called Gasserian ganglion, is a nerve not of motion but of sensation; that its three branches are distributed to certain parts of the eye, the nasal cavities, the palate and tongue; ministering in these parts not to motion, but to sensation, and probably to circulation, nutrition, and secretion; and that the small branch of that nerve (*nervus masticatorius*) is distributed to muscles (*temporalis, masseter, pterygoideus, buccinatorius*), and is a nerve of motion. He also showed that the seventh pair, or lateral facial, presides over sensation and motion in the functions of the head, face, and neck, but mostly over motion.

In 1821, Sir Charles Bell undertook to establish the principle, that of the two nervous trunks distributed to the face, viz., the *trigeminus*, or fifth cerebral nerve, and the *portio dura*, or seventh cerebral nerve, the lateral facial, the former presides over the sensations or common sensibility of the head and face; that it also possesses branches going to the muscles of mastication; whereas the latter nerve regulates the muscular motions of the lips, nostrils, and *velum palati*, and especially in associated action with the motions of respiration.

About the same time Magendie claimed the merit of showing experimentally the fact of the distinction between nerves ministering to sensation and nerves ministering to motion, and of proving that, of the double row of nervous roots issuing in parallel lines from the lateral regions of the spinal chord, the anterior are destined for motion, and the posterior for sensation.

Lastly, Mr Mayo, partly by dissection, partly by experimental inquiry and reasoning, arrived at the conclusion that almost all the branches of the large or gangliophorous portion of the trifacial nerves are nerves of sensation, while those of the small fasciculus, which is void of ganglion, are nerves of motion.

In this manner, by successive steps, has been established one of the most important doctrines on the functions of the nervous chords in modern physiology; and its justice has been confirmed by the labours of many observers. The distinction is most clearly proved by the original experiment of Sir Charles Bell. If the spine be laid open, especially in a cold-blooded animal, as a frog, and the posterior or gangliophorous roots alone be irritated, no movement is produced; but the moment the anterior roots are touched, the extremities are agitated by active convulsive motions.

Of the cerebral nerves, the first or olfactory, the second or optic, and the eighth or auditory, are pure nerves of proper sensation, and are distributed to the sensitive parts of the eye, the nasal cavities, and the cochlea and labyrinth, respectively. The third, fourth, and part of the sixth, or abducent, are motific nerves connected with the movements of the eye. The fifth or trifacial is a very peculiar nerve. The gangliophorous, or rather plexiform part of it, communicates with all the organs of proper sensation,—the eye, the ear in a small degree, the nasal cavities largely, and the palate, mouth, and tongue largely; and it is distributed extensively along with the minute arteries of the face. Of this arrangement the result is, that it is a nerve neither of vision nor of hearing, of smell nor of taste, or deglutition nor of touch, or physiognomical expression, exclusively; but over the whole of these faculties and their proper organs exercises a general modulating power. It maintains between them a mutual consent or harmony of action, absolutely necessary to the due separate exercise of each and the conjoined exercise of all. Lastly, by accompanying the arteries of the face, it regulates the circulation of that region, and may be the means of maintaining between the brain and the facial circulation those conditions and expressions which arise from various mental emotions; as paleness, blushing, indignation, the sense of joy, triumph, the sublime, and similar emotions.

Not less peculiar is the seventh, the small sympathetic of Winslow. Though mostly a motiferous nerve, yet it ministers to motions of a particular order. It is, however, as a nerve distributed to the skin of the face, a nerve contributing to, if not regulating animal sensation and involuntary motion. It is, in fact, as shown by Wrisberg, a double nerve, the large portion of which is devoted to the purposes of animal life, and the small one to those of organic life. It is a musculo-cutaneous nerve of the head and face.

In proceeding further in explaining the respective functions of the nerves, it is requisite to keep in view not only their gangliophorous character and the reverse, but their position as anterior and as posterior nerves, and nerves consisting of anterior and posterior roots.

The ninth pair (*nervus glosso-pharyngæus*), consists of two parts, one large, completing sensation to the root of the tongue and pharynx, the other smaller, moving the pharynx, and connected, notwithstanding, with the tenth pair, pneumogastric, and the great sympathetic.

The tenth pair (*nervus vagus*), or pneumogastric nerve, is chiefly a sensiferous nerve, regulating the sensations of the larynx, the œsophagus and stomach, and the lungs, and placing these organs in harmony as to function. One particularly, the recurrent branches, appear to be motiferous. All the other branches appear to regulate circulation and secretion.

To the accessory nerve, or eleventh pair, seems to belong the function of placing the pulmonary and laryngeal divisions of the pneumogastric in harmony and relation with the external muscles of the back and lateral regions of the neck.

Lastly, the hypoglossal, or twelfth pair, having mostly an anterior origin, are motiferous. They form the motiferous nerves of the muscles of the tongue.

It is to be observed, nevertheless, that though this distinction in functions belongs to particular nerves, yet nerves ministering to sensation, and regulating organic or involuntary functions, and nerves ministering to motion, and regulating either voluntary motions, instinctive motions, or involuntary but associated and necessary motions, are often closely connected, and proceed together in the same sheath, or in close apposition, to the same organ. This, which is observed in the fifth, the seventh, the ninth, tenth, and eleventh, is rendered necessary by the offices which the organs have to perform. The impulse or impression is communicated to the organ, and received by its sensiferous nerves. By these the proper sensation is transmitted, and the motiferous nerves are excited to action. This appears to be the mode in which such actions as sneezing, coughing, yawning, deglutition, and numerous other instinctive and associated actions are called into operation.

Of the spinal nerves it is almost superfluous to speak, after the explanations now given. The splanchnic or great sympathetic appears to be a nerve of organic sensibility and impression, and as such regulates the circulation of the abdominal organs, and transmits their impressions to the central connections. The further continuance of these by its spinal connections establishes a harmonic action with the spinal marrow, always for good purposes, but often under disease producing painful and destructive effects.[1]

The doctrine of reflected action in the nervous chords, as proposed by Prochaska, was either overlooked, and more or less disregarded; or it was thought that the phenomena referred to it were explained, as far as was practicable, by the doctrines of Robert Whytt and Haller. At the same time it was taught by Prevost and Dumas in 1823, that in what is called nervous action, or the operation of nervous influence, there must be, as in galvanism, two currents, an ascending and a descending one; the former proceeding from the ramified to the central end of the nerve, the latter from the central to the ramified or distributed end. In 1826, Sir Charles Bell, in a paper read to the Royal Society, promulgated the general proposition, that, *between the Brain and the Muscle, there is a circle of nerves; one nerve conveys the influence from the Brain to the Muscle; another gives the sense of the condition of the Muscle to the Brain.*[2]

In 1833, Dr Marshall Hall communicated to the Royal Society a paper on the Reflex Function of the *Medulla Oblongata* and *Medulla Spinalis*, in which he undertakes to demonstrate the existence of reflected or retrograding nervous influence, that is, one which proceeds from the ramified, or distributed to the cerebral or cerebro-spinal extremity of the nerve. According to the hypothesis here propounded, the spinal chord is the seat and centre, as it were, of two processes taking place in living animals. It receives sensations caused by impressions on the extreme points of the nerves; and, in consequence of this, it induces or stops actions on certain muscles and muscular organs. An impression acts upon the distributed extremity or extremities of a nerve; this is instantly conveyed by the nerve to the spinal marrow; and in the same instant, the spinal marrow either causes movement, or retains in a fixed state certain muscular organs. As this action or process consists of two parts, an incident impression, and a reflected one causing motion, it was denominated the Reflex Function of the Spinal Marrow; and as it consists in impression supposed to excite or cause movement, it was named by its proposer, excito-motory, and the nerves by the agency of which these movements were induced he denominates Excito-Motory Nerves.[3]

According to Dr Marshall Hall, there are two orders of Nerves. Incident Nerves, proceeding principally from the Cutaneous surface, and the surface of the Mucous Mem-

[1] For further information and illustrations of the principles now stated, I refer the reader to Arnold's Illustrations of the Nerves of the Head and Face—(Heidelberg, 1834. Folio)—and an account of the same work in the forty-third volume of the Edinburgh Medical and Surgical Journal, January 1835, p. 225.

[2] Philosophical Transactions, 1826. Read 25th January 1826.

[3] Philosophical Transactions for 1833. Part II.

General Anatomy. Nerves.

branes to the Spinal Marrow; and Reflex Nerves passing from the Spinal Marrow to a series of muscles destined to be moved simultaneously; and he thinks that he has proved the existence of, 1*st*, an incident motor action, and, 2*d*, an incident motor nerve.[1]

The incident motor branches are those of, I. the Trifacial nerve; II. The Pneumogastric; III. The Glossopharyngeal; and, IV. The Posterior Spinal nerves. To these there are corresponding reflex branches; and in the centre between the two, according to the doctrine, is placed the *Medulla Oblongata* and the Spinal Marrow, as the recipient of impressions and the generator of movements.

Under this system of nerves and nervous movements are placed all the great functions of the animal body; respiration; the acts of ingestion and egestion; the action of the uterus during parturition, and all those movements the object of which is the preservation of the individual from injury, whether arising within the system, or approaching from without.

It is unnecessary here to express upon the merits of this hypothesis any opinion. Its true character is that of placing facts long known and observed, under the head of a doctrine, new, and, it may be, more intelligible and tangible than the former. It is, nevertheless, still in the condition of a hypothesis, though a probable and convenient hypothesis. The further consideration of the subject belongs to the department of physiology.

It may have been observed, that, in speaking of the properties and uses of the nerves, as living and organized textures, we have been obliged to employ various terms which are in common use when speaking of the properties and uses of the nervous system; for instance, Sensibility, Impressions, Sympathy, Irritability, and similar denominations. These terms it would have been desirable to define with as much precision as the imperfections of language and the nature of the subject allow. This part of the subject, however, properly belongs to the doctrine of the functions of the living body, and as such it shall be considered under the head of Physiology.

In the fœtus the nerves are developed with remarkable perfection. I cannot speak from personal observation much earlier than the sixth month, when I have found the nerves of the extremities and voluntary muscles large and distinct. At the eighth month they are still more conspicuous. The anterior crural nerves are in the form of flat white cords, one and a half line broad, and their branches like good-sized threads. The sciatic is still more distinct. In the form of a thick cylindrical cord, fully a line in diameter, and not unlike a piece of whipcord, it is tough, stringy, and resists tension; and its constituent threads are well marked. I immersed a portion of this nerve, three and a half inches long, in *aqua potassæ*, when it first became much firmer and denser than before, assumed in two days the satin fibrous appearance first described by Fontana, and at length by solution of the nervous matter, was separated into chords and neurilematic canals. In this state, preserved in spirit of turpentine, it conveys a tolerably correct idea of the arrangement of the neurilematic canals.

The nerves of the involuntary muscles are equally distinct in proportion. Those of the lung, heart, and splanchnic system are distinct and manifest at the eighth month.

The neurilem is much more vascular in the fœtus than in the adult. In the same fœtus of about eight months I found the neurilem of the sciatic nerve, from the ischiatic notch to its divarication in the ham, covered with a thick network of minute vessels, all injected with dark blood.

General Anatomy.

### *The Nervous Papillæ of Vater.—The Corpuscula of Pacini.*

Nervous Papillæ.

The limits assigned to this article permit not to consider in detail all the modes in which the nervous extremities terminate in the organs, and the membranous surfaces to which they are distributed. But one mode of termination has, since the year 1834, attracted so much the attention of anatomists, that it would be improper entirely to omit the mention of it. This is what are called the Corpuscula of Pacini.

In the year 1741, Abraham Vater, Professor at Wittemberg, made known the fact that the nerves of the thumb terminate, when traced to their extremities, in round or spheroidal bodies, to which he gives the name of *Papillæ Nerveæ*, and *Papillæ Cutaneæ*. This discovery of the peculiar mode in which the digital nerves terminate, was made known in an inaugural dissection by J. G. Lehmann, one of the pupils of Vater; and the preparation from which the description by Lehmann was formed, has been preserved in the Anatomical Collection of Wittemberg to the present time.

The description given by Lehmann, which must be regarded as virtually that of Abraham Vater, is not very minute. Vater, or Lehmann for him, states that he found in the body of a man who had been affected by a spasmodic attack in the right arm and the middle and ring fingers, the nerves distributed to the thumb terminated in numerous small eminences or *papillæ*, which required to be carefully and laboriously dissected from the fat in which they were inclosed. These bodies he compares to the ears of corn. Vater found *papillæ* of the same sort, in small number, attached to the extremities of two branches of the posterior crural nerve, distributed over the dorsum of the foot. This occurrence took place several years previously to the time, 2d November 1741, at which it was made known.[2] On the exact nature of these bodies Vater gives no opinion, further than is to be collected from his calling them Nervous *Papillæ*, and Cutaneous *Papillæ*, and mentioning them in connection with the *consensus* of the parts of the human body. It may be doubted whether he was aware of the signification of these bodies even in an anatomical point of view.

The fact now mentioned has been overlooked and neglected for an entire century; and no one seems to have thought it of sufficient importance after the dissertation of Lehmann to deserve mention. At length, in February 1834, M. Camus, in a minute account of the distribution and termination of the nerves of the hand, described, as existing in the palmar and anterior half of the lateral aspect of the fingers, certain minute bodies, opaque, pearl white, not larger than a grain of mustard-seed, attached to the extremities of the digital nerves. Similar minute opaque pearly-looking bodies, M. Camus found attached to the nerves in the plantar aspect of the foot, most numerous towards the roots of the toes, and in general smaller than those found terminating the nerves of the hands.[3]

Pacinian corpuscula.

It further appears that Philip Pacini, a physician in Pistoja, had seen these minute bodies in 1831, gave an account of them in 1835 to the Medical Society of Florence, described them in the *Nuovo Giornale* of Pisa, gave a second oral communication on them, and demonstrated their existence at the Scientific Congress held at Pisa in October 1839. From this circumstance, and Pacini publishing an enlarged

General Anatomy.

account of these *corpuscula* in 1840, these bodies have been usually designated as the corpuscula of Pacini, and the Pacinian bodies.

Pacinian corpuscula.

In 1836, they were mentioned by Cruveilhier, though not as essential parts of the nervous system; and they were again described by A. G. Andral.

In October 1843, M. Lacauchie announced to the Academy of Sciences at Paris, that he had found in the mesentery and mesorectum of various animals, especially the common cat, minute bodies which are manifestly the same as those seen by Pacini in the fingers. According to Lacauchie, they are ovoidal transparent bodies, with the long diameter somewhat more than one millimetre. With the aid of the microscope he distinguished a peripheral part formed of from 15 to 20 concentric layers, and a central hollow portion, which extends the whole length of the body, terminates at one apex in a shut end, and at the other communicates by means of a serpentine canal with the nearest lymphatic canals. These bodies have since been described more or less minutely by Mayer of Bonn, Pappenheim, and most of all by Henle and Kölliker, in a monograph in 1844, and by Strahl in 1848.

The Pacinian *corpuscula*, which must have been often noticed by observers who studied the chyliferous vessels in the cat, were seen by Pacini first in man, and afterwards in cattle. They are seen normally without exception in adults as in the fœtus and new-born infants. Usually they are numerous in the nerves of the hand and foot, in the palm and sole. They are besides observed in the sacral plexus, in the crural nerve, in some cutaneous nerves of the upper arm and fore-arm, in the epigastric plexus and nerves issuing from it, and in the neighbouring plexuses. Their number in the whole body must be considerable; and in a single hand from 60 to 200 have been numbered. They are either detached or accumulated in small heaps. In all cases they are attached by one end by a stem variable in length to an adjoining nerve. They are for the most part distinctly visible to the naked eye; elliptical or long-oval bodies of opal lustre; and through the more translucent middle, in the long direction, are observed slightly tortuous streaks. In adults their average length is from $1\frac{1}{2}$ to 2 millimetres. In the fœtus they are often so small that either they cannot be seen, or they are seen by the naked eye with great difficulty. At the point of division of the median nerve, and ulnar nerve, in the fingers, and the plantar nerve in the branches going to the toes, they are largest; at the tips of the fingers they are smallest. The stems or peduncles by which these bodies are attached to the nerves join the nerves either at a right angle, or so that they are inclined sometimes more to the central, sometimes more to the peripheral end of the nerve. Not unfrequently two bodies are attached by means of a bifurcated stem. The stems or peduncles appear to be continued backwards in a conical fashion into the *corpuscula*, by which they are easily distinguished by their transparency from the substance of the rest of the corpuscula. This prolongation amounts sometimes to one-fourth part and more of the entire length of the Pacinian body.

When the *corpusculum* is examined under the microscope, it presents numerous fine dark lines, which proceed on the outside or along the periphery of the *corpusculum* by the edges, and within, run parallel to the long axis of the *corpusculum*, and are separated from each other by clear, broader intervals. At the stalk-end of the capsule ($a$), the concentric lines incline to each other, and are continued then, as is observed in large Pacinian bodies, in fine dark lines, which may be seen compressed parallel and closely to the stalk. At the free end, on the other hand, the concentric and parallel lines of the corpuscle are united on both sides; yet here there is also often observed a white line penetrating into the interior of the *corpusculum*, (*ligamentum intercapsulare*,) which appears to correspond with the prolongation of the stalk on the other side. The fine, closely compressed, parallel lines of the proper stalk become towards the nerve progressively more subtile, and in most cases vanish altogether from the eye before they sink into the nerve. In the middle of a corpuscle there is observed a longitudinal space, more or less transparent, which follows in like manner the longitudinal axis of the *corpusculum*. The dark lines lying next to it are more numerous, more closely compressed on each other, and run almost entirely straight. These concentric dark lines appeared to the observer as the outlines of so many capsules placed in layers on each other; and this view was confirmed by careful dissection. In short, when the apex of one *corpusculum* is cut off, there is observed close to the opening a small quantity of fluid, the *corpusculum* collapses, and from the interior proceeds a new *corpusculum*, more sharply defined, and smaller and more pointed than the former. This operation may be repeated several times, always with the same phenomena, except that the size of the *corpusculum* diminishes, and the oval form passes more and more to the cylindrical.

A Pacinian body consists, therefore, of a greater or smaller number of capsules inclosing each other, which are separated

General Anatomy.

Pacinian corpuscula.

from each other by a greater or less quantity of fluid, easily miscible by water. The spaces between the capsules filled with fluid are named by Pacini intercapsular spaces.

The dark parallel lines of the stalk correspond to tubes encased within each other of the sections of the membranes, which tubes are continued into the capsules, yet contain no fluid. The conical prolongation of the stalk within the *corpusculum* is formed in such a manner that the stalk of the inner capsule penetrates further into the same than the outer. The innermost tube of the stalk proceeds without expansion into the innermost capsule forming the central cavity.

The internal central cylinder Henle and Kölliker compare to the primitive nervous fibre. Henle discovered a nervous fibre in the central canal of the corpusculum.

The accuracy of these observations has been in general confirmed by Strahl, who proposes to restore the original merit of discovery to Vater by calling the bodies Vaterian *Corpuscula*.

The Capsules which give the Vaterian Corpuscula their peculiar shape vary much in number and width. Usually there exists, as the early observers represent, a system of internal capsules; but this does not always contain the same number of capsules; and the latter are not in all cases smaller than the outer, but often interrupted in consequence of their width.

The capsule walls consist of structureless filamentous tissue, in which are imbedded *Nuclei*. Fibrous structure Strahl did not recognize even with strong magnifying powers; and at most he only observed a difference of longitudinal and transverse fibres.

Most commonly only one particular nerve-fibre runs into each Vaterian body.

Anatomists are not agreed as to the nature or the uses of these bodies. All that is known is what is now stated; that by one extremity or pole they are connected with the nervous system, and by another with the lymphatic system. As to uses, it seems reasonable to think that in some manner they are concerned in the functions performed by the extremities of the nerve. But on this point there is great uncertainty. They appear not to be particularly connected either with sensation or with the sense of Tact as possessed by the fingers. In the extremities they are observed in spots in which these functions are not expressed with particular energy. They are generally in greatest number in the ball of the thumb; and they are situate in the toes, in parts at which neither sensibility nor Tact can be said to be considerable.

Pacini entertained the idea that they are connected with the development of electricity; and Henle and Kölliker were disposed to favour this opinion. Strahl subjected the opinion to the test of experiment, and arrived at the conclusion that in the Vaterian Papillæ no electricity or electro-magnetism can be demonstrated.[1]

## CHAP. II.—THE PARTICULAR TISSUES.

### *Cerebral System,—Brain.* (*Cerebrum.*)

Brain.

The brain or central part of the nervous system may be regarded as a continuous organ, consisting of three divisions, —the *convoluted*, the *laminated*, and the *smooth* or *funicular* portions. Of these divisions, which are distinguished according to the peculiar external configuration of each, the first part corresponds to what is named the brain proper (*cerebrum*); the second to the small brain (*cerebellum*); and the third to the oblong production contained in the vertebral column, and known under the name of the *spinal chord*.

General Anatomy.

Brain.

The convoluted portion presents two surfaces, an outer or convoluted, and an inner or figurate. The laminated portion in like manner presents two surfaces;—an outer or laminated, and an inner or central. The third has only one surface, which is exterior. These different surfaces, and their mutual relations, will be more minutely explained afterwards. At present we shall examine its physical and anatomical characters as an organic substance.

The three divisions of the central part of the nervous system are composed of a peculiar substance which may be denominated *cerebral matter*, inclosed in delicate vascular membranes. To exhibit the external characters of this substance, these membranes must be removed by careful dissection. When this is done, and the brain is inspected on its surface and after sections, the cerebral matter is observed to vary in colour, consistence, and intimate structure, in different parts of the organ. These varieties of cerebral matter are most easily distinguished, according to their colour, into *white* and *gray* or *cinereous*.

The white cerebral matter is of different shades in different parts of the brain. Its most usual hue is orange-white, or orange-white inclining to reddish-white, or purplish-white. This is most distinctly recognized in the mesolobe (*corpus callosum*), and in the body named *hippocampus major*. The consistence of the white cerebral matter is considerable. It is in general more tenacious and cohesive than the gray matter, and when indurated is less brittle.

A section made by a sharp scalpel appears smooth and of a uniform colour, traversed by reddish points and streaks. It presents nevertheless different appearances in different directions. In certain parts, for example the mesolobe, it presents the appearance of minute capillary lines, arranged in parallel juxtaposition, and giving what is named a fibrous appearance. In other regions, however, as in the white matter of the optic chambers, this cannot be recognized.

White cerebral matter has been examined microscopically by Della Torre, Prochaska, the Wenzels, Sir Everard Home, and M. Bauer.

If we trust the observations of Father Della Torre, the white and gray substance of the brain, *cerebellum*, *medulla oblongata*, and spinal chord, consist of an aggregation of infinite transparent globules, floating in a pellucid, crystalline and somewhat viscid fluid. The only difference which he admits among the matter of these several parts is, that he represents the globules to be largest in the brain, smaller in the *cerebellum*, and still more minute in the *medulla oblongata* and spinal chord. The arrangement of these globules in the central portion of the nervous system he further represents to be promiscuous.

Prochaska placed on a thin plate of glass minute slices of cerebral matter, so thin that they were translucent; and in this state he found it consist of innumerable globular particles, united by delicate, pellucid, flocculent matter, like filamentous tissue. These globules varied in size even in the same part of the brain. In general, however, he found them both in the brain and cerebellum to be rather more than eight times smaller than the globules of the blood. He was unable to ascertain anything regarding their intimate structure.

The Wenzels found the white cerebral matter to consist of very minute globules, or roundish atoms, resembling spherical cells containing proper medullary or white cerebral substance. The dimensions of these globules they did not attempt to estimate; but represent them in general as exceedingly minute, and all of the same size. They could not

[1] Zu den Pacinischen Körperchen (Papillæ. Von A. Vater.) Von Dr J. Carl Strahl. Müller's Archiv, 1848. Seite 165. Edinburgh Medical and Surgical Journal. Volume seventy-third, p. 118, 1850.

recognize any connecting medium. The globular appearance was retained in portions of brain exposed to the action of alcohol and muriatic acid, and in those even which had been dried after induration in alcohol.

M. Bauer placed a thin slice of white cerebral matter on a plate of glass previously moistened, and allowing a drop of water to fall on it, held obliquely, and thereby to diminish its cohesion, brought into distinct view innumerable loose globules, many fragments of fibres of single rows of globules, and bundles of fibres, some of considerable length.

The use of water in this mode of examination is to dissolve and remove a viscid, gelatinous, semifluid substance, on which the adhesive properties of the white matter seem to depend. If water is not used, the brain adheres to the glass, and the globular appearance cannot be recognized.

These globules vary in size from $\frac{1}{2400}$th to $\frac{1}{4000}$th of an inch in diameter; the general or average size being $\frac{1}{3200}$th. Those of the white matter are largest, that is $\frac{1}{2400}$th. They are translucent, whitish, and arranged in lines or rows of single globules, which are attached to each other by the viscid semifluid mucus. The strings or rows of globules are connected into bundles or *fasciculi* by the same medium. There is reason to believe that the translucency of the globules depends on an albuminous fluid, which on immersion in alcohol or acids is coagulated, and thereby rendered opaque.

When a portion of white cerebral matter is immersed in boiling oil, or is steeped for a few days in alcohol, dilute nitric or muriatic acid, or in a solution of corrosive sublimate, it acquires great firmness and solidity, and may be torn or broken like a piece of cheese, which it could not be before, in consequence of its tenacity. Certain parts, for example the mesolobe, appear then to be distinctly fibrous, or to consist of long capillary lines placed in close juxtaposition. On the length of these filaments or fibrils, however, nothing is ascertained. It is also undetermined whether the white cerebral matter is in all parts arranged in the fibrous manner.

White cerebral matter is well supplied with bloodvessels. These, indeed, are minute; but they consist both of vessels containing red and colourless blood. The division of these vessels gives rise to the appearance of red points (*punctula*) and streaks, which are exhibited on the surface of sections. It is believed to be less vascular than the gray cerebral matter.

On the chemical constitution of white cerebral matter we possess no accurate information; all the chemical analyses hitherto made having been directed to brain, without distinction of its different varieties. From the circumstance, however, of its becoming indurated on immersion in alcohol, acids, and solutions of corrosive sublimate, it is manifest that it contains much albumen. It is rendered yellow by nitric acid. If a portion of indurated brain be placed in the sun, or in a warm atmosphere, an oily or unctuous fluid exudes from its surface, which shows that it contains fatty matter; and if brain be immersed in ether, this fatty matter is partially removed.

The analysis of Vauquelin, which is probably very near the truth, shows that 100 parts of cerebral substance, not distinguishing between white and gray matter, consist of 80 parts of water, 7 of albumen, 4·43 of white adipose matter, 0·70 of red adipose matter, 1·12 of osmazome, 1·5 of phosphorus, and 5·15 of acids, salts, and sulphur. Upon the presence of the albuminous matter depends the solidification which the brain undergoes, when immersed in alcohol, acids, or solutions of the metallic salts, by which albumen is coagulated. Upon the presence of the white adipose matter depends the formation of those brilliant white crystalline plates, resembling cholesterine, observed by M. Gmelin, in the brains preserved in the Anatomical Cabinet at Heidelberg. The opinion of this chemist, that it pre-exists in the brain in the form of adipocerous or cholesterine matter, is to a certain extent probable. The elements, at least, of this matter, that is elaine and stearine, must exist in the brain.

Couerbe distinguishes in brain four fatty principles, Cerebrot, Eleencephol, Cephalot, and Stearokonot.[1]

The first is the solid white adipose matter of Vauquelin, the brain wax of Gmelin. Eleencephol is a yellow red oil disagreeable odour. Cephalot is a saponifiable article. Stearokonot, also saponifiable, is hard and pulverizable.

The gray or cinereous cerebral matter, though variable in colour like the white, is in general a mixture of ash-gray and wood-brown, darker than the former, but lighter than the latter. The colour varies at different ages. It is light in early life, and deeper as life advances.

The gray cerebral matter is softer and less viscid and tenacious than white cerebral matter. It is distinctly grannlar, both in the external surface and when torn or broken. This appearance, however, is most distinctly recognized after induration in alcohol or acidulous liquors. In the convoluted part of the brain, where it is most abundant, it does not present the fibrous or parallel linear arrangement, and is merely an aggregated mass of numerous minute granules. It is uncertain whether it presents the fibrous arrangement in other parts of the brain. An appearance of this kind is recognized in the unciform bundle at the inner end of the fissure of Sylvius, and also in the streaked bodies and the annular protuberance. But the appearance alluded to seems to depend not on the genuine fibrous arrangement of the granules of the gray matter, but merely on the gray matter being deposited in streaks and lines between the white. Meckel nevertheless maintains that the gray matter is also fibrous.

According to the observation of Sir Everard Home and M. Bauer, the gray cerebral matter consists of minute globular atoms, smaller than those of the white matter, or varying from $\frac{1}{3200}$th to $\frac{1}{4000}$th of an inch in diameter. These globules appear to be united, though more loosely, by a sero-albuminous fluid of a yellower tint than that of the white matter. Home supposes this albuminous fluid to be less abundant in the gray matter.

Gray cerebral matter is well supplied with bloodvessels, which are large and numerous. It must not be imagined, however, that all the vessels which are observed to enter this substance are therefore distributed to it. These large vessels necessarily penetrate the gray matter of the convoluted surface before they reach the white matter in the centre; and though they send branches to the former, they are ultimately distributed to the latter. The gray cerebral matter, nevertheless, is generally represented to be more vascular than the white; but the circumstance now stated renders this doubtful. The statement of Sir Everard Home, that "the finest and most delicate branches of the arteries and veins are only found in the cortical, *i. e.*, the gray substance," is contradicted by observation; for the vessels are certainly in general larger and more distinct in this than in the white matter. But if they are larger in the former, they are more numerous in the latter. On the whole, perhaps, there is little difference between the vascularity of the white and gray substance of the brain.

The chemieal constitution of gray cerebral substance has not been accurately examined. The results of analysis show, nevertheless, that it contains albuminous matter to the

---

[2] Du Cerveau, consideré sous le point de vue Chemique et Physiologique. Paris, 1834. 8vo.

amount of about 7 per cent., with 0·70 of a peculiar red adipose matter, which is probably the cause of the peculiar colour.

These two varieties of cerebral matter are combined in various modes and proportions in the brain. In general the gray matter is found on the exterior, for instance on the convoluted surface of the brain, and on the laminated surface of the cerebellum; while the white matter is arranged in the central parts. Gray matter, nevertheless, is found in the interior, in the streaked bodies and optic *thalamus*, and in the moriform bodies (*corpora dentata*) of the cerebellum and olivary eminences.

Besides the two varieties of substances now mentioned, a third, of a deeper shade, is found in the brain. Thus, in the centre of the cerebral limbs is a quantity of cerebral matter of a dark or ink-spotted tint, which Vicq d'Azyr therefore named the black spot (*locus niger*) of the limbs of the brain. The nature of this black spot, which is quite uniform, is entirely unknown. It appears merely to be a modification of the gray matter.

A yellow-coloured substance has also been supposed to exist in the *centrum semicirculare geminum*, a narrow band between the striated body and optic thalamus. This substance is certainly firmer than the adjoining white and gray matter, and it is further peculiar in possessing a sort of tint between wax-yellow and wine-yellow. It is highly vascular. Of its other peculiarities, however, we know nothing; and we must be satisfied with regarding it as an anomalous species of animal substance, approaching to gray cerebral matter in colour, but infinitely firmer and more tenacious.

The microscopical observations made by Ehrenberg agree in some points with those made by Prochaska and Bauer; and in others they differ a little.

According to Ehrenberg, the substance of the circumference, or the convoluted part of the brain, consists of a thick, very delicate, vascular network, conveying often numerous blood-globules, and traversed by serpentine tendinous fibres. Besides the thick delicate vascular net of the first substance, Ehrenberg saw in the same, near its utmost edge and its remotest circumference, a very fine-grained soft substance, in which here and there are imbedded larger grains or *nuclei*. These large grains are free, and consist of granules or *nucleoli*, which are connected in rows by means of slender threads to the fine small threads of the substance singly. In the neighbourhood of the medullary substance, the fibrous character of the cortical matter always appears more distinctly; and in the same substance the bloodvessels are larger and less numerous.

The white or medullary matter of the brain shows more distinctly the arrangement of fibres, which proceed in the form of direct and enlarging continuations of the delicate cortical fibres, from certain eminences, that is, the linear or band-like origins of the convoluted surface, in a radiated manner, towards the brain. These are not simple cylindrical fibres; but resemble hollow strings of pearls, the component parts of which are not in contact, but are connected by a canal for a small space; or they resemble tubes or cylindrical canals dilated at intervals into minute bladders. These bladders or *ampullulæ* of the tubes were known to Leeuwenhoeck, who regarded them as globules of fat, which constituted the greatest part of the brain. The connecting canals also he has obscurely indicated. These tubes, uniformly straight, are generally parallel in direction, sometimes, however, crossing each other. Four times Ehrenberg recognized ramification in such individual canals; but anastomoses he never observed. These tubes vary in diameter from $\frac{1}{96}$th to $\frac{1}{3000}$th of one line.

In the neighbourhood of the base of the brain, and in the matter surrounding the ventricles, there are always seen, between these bundles of nodulated or jointed tubes, individual tubes much thicker than the rest. In these thick tubes it is often possible to recognize in their walls an external and internal boundary; or they present, besides their two external boundary lines, other two inner lines, which enable the observer to distinguish the width of the area of the internal cavity of the tubes. These nodulated linear parts of the brain are VARICOSE ARTICULATED TUBES OR CANALS.

The large cerebral tubules of the cerebral matter converge towards and pass into those parts of the base of the brain, where the peripheral nerves arise. Some of the large jointed-tube matter appears to terminate in or be connected with the cerebral cavities, in the walls of which it is well developed. Many jointed or varicose tubes pass into the spinal marrow, and thence immediately proceed to the spinal nerves.

In the spinal marrow the arrangement now described is in some respects reversed. In the brain the most vascular and delicate structure is placed at the exterior; while the least vascular, but perhaps more organized, viz., the varicose tubular structure, is placed at the interior. In the spinal chord the most vascular and delicate part lies in the centre; while it is covered externally by the coarse medullary matter.

Both substances are quite like those in the brain. From the external medullary matter, consisting of large varicose or moniliform tubes, the spinal nerves immediately proceed; and these varicose or jointed tubes, as they emerge from the investing *dura mater*, assume suddenly the form of nerve-tubes, becoming thicker and passing into the pure cylindrical form. These transitions are easily recognized in the posterior part of the spinal marrow.

The optic, the auditory, and the olfactory nerves are immediate continuations of, or productions from, the varicose medullary tubes of the brain. All the other nerves, excepting the sympathetic in the middle of its course, differ from the cerebral matter.

All the other nerves also consist only of cylindrical parallel-lying tubes, about $\frac{1}{120}$th part of a line in diameter, normally never anastomosing. These are the elementary nerve-tubes, which, united in *fasciculi* or bundles, again form larger bundles, which constitute the nerve-chords.

These are the chief facts ascertained by Ehrenberg regarding the minute structure of the brain and spinal chord. These have been mostly confirmed by Berres and Müller. By others, again, the accuracy of these results has been called in question. Thus the observations of Treviranus, Valentin, and Weber tend to show that all the primitive cerebral fibres or tubes are cylindrical, and that the varicose or moniliform appearance is an effect of compression, or the violence employed in subjecting them to microscopic observation. Müller, nevertheless, admits that the primitive cerebral tubes have great proneness to become varicose or beaded.[1]

General Anatomy.

Brain.

The only points which, amidst the discordance of the results of different microscopical observers, from Leeuwenhoeck and Fontana to Ehrenberg, Berres, Treviranus, and Müller, can be regarded as established, are the following: that the convoluted portion of the brain consists of very minute granules or *nucleoli* arranged in rows so as to form fibres, which radiate from the periphery to the inner boundary of the convoluted portion; that near the inner boundary, and as they approach the white cerebral matter, this fibrous arrangement becomes more distinct; and that the white cerebral matter forming the walls of the ventricles and the base of the brain, is composed of tubular cylinders, mostly of large size, and having a cylindrical cavity; but whether these are varicose or not seems undetermined.

The parts named pituitary and pineal glands present several peculiarities deserving attention; but these more properly come under the head of Special than of General Anatomy.

*Flesh, Muscle.* (Μυς,—Μυες,—*Musculus,—Lacertus,—Tori.*) *Muscular Tissue.* (*Tissu Musculaire.*)

Muscle.

The ordinary appearance of the substance named flesh or muscle is familiar; and it is unnecessary to enumerate those obvious characters which are easily recognized by the most careless observer. A portion of muscle, when carefully examined, is found to consist of several animal substances. It is traversed by arteries and veins of various size; nervous twigs are observed to pass into it; it is often covered by dense whitish membranous folds (*fasciæ*), or by serous or mucous membranes, all which shall be examined afterwards; and it is found to contain a large proportion of filamentous tissue. But it is distinguished by consisting of numerous fibres disposed parallel to each other, and which may be separated in the same manner by proper means. The appearance, arrangement, and characters of these fibres demand particular notice.

Muscular Filament.

According to Prochaska, muscle in all parts of the body may be resolved, by careful dissection, into fibres of great delicacy, as minute as silk filaments, but pretty uniform in shape, general appearance, and dimensions. Their diameter appears not to exceed the $\frac{1}{40000}$th part of an inch, whatever be their length. They seem all more or less flattened or angular, and appear to be solid diaphanous filaments. Prochaska, not doubting that these muscular threads (*fila carnea*) are incapable of further division, terms them *primary muscular fibres*.

The microscopical examination of the atomic constitution of the muscular filament, which was first attempted by Leeuwenhoeck, and afterwards prosecuted by Della Torre, Fontano, Monro, and Prochaska, was resumed by Sir E. Home and M. Bauer, and subsequently by Hodgkin and Lister, Mr Skey, M. Mandl, Mr Bowman, Schwann, Henle, Remak, and Kölliker. According to the observations of M. Bauer, each muscular filament appears to consist of a series of globular or oblong spheroidal atoms, disposed in a linear direction, and connected by a transparent, elastic, jelly-like matter. (*Phil. Trans.* 1818, 1826.)

The primary muscular fibres are placed close and parallel to each other, and are united in every species of muscle into bundles (*fasciculi, lacerti*) of different but determinate size; and according as these bundles are large or small, the appearance of the muscle is coarse or delicate. In the deltoid the bundles are the largest. In the *vasti*, *glutæi*, and large pectoral muscles the bundles are greatly larger than in the *psoæ*. In the muscles of the face, of the ball of the eye, of the hyoid bone, and especially in those of the perinæum, these bundles are very minute, and almost incapable of being distinguished. The number of ultimate filaments which compose a bundle varies in different muscles, and probably in different animals. In a muscular fibre of moderate size in the human subject, Prochaska estimates them to vary from 100 to 200; and, in animals with larger fibres, at double, triple, or even four times that number. There is reason to conclude, from correct microscopic observation, that the largest do not exceed the eighth part of one inch, and that the smallest are not less than one-sixteenth.

General Anatomy.

Muscular Filament.

According to Mr Skey, a single muscular filament has a diameter of $\frac{1}{400}$th part of one inch. According to Mr Bowman, who has given the diameter of the primitive fibre in many animals, both of the Vertebrated classes and the Aspondylous tribes, the diameter varies from $\frac{1}{512}$th part to $\frac{1}{209}$th in the male, and from $\frac{1}{615}$th to $\frac{1}{784}$th part of one inch in the female of the human race. In the Mammalia and Birds, they are in general smaller. In the horse, from $\frac{1}{1100}$th to $\frac{1}{508}$th; in the cow, from $\frac{1}{370}$th to $\frac{1}{192}$th; in the sheep, from $\frac{1}{610}$th to $\frac{1}{520}$th. In the owl, the diameter of these primitive filaments are from $\frac{1}{1000}$th to $\frac{1}{600}$th; in the turkey, from $\frac{1}{700}$th to $\frac{1}{550}$th part of one inch.

When the muscular fibre is examined by the microscope, it is found to present transverse or cross lines, of great minuteness. These transverse streaks (*striæ*) are conceived to indicate circular annular markings going all round the fibre. They are placed closely together, but varying much in thickness and in number; a portion of the length of the fibre, equal to its diameter, containing, according to Mr Skey, from sixteen to twenty-five streaks.

These transverse lines are not seen with equal distinctness in all the muscular fibres of the voluntary muscles. When distinct, they present themselves in the form of rings, pretty well defined, the extremities of which may be distinctly traced, encircling the fibre, equidistant from each other, uniform in diameter, and apparently raised from the surface into ridges, having depressions between them. Mr Skey infers, as in certain lights light-coloured lines are seen, and dark intervening lines, that the light lines are the elevated *striæ*, and the dark-coloured lines are the intermediate depressions.

These alternate light and dark-coloured transverse lines are characteristic of voluntary muscles in all parts of the body, and in all animals. They are not observed in the muscles of organic life, or those of the involuntary organs, the heart excepted; for instance, the muscular fibres of the stomach, of the intestinal canal, and the bladder.[1]

The muscles which present these cross-lines are sometimes named Striped muscles; and as the aspect remotely imitates a string of beads, they are occasionally called Beaded muscles. In consequence of the stripes being found solely in the voluntary muscles, the latter are often called Striped and Beaded muscles.

The nature of these transverse lines and markings is not perfectly known. Prochaska appears to have believed that they were produced by minute flexuosities of fibrils, and connected in some manner with the filamentous tissues. Fontana believed that they were caused by small diaphragms or partitions of the primary filaments. Mr Skey remarks, that the *striæ* are invariably large as the fibre is small, while the broad fibres exceeding the average diameter of $\frac{1}{400}$th part of one inch, exhibit the most delicate and minute pencilling possible. He infers that these *striæ* are ridges or elevations on the longitudinal fibre, leaving between them depressions considerably smaller than the globules of the blood; that each fibre is divisible into *fibrillæ*, which are composed of many ultimate filaments, and which are arranged in

[1] On the Elementary Structure of Muscular Fibre of Animal and Organic Life. By F. C. Skey, F.R.S. Phil. Trans., Lond. 1837. Vol. xxi. p. 371. On the Minute Structure and Movement of Voluntary Muscle. By W. Bowman. *Ibid.* 1840, Art. xxi. p. 457.

parallel lines round the axis of the fibre; that the muscular filaments have a diameter of about the third part of a globule of the blood; that they are tubular, and contain a soluble glutinous substance; and that this structure belongs to all the external muscles, and all the internal muscles connected to any form of tendinous matter.

According to Mr Bowman, several of these views of Mr Skey are not susceptible of strict proof. Mr Bowman represents the primitive *fasciculi* of the fibre of voluntary muscles to consist of elongated polygonal masses of primitive component particles, or what he calls Sarkous elements, arranged and united together both by their ends and by their sides, so as to constitute in these directions respectively *fibrillæ* and disks, both of which exist together in the perfect unmutilated muscular filament, and either of which may, in certain cases, be detached separately. According to the same observer, the dark longitudinal striæ are shadows between *fibrillæ;* the dark transverse streaks are shadows between disks. The primitive fasciculus consists of primitive component segments or particles, arranged so as to form in one sense *fibrillæ*, in another disks; and which of these two present themselves to the observer, depends upon the amount of adhesion. Generally, in a recent fasciculus, there are transverse *striæ* or stripes, showing the division into disks, and longitudinal lines marking the division into fibrillæ. These *striæ*, in short, are the edges or focal sections of plates or disks arranged vertically to the course of the fasciculi, and each of which is composed of a single segment from each fibrilla.

Ultimate Filaments.

The *fasciculi* are not tubular and hollow, but consist of a true bundle of *fibrillæ*. That this is the fact, Mr Bowman argues, is proved by making a transverse section, which presents no appearance of any cavity.

By cutting a muscle across, these bundles are observed to differ, not only in size, but in shape. Some are oblong and rhomboidal, others present a triangular or quadrangular section, and in some even the irregular pentagon or polygon may be recognized.

According to the observations of Kölliker, the form most usual is that of the hexagon, not quite regular; and when two sides run into one, it assumes the shape of the pentagon. Bowman merely says, that they are in all animals polygonal, though in some instances they make a near approach to the cylindrical form. This is easily understood. If the angles be rounded, the filament that might be polygonal or hexagonal becomes cylindrical.

Sarkolemma.

These bundles or *fasciculi* are united by filamentous tissue of great delicacy. Each filament or fibril is inclosed in a sheath of peculiar matter, described by Schwann, and afterwards by Bowman, under the name of *Sarkolemma*, or Flesh Coat. This structure is entirely different, according to the last author, from filamentous tissue, either penetrating or generally investing. It may be discovered in unbroken fasciculi, in the form of a straight linear margin, quite unconnected with and independent of the *striæ*. The sarkolemma is tougher and firmer than the muscular filament.

The fibrils and fibres thus inclosed in *Sarkolemma* are united into Fasciculi, which are inclosed by filamentous tissue, and are penetrated by arteries, veins, and nerves. The whole are surrounded by filamentous tissue, which often contains fat; in many instances covered by fasciæ; in all attached by tendons.

This fascicular arrangement appears to be confined to the muscles of voluntary motion. It is not very distinct in the heart or diaphragm; and in the urinary bladder and intestinal canal it is not recognised. Nor is the parallel arrangement of the ultimate filaments always strictly observed in the involuntary muscles. The component fibres of this order of muscles are often observed to change direction, and unite at angles with each other. This fact, which was observed by Leeuwenhoeck, has been verified by Prochaska.

The colour of muscle varies. In man and the mammiferous animals, at least adult, it is more or less red; in many birds and fishes it is known to be whitish; in young animals it is grayish or cream-coloured; and the slender fibres which form the middle coat of the intestines in all animals are almost colourless. The colour of the muscles of voluntary motion in man is red or fawn; but repeated washing or maceration in alcohol or alkaline fluids renders them much paler.

The examination of the physical properties of muscle has occupied the industry of Muschenbroek, Croone, Browne Langrish, Wintringham, and others of the iatro-mathematical school. I cannot perceive that minute knowledge of these properties is of much moment to the elucidation either of its sound or its morbid states. Amidst the variable results obtained in such an inquiry, the only certain point is, that muscular fibre has less tenacity and mutual aggregation than most other tissues. It sustains much less weight and force of tension without giving way.

Chemical analysis has not yet furnished any satisfactory results on the nature of muscular tissue; but the general results of the numerous experiments already instituted show that muscle contains fibrin, albumen, gelatine, ex tractive matter (osmazome), and saline substances. It is difficult to say how far the gelatine is to be regarded as proper to muscle, or derived from the filamentous tissue in which it certainly exists. The saline matters are common to muscle with most other organic substances. There is reason to believe that fibrin in considerable quantity and albumen and osmazome in smaller proportion, are the proper proximate principles of muscle. Though the various proportions of these principles have been stated in numbers by chemists, it is impossible in the present condition of animal chemistry to place any reliance on them. It is also to be remembered that the relative proportion of the proximate principles varies at different periods of life. In early life the muscular fibre contains a large proportion of gelatine, and very little albumen, fibrin, or osmazome. In adult age, however, the gelatine is very scanty, and the fibrin is abundant. The albumen and gelatine found in muscle seem to be derived chiefly from the filamentous tissue and the aponeurotic intersections.

During life the muscular fibre possesses the property of shortening itself or contracting under certain conditions. These may be referred to the following heads: 1*st*, The will in the voluntary muscles; 2*d*, proper fluids in the involuntary muscles, as the blood to the heart, articles of food or drink in the stomach, chyme in the small intestines, excrement in the large intestines, urine in the bladder, &c.; 3*d*, mechanical irritants in all muscles; 4*th*, chemical irritants; and, 5*th*, morbid products generated in the course of disease.

This property of contracting has received various names: contractility, *vis contractilis* of L. Bellini; irritability of Glisson; *vis vitalis* of De Gorter and Gaubius; excitability, mobility, *vis insita, vis propria* of Haller; and the organic contractility of Bichat. It is peculiar to muscular fibre, and is found in no other living tissue.

The inquiry into the properties peculiar to muscles, and the influence of the brain and nerves over muscular contraction, forms an interesting subject of investigation, on which many facts have been communicated since the time of Haller and Whytt, and within the last forty years by Nysten, Le Gallois, Wilson Philip, Bell, Magendie, Flourens, Fodera, Rolando, and Longet. But it is too extensive to be considered in this place; and, for information

General Anatomy. Muscle.

on the subject, I refer to the ordinary physiological works, and to those journals in which these researches are detailed.[1]

The muscles have been divided, according to the manner in which the phenomena of contraction take place, into, 1*st*, muscles obedient to the will, or voluntary; 2*d*, muscles not under the influence of the will, or involuntary; and, 3*d*, muscles of a mixed character, the motions of which are neither entirely dependent nor independent on the will.

The first order comprehends all the muscles of the skeleton; the second includes the hollow muscles, as the heart, stomach, and intestinal canal; and in the third are contained such muscular organs as the diaphragm, intercostal muscles, bladder, rectum, &c.

The muscles have also been distinguished, according to their mechanical shapes, into long muscles (*musculi longi, vel teretes*), broad muscles (*musculi lati*), and irregular muscles, or those of mixed form. The long muscles are found chiefly in the extremities; the broad muscles in the trunk; and those of irregular shape either in the trunk, or passing from this to the extremities. From the direction of their fibres, several of them are distinguished into penniform and semipenniform.

### *Sinew, Tendon.* (*Tendo.*)

Tendon.

Sinew or tendon was united by Bichat with ligament, fascia, aponeurosis, and periosteum, under the general name of *fibrous system;* and the substance of this arrangement has been adopted by Gordon, Meckel, and Beclard. From personal observation, however, I am inclined to regard tendon as essentially distinct, at least in the present state of knowledge, from these substances. Examined anatomically, it does not bear a very close resemblance to any of them; and in its known chemical properties it is considerably different.

The appearance of this substance must be familiar. Almost cylindrical in shape, but flattened at the muscular end, and tapering where inserted, a tendon consists of numerous white lines as minute as hairs, of satin-like glistening appearance, placed parallel and close to each other. A tendon is easily divided, and torn into longitudinal or parallel portions; and by the forceps very minute fibres may be detached and removed with ease, its whole length. These facts show the great tenacity of this tissue, and the regular parallelism with which the component fibres are united. The last circumstance distinguishes them completely from ligaments and periosteum, in which the fibres cross in all directions, and in consequence of which these tissues cannot be so easily split or separated. These fibres are united by filamentous tissue.

Tendon is softened and more easily separable by maceration in water or alkaline fluids; it is crisped by acid fluids, and rendered translucent by immersion in oil of turpentine. It has not been injected, but it is presumed to have blood-vessels and absorbents. No nerves have been traced into it.

Tendon when boiled becomes soft and large, assumes the appearance of a transparent gelatinous substance, and finally, if the boiling be continued, is dissolved and converted into gelatine. This fact, which is well known to cooks, who prepare jellies from tendinous parts of young animals, shows that tendon consists principally of gelatine, disposed in an organized form.

A species of flattened tendons, to which the name of *aponeurosis* has been given, may justly be united with this tissue. The best examples are in the aponeurotic or tendinous expansion of the external oblique muscle of the abdomen, the aponeurotic part of the occipito-frontal muscle of the head, and the upper or broad end of the *tendo Achillis.* The anatomical structure and the chemical properties of each of these varieties of animal substance are quite similar, and somewhat different from that which has been termed *fascia.*

General Anatomy. Tendon.

### *White Fibrous System. Ligament.* (Δεσμος, οἱ Δεσμοι.) *Periosteum,—Dura Mater,—Fascia.*

Against the formation of this order of tissues fewer objections can be urged, though ligament and periosteum undoubtedly furnish its most perfect examples; and it may be doubted whether *fascia* ought to be referred to it, or arranged with tendon and aponeurosis. The *dura mater*, the *tunica albuginea*, and the fibro-synovial sheaths, are to be regarded as compound membranes. Ligament; periosteum.

Ligament and periosteum are easily shown to consist of strong whitish or gray fibres, as minute as threads or hairs, interwoven together in various directions, and thus forming an animal substance which is not to be split or torn asunder as tendon; but when ruptured by extreme force presents an irregular ragged surface or margin. Maceration in water or alkaline fluids separates the component fibres, and shows their irregular disposition more distinctly. They are crisped by affusion of boiling water, or immersion in acids; and they become translucent by immersion in oil of turpentine.

The properties of this tissue are chiefly physical. Those which are vital are referable to its organization and nutrition. That it is powerfully resisting, and is one of the toughest and strongest tissues in the animal body, is evinced not only by the numerous experiments recorded in the writings of the iatro-mathematical physiologists, but by the barbarous mode of punishment by rending the limbs asunder by horses. It is supposed to possess the exhaling ends of arteries and colourless veins. No nerves have been recognised; and Bichat expresses his ignorance of absorbents being traced into it.

Ligament when boiled yields a small portion of gelatine, but obstinately resists the action of boiling water, and retains both its shape and tenacity or cohesion. The crispation which it undergoes in boiling water, alcohol, and diluted acids, seems to indicate that albuminous matter forms its chief chemical principle.

As to their mechanical shape, the ligaments are divided by Bichat into two sorts; those in regular and those in irregular bundles. The former comprehends all the distinct clusters of ligamentous structure, which, sometimes in a cylindrical, sometimes in a flattened shape, connect the articulating ends of bones, and form the lateral ligaments of the various articulations. The latter consists of those loose parcels of ligamentous fibres which are found in various regions of the skeleton, not in regular cylindrical or longitudinal bands, but irregularly connecting bones not admitting of articular motion; for instance, at the *symphysis pubis* and the sacro-iliac junction. The division of Beclard into articular, non-articular, and mixed, is more comprehensive and more natural. The first are those which connect the articular extremities of different bones. The second are those which, attached to different parts of the same bone, convert notches into foramina, as in the orbital arch and the supra-scapular hollow, or close openings, and

[1] *Elementa Physiologiæ*, tom. iv. lib. xi. sect. 2; Whytt *on the Vital and Involuntary Motions*: *Journal de Physiologie*, tom. i. ii. &c. *Archives Générales*, passim. Müller's Archiv fur Anatomie und Physiologie, *passim*.

General Anatomy.

Ligament; periosteum.

give attachment to muscles, as the obturator ligament. The last are those which, like the sacro-ischiatic or the interosseous ligaments of the fore-arm and leg, connect bones susceptible of little or no motion, and especially give attachment to muscles. The two latter species of ligaments approach closely in their characters, physical and anatomical, to periosteum, and are probably to be regarded as modifications of this membrane.

The articular or perfect ligaments are naturally divisible into two subgenera,—the capsular and the funicular.

The *capsular* ligaments, or the fibrous capsules (Bichat), consist of cylindrical ligamentous sheaths attached all round to the ends of the articulating bones, and intimately interwoven with the periosteal tissue. Consisting essentially of fibro-albuminous matter strongly compacted, they are surrounded by cellular tissue, or rather celluloso-adipose tissue, and are lined internally by synovial membrane. Though the most perfect examples of the capsular form of ligament are presented in the scapulo-humeral and coxo-femoral articulations, less complete ones, nevertheless, are seen in the other joints. In those of the knee and elbow, an arrangement of this kind may be demonstrated; and minute capsules may be shown to connect the oblique articular surfaces of the vertebræ with each other.

The *funicular* ligaments, which consist of round chords or flat bands, are employed in connecting the articular ends of bones either without or within the cavity of the joint. Of those of the former description, the best examples are seen in the elbow and knee joints, and in the wrist and ankle, where they are termed *lateral* ligaments (*l. lateralia, accessoria*). Of the latter instances are the round ligaments (*ligamenta teretia*) of the shoulder and hip joints, and the crucial ligaments of the knee-joint. These receive an investment of synovial membrane.

Fascia.

Of the white fibrous tissues, one of the most important is that denominated *fascia*. Consisting in intimate structure of long fibrous threads placed in parallel juxtaposition, sometimes obliquely interwoven and closely connected by filamentous tissue, it forms a whitish membranous web, variable in breadth, of some thickness and great strength. Fascia is perhaps, not excepting the skin, the most extensively distributed texture of membranous form in the animal body. It not only covers, if not the whole, at least by far the greatest part of the muscles of the trunk and each limb, but it sends round each muscle productions by which it is invested and supported, and even penetrates by minute slips into the substance of individual muscles. Of several of the large muscles it connects the component parts, as is seen in the *recti abdominis;* to many it affords points of origin or insertion; and to all it furnishes more or less investment and support. Most of the tendons, especially the flexor and extensor tendons, are inclosed by it; and their synovial sheaths derive from it their exterior covering. At the extremities of the bones it is connected with the ligaments and periosteum, with which it is closely interwoven; and it forms a general investment to the articular apparatus.

Though fascia may thus be viewed as one membranous web consisting of many parts all directly connected with each other, it is the practice of anatomists to distinguish its divisions according to the region which they occupy. Thus, in the fore-part of the neck and chest is found a fascia, the relations and uses of which have been well described by Mr Allan Burns. In the cervical region we find a firm fascia descending from the occipital bone along the vertebræ, covering and connecting the muscles of each side till it reaches the loins, where, in the form of a thick strong membrane, it forms the *lumbar fascia* (*fascia lumborum*). It may further be traced over and between the *glutæi* muscles, connected afterwards with the broad femoral fascia (*fascia lata*), and thence over the knee and leg to the foot. Much in the same manner a membranous web, thinner and more delicate, but of the same structure, may be traced from the chest along the upper extremity, till at the wrist it is identified with the annular ligament, and in the hand with the palmar fascia. In all these situations the general fascial envelope sends slips or productions (*fasciæ intermusculares*) between the muscles, and into their substance.

*Yellow Fibrous System. Elastic Ligaments of* John Hunter. (*Ligamenta Flava,—Ligamentum Nuchæ,—Tissu Fibreux Jaune*, Beclard.)

Elastic ligaments.

The yellow ligaments (*ligamenta flava*) which connect the spinous processes of the vertebræ to each other differ considerably from the articular ligaments and the periosteum, and suggested to Beclard the necessity of establishing a particular order of fibrous tissues, to which he applies the denomination of *yellow or tawny fibrous system.* Under this he includes also the proper membrane of the arteries; that of the veins and of the lymphatic vessels; the membranes which form excretory ducts; that of the air-passages; the fibrous covering of the cavernous body of the urethra, and perhaps that of the spleen. The actions and occasional distensions of which these parts are the seat require, it is said, a tissue, the resistance and elasticity of which may at once counteract any extraordinary effort, and cause them to resume their original state, when the distending cause ceases to operate. In the lower animals this purpose is more conspicuous than in the human subject. The posterior cervical ligament (*ligamentum nuchæ*, Arab.; *cervicis*, Lat.) in the camel, giraffe, deer, and ox, counteracts the tendency to inclination of the head; and a similar membrane strengthens the abdominal parietes, and resists the weight and distending power of the *viscera*. In the feline tribe an elastic ligament inserted into the unguinal phalanges retains them extended so long as the muscles do not alter their direction. The shells of the bivalve molluscous animals, as oysters, mussels, &c., are opened by a similar fibrous tissue as soon as the muscles which close them are relaxed.

The disposition of the component fibres is the same in the elastic as in the common white fibrous system. Their colour, which is yellow or tawny, is generally more distinct in the dead subject. They are said to be less tenacious, but more elastic, than those of any other tissue. In respect to chemical composition, they appear to contain a considerable quantity of fibrin in a peculiar condition, combined with some albumen and a little gelatine. Their other properties are not very conspicuous.

*Bone.* (Οστεον,—*Ossa,—Tissu Osseux,*—Die Knochen.)

Bone.

Bone, which is the hardest and most durable of the animal solids, may be defined to be an organized substance, consisting of a combination of animal and calcareous matter, and constituting by its solidity the chief support of the soft parts generally.

In the vertebrated animals it is moulded into pieces of definite shape and size, which are connected either by ligaments, cartilage, or fibro-cartilage, and which constitute the skeleton of the animal. In the mammalia and birds these pieces appear in their most perfect characters, as to solidity, mechanical shape, and numerical extent. In the human subject, though in these respects they partake of the characters common to the bones of the mammalia, in several senses these characters are more conspicuous than in the lower animals.

General Anatomy.

Bone. External forms.

1. The bones of the human skeleton are distinguished, according to the varieties of mechanical figure, into long and cylindrical bones (*ossa longa* sive *cylindrica*), flat bones (*ossa lata* sive *plana*), and short or irregular bones (*ossa brevia* sive *mixta*).

The long bones are confined to the extremities, where they are subservient to the locomotive apparatus, by acting alternately as points of support and as levers movable by the muscles in different directions. Placed in the centre, they are surrounded almost entirely by muscles; and are observed to diminish in length, but increase in number, the farther they recede from their attachment to the trunk. From this inverse arrangement it results that near the trunk the members are distinguished for extent, and remote from it for variety and multiplicity of motion.

The long bones agree in presenting cylindrical or prismatic shafts (*diaphyses*) terminated by large, bulky, and extensive extremities (*epiphyses*). The former are generally small and slender compared with the latter and with the size of the limb, and thus afford room for the bellies of muscles attached to them. The large size of the latter is well suited for the extent of the articular surfaces; and being covered by slender tendons and the taper extremities of muscles, they do not in general add to the bulk of the member.

The shafts of the long bones are in general marked by longitudinal rough lines, to which muscles or fasciæ are attached, and between which are found plane or hollow surfaces for lodging the bellies of the muscles. These lines are rarely straight; and the slight obliquity which they observe gives the bone the appearance of being twisted. This is well seen in the *humerus* and *tibia*.

The extremities of the long bones are marked in general by eminences and hollows, or processes (*apophyses*) and depressions (*foveæ; fossæ*). These inequalities, if tipped with cartilage and synovial membrane, are for the purpose of articulation with other bones. When they are simply formed of bone, they are for the attachment either of ligaments or tendons.

The shafts of the long bones consist chiefly of dense compact bone, containing in the adult a longitudinal cavity, which is easily exposed by a longitudinal section of the bone. This cavity is not cylindrical, but tapers considerably at each end; nor is it in all instances equally complete. Largest and most capacious about the middle, where it is bounded by the solid, compact, bony walls of the *diaphysis*, as the latter diminish in density they increase in bulk by the formation of numerous minute intersecting columns of bone, which progressively increasing in number towards the end of the shaft, contract the cavity, until at length it is obliterated in the lattice-work and cells (*cancelli*) formed by their mutual intersection. This cavity is the medullary canal. It is seen in its most perfect form in the *humerus* and *femur*, in the *tibia* and *fibula*, and in the *radius* and *ulna*. In the phalanges it can scarcely be said to exist. The two forms of bony structure demonstrated in such a section are distinguished as the *dense* or *compact*, and the *loose*, *reticular*, or *cancellated*.

The medullary cavity is lined by a vascular filamentous membrane, with numerous cells, containing the variety of animal fat denominated marrow. The effect of this arrangement is to render the bone lighter than if perfectly solid, without any diminution of strength. This cavity is wanting in the original formation of the bone; and it begins to be formed when the matter of the *diaphyses* becomes dense and compact. It is again obliterated in consequence of fracture or other injuries, succeeded by adhesive or depository inflammation, when it is filled by gelatinous animal matter; and it is once more excavated as the walls of the diaphysis acquire solidity.

The flat bones are in general less connected with the locomotive apparatus than with the protecting part of the skeleton. By mechanical configuration they serve to contain various organs essential to the economy; and when they admit of motion, this is rarely locomotive, but connected with the purposes of the contained organs. The bones of the cranium and pelvis furnish the best examples of bones destined solely to protect, and as locomotive agents affording only points of support. The ribs, again, which are to be viewed as flat bones, not only form the protecting walls of the chest, and furnish support to the muscles of the upper extremities, but further undergo a slight motion, by means of which the dimensions of the chest are alternately enlarged and diminished. The vertebræ combine the characters of flat bones and irregular bones, approaching by their spinal plates to the former class, and by their bodies to the latter.

In number the flat bones vary according to the purpose to which they are applied, and the nature of the cavities which they form. In the cranium and pelvis their numerical extent appears to bear relation chiefly to the facility of ossification,—a process which advances with equal rapidity in each individual piece. In the chest, again, this property is regulated by the kind of motion which the ribs are destined to undergo. The vital organs of circulation and respiration would no doubt have been more securely protected had they been inclosed, like the brain, in a continuous and complete osseous case; but by this arrangement the motions of inspiration and expiration must have been very limited.

The flat bones agree in being convex and concave in opposite directions; in possessing two surfaces, an external and an internal, and a circumference; and in consisting of an external and internal table or thin plate of bone, with loose cancellated structure interposed. This arrangement is most conspicuous in those of the cranium, in which the cancellated structure is distinguished by the name of *diploe*. It is nevertheless equally distinct in the ribs, the scapula, and the pelvic bones. In some instances in the latter, the diploe is obliterated, and the two tables approach each other so closely, that they form one bone; and occasionally this is destroyed, and the bone appears perforated. These effects are the result of long-continued muscular action.

The cancellated structure of the flat bones is lined by a vascular filamentous membrane, containing a small proportion of marrow, less oleaginous than that of the long bones, and entirely resembling those of the cancellated structure of their epiphyses.

The short bones are situate in parts requiring the combination of mobility and solidity; for example, the vertebral column, the *carpus* and *metacarpus*, the *tarsus* and *metatarsus*. Considerable extent of surface, numerous articular and ligamentous connections, with few muscular or tendinous insertions, are their leading external characters.

They consist of a single thin external plate of bone, inclosing a large proportion of cancellated structure, lined by vascular filamentous tissue, containing semifluid marrow, without much oil. While this arrangement combines very small specific gravity with sufficient firmness and solidity, it renders them more liable to derangements of organization than other parts of the osseous system.

Though the bones are thus distinguished according to general characters, it is often impossible to apply them accurately. The same bone may unite the characters of long and short bone, or flat and short bone, or long and

Bone. External forms.

flat bone. All the long bones indeed are in their epiphyses similar to the short bones.

In external figure the bones present certain eminences or processes (*apophyses*), and pits or cavities (*foveæ; fossæ*). The eminences are either articular or non-articular. The former, which are covered with cartilage or fibro-cartilage, belong to the subject of the connections of bones. The latter may be referred to three heads: 1*st*, eminences of insertion for ligaments, tendons, or aponeuroses; 2*d*, eminences of reflection for the transit of tendons round a pulley; and, 3*d*, eminences of impression, or those which correspond to various soft parts in contact with the bones.

The eminences of insertion appear in various shapes, and are distinguished into tuberosities and tubercles (*tubera*), spines (*spinæ*) or spinous processes, styloid processes (*styli*), crests (*cristæ*), and lines (*lineæ*), which are generally rough and elevated. These impressions are always more conspicuous in the male than in the female, in the old than in the young, in the robust and muscular than in the delicate and feeble, and in carnivorous than in herbivorous animals. In some instances, as in the case of the ischial tuberosity, the great trochanter and anterior tuberosity of the humerus, the eminences present individual facettes for the attachment of each tendon or muscle.

Of the eminences of reflection, the best examples are in the unciform process of the pterygoid process of the sphenoid bone, and the lower extremity of the *fibula*.

The depressions are either articular or non-articular. The latter consist of cavities of insertion, reception, transmission and motion, impression and nutrition.

The first, which give attachment to ligaments, tendons, or aponeuroses, are useful in augmenting the extent without increasing the size of bones. The pterygoid cavities, the digastric *fossa*, and that at the base of the great trochanter, afford examples of these cavities.

Of the cavities of reception, examples are seen in the cerebral and cerebellic *fossæ*, and in the grooves for arteries or nerves; for instance, that at the lower margin of the ribs, and the various openings in the cranium for the transit of vessels and nerves.

Cavities of motion are those over which tendons play in the contraction of muscles; the bicipital groove, the hollow between the ischial spine and tuberosity, and that in the *fibula* for the *peronæi*, are examples.

The cavities of impression alternate with the eminences, and are to be regarded as in general the cause of these eminences.

The cavities of nutrition are those minute orifices through which vessels convey to the substance of the bone, or the medullary membrane, the materials of its nutrition. Each long bone has one considerable hole of this kind in its shaft, and numerous minute ones in its extremities. The former is the orifice of a canal to the medullary cavity. The latter are supposed to belong chiefly to the cancellated structure.

Internal structure.

2. Several attempts have at different times been made to ascertain the atomic constitution of bone, but without much success. Malpighi, though he corrected the extravagant fiction of Gagliardi regarding the osseous plates and nails, fancied bones to be composed of filaments, which Leeuwenhoeck represented as minute tubes (*tubuli*). By Clopton Havers, again, the ultimate particles of bones were imagined to be fibres aggregated into plates (*laminæ*) placed on each other, and traversed by longitudinal and transverse pores (*pori*).[1] This view was adopted by Courtial, Winslow, Palfyn, Monro, and Reichel, who was at some pains to demonstrate this arrangement of plates and minute tubes by microscopical observation. These notions were first questioned by Scarpa, who, in 1799, undertook to show by examinations of bone deprived of its earth by acid, and long macerated in pure water, that it consists, both externally and internally, of reticular or cellular structure. So far as I understand what idea this eminent anatomist attaches to the terms *reticular* and *cellular*, I doubt whether this opinion is better founded than any of the previous ones. After repeating his experiment of immersing in oil of turpentine bone macerated in acid, I cannot perceive the reticular arrangement which Scarpa describes. Recently bone has been submitted to microscopic examination by Mr Howship, who revives the opinion of the existence of minute longitudinal canals, as taught by Leeuwenhoeck, Havers, and Reichel, but with Scarpa maintains the ultimate texture not to be laminated, but reticulated. Lastly, the existence of fibres and plates, which is admitted by Blumenbach, Bichat, and Meckel, apparently on insufficient grounds, is to be viewed as an appearance produced by the physical, and perhaps the chemical qualities of the proper animal-organic matter of which bone consists. Though it does not demonstrate, it depends on, the intimate structure of this body.

Bone. Internal structure.

The minute structure or atomic constitution of bone is probably the same in all the pieces of the skeleton, and is varied only in mechanical arrangement. When a cylindrical bone is broken, and its surfaces are examined with a good magnifying glass, or when minute splinters are inspected in a powerful microscope, it appears to be a uniform substance without fibres, plates, or cells, penetrated everywhere by minute blood-vessels. Its fracture is uneven, passing to splintery. In the recent state its colour is bluish-white; but in advanced age the blue tinge disappears. Delicate injection, or feeding an animal with madder, shows the vascularity of this substance.

To have a clearer and more accurate idea of the minute structure of bone, it is requisite to break transversely a long bone, and examine its fractured surface by a good glass, or to examine in the same manner the transverse fracture of a long bone which has been burnt white in a charcoal fire. The broken surface presents a multitude of minute holes, generally round or oval, which are larger towards the medullary cavity, but become exceedingly minute towards the outer surface of the bone. Of these minute holes no part of the bone, however compact in appearance, is destitute; and the only difference is, that they are more minute, and more regularly circular towards the outer than towards the medullary surface. These circular holes are transverse sections of the *tubuli* of Leeuwenhoeck, the longitudinal pores of Havers (*Osteologia*, p. 43 and 46), the pores and *tubuli* of Reichel, and the longitudinal canals of Howship. They communicate with each other by means of their great multiplicity and slight obliquity and tortuosity. They contain not blood-vessels exclusively, but divisions of the vascular filamentous tissue, which secretes the marrow. They are seen very distinctly in bones which have been burnt. After many care-

General Anatomy. Bone. Internal structure.

ful examinations, I have never been able to observe holes in longitudinal fractures of bones; and I therefore infer that there are no transverse pores.

These capillary pores are seen in the flat bones of the scull. I find them in the compact matter of the outer and inner tables of the occipital bone when well burnt, in which they seem to pass gradually from the lattice-work of the *diploe* to the distinct pores of the tables. I doubt, however, whether these pores can be said, as in the long bones, to indicate canals. They seem rather to belong to a very delicate cancellated structure. The pores are most numerous and distinct in the bones of young subjects.

Though these circular pores are most distinct in calcined bones, and might therefore be thought to be the result of the burning, yet that they are not, I infer from the circumstance that they are seen by a good glass in the transverse fracture of splinters of the femur and other large bones.

If a portion of bone be immersed in sulphuric, nitric, muriatic, or acetic acid properly diluted, it becomes soft and pliable, and when dried, is found to be lighter than before; yet it is impossible to discover that any particle of its substance has been removed, or that its mechanical shape and appearance are changed.

If a portion of bone be placed in a charcoal fire, and the heat be gradually raised to whiteness, it burns first with flame, and at length becomes quite red. If then it be removed carefully and slowly cooled, it appears as white as chalk, is found to be very brittle, and to have lost something of its weight. Yet neither in this case does any part of its substance appear to be removed, nor is its mechanical figure or appearance altered.

Chemical examination, however, informs us that in the first case a portion of earthy matter (phosphate of lime) is removed by the agency of the acid, and held suspended in the fluid, while the pliant but otherwise identical piece of bone consists chiefly, if not entirely, of animal matter; and that, in the second case, this animal matter is removed by destructive decomposition, while the earthy matter is left little changed by the action of fire. Every particle of bone, therefore, however minute, consists of animal or organic, and earthy or inorganic matter, intimately united; and it is impossible to touch, with the point of the smallest needle, any part of bone which is not thus constituted. A piece of bone consists not of cartilaginous fibres varnished over, as Herissant imagined, with earthy matter, but of a substance in which every atom consists of animal and earthy matter intimately combined.

There is therefore no ground for dividing osseous tissue into compact and spongy, as the old anatomists did; for though the middle parts of long bones are denser and heavier than their ends, or the bodies of the vertebræ, the difference consists not in chemical composition, but in mechanical arrangement. On dividing the head of a long bone, the lattice-work, or *cancelli*, as they are named, are formed by many minute threads of bone, crossing and interlacing with each other. But each thread is equally dense, and consists of the same quantity of animal and earthy matter, as the most solid part of the centre of the same bone. These threads, however, instead of being disposed compactly so as to take a small space, are so arranged that they occupy a large one, and present considerable bulk.

Though bone has been submitted to analysis by many eminent chemists, the results hitherto obtained cannot be said to be quite satisfactory. The most recent is that of Berzelius, who, in 100 parts of bone from the thigh of an adult, gives the following proportions: of gelatine 32·17, blood-vessels 1·13, phosphate of lime 51·04, carbonate of lime 11·30, fluate of lime 2·00, phosphate of magnesia 1·16, hydrochlorate of soda and water 1·20.

These results by no means agree with those obtained by Fourcroy and Vauquelin, who found neither fluoric acid nor phosphate of magnesia, but discovered oxides of iron and manganese, silica, and alumina, in bone. Sulphate of lime, which was found in the experiments of Hatchett, was shown by Berzelius to be formed during calcination. It is, however, obvious that a little more than a third part of bone consists of animal matter, which appears to be either gelatine, or a modification of that principle; and that the remainder, nearly equal to two thirds, consists of earthy matter, which is chiefly phosphoric acid combined with lime. The carbonic acid said to be united with lime may result from the decomposition of the animal matter. The other saline substances are not peculiar to bone, but, being common to it and the other animal tissues, and even the fluids, may be supposed to be derived from the blood left in the bone at the moment of death.

The animal matter of bones was at one time presumed to be cartilage; but this appears to be an assumption, derived from the superficial resemblance which it bears to this substance. It does not appear to be mere gelatine; for though this principle is obtained from bone, and bones are economically used in manufacturing glue, they do not furnish the same proportion of jelly as tendon, nor are they so useful in making soups, as was once paradoxically maintained by some chemists. It is probable that the gelatine is under a peculiar modification, or combined with some principle which is not well understood. The sulphur formed during calcination seems to show that this animal matter contains albumen. There is no fat in bones; and in the experiments in which this substance was found, it is evident that marrow had been mingled with the bones employed.

Organization.

Though bones were arranged by the ancients among the bloodless organic substances, they receive a considerable proportion of this fluid, and injection shows them to be highly vascular. In early life especially these vessels are numerous; and even in the grown adult, when death takes place by strangulation or by drowning, the bones are found to be naturally well injected. In old age the vessels are less numerous, but they are larger. From the capillary vessels distributed through their substance, bones derive the pale blue or light pink colour by which the healthy bone is characterized. When this tint becomes intense, it indicates inflammation or some morbid state of the vessels of the bone. When it is lost, and the bone assumes a white or yellow colour, the part so changed is dead.

Anatomists distinguish three orders of vessels which enter the substance of bones; the first, those which penetrate the bodies of long bones to the medullary cavity (*arteriæ nutritiæ, arteriæ medullares*); the second, those which go to the cellular structure of the bone; and the third, those which go to the compact or dense matter of the bone. The view is only partially correct. The large vessels termed nutritious certainly proceed chiefly to the cavity of the bone, and are distributed in the medullary membrane. These, however, are not the only vessels which proceed to this part of the bone. *First*, I have often traced several large vessels, entering not by the middle, but the ends of the long bones, into the loose cancellated texture, and actually distributed on the *medulla* in this part of the bone. In dried bones also the canals of these vessels may be demonstrated, extending from the surface to the body of the bone. *Secondly*, the nutritious vessels are not constant; and when they are wanting, those of the ends of the bone, or of the *cancelli*, are much larger and more numerous than in ordinary circumstances.

Bone. Organization.

The communication between these and the branches of the nutritious vessels, which is admitted by Bichat, may be easily demonstrated. The *third* order of vessels are those which may be termed *periosteal*, in so far as they consist of an infinite number of minute capillaries, some red, some colourless, proceeding from the periosteum to the bone, and contributing to maintain the connection between the two. The short bones and the flat bones, which are destitute of nutritious arteries, receive blood from the two latter orders, but principally from the periosteal vessels. In the scull these vessels are often highly injected in apoplectic subjects, and in persons killed by drowning or strangulation.

The veins of bones are peculiar in their arrangement. The nutritious artery is accompanied by a social vein; the articular and periosteal vessels are said to be destitute of corresponding venous vessels. According to Dupuytren, however, minute venous capillaries arise from the substance of the osseous tissue, precisely as in other tissues, and, uniting in the same manner, form twigs, branches, and trunks, which finally terminate in the neighbouring veins. Lymphatics are not found in bones, nor have nerves been traced into their substance.

Marrow.

To complete the anatomical history of bone, it is requisite to examine shortly the marrow. The interior of the long bones contains a quantity of fat, oleaginous matter, which has been long known under the name of *marrow* (*μυελος οστιτης, medulla*); and a similar substance, though in smaller quantity, is found in the loose cancellated tissue of the flat and short bones. It is in the first situation only that it is possible to examine the anatomical characters of this substance. It is sufficiently similar to fat or animal oil in other parts of the body, to lead us to refer it to that head. In other respects its chemical qualities have not been much examined; but an analysis by Berzelius shows that it consists chiefly of an oily matter, not unlike butter in general properties. The filaments, blood-vessels, albumen, gelatine, and osmazome found by this chemist in marrow, and which did not exceed 4 parts in the 100, are derived from the filamentous tissue, in which the medullary particles are deposited.

Medullary membrane.

The medullary membrane, which has been considered as an internal periosteum, is imperfectly known. There can be no doubt, however, of its existence, which is demonstrated by opening transversely or longitudinally the medullary canal of a long bone, and boiling it for about two hours. The marrow then drops out; and it will be found to be deposited in the interstices of a filamentous net-work of animal matter, like fine cellular tissue, which may be traced not only into the lattice-work of the extremities, but into the longitudinal canals of the cylindrical bones. It is traversed by blood-vessels, which are observed to bleed during amputation. No nerves have been found in it. The medullary membrane, in short, may be regarded as an extensive net-work of very minute capillaries united by delicate filamentous tissue. From these capillaries the marrow is deposited as a secretion. (Mascagni, Howship.)

Developement.

3. The progressive formation of the osseous system has given rise to many researches by Kerckringius, Vater, Baster, Duhamel, Nesbitt, Haller, Dethleef, Reichel, Albinus, John Hunter, Scarpa, Senff, Troja, Meckel, Howship, Medici, Serres, Lebel, Schultze, Beclard, and Dutrochet; and it is a proof of the complicated nature of the subject, that it continues to give rise to fresh investigation. The inquiry resolves itself into two parts,—the history of the process of ossification as it takes place originally in the fœtus and infant, and the history of its progress as a process of repair when bones are divided, broken, or otherwise destroyed or removed.

Bone. Developement.

From the first formation of the embryo to the termination of fœtal existence, and thenceforth to the completion of growth, the bones undergo changes in which various stages may be distinguished. In the first weeks of fœtal existence it is impossible to recognise any thing like bone; and the points in which the bones are afterwards to be developed consist of a soft homogeneous mass of animal matter, which has been designated under the general name of mucus. Some time between the fifth and the seventh week, in the situation of the extremities, may be recognised dark opaque spots, which are firmer and more solid than the surrounding animal matter. About the eighth week, the extremities may be seen to consist of their component parts, in the centre of each of which is a cylindrical piece of bony matter. Dark solid specks are also seen in the spine, corresponding to the bodies of the vertebræ; and even the rudiments of spinous processes are observed in the shape of minute dark points. In the hands and feet rings of bone are seen in the site of the metacarpal and metatarsal bones. All the joints consist of a semi-consistent jelly-like matter, liberally supplied by blood-vessels. At ten weeks the cylinders and rings are increased in length, and are observed to approach the jelly-like extremities, which are acquiring the consistence of cartilage, and when divided present irregular cavities. At the same time the parts forming the head are highly vascular; and between the membranes are deposited minute points of bony matter, proceeding in rays from a centre, which, however, is thinner and more transparent than the margin. (Howship.)

Between thirteen weeks and four months the cavities in the jelly-like cartilaginous matter receive injection. The membranes of the head are highly vascular, transmitting their vessels through the intervals of the osseous rays, which are occupied abundantly by stiff, glairy, colourless, mucilaginous fluid.

In the seventh month the bony cylinder of the thigh-bone and its epiphyses contain canals perceptible to the microscope. In the head the bones are proceeding to completion; the pericranium and dura mater are highly vascular; and a quantity of reddish semitransparent jelly between the scalp and the scull, which contain numerous minute vessels, Mr Howship regards as the loose cellular state of the fœtal pericranium. This is, however, doubtful. The cylindrical bones have at this period no medullary cavity, but present in their interior a loose bony texture.

Between the seventh and eighth months, in a fœtus ten inches long, the humerus consists of a cylinder of bone placed between two brownish, firm, jelly-like masses, which correspond to the epiphyses, inclosed by periosteum, which adheres loosely by means of filamentous and vascular productions. The radius is a thin bony rod, also between two jelly-like epiphyses. The ulna is still thinner, more slender and flexible, and even compressible. The interosseous ligament is a continuous duplicature of the periosteum. The metacarpal bones are much as before, only larger. The hands and fingers are complete; but the phalanges consist of minute semi-hard grains, inclosed in periosteum, which forms a general sac to them, and to the intermediate connecting parts. The middle and unguinal phalanges can scarcely be called osseous. The *femur*, like the *humerus*, is an osseous cylinder between two jelly-like epiphyses, enveloped in loosely adhering periosteum. The *tibia* and *fibula* are like the *radius* and *ulna*. The metatarsal bones are cylindrical pieces, firm, but not very hard. The first phalanx of the toes is complete; the other two, though the toes are fully formed, are much of the consist-

General Anatomy.

Bone. Developement.

ence of cartilage. The carpal and tarsal bones are in the state of the epiphyses, but of a gray colour.

In this state of the osseous system, the periosteum, which is continuous, and appears to make one membrane with the capsular ligaments and the deep-seated portions of the fascia, adheres to the bone chiefly by arteries and filamentous productions; and so loose is this connection, that a probe may be inserted beneath it, and carried round or inwards, unless where these connections are situate. Another point where the periosteum adheres firmly is at muscular insertions, to the *humerus* at the insertion of the deltoid, and to the *femur* at that of the *glutæus*.

In the vertebral column the bodies of the vertebræ and the spinous plates are formed; and minute specks are beginning in the site of the transverse processes.

In the scull the parietal bones are well-formed shells of bone, though very deficient at the mesial plane, the anterior margin, and the upper anterior angle. The pericranium is distinctly membranous and vascular; and the red jelly-like fluid noticed by Mr Howship is exterior to this membrane.

At the period of birth the cylindrical bones contain tubular canals filled with a colourless glairy fluid, and terminating in the surface of ossification. As the bones previous to this period are homogeneous, and contain no distinct medullary cavity, but present in their interior a soft or loose bony texture, it is reasonable to suppose that the developement of the longitudinal canals is connected with the formation of the medullary cavity. At birth, in the *femur* may be distinguished a medullary cavity beginning to be formed, about half a line broad, but still very imperfect.

After birth, the two processes of the formation of tubular canals and medullary cavity go on simultaneously; and at the same rate nearly, the outer part of the cylindrical bones acquires a more dense and compact appearance. The epiphyses, also, which are in the shape of grayish jelly-like masses, begin to present grains and points of bone. Previously to this, Mr Howship represents them, while still cartilaginous, as penetrated by canals or tubes, which gradually disappear as ossification proceeds. The carpal and tarsal bones appear to observe the same course in the process of ossification.

In the bones of the scull, however, a different law is observed. The osseous matter is originally deposited in linear tracts or fibres, radiating or diverging from certain points termed centres of ossification. Each bone is completed in one shell without *diploe* or distinguishable table. Afterwards, when they are completed laterally, or in the radiating direction, the cancellated arrangement of the *diploe* begins to take place apparently in the same manner in which the medullary cavity and compact parts of the long bones are formed.

In the process now described, it is important to observe that the bony matter is deposited round the soft parts, and that the cavities, holes, and canals of bones are merely parts in which the previous existence of vessels, nerves, ligaments or tendons, prevents the subsequent formation of bone.

It has been generally supposed that the formation of cartilage is a preliminary step to that of bone. This, however, seems to be a mistake, arising from the circumstance that cartilage is often observed to be converted in the living body into bone. Neither in the long nor in the flat bones is any thing like cartilage at any time observed. The epiphyses, indeed, present something of the consistence of cartilage, but it has neither the firmness nor the elasticity of that substance. It is a concrete jelly, afterwards to be penetrated by calcareous matter. The flat bones are from the first osseous; and though their margins are soft and flexible, in consequence of their recent formation and moist state, they have still a distinct osseous appearance and arrangement, and bear no resemblance to cartilage. In short, true bone seems never at any period of its growth to be cartilaginous.

General Anatomy.

Bone. Developement.

The progressive growth of bones is effected by accretion of new matter to their extremities. The cylindrical bones elongate by the addition of new matter to the extremities of their *diaphyses*, and the flat bones by the enlargement of their margins. The latter fact is established by simple inspection during the process of ossification of the cranial bones. In proof of the former, the experiment of John Hunter is decisive. In the *tibia* of a pig he bored two holes, one near the upper, the other near the lower end, with an interval of two inches exactly, and inserted into each hole a small leaden shot. After some time, when the animal had grown, and the length of the bone was increased, on killing it, the space between the leaden shots was found, as at first, to be exactly two inches,—thereby showing that no elongation had taken place between the perforations. The experiment was often repeated with the same result.

The period at which ossification is completed varies in different individuals. It may be said to be indicated by the completion of the medullary canal, by the ossification of the *epiphyses*, and their perfect union with the osseous cylinder (*diaphysis*). The first circumstance is indefinite. The two latter, though more fixed, are still liable to great variation. The epiphyses are rarely united before the age of 14 or 15; and they may continue detached to the 20th or 21st year. In general, however, they begin to unite or to be *knit*, as is said, between the 15th and 20th years.

That the main agents of original ossification are the periosteum and its arteries, the proofs are manifest. The formation of bone can be ascribed to the vessels of two agents only,—the periosteum and the medullary membrane. That the latter is not concerned in the production of bone in the fœtus, must be inferred from the fact that at that period it cannot be said to exist. To the periosteum, therefore, and its vessels must be ascribed the process of fœtal ossification. Of this a cumulative proof is found in the circumstance, that the periosteum adheres more firmly at the ends than the middle of the bones; and that the pericranium and *dura mater*, which perform the part of periosteum to the bones of the scull, are visibly concerned in the formation and successive enlargement of these bones. But though the periosteal vessels are the main agents of ossification originally, there is reason to believe that the medullary vessels contribute to its growth and nutrition after it is formed. This may be inferred from the phenomena of fractures, of diseases of the bones, and of those experiments in which the medullary membrane is injured. The periosteum, however, does not act by ossification of its inner layers, as Duhamel, misled by a false analogy between the growth of trees and bones, laboured to establish.

A peculiar form of the osseous system requiring notice are the sesamoid bones. These, which derive their name from their minuteness, (σησαμη, a *grain*), most of them, excepting the knee-pan, being of the size of a grain or pea, are confined to the extremities, and are situate chiefly in positions in which they give points of support to the tendons of the flexor muscles. (Tendons of the *gemelli*, *tibialis posticus*, *peronæus longus*, &c.) The peculiarity of these bones is, that they are formed invariably in the substance of fibrous organs, as tendons in the case of the knee-pan and the sesamoid bones of the *gemelli*, *tibialis posticus*, and *peronæus longus*; or ligaments

General Anatomy.

Bone. Developement.

in the case of those situate between the chiro-phalangeal and podo-phalangeal articulations. With this peculiarity their mode of ossification corresponds. At first albuminous or fibro-albuminous, in process of time they are penetrated by calcareous matter, and present an osseous texture, which, however, is much less firm than that of genuine bone. The period at which this deposition commences and is completed varies in different individuals; and hence scarcely in any two persons of the same age is the number of sesamoid bones the same. Though the patella may be ossified at the 20th year, the minute sesamoid bones are sometimes not formed before the 30th or even the 40th. In the patella, when ossified, we find a medullary organ; but it is uncertain whether the others acquire this mark of osseous character. These bones resemble the epiphyses in uniting, when divided, by fibro-albuminous matter.

Junctions. 4. The bones of which the skeleton consists are united in two modes; 1*st*, by movable junction (*diarthrosis*); 2*dly*, by immovable junction (*synarthrosis*). Both modes of union bear the general name of *articulation*, though this term would with greater propriety be confined to the first or movable union. By this are connected all the bones concerned in locomotion, and some of those devoted to the organic functions, as the ribs and the lower jaw. The second is employed in the union of bones forming the walls of cavities.

In the movable union, the articular surfaces are united in two modes. In the first, in which one bone moves on the other with different degrees of freedom, the articular surfaces are covered by cartilage and synovial membrane, and the bones are united by ligaments and tendons. In the second (*amphiarthrosis*), in which the motion is confined to a species of torsion or imperfect rotation, the bones are united without articular surface by fibro-cartilage. The first is exemplified in the articulations of the extremities; the second is seen in the union of the bodies of the *vertebræ* and the bones of the pelvis.

The several forms of movable union with free motion, or articulations proper, may be referred to four heads, according to the nature of the motions performed. The first is the motion of radio-central opposition, or pivot-motion in every direction, in which the bone moves in its articular cavity, not only backwards and forwards, or by flexion and extension, but by abduction and adduction, and, by the succession of these motions, may describe a cone with the apex at the joint, or what is termed circumduction. This most extensive form of motion is found in the scapulo-humeral and coxo-femoral articulations only. The second form of articular motion is antero-posterior opposition, or cardinal motion (*cardo*, a hinge), in which the bones move on each other by flexion and extension, as a gate on its hinges. This, which is sometimes named limited opposition, is found in the femoro-tibial and humero-cubital joints, and all those which undergo flexion and extension. The third form of motion is that of rotation, in which the bone revolves on its axis,—an infrequent variety, confined chiefly to the humerus and femur. The fourth, which is the gliding motion, though common to all articular surfaces, is nevertheless the peculiar motion of the carpal and tarsal bones.

In the immovable union the surfaces are united in three modes. The first is by mutual indentation, or what is named suture (*sutura vera*), in which the margin of one bone is dovetailed by alternate serrated teeth and notches, into that of another. The second is by juxtaposition (*harmonia*), in which the margin of one bone is simply fitted to that of another. A peculiar variety of this is, when the acute margin of one bone is received between the bifid margin of another, as the azygos process of the sphenoid bone is received by the plates of the *vomer*; (*schindylesis*.) The third mode of immovable union is by implantation or insertion (*gomphosis*), as the teeth are inserted into the alveolar cavities of the superior and inferior maxillary bones.

Bone. Junctions.

The following table exhibits a view of these modes of junction, with their appropriate appellations.

### JUNCTIONS OF BONES.

I. IMMOVABLE; (*SYNARTHROSIS*.)

Continuous Bony Surfaces, united by Bone and Membrane.

| | | | |
|---|---|---|---|
| Mutual Indentation. | *Sutura.* | α *S. Serrata*, sive *Dentata*. | Coronal, Sagittal, and Lambdoidal Sutures. |
| | | β *Sutura Limbosa*. | Spheno-parietal Suture. |
| | | γ *Sutura Squamosa*. | Temporo-parietal Suture. |
| Juxtaposition. | *Harmonia.* | *H. Simplex.* | *H. Schindylesis.* |
| Implantation. | *Gomphosis.* | | The Teeth in the *alveoli*. |

II. SEMIMOVABLE; (*AMPHIARTHROSIS*.)

Continuous Surfaces, united by Fibro-Cartilage.

| | | | |
|---|---|---|---|
| Rotation and Torsion. | *A. Rotatio.* | | The Bodies of the *Vertebræ*. |
| Cardinal Opposition. | *A. Lateralis.* | *Symphysis.* *Synchondrosis.* *Synneurosis.* | Bones of the Pelvis. |

III. MOVABLE; (*DIARTHROSIS*.)

Contiguous, Cartilaginous Surfaces, united by Ligaments.

| | | |
|---|---|---|
| Radio central Opposition. | 1. Unlimited Opposition, Circumduction, and Rotation. | (*Arthrodia*). The Scapulo-humeral Articulation. (*Enarthrosis*). Cup and Ball-joint. The Ilio-femoral. |
| | 2. Unlimited Opposition, and Circumduction. | (*Arthrodia*). Temporo-maxillary, and Sterno-clavicular. (*Enarthrosis*). Cup and Ball-joint. Radio-carpal, Chiro-phalangeal, &c. |
| | 3. Limited Opposition, Flexion, and Extension. | (*Ginglymus*). Cardinal Joint. Femoro-tibial, Phalangeal. |
| | 4. Rotation. | (*Diarthrosis Trochoides*). (Lateral *Ginglymus*). Radius and Ulna, Atlas and Axis. |
| | 5. Gliding. | (*Diarthrosis Planiformis*). *Amphiarthrosis* of some authors. The Carpal and Tarsal Bones; the Oblique Processes of the Vertebræ. |

### *Teeth.* (*Dentes.*)

Every tooth consists of two hard parts; one external, white, uniform, somewhat like ivory; the other internal, similar to the compact structure of bone. Teeth

The first, which is named enamel, is seen only at the crown of the tooth, the upper and outer part of which consists of this substance. It is white, very close in texture, perfectly uniform and homogeneous, yet presenting a fibrous arrangement. Extending across the summit of the tooth in the manner of an incrustation, it is thick above, and diminishes gradually to the root, where it disappears. This fact is demonstrated by macerating a tooth in dilute nitric acid, when the bony root becomes yellow, while the crown remains white.

The enamel is not injectible, and is therefore believed to be inorganic. It is also filed and broken without being reproduced; nor does it present any of the usual properties which distinguish organized bodies. The piercing sensation which is communicated through the tooth from the impression of acids seems to depend on the mere chemical operation, and not on the physiological effect. On the whole, the enamel is to be viewed as the inorganic result of a process of secretion or deposition.

The bony part of the tooth is the root and that internal part which is covered on the sides and above by the enamel. It consists of close-grained bony matter, as dense as the compact walls of the long bones, or the petrous portion of the temporal bone. The fibres which are said to be seen in it are exactly of the same nature as those in bone.

In the interior of the bony part of each tooth is a cavity which descends into the root, and communicates at its extremity with the outer surface by openings corresponding with the number of branches into which the root is divided. This cavity, which is large in young or newly formed teeth, and small in those which are old, contains a delicate vascular membrane, which has been named the pulp of the tooth. It is best seen by breaking a recent tooth by a smart blow with a hammer, when the soft pulpy membrane may be picked out of the fragments by the forceps. It then appears to be a membranous web with two surfaces, an exterior adhering to the bony surface of the dental cavity by minute vessels; the other interior, free, and, so far as can be determined of a body so minute, resembling a closed sac.

The developement and growth of the teeth is a process of much interest.

At what time the first rudiments of teeth appear seems not to be determined with accuracy. In the fœtus, between the seventh and eighth month, I can merely distinguish in the centre of the vascular membrane of the alveolar cavity a minute firm body like a seed. I have, however, seen the crowns of teeth formed in fœtuses which, I have reason to believe, had not attained the seventh month. But whatever may be the exact period, the process is nearly as follows.

While the bones of the upper and lower jaw are in the process of formation between the third and fourth months, (fourth and fifth, Bichat, tom. iii. p. 93,) a series of soft, membranous, vascular sacs inclosed within the general cavity of the periosteum, may be recognised at their lower and upper margins, which are still without those osseous plates which afterwards constitute the *alveoli.* Each of the sacs now mentioned consists, like a serous membrane, of two divisions,—one external, attached to the periosteum, the other folded within it, and forming a closed cavity. The outer or periosteal deposits in the intervals between each sac, bone, which eventually constitutes the transverse *septa* of the *alveoli.* From the inside of the inflected portion the process of dentition commences some time between the fifth and seventh month, by the deposition of matter from the vessels at the lowest point of the alveolar division of the sac. This matter is to constitute the crown of the tooth, which is invariably formed first. After the deposition of the first portions, these are pushed upwards by the addition of successive layers below them, and necessarily carry the inflected part of the sac before them. As this process of deposition advances, the tooth gradually fills the sac, and rises till it reaches the level of the alveolar margins. If a tooth be examined *in situ,* near the period of birth, it is found to consist of the crown, with portions of enamel descending on every side, and forming a cavity in which a cluster of blood-vessels proceeding from the sac is lodged. In the mean time, bone is deposited from the periosteal division all round each sac, so as to form the *alveoli.*

After the enamel has been deposited the bone begins to be formed; and as this process advances, the tooth is still forcibly thrust upwards by the addition of matter to its root. When the latter is well completed, the vessels become smaller and less abundant, until, when the tooth is perfect, they shrink to a mere membrane, which lines the cavity of the tooth, and still maintains its original connection with the alveolar membrane, by the minute vascular production which enters the orifice or orifices of the root.

Physiological authors have thought it important to mark the period at which the teeth appear at the gums; and in general this takes place about the sixth or seventh month after birth. This mode of viewing the process of dentition, however, gives rise to numberless mistakes on the period of teething. The process, as we see, commences in the early period of fœtal existence; and the time at which they appear above the gums varies according to the progress made in the womb. In some the process is rapid, in others it is tardy; and even the stories of Richard III. and Louis XIV. receive confirmation from the fact of 19 examples cited by Haller, of infants born with one or more teeth above the gum. Generally speaking, the crown is completed at the period of birth; and, according as the formation of the root advances with rapidity or slowly, dentition is early or late.

What is here described is the process of the formation of the first or temporary set of teeth, which consist, it is well known, of twenty. In that of the second set the same course is observed. In the same manner is observed a row of follicular sacs, though not exactly in the original *alveoli,* yet attached to the sacs of the temporary teeth by vascular membranes; in the same manner deposition begins at the bottom of the free surface of the sac by the formation of the crown; and in the same manner the crown is forcibly raised by the successive accretion of new matter to its base. The moment this process commences, a new train of phenomena takes place with the primary teeth. The follicular sacs of the new or permanent teeth are liberally supplied with vessels for the purpose of nutrition; and as these blood-vessels increase in size, those of the temporary teeth diminish; and the supply of blood being thus cut off, the latter undergo a sort of natural death. The roots which, as being last formed, are not unfrequently incomplete, now undergo a process of absorption; and the tooth drops out in consequence of the destruction of its nutritious vessels. Some authors have ascribed this expulsion to pressure, exercised by the new tooth. They forget, however, that before the new tooth can exert any pressure, it must be in some degree formed; and to this a vascular system is indispensable.

The increased number of the teeth when permanent, the enlargement of the jaws, and the consequent expansion of the face, though interesting, are foreign to the present inquiry.

*Gristle, Cartilage.* (*Cartilago,—Tissu Cartilagineux.*)

Cartilage.

The cartilaginous system or tissue is found at least in three different situations of the human body; 1*st,* on the articular extremities of the movable bones; 2*d,* on the connecting surfaces or margins of immovable bones; 3*d,* in the parietes of certain cavities, the motions and uses of which require bodies of this elastic substance.

The organization of gristle is obscure and indistinct. On examination by the microscope, its surface is pearl-white, uniform and homogeneous, firm and glistening, with numerous minute pores. William Hunter represents the articular cartilages as consisting of longitudinal and transverse fibres. (*Phil. Trans.* vol. xlii.) Herissant represents those of the ribs as composed of minute fibres mutually aggregated into bundles connected by short slips, and twisted in a spiral or serpentine direction. (*Mém. de l'Acad.* 1748.) By Delasone, the articular cartilages

General Anatomy. Cartilage.

are said to consist of a multitude of minute threads, mutually connected and placed at right angles to the plane of the bone, but so as to radiate from the centre to the circumference. (*Ibid.* 1752.) The general fact of fibrous structure is confirmed by Bichat, who states that it is possible to recognise longitudinal fibres, which are intersected by others, oblique or transverse, but without determinate order. In its purest form no blood-vessels are seen in it, nor can they be demonstrated by the finest injections. In the margins of those pieces of gristle, however, which are attached to the extremities of growing bones, blood-vessels of considerable size may often be seen, even without the aid of injection. In young subjects a net-work of arteries and veins, which is described by Hunter under the name of *circulus articuli vasculosus,* may be demonstrated all round the margin of the cartilage at the line between the epiphysis and it. They terminate so abruptly, however, that they cannot be traced into the substance of the latter. The most certain proofs, however, of the organic structure of this substance are the serous exudation which appears in a few seconds on the surface of a piece of cartilage after division by the knife; and the fact that it becomes yellow during jaundice, and derives colour from substances found in the blood. Neither absorbents nor nerves have been found in it. The cellular texture said by Bichat to form the mould for the proper cartilaginous matter appears to be imaginary.

The articular cartilages adhere to the epiphyses by one surface, which consists of short perpendicular fibres placed parallel to each other, and forming a structure like the pile of velvet. This is easily demonstrated by maceration, first in nitric acid, and then in water. The free or smooth surface is covered by a thin fold of synovial membrane, which comes off in pieces during maceration. The existence of this, though recently denied by Gordon, was admitted by William Hunter, and may be demonstrated either by boiling, maceration, or the phenomena of inflammation, under which it is sensibly thickened. All other cartilages are enveloped, unless where they are attached to bones, by a fibrous membrane, which has been therefore named *perichondrium.* The existence of this may be demonstrated by dissection, and also by boiling, which makes it peel off in crisped flakes.

The chemical properties of cartilage have not been accurately examined. Boiling shows that it contains gelatine; but as much of the matter is undissolved, it may be inferred that it is under some modification, or united with some other principle, perhaps albumen. Immersion in nitric acid or boiling fluids induces crispation, and it dries hard and semitransparent like horn.

### *Fibro-Cartilage, Chondro-Desmoid Texture.* (*Cartilago Fibrosa,—Tissu Fibro-Cartilagineux.*)

Fibro-cartilage.

Intermediate between the cartilaginous and the fibrous tissues, Bichat ranks that of the fibro-cartilages, which comprehends three subdivisions: 1*st*, the membranous fibro-cartilages, as those of the ears, nose, windpipe, eyelids, &c.; 2*d*, the inter-articular fibro-cartilages, as those found in the temporo-maxillary and femoro-tibial articulations, the intervertebral substances, and the cartilaginous bodies uniting the bones of the pelvis; 3*d*, certain portions of the periosteum, in which, when a tendinous sheath is formed, the peculiar nature of the fibrous system disappears, and is succeeded by a substance belonging to the order of fibro-cartilages.

Beclard follows Meckel in rejecting the first subdivision, the individuals of which are quite similar to ordinary cartilage, in wanting the distinct fibrous structure, and being covered by perichondrium, the fibres of which have caused them to be regarded as fibro-cartilages. On this principle Beclard gives the following view of the fibro-cartilages.

General Anatomy. Fibro-cartilage.

1*st*, Fibro-cartilages free at both surfaces; those in the form of *menisci*, which are placed between the articular surfaces of two bones (*fibro-cartilagines inter-articulares*). These are seen in the temporo-maxillary, sterno-clavicular, and femoro-tibial articulations, and occasionally in the acromio-clavicular and the ulno-carpal joints. These ligaments are attached either by their margins or their extremities, and are enveloped in a thin fold of synovial membrane. 2*d*, Fibro-cartilages attached by one surface. Of this description are those employed as pulleys or grooves for the easy motion of tendons; for instance, the chondro-desmoid eminences attached to the margin of the glenoid cavity for the long head of the *biceps*, and at the sinuosity of the ischium for the tendons of the *obturatores.* 3*d*, Fibro-cartilages, which establish a connection between bones susceptible of little individual motion, as the intervertebral bodies; or which unite bones intended to remain fixed, unless under very peculiar circumstances, as those which form the junction of the pelvic bones. (*Symphysis pubis; sacro-iliac synchondrosis.*)

The peculiarities of these substances consist in their partaking in different proportions of the nature of cartilage and white fibrous tissue, and, consequently, in possessing the toughness and resistance of the latter with the elasticity and flexibility of the former. The structure of the fibro-cartilaginous tissue is easily seen in the intervertebral bodies, and in the cartilages uniting the pelvic bones. In the former, white concentric layers, consisting of circular fibres placed in juxtaposition, constitute the outer part, while the interior contains a semifluid jelly. The concentric fibrous layers are cartilage in a fibrous shape. In the latter situation the fibrous structure is equally distinct, while the cartilaginous consistence shows the connection with that organic substance. A similar arrangement is remarked in the inter-articular cartilage of the temporo-maxillary articulation, and in the semilunar cartilages of the knee-joint. In all, the fibrous is said to predominate over the cartilaginous structure. Their physical properties are distensibility and elasticity. Though they are at all times subjected to considerable pressure, they speedily recover their former size. Though their chemical composition is not exactly known, they evidently contain much gelatine.

### *Gland. Glandular System.* (*Glandulæ.*)

Gland.

The name *gland*, though rather vaguely used, may be properly restricted to designate organs of a definite structure, consisting of arteries, veins, and excretory tubes, arranged in a peculiar manner, and destined to separate from the blood a fluid of peculiar chemical and physiological properties. The organs of this description may be arranged in two general divisions,—the follicular glands, or those which occur in an isolated form; and the conglomerate glands, or those which, being of larger volume, are understood to consist of numerous small glands combined in one general organ. The former embraces the sebaceous glands of the skin and the muciparous glands of mucous membranes; in the latter are comprehended the lacrymal and salivary glands, with the tonsils, the pancreas, the liver, the kidneys, the testicles of the male, and *mammæ* of the female, and perhaps the prostate gland. To a third head, denominated that of *imperfect glands,* Meckel refers such organs as the thymus, the suprarenal capsules, the thyroid, and the spleen. But since the term *imperfect* implies here a contradiction, and since it is by no means ascertained, either that these organs secrete, or that their secretions are removed by the lymphatics, it is manifest that they cannot be justly associated with the organs above defined as examples of glands.

The follicular glands, though most minute, are nevertheless distinguished by the most simple and intelligible structure. They consist of small hollow spherical sacs, or minute membranes moulded into the saccular form, in the attached surface of which are distributed numerous minute arteries and veins, and the free surface of which is smooth and covered with the fluid secreted. The quantity of vascular substance with filamentous tissue surrounding the attached surface of these glands, makes them occasionally project from the surface of the membrane to which they are attached. In ordinary circumstances, however, they cause no elevation, and appear in the form of simple sacs with a narrow orifice. These glands belong to two textures only of the animal body,—the skin and the mucous membrane. In the former they are named *sebaceous glands*, from the fluid which they secrete containing a small portion of fatty matter. In the latter they are named *follicles*, *crypts*, or *muciparous glands*.

In certain regions of the mucous membranes, for instance in the male *urethra*, the crypts are arranged in such a manner that they constitute large sinuous cavities, the free surface of which secretes serous mucus copiously. These cavities, which have the further effect of increasing much the superficial extent of the membrane, are denominated *lacunæ*. The peculiarity of this form of mucous gland appears to consist in its membranous sac having unusual extent, and consequently in the glandular vessels being more expanded than in the ordinary glands.

The structure of the conglomerate glands is more complicated. Each gland consists of numerous minute portions of definite figure, named lobules; and each lobule may be resolved into granules, also of definite shape, intimately connected by filamentous tissue. These granules, which have since the time of Malpighi been denominated *acini*, are found to consist of clusters of minute arteries and veins aggregated together, with minute tubes for conveying away the secreted fluid. On these points anatomists are agreed. They are seen most distinctly in the liver and kidney, and may be demonstrated in the pancreas, testicles, and female breast, by injection. Every *acinus*, in short, may be said to consist of two parts, a vascular or supplying, and a tubular or excreting.

On the manner in which these two parts of the *acinus* communicate, however, there is less certainty and precision. In this difficulty, as the point is scarcely a matter of observation, conjecture has been resorted to; and the opinions of anatomists have been divided between two parties. According to one, at the head of which may be placed Ruysch, Haller, William Hunter, and Hewson, the minute arteries terminate directly in the excretory ducts, without intermediate substance. According to the other opinion, which is that of Malpighi, between the arteries and the excretory tubes there are placed minute membranous *vesiculæ* or pouches, in the substance of which the arteries, still more minutely divided, are distributed, and from the free surface of which the process of secretion goes on. In short, each *acinus*, according to Malpighi, is a separate follicle, and the conglomerate glands consist merely of numerous follicles, combined so as to form a large general secreting organ.

Between these two views of the intimate nature of the glandular tissue there is less difference than at first sight might be imagined. The chief difference is in the ultimate arrangement of the glandular capillaries. According to the view of Malpighi, these capillaries are arranged in clusters, as it were, round the beginning of the excretory pore, so that even in this condition the termination of the former class of vessels is the commencement of the latter. Conversely, it may be said, that since the delicate membrane in which the secreted fluid first appears necessarily receives the capillary terminations, the latter cannot be said to communicate directly with the excretory tubes. The correct view of the matter is, that by the term *vesicles* are not to be understood large sacs, but merely the rounded recess of the membrane which forms the excretory tubes. Further, since the researches of Hewson and Monro show that in the kidney and the testicle the arteries are convoluted, it may be inferred that this is the character of the capillary arrangement of the glands; and that it is requisite to the performance of the process of secretion that the vessels be disposed in such a tortuous manner as to prevent too rapid motion of the blood.

The conglomerate glands, we have seen, consist chiefly of minute vascular ramifications infinitely subdivided. In all the glands, excepting the liver, these vessels consist of arteries to convey blood to the organ, and veins to return it to the system; and in all the glands, excepting the liver, it is a peculiar circumstance that the same arterial trunk conveys blood for nourishing the gland, and for supplying the materials of the secretion. All the secretions, therefore, excepting that of the liver, are derived from arterial blood. The liver alone, besides receiving a considerable artery, derived from the cœliac trunk, is remarkable for being chiefly supplied with blood from a large venous trunk, formed by the union of the veins of the stomach and spleen, and the mesenteric and mesocolic branches, and which after this union is again subdivided into ramifications in the substance of the gland. Injection shows that the branches and twigs of this vein anastomose freely with those of the hepatic artery; and though it might be imagined that the latter is intended chiefly to nourish the gland, and the former to supply the materials for secretion, this circumstance, with the fact that in some rare instances the *vena portæ* is not distributed in the liver, shows that at present this opinion must be adopted with caution.

Besides arteries, veins, and excretory tubes, glands are supplied with lymphatic vessels, which are arranged in two sets, superficial and deep. The former are confined to the surface of the organ, over which they may be seen creeping in every direction, and belong chiefly to the membranous coverings of the glands. The deep-seated lymphatics are those which penetrate the substance of the glands, and in general accompany the large blood-vessels.

Every gland receives a proportion of nervous branches, generally from the nerves of the sympathetic system. These branches accompany the blood-vessels in penetrating the substance of the glands, and are distributed much in the same manner as the arteries before their ultimate division. They exercise some influence over the process of secretion; but the nature and extent of this influence are still undetermined.

Each gland contains a quantity of filamentous tissue, which envelopes the blood-vessels, tubes, lymphatics, and nerves, and constitutes a large proportion of the mass of the gland. The simple tissues, thus united, are inclosed in a general membranous covering, which also partly contributes with these tissues to retain it in its situation. These membranous coverings vary in different glands. In the liver and pancreas it is the peritoneum; the kidneys are inclosed in a peculiar tunic; the testes are contained in a fibrous membrane; and the *acini* of the lacrymal

General Anatomy.

and mammary glands appear to be covered by a form of condensed filamentous tissue.

### CHAP. III.—ENVELOPING TISSUES.

*Skin.* (*Cutis, Pellis.*) *Cutaneous Tissue, Dermal Tissue.* (*La Peau, Tissu Dermoide,*—Die Haut, Das Fell.) *Fell*, old English; *with its appendages, Scarf-skin or Cuticle, Nail, Hair.* (*Cuticula, Epidermis,—Tissu Epidermoide et Tissu Pileux.*)

Skin.

Skin has been said to consist of three parts, true skin (*cutis vera*), mucous net (*rete mucosum*), and scarf-skin or cuticle. Haller, Camper, and Blumenbach, are inclined to deny the existence of the mucous net in the skin of the white, and to admit it in that of the negro only; and in point of fact, indeed, its existence has been demonstrated in the negro race only, and inferred by analogy to exist in the white. "When a blister has been applied to the skin of a negro," says Cruikshank, "if it has not been very stimulating, in twelve hours after a thin transparent grayish membrane is raised, under which we find a fluid. This membrane is the cuticle or scarf-skin. When this with the fluid is removed, the surface under these appears black; but if the blister had been very stimulating, another membrane, in which this black colour resides, would also have been raised with the cuticle. This is *rete mucosum*, which is itself double, consisting of another gray transparent membrane, and of a black web very much resembling the *pigmentum nigrum* of the eye. When this membrane is removed, the surface of the true skin, as has been hitherto believed, comes in view, and is white like that of a European. The *rete mucosum* gives the colour to the skin; is black in the negro; white, brown, or yellowish in the European." (*Experiments on the Insensible Perspiration*, &c. London, 1795.)

Bichat denies the existence of a mucous varnish (*corpus mucosum*) such as Malpighi describes it, and regards the vascular surface of the corion as the only mucous net.

According to Chaussier the skin consists of two parts only, the *derma* (*δεgμα, cutis vera*) or corion, and the *epidermis*, cuticle, or scarf-skin; the first embracing the organic elements of this tissue; the second being an inorganic substance prepared by the organic, and deposited on its surface. This opinion is adopted by Gordon, according to whom the skin consists of two substances placed above each other, like layers or plates (*laminæ*), the inner of which is the true skin, the outer the cuticle or scarf-skin. Beclard, on the contrary, thinks that a peculiar matter, which occasions the colour by which the several races are distinguished, is found between the outer surface of the corion and the cuticle; and that no fair race is destitute of it except the *albino*, the peculiar appearance of whom he ascribes to the absence of the mucous net of the skin.

The *corion* of the human skin (*pellis, corium, derma, cutis vera*) seems to consist chiefly of very small dense fibres, not unlike those of the proper arterial coat, closely interwoven with each other, and more firmly compacted the nearer they are to its outer or cuticular surface. The inner surface of the corion is of a gray colour; and in almost all parts of the body presents a number of depressions varying in size from $\frac{1}{12}$th to $\frac{1}{10}$th of an inch, and consequently forming spaces or intervals between them. These depressions, which correspond to eminences in the subjacent adipose tissue, have been termed *areolæ*. They are wanting in the corion of the back of the hand and foot only.

The outer or cuticular surface of the corion is smooth, of a pale or flesh-red tinge, and is much more vascular than its inner surface. It presents further a number of minute conical eminences (*papillæ*), which, according to the recent observations of Gaultier and Dutrochet, are liberally supplied with blood-vessels, and are the most vascular part of this membrane. In the ordinary state of circulation and temperature during life these eminences are on a level with the surrounding *corion*; but when the surface is chilled, this membrane shrinks, while the papillæ either continue unchanged or shrink less proportionally, and give rise to the appearance described under the name of *goose skin* (*cutis anserina*). This surface was said by the older anatomists to present numerous orifices or pores; but according to Gordon, if we trust to observation, no openings of this kind can be recognised, either by the eye or the microscope, except those of the sebaceous follicles. The hairs, indeed, are found to issue from holes in the corion, but they fill them completely.

In certain situations, for instance at the entrance of the external auditory hole, at the tip of the nose, on the margins of the eyelids, in the armpits, at the nipple, at the skin of the pubes, round the anus and the female pudendum, are placed minute orifices, from which exudes an oleaginous fluid, which is quickly indurated. These openings lead into the cavities of small sacs called follicles (*folliculi*) or sebaceous glands (*glandulæ sebaceæ*). These sacs, the structure of which is noticed above, consist of hollow surfaces secreting an oleaginous fluid, which is progressively propelled to the orifice, where it soon undergoes that partial inspissation which gives it the sebaceous or suet-like aspect and consistence.

The corion is liberally supplied with blood-vessels, nerves, and absorbents. After a successful injection, its outer surface appears to consist of a uniform net-work of minute vessels, subdivided to an infinite degree of delicacy, and containing during life blood coloured and colourless. It can scarcely be doubted that this vascular net-work (*rete vasculosum*) is the only texture corresponding to the *reticular body* of the older anatomists.

It is well known that this membrane, when boiled sufficiently long, is converted into a viscid glutinous liquor, which consists chiefly of gelatine (Chaptal, Seguin, Hatchett, Vauquelin, &c.), and that glue is obtained from it for the purposes of art. As, however, in these operations a portion of matter is left undissolved, and as glue is completely soluble in water, while skin resists it for an indefinite time, it may be concluded, that though the chief constituent of the corion is gelatine, it is under some peculiar modification not perfectly understood. The union of this organized gelatine with the vegetable principle denominated *tannin* forms leather, which is insoluble in water.

Cuticle.

Cuticle or scarf-skin (*epidermis, cuticula*) is a semi-transparent, or rather translucent layer of thin light-coloured matter, extended continuously over the outer surface of the corion. Its thickness varies, being thinnest in those parts least exposed to pressure and friction, but thickest in the palms and soles. It is destitute of blood-vessels, nerves, and absorbents; and there is reason to believe, from observing the phenomena of its reproduction, that it is originally secreted in the form of a semi-fluid viscid matter by the outer surface of the corion; and that, as it is successively worn or removed by attrition, it is in like manner replaced by a constant process of secretory deposition. This semifluid viscid matter, which in truth is found between the outer surface of the corion and the firm cuticle, is the substance mentioned by Malpighi, and so often spoken of as the mucous net (*corpus mucosum*). It is inorganic; and it is impossible to explain its production otherwise than by ascribing it to the outer vascular surface of the corion.

General Anatomy. Skin. Cuticle is rendered yellow and finally dissolved by immersion in nitric acid. It is also dissolved by sulphuric acid in the form of a deep brown pulp. These, and some other experiments performed by Hatchett, show that it consists chiefly of modified albuminous matter.

This description shows, that if strict observation be trusted, the mucous net has no existence, at least in the European. In the Negro, Caffre, and Malay, however, a black membrane is said to be interposed between the corion and cuticle, and to be the cause of the dark complexion of these races. On this subject I refer to the description given by Cruikshank, which is the best (*Experiments*, &c. p. 31, 41, and 43); the Essay of M. Gaultier, already quoted; and the observations of Beclard. What is found in the skin of the mixed or half-caste races, *i. e.* the offspring of an African and a European, or of a mulatto and European? and how is the transition between this colouring layer and its insensible diminution effected?

Nail. Nail is a substance familiarly known. On its nature and structure we find many conjectures, but few or no facts, in the writings of anatomists; and almost all that has been written is the result of analogical inference rather than of direct observation. It is known that the nails drop off with the scarf-skin in the dead body; that they are diseased or destroyed by causes which act on the outer surface of the corion, and produce disease of the cuticle; and that, if forcibly torn out, the surface of the corion to which they were attached bleeds profusely and inflames. In other respects they are inorganic; but these facts warrant the conclusion that the root of the nail is connected with the organic substance of the corion, and that the whole substance is the result of a process of secretion similar to that by which the cuticle is formed.

According to the experiments of Hatchett, they consist of a substance which possesses the properties of coagulated albumen, with a small trace of phosphate of lime.

Hair. The *root* of a hair is not only that part which is contained in the bulb, but the portion which is lodged in the skin. The *middle part* and the *point* are those which project beyond the surface of the skin. The *bulb* is a small sac fixed in the inner surface of the corion, in the contiguous filamentous tissue, and in which the root is implanted.

Every hair is cylindrical, tapering regularly from the root to the point, and solid, but containing its proper colouring matter in its substance. The colour varies, but the root is always whitish and transparent, and softer than the rest; the fixed or adhering part of the root is almost fluid. When hair is decolorized, it becomes transparent and brittle, and presents a peculiar silvery-white colour; and as hairs of this kind are few or abundant, it gives the aspect of gray, hoary, or white hair.

The bulb, though visible in a hair plucked out by the root, is too small in human hair to be minutely examined; and Chirac, Gaultier, and Gordon, have therefore described its structure and appearances from the bulbs of the whiskers of large animals, the seal for example, in which it is much more distinct. According to researches of this kind, every bulb forms a sort of sac or follicle, which consists of two tunics, an inner one, tender, vascular, and embracing closely the root of the hair; and an outer, which is firmer and less vascular, and surrounds the inner one, while it adheres to the filamentous tissue and the inner surface of the corion. When the hair issues from the bulb, it passes through an appropriate canal of the corion, which is always more or less oblique, but which, as has been already said, it fills completely; and it afterwards passes in a similar manner through the scarf-skin. Nervous filaments have been traced into the bulbs of the whiskers of the seal by Rudolphi and the younger Andral. The bulb or follicle, in short, is organic, and forms by secretion the inorganic hair.

General Anatomy. Hair.

The structure of hair appears to be either so simple, or so incapable of being further elucidated, that anatomists have not given any facts of consequence regarding it. Its outer surface is believed to be covered with imbricated scales, because in moving a single hair between the finger and thumb it follows one direction only.

Hair is believed to be utterly inorganic, though the phenomena of its growth, decoloration, and especially of the disease termed Polish plait (*plica Polonica*), have led various authors to regard it as possessed of some degree of vitality. These phenomena, however, may be explained by the occurrence of disease in the bulbs or generating follicles. Hair is insoluble in boiling water; but Vauquelin succeeded in dissolving it by the aid of Papin's digester. From the experiments of this chemist, and those of Hatchett, it may be inferred that hair consists of an animal matter, which appears to be a modification of albumen, a colouring oil, and some saline substances.

*Mucous Membrane, Villous Membrane.* (*Membrana Mucosa, M. Mucipara, M. Villosa,—Tissu Muqueux,* Bichat.)

Mucous membrane. The organic tissue or membrane to which the name of *mucous* or *villous* has been applied, consists of two great divisions, the gastro-pulmonary and genito-urinary.

The first or gastro-pulmonary division comprehends that membranous surface which commences at the various orifices of the face at which it is contiguous with the skin, and is continued through the lacrymal and nasal passages, and even the Eustachian tube, by the larynx on the one hand to the windpipe and bronchial membrane, and by the œsophagus on the other through the entire tract of the alimentary canal, at the opposite extremity of which it is again identified with the skin.

The distribution of the second division, or the genito-urinary mucous membrane, is slightly varied according to the differences of sex. In the male it is connected with the skin at the orifice of the urethra, from which it proceeds inwards toward the bladder, sending previously small prolongations through ducts on each side of the *veru montanum*, from which it is believed to be continued through the *vasa deferentia*, to the *vasa efferentia* of the testicle. Continued over the inner surface of the urinary bladder, it is prolonged through the ureters to the pelvis and infundibula of the kidney. In the female, besides passing in this direction, it ascends into the womb, and passes through the Fallopian or uterine tubes, at the upper extremity of which it terminates in an abrupt opening into the sac of the peritoneum—the only instance in the whole body in which a mucous and serous surface communicate freely and directly.

These two orders of membranous tissue have each two surfaces, an attached or adherent, and a free one. The adherent surface is attached, 1*st*, to muscles, as in the tongue, most of the mouth and fauces, œsophagus, and whole alimentary canal, and the bladder; 2*d*, to fibrous membranes, as in the nasal cavities and part of the larynx, in which it is attached to periosteum or perichondrium, the palate, ureter, and pelvis of the kidney; 3*d*, to fibro-cartilages, as in the windpipe (*trachea*), and bronchial tubes.

The free surface is not uniform or similar throughout. The appearance of the pituitary or Schneiderian mem-

General Anatomy.

Mucous membrane.

brane is different from that of the stomach or intestines; the surface of the tongue and mouth is different from that of the trachea; and the free surface of the urethra is unlike that of the bladder. These variations depend on difference of structure, and are connected with a difference in properties; yet anatomists have improperly applied to the whole what was peculiar to certain parts only, and have thus created a system in which some truth is blended with much misrepresentation.

Mucous membrane consists, like skin, of a *corion* or *derma*, and an *epidermis* or *cuticle.*

The mucous corion is a firm, dense, gray substance, which forms the ground-work of the membrane in most regions of the body, but which is evidently represented by the fibrous system, *e. g.* the periosteum or perichondrium, in some other situations. It is most distinctly seen in the mouth and throat, and in various parts of the alimentary canal. In the first situation it is more vascular, less gray and dense, than in the intestinal mucous membrane.

It possesses two surfaces, an inner, adherent to the submucous filamentous tissue, and an outer or proper mucous surface. In the stomach, the mucous corion is in the form of a soft but firm membranous substance, about $\frac{1}{6}$th or $\frac{1}{8}$th of a line thick, tough, of a dun-gray or fawn colour (intermediate between Sienna-yellow and ochre-yellow, Syme), slightly translucent, and sinking in water. The attached or inner surface is flocculent and tomentose, and a shade lighter than the outer, which presents a sort of shag or velvet, consisting of very minute piles. This, when examined by a good lens at oblique light, appears to consist of an infinite number of very minute roundish bodies closely set, but separated by equally minute linear pits, and occasionally circular depressions. In the ileum it presents much the same characters; but the minute bodies of its shaggy surface are still larger and more distinct, and may be seen by the naked eye. In the windpipe, again, it is rather thinner and lighter coloured; and while its outer surface presents numerous minute pores, it is much smoother than in the alimentary canal, and entirely destitute of those minute bodies seen in the latter. It nowhere presents any appearance of fibres.

The mucous corion rests on a layer of filamentous tissue, firm and dense, and of a bluish-white colour,—a character by which it is distinguished from the soft fawn-coloured mucous membrane. This submucous filamentous tissue is what is erroneously termed the *nervous coat* by Ruysch, Albinus, and some of the older anatomists.

In certain parts the mucous corion is covered by a thin transparent membrane, named the *epidermis* or cuticle, which is most easily shown by boiling or scalding a portion of mucous membrane, and then peeling off with care the outer pellicle. This experiment succeeds best in the mucous membrane of the mouth and palate, in which, therefore, the existence of mucous epidermis cannot be doubted. The observations of Wepfer, Haller, and Nicholls, and especially of Bleuland (*Observationes Anatomico-Medicæ de Sana et Morbosa Œsophagi Structura*, Lug. Bat. 1785), are sufficient to prove its existence in the œsophagus. Bichat admits that, though it may be demonstrated at the cutaneous junctions of the mucous surfaces, it cannot be recognised in the stomach, intestines, bladder, &c. From the numerous dissections of Home (*Phil. Trans.* 1807, 1810, 1813), it results that the mucous epidermis, both in the human subject and in most *mammalia* and birds, terminates abruptly at the cardiac orifice of the stomach. In ruminant animals the mucous *epidermis* is continued over the first two stomachs, but cannot be traced in the third and fourth. In the whale tribe, in which the stomach is also quadruple, the *epidermis* is confined to the first cavity. In birds of the grazing tribe, the mucous *epidermis* is continued over the gizzard, but terminates at the opening into the stomach. This conclusion as to the human subject is confirmed by Beclard, who further adds, that in the genito-urinary system it cannot be traced beyond the neck of the womb and that of the bladder.

General Anatomy.

Mucous membrane.

In most mucous membranes are found minute oval or spheroidal bodies, slightly elevated, and presenting an orifice leading to a blind or shut cavity. As they are believed to secrete a fluid analogous to or identical with mucus, they are named mucous glands; and from their shape and situation they are also denominated follicles (*folliculi*) and *cryptæ.* Though more or less abundant in all the mucous membranes, they have been most frequently examined in those of the alimentary canal, where they were first accurately described by Brunner and Peyer. (*Glandulæ Peyerianæ.*) In this situation they are situate in the substance of the mucous corion. Their structure is simple. The orifice leads into a saccular cavity, with a smooth, uniform surface, which secretes the fluid which oozes from them. This membranous sac is lodged in a reddish-coloured, dense, anormal matter, which is probably filamentous tissue enveloping minute blood-vessels; but of the minute structure of which nothing is accurately known. In the state of health these bodies are so minute that it is very difficult to recognise them. I have seen them, nevertheless, in the tracheo-bronchial membrane by the eye and by a lens. When the membranes are inflamed they become larger and more distinct. In the bladder, the womb, the gall-bladder, and the seminal vesicles, they are not distinctly seen, and cannot be satisfactorily demonstrated. It is unnecessary, however, to follow the example of Bichat in trusting to analogy to prove their existence; for they are not necessary to the secretion of mucous fluid, as he seems to imagine. Those in the urethra, first well described by William Cowper, are distinct examples of follicles in the genito-urinary surface. The sinuosities (*lacunæ*), first accurately described, if not discovered, by Morgagni (*Adversaria Anatomica*, iv. 8, 9, &c.), though not exactly the same in conformation and structure, seem to be very slightly different.

In certain regions of the mucous membranes, especially at their connections with the skin, are found minute conical eminences denominated *papillæ.* They are distinctly seen in the mucous membrane of the tongue, where they vary in size and shape, and in the body named *clitoris.* They are elevations belonging to the mucous corion, covered by epidermis, and they are liberally supplied by blood-vessels, the veins of which present an erectile arrangement, and with minute nervous filaments.

In the stomach, duodenum, and ileum, this membrane is collected into folds or plaits, which have received in the former situation the name of *rugæ*, or wrinkles; and in the latter the name of *plicæ*, or folds, and *valvulæ conniventes*, or winking valves. In the vagina also are transverse *rugæ*, which in like manner are folds or duplicatures of its mucous membrane. Those of the œsophagus, which have been described by Bleuland, are longitudinal. In the tracheo-bronchial membrane, and in the membranous and spongy portions of the urethra, we find them in the shape of minute plaits or wrinkles in the long direction of their respective tubes, but rarely of much length. The object of these folds, which are peculiar to the mucous membranes, appears to be to increase the extent of surface, and to allow the membrane to undergo considerable occasional distension.

In certain points, where a communication is observed between the general mucous surface and the cavities or recesses of particular regions, anatomists, unable to demonstrate a mucous membrane, have inferred its existence as a continuation of the general surface. In the tympanal cavity, to which the Eustachian tube leads, the existence of a mucous or fibro-mucous membrane is rather presumed from analogy than proved by observation. We know that, where the biliary and pancreatic ducts enter the duodenum, and for a considerable space towards the liver, the interior appearance is that of a fine mucous surface provided with *lacunæ* and villosities; but it is impossible to say at what point of the hepatic duct, or of the smaller canals of which it is formed, the mucous membrane terminates. The tracheal membrane, when traced to the bronchial divisions, presents no arrangement, either of *papillæ*, piles, or villosities; and nothing is perceived except a smooth uniform surface, of a colour between gray, dun, and red or purple, which is moistened with a viscid semi-transparent fluid, and which is as like the peritoneum as the intestinal mucous membrane. Lastly, the situation where the existence of the mucous system, though believed, is most uncertain, is in the interior of the *vasa deferentia*, where they take their origin from the *vasa efferentia* of the *testis*. Regarding the organization of these tubes, no sensible evidence can be obtained, and whatever is stated concerning it is the result of analogical inference.

Though these membranes have been designated by the general name of *mucous*, the action of their surface is not in every situation the same. It is not easy to limit the signification of the term *mucus;* for this fluid varies in the nasal passages, in the trachea and bronchial membrane, in the œsophagus, stomach, and intestines, and in the urinary bladder and ureters. But it may be stated that many parts of the two mucous surfaces never in the healthy state secrete any modification of this animal matter; and in others the membrane is almost always moistened by a different fluid. The mucous or villous membrane of the eyelids is never in the healthy state occupied by mucus, but is uniformly moistened with the tears; the membrane of the mouth and throat is moistened with saliva only; the urethra presents a peculiar viscid fluid, which seems to exude from many minute vessels opening along its surface, as in the *lacunæ*, but which is widely different from mucus. All those parts, in short, which are not in perpetual, but only occasional, contact with foreign or secreted substances, seem to present no mucus in the healthy state; whereas the surfaces of the stomach, intestines, gall-bladder, and urinary bladder, are constantly covered with a quantity, more or less considerable, of this animal secretion.

The chemical properties of mucous membranes are completely unknown. The analysis of the fluid secreted by them has been executed by Fourcroy, Berzelius, and others, but is foreign to the subject of this article.

That the mucous membranes are liberally supplied with blood by vessels both large and numerous, is proved not only by the phenomena of injections, but by the red colour of which many of their divisions are the seat. This coloration, as well as the injectibility, is not indeed uniform; for in certain regions mucous surfaces are pale or light blue, in others their redness is considerable.

Thus, in those regions in which the mucous membranes coalesce with the periosteum, forming fibro-mucous membranes, *e. g.* in the facial sinuses, the tympanal cavity and the mastoid cells, the colour is pale blue, or approaching to light lilac. In the bladder, in the large intestines, in the excretory ducts in general, though pale, this colouring becomes more vivid. In the pulmonic mucous membrane it is slate-blue, verging to pale pink. In the stomach, duodenum, small intestines, and the vagina, it becomes still more marked. In the uterus it varies according to the period or the intervals of menstruation.

Examined in the gastro-enteric mucous membrane, in which they are most numerous, these vessels are found to consist of an extensive net-work of capillaries divided to an infinite degree of minuteness, mutually intersecting and spreading over the upper or outer surface of the mucous corion. This vascular net-work, though demonstrated by Ruysch, Albinus, Haller, and Bichat, has been beautifully represented in the delineations of Bleuland, who thinks he has traced their minute ramifications into the *villi*. These minute vessels are derived from larger ones, which creep through the submucous cellular tissue, and penetrate the mucous corion, the substance of which receives few or no vessels, to be finally distributed at its exterior surface.

The arrangement of the vessels which supply the mucous surfaces is peculiar. Penetrating, in the form of considerable trunks, between the folds of the serous membranes, they divide in the subserous cellular tissue into branches of considerable size; and here they form those numerous anastomotic communications which constitute the arches so distinctly seen in the ileum. From the convexity of these arches are sent off most of the small vessels, which are then fitted, after passing through the muscular layer and the submucous tissue, to enter the mucous corion.

The capillary terminations, then, of these arteries, and their corresponding veins, constitute the physical cause of the coloration of the mucous membranes. This coloration, however, is not at all times of the same intensity in the same membrane, and varies chiefly according to the state of the organ which the membrane covers. The coloration of the gastro-enteric mucous membrane undergoes, even within the limits of health, many variations. Thus, according to the absence or presence of such foreign substances as are taken at meals, the mucous membrane is pale, or presents various shades of redness. At the period of menstruation the uterine mucous membrane becomes red and injected. Pressure on any of the venous vessels renders the mucous membranes blue, purple, or livid, as is seen in *prolapsus*, and more distinctly in *asphyxia*, in which all the mucous membranes assume a livid tint. (Bichat.) The varieties of red colour observed in the gastric mucous membrane by Dr Yellowly are to be ascribed partly to the latter cause, partly to the vascular redness which the presence of foreign bodies occasions. (*Medico-Chirurg. Trans.* vol. iv. p. 371.) The pulmonary division of this membrane is of an ash-gray or dun colour, inclining to pale blue or light red. These colours vary, nevertheless, according to the facility or the difficulty with which the blood moves through the pulmonary capillary system. It is also freely supplied with blood-vessels derived chiefly from the bronchial arteries. These vessels, after accompanying the bronchial tubes and their successive subdivisions, divide into minute branches which penetrate the mucous corion, which here is white, dense, and fibrous, and after anastomosing with the capillaries of the pulmonary artery and veins, form a minute delicate net-work on the outer surface of the pulmonary mucous membrane. According to Reisseissen, to whom we are indebted for a careful examination of these vessels, a successful injection of them from the bronchial arteries renders the whole mucous membrane of the *bronchi* entirely red to the unassisted eye. (*Ueber den Bau der Lungen*, u. s. w. Berlin, 1822.)

General Anatomy.

Mucous membrane.

The termination of arteries at the mucous surfaces has at all times occupied the attention of anatomists and physiologists; but it is not a matter of sensible demonstration. The thin serous or sero-mucous fluid with which they are moistened has led every author almost, and among the rest Haller and Bichat, to infer the existence of arteries with orifices, or what are termed exhalant vessels. It has been admitted, nevertheless, more on analogical than direct proofs. The injections of Bleuland, the only experiments, after those of Kawe Boerhaave, which tend to confirm the conclusion, require nevertheless to be repeated and varied.[1]

That lymphatics are distributed to mucous membranes, is a point well established. Cruikshank saw the lymphatics proceeding from the pulmonic mucous membrane loaded with blood in persons and animals dying of hæmoptoe. Their existence in the gastro-enteric mucous membrane has been long established.

The mucous surfaces are also freely supplied by nervous twigs and filaments, derived in general from the nerves of automatic life. It is a mistake, nevertheless, to ascribe to these filaments the sensibility and other properties of the mucous membranes, which possess intrinsically certain vital properties independently of the nervous filaments with which they are supplied; and the principal use of these filaments appears to be to regulate these properties, especially that of secretion.

The connection between the mucous membranes and the skin was first demonstrated by Bonn, who traces their mutual approximation and reciprocal transition into each other, and represents the former as an interior production of the latter, enveloping the internal as the skin incloses the external organs. This view has been adopted by Meckel and Beclard, to whom I refer for the proofs of its accuracy. I cannot conclude the subject, however, without observing that one of the most conclusive arguments in its favour is derived from the circumstances of the developement of the intestinal canal during the first months of uterine life. The history of this curious process, which has been investigated by Wolff, Oken, and Meckel, shows that at this period the gastro-enteric mucous membrane, which is previously formed by the vitellar membrane of the *ovum*, and the *allantois* or vesical membrane, which afterwards forms the genito-urinary mucous surface, are in direct communication on the median line, and afterwards at the navel, with the skin or exterior integument.

### *Serous Membrane, Transparent Membrane. (Membrana Pellucida, M. Serosa.—Tissu Sereux.)*

Serous membrane.

The *pleura* and *peritoneum* are the best examples of the tissue which has been named *serous*, from the fluid with which it is moistened, and which may be termed *transparent* or *diaphanous* as its distinctive character.

The distribution or mechanical arrangement of these membranes is peculiar, and though not well understood by anatomists, till Douglas, by his description of the peritoneum, rendered it clearer, may now be said, by the labours of Hunter, Carmichael Smyth, and Bichat, to be quite intelligible. In this, nevertheless, there are certain peculiarities which may perplex the beginner, and prevent him from obtaining at first a clear idea of the distribution and configuration of the pellucid membranes. Thus they have neither beginning nor termination; they have neither orifice nor egredient canal; and they are not continuous with any other membrane or texture.

General Anatomy.

Serous membrane.

Every serous membrane consists of a hollow sac everywhere closed, and to the cavity or interior surface of which there is no natural entrance; a circumstance from which they have been denominated *shut sacs* (*sacci occlusi; sacs sans ouverture*). In every serous membrane one part is inverted or inflected, or reflected, as is commonly said, within the other, so that the inner surface of the former part is applied with more or less accuracy to the inner or like surface of the latter. This mode of disposition has suggested the homely and trite, but not inappropriate comparison of a serous membrane to a night-cap, one half of which is folded or doubled within the other, so that while one half of the inner surface is applied to the remaining half, no communication exists between the inner and the outer surface. Every serous membrane, in short, is a single sac, one half of which is doubled within the other.

In every serous membrane the outer surface of the unreflected portion is applied over the walls of the region which the serous membrane lines, while the outer surface of the inflected portion is applied over the organ or organs contained in that region. From this arrangement it results that each organ covered by serous membrane is not contained in that membrane, but is on its exterior surface, and that of every organ so situate, one part at least, viz. that at which its vessels and nerves enter, is always uncovered. Thus the lungs are on the outer surface of the *pleura;* the heart is on the outside of the *pericardium;* the stomach, intestines, liver, spleen, and pancreas, are on the outside of the *peritoneum;* and the testicles are on the outside of the *perididymis.* In the same manner the lungs, though invested by pleura before and behind, at their apex and their base, are uncovered at their roots, or the points where the bronchial tubes and great blood-vessels enter their substance; the heart is uncovered by pericardium at the upper part of the auricular cavities; and the intestinal canal is uncovered along the whole of that longitudinal but tortuous line by which the mesentery is attached, and at which its proper vessels and nerves are transmitted.

To comprehend more distinctly the arrangement of the pellucid membranes, it is expedient, by an effort of abstraction, to trace the course of any one of them, having previously thrown out of the question the means by which their interior free surface is exposed. In this mental process it is requisite to remember that there is no initial point save what is arbitrarily made. If, for example, the course of the *pleura* be traced, the membrane presents no natural boundary from which the anatomist is to commence his demonstration; and he must fix artificially on any point which he finds most convenient for the purpose. Commencing with this understanding, from the circumference of the spot termed *root* of the lungs, the membrane may be traced first along the internal surface of the chest formed by the ribs and intercostal muscles, forwards to the sternum, upwards to the first rib and *apex* of the thoracic cavity, downwards to the diaphragmatic insertions, and over the surface of that muscle, and the outer surface of the pericardium again to the circumference of the root or connection of the lungs. From this point again it may be traced over the surface and between the lobes of these organs, both of

---

[1] *Experimentum Anatomicum, quo Arteriolarum Lymphaticarum existentia probabiliter adstruitur,* &c. a Jano Bleuland, M. D. Lugd. Bat. 1784. *Item,* Jani Bleuland, M. D. &c. *Vasculorum Intestinorum tenuium Tunicis subtilioris Anatomes Opera Detegendorum Descriptio Iconibus illustrata.* Trajecti, 1797.

which, as already stated, are thus situate on the outside of the pleura. The course first described is that of the *unreflected* or *exterior* division of the pleura. The second, or that over the organ covered, is the course of the *inflected* or *doubled* portion of the membrane, which is thus necessarily smaller, and less extensive, than the former.

The arrangement thus sketched, which may be easily shown to be applicable to all the serous membranes, demonstrates their twofold character of lining the walls of a cavity and covering the organs contained. From an idea of this property, the old anatomists applied to them the epithet of *membranæ succingentes.*

In tracing the course of the serous membranes, the anatomist observes that they present productions which float with more or less freedom in the cavity formed by the free surface, and which may be generally shown to consist of two folds of the single membrane produced beyond the inclosed organ, but still maintaining the unity of the membrane. Of these prolongations, the most distinct examples are the *epiploon* and the *appendices epiploicæ* of the peritoneum. Less manifest instances are the adipose folds of the *pleura* near the *mediastinum*, and the bladder-like appearance at the base of the heart, within the *pericardium.* The synovial fringes in the interior of the synovial membranes, which belong to a subsequent head, are nevertheless of the same general character. Between the folds of these productions there is invariably more or less adipose substance, which indeed is observed in some quantity in various parts of the filamentous tissue on the outer surface of the serous membranes in general.

Every serous membrane I have above represented as a hollow sac everywhere continuous, and the outer surface of which has no communication with the inner. To this character the only exception is the peritoneum in the female, which is perforated at two points, corresponding to the upper extremity or orifice of the Fallopian or oviferous tubes. This has been already mentioned as the only spot at which the mucous and serous surfaces communicate directly with each other.

Every serous membrane consists of a thin, colourless, transparent web or pellicle, through which the tissue of the subjacent organ or parts may be easily recognised; and every serous membrane presents two surfaces, an attached or adherent, and a free or unadherent.

The attached surface, which is also termed its *outer* one, is that by which it is connected to the tissue or organ which it covers; it is somewhat irregular, flocculent or tomentose, and is evidently connected by fine filamentous tissue. The degree of attachment is very variable in different membranes, and in different points of the same membrane. In general, serous membranes adhere much less firmly to the walls of cavities than to the surface of the contained organs. Thus, the abdominal *peritoneum* and the costal *pleura* are more easily removed than the intestinal *peritoneum* and the pulmonic *pleura.* The *peritoneum* adheres feebly to the bladder, to the liver, and to the pancreas—more intimately to the different regions of the intestinal tube, and seems to be almost identified with the substance of the female organs of generation. From the interior of the capsular *pericardium*, and from the vaginal coat, it is almost impossible to detach the serous pellicle. The former, however, is peculiar in having between the serous surface and the fibrous membrane no filamentous tissue, upon the abundance or deficiency of which the degree of adhesion depends.

The free or unadherent or *inner* surface is very smooth, polished, and uniform; moistened with a watery fluid, from which it derives its shining appearance; and destitute of fibres or any other trace of organic structure. From this smooth, polished aspect, which is a peculiar attribute of the free surface of serous membrane, all the organs covered by it derive their glistening appearance. Thus the exterior surface of the lungs derives its appearance from the pleura, the heart from the pericardium, and the liver and intestinal canal from the peritoneum. A successful injection of size or turpentine, coloured with vermilion, brings into view so many capillary blood-vessels in this membrane, that it might be supposed at first sight to consist entirely of minute arteries and veins. Further, by proper management, lymphatics may be injected in it with quicksilver to a degree equally minute and delicate. From these experiments, therefore, it may be concluded that serous membrane is chiefly composed of minute arteries and veins conveying colourless fluids, and of vessels connected with the general trunks of the lymphatic system. Whether it contains any thing else but vessels of this kind, or has a proper substance or tissue, remains to be ascertained. Though nerves are often seen passing along their outer or attached surface to the neighbouring tissues, none have hitherto been traced either into the pleura or peritoneum.

By most of the older anatomists, and among others by Haller, serous membrane is considered as of the nature of filamentous tissue or cellular membrane, more or less closely condensed (*tela cellulosa stipata*); and this view is adopted and maintained by Bordeu, Bichat, Meckel, and Beclard, the last of whom, however, thinks they partake of ligamentous characters. Macerated, they become soft, thick, and pulpy; and are finally resolved into flocculent filamentous matter. In the course of decomposition in the dead subject they first lose their glistening aspect, then become covered by a foul, dirty coating of viscid matter, which appears to exude from their surface; and eventually they are dissolved into shreds. Immersion in boiling water renders them thick, firm, and somewhat crisp. When dried they become thin, clear, and transparent, and, if preserved from humidity or the attacks of animals, may remain long unchanged. The experiments of Hatchett, Fourcroy, and Vauquelin, show that they contain gelatine and a little albumen; but no precise information on their chemical composition has yet been given.

The principal character of the serous membranes is that of isolating the organs which they cover, and to the structure of which they are adventitious, and forming shut cavities, in which there is incessant exhalation and absorption. In some instances they evidently contribute to facilitate the mutual motions of contiguous and corresponding surfaces. From their free surfaces is secreted a fluid containing a small portion of albumen (Hewson, *Experimental Inquiries*, vol. ii. chap. vii.; Bostock, Nicholson's *Journal*, vol. xiv. p. 147, and *Medico-Chirurgical Transactions*, vol. iv.), which is greatly augmented during the state of disease.

The mode of developement of the pellucid membranes is not well ascertained. The investigations regarding organogenesy by Oken, Meckel, and Tiedemann, disclose facts which induce Meckel to hazard the opinion that some of them are not at all times shut sacs. I doubt, however, whether the fact which he adduces for this purpose implies the open condition of the pericardium and the peritoneum. In the case of the former the developement of the heart proceeds from the basis generally, without affecting the integrity of the investing membrane. In the case of the latter there is more reason to believe that, at the navel, at least, the peritoneum is either open, or is continuous with the vitellar membrane.

In the fœtus the serous membranes are so thin, that

General Anatomy. Serous membrane.

they are much more transparent than in the adult. In small animals also, they are more transparent than in large, and in cold-blooded animals than in the mammiferous. Of some also the disposition varies at different periods. Thus the descent of the testicle,—a process which has been well explained by Albinus, Haller, Wrisberg, and Langenbeck,—is attended with a remarkable change in the arrangement of that portion of peritoneum which the gland impels before it.

*Synovial Membrane.* (*Membrana Synovialis; Bursæ Mucosæ.*)

Synovial membrane.

Bichat enumerates several circumstances in which he conceives that serous and synovial membranes differ from each other. Gordon, who doubts how far the distinctions are well founded as the basis of anatomical arrangement, admits, however, the following peculiarities.

Synovial membrane resembles serous membrane in being a thin, transparent substance, having one smooth free surface turned towards certain cavities of the body, and another connected by delicate cellular tissue to the sides of these cavities, or to the parts contained in them. But it differs from serous membrane in the following circumstances. 1*st*, It possesses little vascularity in the healthy state; no blood-vessels are almost ever seen in it after death, nor can they be made to receive the finest injection. 2*d*, Its lymphatics are quite incapable of demonstration. 3*d*, Very delicate fibres, like those of cellular substance, or like the finest filaments of tendon, are distinctly seen in it after slight maceration. 4*th*, It is considerably less strong than serous membrane. On these grounds, therefore, synovial membrane is to be anatomically distinguished from serous membrane.

The synovial membrane, as described above, is found not only in each of the movable articulations, but in those sheaths in which tendons are lodged, and in which they undergo considerable extent of motion, and in certain situations in the subcutaneous filamentous tissue.

The distribution of the synovial membranes is much the same in all these situations. They are known to line the ligamentous apparatus of each joint, capsular and funicular; and they are also continued over the cartilaginous extremities of the bones of which the articulation consists. This continuation, which was originally maintained by Nesbitt, Bonn, and William Hunter, and was demonstrated by various facts by Bichat, has been lately questioned by Gordon and Magendie, the former of whom especially thinks it unsusceptible of anatomical proof. The cartilaginous synovial membrane is certainly not so easily demonstrable as the capsular, for the same reason which I have already assigned regarding the difficulty of isolating the capsular pericardium, the ovarian peritoneum, and the serous covering of the *tunica albuginea*,—the want of filamentous tissue.

The presence of synovial membrane in the articular cartilages is nevertheless established by sundry facts. 1*st*, If a portion of articular cartilage be divided obliquely, and examined by a good glass, it is not difficult to recognise at one extremity of the section a thin pellicle, differing widely in aspect, colour, and structure, from the bluish-white appearance of the cartilage. 2*d*, If the free surface of the cartilage be scraped gently, it is possible to detach thin shavings, which are also distinct from cartilage in their appearance. 3*d*, The free surface of the cartilage is totally different from the attached surface, or from a section of its substance, and derives its peculiar smooth polished appearance from a very thin transparent pellicle uniformly spread over it. 4*th*, If articular cartilage be immersed in boiling water, this thin pellicle becomes opaque, while the cartilage is little changed. 5*th*, Immersion in nitric or muriatic acid, which detaches the cartilage from the bone, gives this surface a cracked appearance, which is not seen in the attached surface, and which is probably to be ascribed to irregular contraction of two different animal substances. 6*th*, The existence of this cartilaginous synovial membrane is demonstrated by the morbid process with which the tissue is liable to be affected. On the whole, therefore, little doubt can be entertained that the representation of their course, as given originally by Nesbitt, Bonn, and Hunter, is well founded.

General Anatomy. Synovial membrane.

The same views may be applied to the synovial linings of the tendinous sheaths, which are equally to be regarded as shut sacs.

Attached to the free surface of each synovial membrane is a peculiar fringe-like substance, which was long supposed to be an apparatus of glands (glands of Havers) for secreting synovial fluid. It is now known that these fringes are merely puckered folds of synovial membrane, and that, although synovia is abundantly secreted by them, this depends merely on the great extent of surface which is the necessary consequence of their puckered arrangement. This arrangement is easily demonstrated by immersing an articulation containing the fringed processes in clear water, when they are unfolded and made to float, and show their connections, figure, and terminations. They are analogous to the free processes of serous membranes, and like them are double, and contain adipose matter.

The synovial sheaths (*bursæ mucosæ*) are very numerous, and are generally found in every tendon which is exposed to frequent or extensive motion.

Though the fluid prepared by these membranes has been examined by Margueron, Fourcroy, John Davy, Orfila, and other chemists, it cannot be said that its chemical composition is accurately determined. It is said to contain water, albumen, incoagulable matter regarded as mucilaginous gelatine, a ropy matter, and salts of soda, lime, and some uric acid. On the presence of the incoagulable gelatine depends its utility in diminishing friction in the finer kinds of metallic machinery employed in watches and chronometers.

[illegible] that the peritoneum varies at different periods. Thus the thinness of the peritoneum,—a property which has been well explained by Albinus, Haller, Walther, and Lieutaud,—[illegible] with a remarkable change in the [illegible] portion of peritoneum [illegible] the gland [illegible] below it.

*Synovial Membrane. (Membrana Synovialis; Synovial Membrane.)*

Bichat enumerates several circumstances by which the proper serous and synovial membranes differ from each other. Gordon, who doubts how far the distinctions are well founded as the basis of anatomical arrangement, admits, however, the following peculiarities.

Synovial membrane resembles serous membrane in being a thin, transparent substance, having one smooth free surface turned towards certain cavities of the body, and the other connected by delicate cellular tissue to the sides of these cavities, or to the parts contained in them. But it differs from serous membrane in the following circumstances. 1st, It possesses little vascularity in the healthy state; no blood-vessels are almost ever seen in it after death, nor can they be made to receive the finest injection. 2d, Its lymphatics are quite incapable of demonstration. 3d, Very delicate fibres, like those of cellular substance, or like the finest filaments of tendon, are distinctly seen in it after slight maceration. 4th, It is considerably less strong than serous membrane. On these grounds, therefore, synovial membrane is to be anatomically distinguished from serous membrane.

The synovial membrane, as described above, is found not only in each of the movable articulations, but in the sheaths in which tendons are lodged, and in which they undergo considerable extent of motion, and in certain situations in the subcutaneous filamentous tissue.

The distribution of the synovial membranes is much the same in all these situations. They are known to line the ligamentous apparatus of each joint, capsular and funicular; and they are also continued over the cartilaginous extremities of the bones of which the articulation consists. This continuation, which was originally maintained by Nesbitt, Bonn, and William Hunter, and was demonstrated by various facts by Bichat, has been lately questioned by Gordon and Magendie, the former of whom especially thinks it unsusceptible of anatomical proof. The cartilaginous synovial membrane is certainly not so easily demonstrable as the capsular, for the same reason which I have already assigned regarding the difficulty of isolating the capsular pericardium, the ovarian peritoneum, and the serous covering of the *tunica albuginea*,—the want of filamentous tissue.

The existence of synovial membrane in the articular cartilages [illegible]. 1st, It is [illegible] and [illegible] or a [illegible] from the [illegible] ing widely in aspect, colour, and structure [illegible] [illegible]-white appearance of the cartilage. 2d, If the surface of the cartilage be scraped gently, it is possible to detach thin shavings, which are also distinct from cartilage in their appearance. 3d, The free surface of the cartilage is [illegible] different from the attached surface, or from a section of its substance, and derives its peculiar smooth polished appearance from a very thin transparent pellicle uniformly spread over it. 4th, If articular cartilage be immersed in boiling water, this thin pellicle becomes opaque, while the cartilage is little changed. 5th, [illegible] in nitric or muriatic acid, which detaches the cartilage from the bone, gives this surface a crackled appearance, which is not seen in the attached surface, and which is probably to be ascribed to irregular contraction of two different animal substances. 6th, The existence of the cartilaginous synovial membrane is demonstrated by the morbid process with which the tissue is liable to be affected. On the whole, therefore, little doubt can be entertained that the representation of their course, as given originally by Nesbitt, Bonn, and Hunter, is well founded.

The same views may be applied to the synovial linings of the tendinous sheaths, which are equally to be regarded as shut sacs.

Attached to the free surface of each synovial membrane is a peculiar fringe-like substance, which was long supposed to be an apparatus of glands (glands of Havers) for secreting synovial fluid. It is now known that these bodies are merely [illegible] folds of synovial membrane, and that though synovia is abundantly secreted by them, this depends merely on the great extent of surface which is the necessary consequence of their puckered arrangement. This arrangement is easily demonstrated by immersing an articulation containing the fringed processes in clear water, when they are unfolded and made to float, and show their connections, figure, and terminations. They are analogous to the free processes of serous membranes, and like these are double, and contain adipose matter.

The synovial sheaths (*bursæ mucosæ*) are very numerous, and are generally found in every tendon which is exposed to frequent or extensive motion.

Though the fluid prepared by these membranes has been examined by Margueron, Fourcroy, John, Davy, Orfila, and other chemists, it cannot be [illegible] its chemical composition is accurately determined. It is said to contain water, albumen, incoagulable matter regarded as mucilaginous gelatine, a ropy matter, and salts of soda, lime, and some uric acid. On the presence of the incoagulable gelatine depends its utility in diminishing friction in the finer kinds of metallic machinery employed in watches and chronometers.
